Vagus nerve stimulation in 5 patients with drug-resistant epilepsy in western China

Department of Neurology, Xijing Hospital, Fourth Military Medical University, China; 'Department of Neurosurgery, Xijing Hospital, Fourth Military Medical University, Xi'an, China

Purpose: This study was designed to assess the efficacy and safety of vagus nerve stimulation in adults with drug-resistant epilepsy.

Methods: In this retrospective review, a database was prospectively created with 5 patients from western China, who underwent vagus nerve stimulation by internal magnetic stimulation.

Results: The most common etiology was drug-resistant epilepsy, and the duration of epilepsy ranged from 1 to 20 years. All patients received vagus nerve stimulation for periods ranging from 3 to 12 months. The mean follow-up period was 6 months. The outcomes were measured using the Epilepsy Quality of Life Inventory (EQLI) and the Clinical Global Impression (CGI).

Conclusion: Vagus nerve stimulation was well tolerated and effective in improving the quality of life for patients with drug-resistant epilepsy in western China.

doi:10.1016/j.jns.2013.07.018
nerve stimulator implantation for drug-resistant epilepsy between July 2011 and March 2012; all of the patients were males aged 19 to 31 at the time of implantation. All patients in the primary implantation group had adequate follow-up (>3 months from implantation) and no patient had early device removal because of infection.

**Results:** Duration of vagus nerve stimulation treatment varied from 7 to 15 months. Seizure freedom was achieved in 3 patients, 80% seizure reduction in 1 patient, and no improvement in 1 patient. No permanent injury to the vagus nerve occurred to any patient.

**Conclusion:** Vagus nerve stimulation is a safe and effective palliative treatment for focal and generalized drug-resistant epilepsy in adults in western China. When this treatment was used in conjunction with a multidisciplinary and multimodality treatment regimen including aggressive antiepileptic drug regimens, 3 in 5 patients with drug-resistant epilepsy experienced seizure free. Long-term prospective randomized trials are needed for patients with drug-resistant epilepsy to potentially expand the number of patients who may benefit from this palliative treatment.

**Seizure freedom of Epilepsia Partialis Continua (EPC) with vagus nerve stimulation (VNS) therapy: A case report**

*Department of Neurology, Xijing Hospital, Fourth Military Medical University, Xi’an, China; Department of Neurosurgery, Xijing Hospital, Fourth Military Medical University, Xi’an, China*.

Vagus nerve stimulation (VNS) is generally considered as a palliative treatment for patients with drug-resistant partial onset epilepsy. We report a case that a patient with drug-resistant generalized onset epilepsy, Epilepsia Partialis Continua (EPC) became seizure free for 13 months with VNS combined with antiepileptic medication regimens. A 21-year-old, right-handed man started having seizures at the age of 18. He reported countless limbs shaking for about 10 s, and occasional generalized tonic–clonic seizures at a frequency of 5–7 times per year. He was initially treated with valproic acid (VPA) and carbamazepine (CBZ) with minimal benefits. Then he was treated with lamotrigine (LTG) 200 mg daily, Levetiracetam (LEV) 1250 mg daily and topiramate (TPM) 200 mg daily with minimal benefits for the last several months. His long-term video-EEG monitoring revealed small spike wave discharges. Sometimes he couldn’t say a word or have dinner for the twitch of the mouth. A vagus nerve stimulator was subsequently implanted in Sept 2011. Initial stimulation parameters were: current output 0.25 mA, frequency 30 Hz, pulse width 250 ms, 30 s signal on time, and 5 min signal off time. The patient had two wild twitches of the mouth per week. Then his stimulation current output was changed to 0.50 mA, and his seizure became countless as pre-operation. Fortunately, he became seizure free after his stimulation current reverted to 0.25 mA. After one month of seizure freedom, the patient withdrew his LEV and TPM. He has remained seizure free for almost 9 months, during which time he has been gainfully employed.

**Temporal lobe epilepsy patients associated with mild focal cortical dysplasia. Quantitative assessment by cortical surface analysis**

O. Trápaga Quincoses, L. Morales Chacón, R. Rodríguez; A. Sánchez, M. Zaldívar. International Center for Neurological Restoration (CIREN), Havana, Cuba; Neuroimage, Havana, Cuba; Clinical Neurophysiology, International Center for Neurological Restoration (CIREN), Havana, Cuba.

**Objective:** To evaluate temporal lobe cortical surface through quantitative magnetic resonance imaging (MRI) and it’s relation to postsurgical evolution in patients with temporal lobe epilepsy associated with mild focal cortical dysplasia with MRI negative.

**Methods and subjects:** Measurements of cortical surface area (SA), cortical thickness (CT), folding index (FI) and volume were generated with FreeSurfer in 10 patients and 20 subject controls. High resolution pre-surgical T1-weighted volume scans 160 contiguous slices were obtained for each subject.

**Results:** The patient group displayed significantly reduced volume in entorhinal cortex, parahippocampus, superior and inferior temporal gyrus; SA was also greater in ipsilateral neocortical epileptogenic zone when compared to the control group. An increase of the CT was also shown in entorhinal cortex and parahippocampus. In addition, the ipsilateral neocortex showed an increase folding index (p < 0.0001 Test Mann–Whitney). Class 1 Engel’s patient had greater volume of mesial structures and smaller volume in neocortex. CT was lower in entorhinal cortex and parahippocampus, whereas the SA has a tendency tended to be higher in best evolution patients (p < 0.0008 Test Mann–Whitney).

**Conclusions:** Patient’s with TLE associated with mild FCD showed significant volume reductions and CT increase in entorhinal cortex and parahippocampus. There was also an increase of the SA and a significant volume decrease in ipsilateral temporal lobe epileptogenic zone. Patients who had better clinical evolution showed bigger volume in the mesial structures associated with smaller neocortical volume and SA increase (superior and inferior temporal lobes).

**Disrupted migration of GABAergic interneurons lead to the epileptogenesis: Interneuron pathology associated with Arx mutation**

M. Itoh, Mental Retardation and Birth Defect Research, National Center of Neurology and Psychiatry, Kodaira, Japan.

**Aim:** X-linked lissencephaly with abnormal genitalia (XLAG), showing severe neonatal seizure and developmental delay, is a rare disorder caused by mutations in the aristaless-related homeobox (ARX) gene, located in Xp22.13. Arx-null mice for human XLAG model showed loss of tangential migration of GABAergic interneurons. However, GABAergic interneuron distribution of XLAG brain has never been reported. In the present study, we investigated subpopulation of GABAergic interneurons in the brain of an infant with XLAG, who had a nonsense mutation of the ARX gene, compared with those of age-matched normal control and Miller–Dieker syndrome.

**Methods:** We performed immunocytochemistry for interneuron and migration markers.

**Results:** Glutamic acid decarboxylase (GAD)- and calretinin (CR)-containing cells were significantly very few in the neocortex and, interestingly, located in the white matter and neocortical subventricular...
zone, while neuropeptide tyrosine and cholecystokinin positive cells were normal. From previous rodent studies, the imbalance of GABAergic interneurons may be derived from the caudal ganglionic eminence tangential migration. Also, in the neocortical subventricular region, the GAD- and CR-containing cells had Mash-1 protein, like a radial migration marker, and nestin protein.

**Conclusion:** ARX protein controls not only tangential migration of GABAergic interneurons from the ganglionic eminence, but also may serve to induce radial migration from the neocortical subventricular zone.

**Neurometabolic effect of repetitive transcranial magnetic stimulation in epileptic brain: A sham-controlled proton magnetic resonance spectroscopy study**

V. Kistena1, V. Evtisteneva2, I. Bulaeva3, R. Sakovich4, B. Dubovik4, 1Neurology and Neurosurgery, Minsk, Belarus; 2Belarusian Medical Academy of Postgraduate Education, Minsk, Belarus; 3Institute of Traumatology, Minsk, Belarus; 4Radiology, Belarusian Medical Academy of Postgraduate Education, Minsk, Belarus

**Background:** Repetitive transcranial magnetic stimulation (rTMS) is a perspective method to reduce seizures at resistant epilepsy. Mechanisms of rTMS action are active researched.

**Objective:** The study was designed to evaluate the neurometabolic effect of single and ten sessions of low-frequency repetitive transcranial magnetic stimulation over temporal lobe.

**Patients and methods:** Sixteen epilepsy patients (mean age = 28.1 ± 2.9 years) were enrolled in a prospective single-blind, randomized study [sham (n = 7) vs. real (n = 9)]. rTMS (1 Hz, 20% MMI intensity of ring coil) was performed during 10 min over the temporal lobe projection with focusing on hippocamp. Hippocampal brain regions bilaterally were investigated by single-voxel proton magnetic resonance spectroscopy 

**Results:** Our results showed a significant reduction of seizure frequency after real 10 rTMS sessions that lasted for at least 3 months following the concomitant MRS measures of Cho, total Cr, Naa concentrations, and ratios of Cho/Cr, Naa/Cr and Naa/Cho.

**Conclusions:** Our study’s results suggest that there is not a strong but low-medium correlation between qEEG and MRS findings of patients with TLE that would be explained by concomitant but different pathogenetical factors causing both MRS pathologies and qEEG abnormalities.

**The effect of antiepileptic drugs on IQ in children with epilepsy**

I. Khusainova, T. Khusainov. Department of Pediatric Neurology, Tashkent Pediatric Medical Institute, Tashkent, Uzbekistan

**Objective:** Measures in this study focused primarily on IQ scores in children suffering from epilepsy with special emphasis on different antiepileptic medications.

**Material and methods:** Our study cohort included 56 patients (30 girls and 26 boys) with a mean age of epilepsy onset 8.9 ± 2.64 years, ranged from 5 to 15 years. The cognitive functions were analyzed every six months from January 2011 through February 2013 by using the batteries of neurocognitive tests.

**Results:** The duration of epilepsy was ranged from one to nine years, with the mean age of 4.18 ± 1.79 years. In the carbamazepine group the IQ scores decreased from 85.9 ± 9.48 to 79.45 ± 6.99 at last follow-up period (t = 3.129, p = 0.006). Patients who take valproic acid have demonstrated lower intelligence scores 75.25 ± 5.06 compared with baseline 80.95 ± 6.8 (p = 0.001, t = 3.77, 95% CI). In the topiramate group the IQ scores have also declined to 69.95 ± 9.01 compared with baseline 80.40 ± 6.36 (t = 8.09, p = 0.003, 95% CI). Patients on levetiracetam have shown improvement in intelligence scores that can be associated with significantly decreased seizure frequency in this group. Cognitive outcomes were defined as either measure was worse in patients with higher seizure frequency (more than one seizure per month), t = 2.16, p = 0.038.

**Conclusion:** Antiepileptic drugs as well as seizure frequency can impact on cognition in children with epilepsy. However, this association was dose dependent. An improved diagnostic and treatment methods of the consequences of epilepsy in childhood can increase the probability of a favorable prognosis.

Topic: 1—Epilepsy  
Outcomes of using prednisolone and ACTH in infants with West syndrome  
L. Khusainova, T. Khusainov, G. Sadikova. Department of Pediatric Neurology, Tashkent Pediatric Medical Institute, Tashkent, Uzbekistan  
Objective: Hormonal treatment of infants suffering from West syndrome is widely used. The aim of the current study was to compare the efficacy and cost of oral prednisolone and synthetic ACTH (Synacthen Depot) therapy in the treatment of infants with West syndrome from Uzbekistan.  
Material and methods: In this retrospective cohort study thirty-four infants were included with new-onset West syndrome who have been treated in the Republic Children’s Hospital since September 2010. Inclusion criteria were presence of clinical spasms, hypsarrhythmic patterns on EEG, neuropsychic impairment and at least six months of follow-up period. Based on the 2004 United Kingdom Infantile Spasms Study (UKISS) we used high-dose of oral prednisolone (4 mg/kg). A single intramuscular injection of ACTH at doses of 40–60 IU/day has been used according to our protocol.  
Results: Twenty two males and twelve females were participated in this study. Mean age of seizure onset was 5.7 ± 2.4 months. Twenty-one infants (61.7%) were identified as symptomatic whereas thirteen (38.3%) were cryptogenic. Fourteen (41.2%) infants received ACTH injection whereas twenty (58.8%) infants received oral prednisolone. Initial response to first line therapy was similar (71.4% for ACTH and 65% for prednisolone, p = 0.24). Adverse events were reported in fifteen (75%) infants who have received prednisolone compare with eleven (78.6%) infants who were on ACTH.  
Conclusion: Prednisolone and ACTH showed no significant difference in the initial treatment of West syndrome. We are prescribing oral prednisolone as a less expensive alternative of ACTH therapy of West syndrome.

EEG phase relationship among electrodes for child absence epilepsy  
Z. Meiyuna1, Z. Benshu2, Z. Benshu3, C. Ying2, W. Fenglou2. 1Department of Neurology, Tianjin Union Medical Centre, Tianjin, China; 2Mechanics Department, Tianjin University, Tianjin, China; 3Neurology Department, General Hospital of Tianjin Medical University, Tianjin, China  
Background: EEG phase relationship among electrodes in seizures of child absence epilepsy (CAE) is not conform.  
Objectives: To investigate EEG phase relationship among electrodes in seizures of CAE and compare it with that of normal controls.  
Patients and methods: The transient EEG signals of 10 clinical seizures with 20 sub-clinical epilepsy-form discharge in 15 cases of children absence epilepsy and 12 normal controls are recorded at awake and eye-closed state. Wavelet transform is employed to unfold the digital EEG signals into multi-scale components. The phase-lock average waveforms (PLAW) of different electrodes are obtained by phase-lock conditional sampling and phase-lock average techniques. The phase differences among electrodes are determined by correlation functions for PLAW. The phase relationships among electrodes of PLAW in CAE are compared with that of the 12 normal children at the same age.  
Results: There exists phase-difference in PLAW among electrodes of normal controls. A phase-difference of PLAW between forehead lead and occipital lead is about π/2 for normal controls. There are two types of phase-difference for CAE. One type is the PLAW of all electrodes are synchronized while another type is that the phase-difference between forehead lead and occipital lead is about π.  
Conclusions: Phase-lock conditional sampling and phase-lock average techniques are employed to obtain the phase-difference of the PLAW among electrodes. The study result shows that the phase-difference among electrodes for CAE is different from that of normal controls and there are two types of phase-difference for CAE, whose mechanism remains to be furtherly explored.

Cross-reactivity of anti-epileptic drugs and its association with the HLA-B*1502 allele in Han Chinese patients  
W. Wang, F.Y. Hu, X.T. Wu, D.M. An, B. Yan, D. Zhou. West China Hospital, Sichuan University, Chengdu, China  
Background: Recently, a few patient cases that were positive for the HLA-B*1502 allele have been reported to exhibit cross-reactivity to AEDs, suggesting that the HLA-B*1502 allele may contribute to the genetic susceptibility to the cross-reactivity of cutaneous adverse reactions (cADRs) to AEDs. However, there is limited convincing evidence, and this hypothesis is still controversial owing to the small sample sizes used in previous studies. Thus, it is necessary to further explore the potential association between the cross-reactivity of AEDs and the HLA-B*1502 allele.  
Objective: The aim of this study was to investigate the cross-reactivity between different types of AEDs in Chinese patients and to detect its association with the HLA-B*1502 allele.  
Patients and methods: A total of 107 subjects, including 37 patients and 70 healthy volunteers, were tested for the HLA-B*1502 allele. All of the patients had a history of cADRs induced by one AED.  
Results: Twelve out of 37 patients had experienced cross-reactivity, of which only two patients carried the HLA-B*1502 allele. The allele frequencies of HLA-B*1502 in the cross-reactivity group (2/12 = 16.7%), tolerant group (5/25 = 20.0%) and healthy control group (5/70 = 7.1%) were not significantly different (P > 0.05).  
Conclusion: Physicians should avoid prescribing aromatic AEDs as an alternative drug in patients who experienced aromatic AED-induced cADRs. Although the HLA-B*1502 allele is not a universal risk predictor for the cross-reactivity of cADRs to AEDs, but it may be a specific marker for cross-allergic reactions between CBZ and OXC as well as between CBZ and PHT.

Predetermining risk factors for development of epilepsy in children with encephalitis  
N. Sharipova, A. Khatilova. Neurology, Child Neurology & Medicine Genetics, Tashkent Pediatric Medical Institute, Tashkent, Uzbekistan  
In some cases, seizures, occurring in acute encephalitis, disappear completely, but at the majority of patients is developing symptomatic epilepsy.
Purpose: Identify risk factors for the formation of the epileptic focus in encephalitis.

Materials and methods: The study involved 30 patients with symptomatic epilepsy at the age of 6 months till 5 years old who had encephalitis of various etiologies. Anamnesis of patients, the data of clinical research, electroencephalography, and MRI have been analyzed.

Results: The analysis of anamnesis of patients was identified cerebral ischemia in perinatal period in 18 (60%) cases. Inflammatory disease of the brain in patients has developed as a result of the intestinal infection in 11 (36.7%), of respiratory viral infection in 15 (50%), of vaccination in 4 (13.3%) cases. Seizures were generalized tonic-clonic character in 12 (40%), tonic in 11 (36.7%) cases and in 7 (23.3%) cases were generalized tonic-clonic seizures with focal component. Serological examination of blood showed increasing of antibody titer IgG fraction to herpes simplex virus in 18 cases and in 12 cases to cytomegalovirus.

On MRI in 7 (23.3%) cases were identified structural changes in the brain: gipogeneziya callosum in 4 (13.3%), shizentsefaliya in 2 (6.6%) and porentsefaliya in 1 (3.3%) case.

Conclusion: The formation of epileptic focus determines many factors, including intra-uteri infection, chronic hypoxia, hereditary factors, structural changes of the brain, and inflammatory diseases of the brain in most cases, are the impetus for the manifestation of epileptic seizures.

Review article: Epilepsy in Ethiopia
D. Worku. Neurology, Addis Ababa University, Addis Ababa, Ethiopia

Background: Chronic non-communicable diseases, such as epilepsy, are increasingly recognized as important health care problems in developing countries. The most prevalent neurological disorder identified was epilepsy.

Methods: A review of journals was done on papers: movement disorders in Ethiopia available until the end of June, 2011 at the main Library of Addis Ababa University, School of Medicine, Department of Neurology.

Results: It was estimated 360 to 400 thousand epileptic Ethiopians are living with poor medication. The prevalence of epilepsy was estimated 360 to 400 thousand epileptic Ethiopians—13% were treated with antiepileptic drugs in cities like Addis Ababa. Traditional treatment with local herbs, holy water and amulets was the most common. Only 1.6% had been treated with recognized antiepileptic drugs in rural part of the country and as few as 13% were treated with antiepileptic drugs in cities like Addis Ababa.

Conclusions: Despite health education on epilepsy given to the community, a minority of subjects were treated with AEDs, which may reflect the inadequacies of the health services and transportation difficulties faced by the patients.

Topic: 1—Epilepsy
Electro-clinical profile and identification of predictors of seizure control in adults with complex partial seizures in Kano, northwestern Nigeria
L.F. Owolabi1, S. Sale2, S.D. Owolabib, 1Department of Medicine, Aminu Kano Teaching Hospital, Bayero University, Kano, Nigeria; 2Department of Psychiatry, Aminu Kano Teaching Hospital, Bayero University, Kano, Nigeria

Background: Ability to predict seizure control with future treatment can be very useful in the management of patients with CPS. However, there is paucity of data on CPS in northwestern Nigeria. The aim of the study was to profile the clinical and EEG characteristics of CPS as well as evaluate independent determinant of a 2-year seizure control of CPS.

Method: This was prospective systematic study of patients with CPS in two tertiary hospitals in over a period of 4 1/2 years. The patients were followed up for a minimum of a 2-year period to determine their seizure control status.

Results: A total of 158 (105 males and 53 females) were enrolled. Thirty (19%) were lost to follow up. Their age ranged between 15 and 85 (median = 30.5) years. Sixty six (41.7%) patients had aura and 65 (60.8%) had automatism. The most common aura and automatism were abnormal epigastric sensation and oro-alimentary respectively. Twenty eight (18%) had associated behavioral manifestations. EEG abnormality was recorded in 56 (53.9%). Sixty seven (42.4%) had tried traditional treatment before having been seen by a physician. On AED, 117 (55.7%) had adequate seizure control. Duration of epilepsy was identified as the only independent determinant of a 2-year seizure control.

Conclusion: Complex partial seizure was one of the most common seizure types in adult epilepsy occurring commonly between the second and fourth decade of life. Abnormal epigastric sensation and oro-alimentary automatism were the most common aura and duration of epilepsy > 2 years was the only independent determinant of a 2-year seizure control.

An assessment of clinical practice toward pharmacological treatment of epilepsy: A survey of adult neurologists in R. Macedonia
I. Kuzmanovski1, E. Cvetkovska2, B. Boskoski3, 1Neurology of Development Period, Skopje, FYROM — The Former Yugoslav Republic of Macedonia; 2Clinic of Neurology, Skopje, FYROM — The Former Yugoslav Republic of Macedonia

Purpose: The aim of the study was to evaluate clinical practice toward pharmacological treatment of epilepsy among adult neurologists in Macedonia.

Methods: A questionnaire was developed that addressed decisions about when to start and to stop antiepileptic drug (AED) treatment, as well as the choice of the first and alternative drugs about different types of seizures.

Results: 24 neurologists answered the questionnaire. Half of them would administer antiepileptic drug after first unprovoked seizure considering EEG, MRI and other investigations, while the others will wait for second seizure. For most of them discontinuation of the treatment should be individualized, while the others would do that...
after 3–5 or more than 5 years of seizure-free period. Most commonly used first-line drugs for partial seizures were carbamazepine and lamotrigine, while the second choices vary among a number of new generation and older AEDs. For generalized tonic–clonic seizures, absences and myoclonic jerks, valproate was by far the most commonly used AED (surprisingly, carbamazepine was drug of choice for absences for 16.5% of neurologists). Valproate is prescribed by almost all of neurologists when patients have several types of seizures. Alternatives for patients with mixed seizures were usually lamotrigine and topiramate. Commonly prescribed doses of AEDs tend to be lower to moderate and almost no one administers maximal tolerance doses. **Conclusion:** A survey showed that prescription patterns in high percent were in concordance with current evidence about the spectrum of efficacy of individual AEDs in different types of seizures. Yet some of results are a cause of concern.

**Socio-demographic profile and management of patients living with epilepsy in Dakar, Senegal**

M. Fall, Internal Medicine, Cheikh Anta Diop University, Dakar, Senegal; Neurology, Cheikh Anta Diop University, Dakar, Senegal

Epilepsy remains a major public health problem especially in developing countries where access to new therapies remains limited. We conducted a cross-sectional study over a period of eight months from November 2009 to June 2010 at Fann Hospital and Health Center Pikine through research on adherence. The objective was to describe the sociodemographic profile and management of patients living with epilepsy. The study involved patients living with epilepsy aged over 15 years, diagnosed clinically with epilepsy and/or confirmed by an EEG and put under antiepileptic drug for more than 3 months. We recruited 411 patients aged 15–74 years with a mean age of 28.93 years. The age range was 15–24 years with 44.6% majority. The male sex predominated with 52.3% and the sex ratio was 1.09. Singles outnumbered with 64.7%. The level of education was the most representative secondary with 29.4% in patients without profession were 35.5%. Most of the patients were from semi-urban areas with 47.7%. Generalized seizures were more frequent with about 70%. Most of the patients were taken care of either by their family or by their own expense.

**Peculiarities of the epilepsy immunopathogenesis**

R. Azizova, a Y.N. Madjidova, a R.B. Azizova, a G.S. Rakhimbaeva b

aTashkent Medical Academy, Tashkent, Uzbekistan; bNervous Diseases, Tashkent Medical Academy, Tashkent, Uzbekistan

Epilepsy remains to be one of the actual problems of the modern neurology. In the 60s of the 20th century Semenov V.F. laid the foundation of new direction in the study of epilepsy pathogenesis. Particularly, he proposed a hypothesis about the role of autoimmune mechanisms of epilepsy.

**Purpose:** To study immunological aspects of idiopathic and symptomatic epilepsy with determination of the role of immunological pathomechanisms of their development.

**Material and methods:** There 52 patients with symptomatic and idiopathic epilepsy that were studied. Thirty eight patients (group I) had idiopathic epilepsy. In this case we studied level of neurotropic autoantibodies to NF-200, GFAP, S100, OBM, Voltage-dependent Ca channels, glutamate receptors, GAMC-, dopamin, serotonin and n-choline-receptors.

**Results:** Neuroimmune change in epilepsy is accompanied by increase in autoantibodies to the receptors of choline, GAMC, dopamin, serotonin and borderline deviations to the protein B2 glycoprotein. However, more reliable in comparison with parameters of control group contents of autoantibodies was noted to such neurospecific proteins such as NF-200, S100 and to double-helical DNA.

**Conclusion:** The parameters of the protein S100 in both groups were higher and reliably differ from control group. In the patients from group II there was noted increase in autoantibodies to double-stranded DNA that in this case may be considered as the marker of the autoimmune process in the central nervous system.

**Anthropological and epidemiological study of epilepsy in the region of Tangier (Morocco)**

Y. Bahbitti, a B. Benazzouz a, F. Moutaouakil b, A. Ouichouia, A. El Hessnia c, A. Mesfioui a, aBiology, Laboratory of Genetics, Neuroendocrinology and Biotechnology, Unit of Nervous and Endocrine Physiology, Faculty of Sciences, University Ibn Tofail, Kenitra, Morocco; cNeurology, Al Kortobi Hospital, Kenitra, Morocco

**Objectives:** Determine the knowledge, attitudes and beliefs of the public towards epilepsy in Tangier region (northern Morocco).

**Methodology:** Performed in the Neurology Department at the Hospital Al Kortobi Tangier, via a standardized questionnaire about epilepsy, conducted on 180 participants (patients and family members).

**Results:** The study revealed that the disease is unknown in this region because 66.1% of respondents have not “read” or “heard”, about a disease called “epilepsy”, 60% did not know a person with epilepsy, yet 90% of the respondents attended convulsions. Concerning the public’s attitude towards epilepsy, the least we can say is that the rejection and marginalization watch with epilepsy: 70% do not allow their children to play with people who may suffer from convulsions. 80% of the respondents do not allow their children to marry sometimes with people making seizures. 50.6% of respondents believed that epileptics cannot exercise any craft. Worse, 40% of respondents believed that epilepsy is a form of mental retardation. 15.6% of the people interviewed believed that the main cause of epilepsy is supernatural (jinn, witchcraft) and 20.6% think it’s caused by stress. 15.6% think it is related to the alcohol and drugs. As for treatment, 68.9% of our sample suggested to ask doctor advice to treat epilepsy, 46.7% using Fkh’s help, 8.3% see a psychologist. 11.10% of people with epilepsy use the plant Ruta graveolens to treat epilepsy.

**Conclusions:** Epilepsy remains a misunderstood disease and is still subject to wrong interpretation. Awareness campaigns should be conducted to clarify certain aspects of epilepsy.

Epilepsy: Analysis of electroencephalograms and cerebral maturation
Y. Babriti1, F. Moutouakil2, B. Benazzouz3, A. Ouichoua4, A. El Hessni5, A. Mesfioui2. 1Biology, Laboratory of Genetics, Neuroendocrinology and Biotechnology, Unit of Nervous and Endocrine Physiology, Faculty of Sciences, University Ibn Tofail, Kenitra, Morocco; 2Neurology, Al Kortobi Hospital, Tangier, Morocco

The objective of this study was to emphasize why and how the change in brain electrical activity in children, adolescents, adults and old men, and take, therefore, a relationship between the evolution of the EEG and epilepsy related to cerebral maturation.

Methods: A clinical study based on analysis of 100 electroencephalograms (EEGs) of epileptic and normal subjects of different ages was carried out at the hospital Al-Kortobi of Tangier, Service of Neurology (Morocco).

Results: Analysis of electroencephalograms showed, first, that during childhood the EEG is characterized by the gradual transformation of brain waves (Delta–Theta–Beta–Alpha) in time reflecting the different stages of brain maturation. On the other hand, there is a regional component of brain maturation in a posterior–anterior gradient chronological. Completion maturation is set between 12 and 14 years.

Conclusions: One thus understands why the newborn babies make mainly motor seizures and why the occipital epilepsy begin preferentially in the very first months from life, while the frontal epilepsy appear only seldom before the 2 year age, and the temporal epilepsy seldom before 8–10 years.

Abstract—WCN 2013
No: 373
Topic: 1—Epilepsy
Vascular seizures
D. Ndoo1, A. Kuqo2, A. Rrojib3, S. Mijo4, E. Kikuc5, J. Krujac6. 1Neurology, Al Kortobi Hospital, Tangier, Morocco; 2Neurology, Al Kortobi Hospital, Tangier, Morocco; 3Neurology, Al Kortobi Hospital, Tangier, Morocco; 4Neurology, University of Tangier, Tangier, Morocco; 5Medical Faculty, Nis, Serbia; 6Medical Faculty, Nis, Serbia

Objective: 39 vascular seizure patients admitted on last 6 months 2012, aged from 20 to 88 years (mean 60.71 years), 18 M; 21 F were evaluated.

Previously hypertension prevailed in 32 patients isolated or associated with: atrial fibrillation, smokers, diabetes mellitus, cerebral palsy, thrombotic syndrome, post-traumatic vertebral dissection stroke, mitral stenosis and clipped aneurisma. Etiology: hemorrhagic (49%), ischemic (61%); post-ischemic 22, post-hemorrhagic 8, acute ischemic 3, acute repeated ischemic 4 and acute hematoma 3 patients. Seizures determining epilepsy followed stroke mainly 15 months/monthly 1–6 m after (74%), while immediate seizures occurred in (26%). Partial motor mostly secondary generalized prevailed (59%), generalized without evident laterality (18%), partial complex (18%), and partial sensory seizures (5%). 16% had secondary generalized SE from partial motor onset. Stroke lateralization; left (46%) to right sided (39%) while bilateral (15%). Lobar localization; F (44%) isolated or spread to P/T (9/8), T (41%) lying to P in 9 or T/T-insular in 7, while bilateral localization in 6 (15%). EEG: Ictal; F, F-T discharge (5%), right F dominated PLEDs (10%). Unrealized (5%) or interictal (80%) in which anterior bilateral unilaterally predominated (41%), focal (23%), bilaterally anterior / posterior to diffuse (16%). AEDs: VPA 13, CBZ 8, TPM 2, LEV 2, GBP 4, DHT 6, CNZ in 3 while two cases of repeated ischemic hemispheric stroke died.

Conclusion: Hypertension was the main cause of stroke determining seizures and women were more affected. Ischemic stroke slightly prevailed, while lobar F and T localization were mostly affected.

Topic: 1—Epilepsy
Seizure severity and health related quality of life of adult Nigerian patients with epilepsy
P.B. Adebayo1, R.O. Akinyemi2, S.A. Ogun3, A. Ogunning4. 1Department of Medicine, Neurology Unit, Ladoke Akintola University of Technology, Ogbomosa, Nigeria; 2Department of Medicine, Division of Neurology, Federal Medical Centre, Abeokuta, Nigeria; 3Department of Medicine, Neurology Unit, Olabisi Onabanjo University, Sagamu, Nigeria; 4Department of Medicine, Neurology Unit, University College Hospital, University of Ibadan, Ibadan, Nigeria

Backgrounds: There is paucity of information about the association of seizure severity and quality of life in PWE in sub-Saharan Africa. We hypothesized that seizure severity will significantly influence QoL of Nigerian PWE.

Objective: We evaluated the relationship of seizure severity to health related quality of life of patients with epilepsy being followed up in an outpatient neurology clinic in southwestern Nigeria.

Materials and methods: Eighty-eight consecutive patients with epilepsy who met the recruitment criteria completed the study questionnaire in company of an eyewitness. The study questionnaire comprised of the National Hospital Seizure Severity Scale (NHSS), the Quality of Life Inventory in Epilepsy (QOLIE-31) and the Beck’s Depression Inventory—II (BDI-II).

Results: We found a minute association between seizure severity and QOLIE-31 total score (r = −.262, p = .014). This association was washed off in the context of depression. However, increased seizure severity predicted a worse QOLIE-31 seizure worry (R² = 0.311, β = −.289; p = 0.003). On a multivariate regression analysis, generalization of seizures and the presence of falls were items on NHSS that predicted a worse QOLIE-31 seizure worry score and time to recover predicted a worse QOLIE-31 total score.

Conclusions: Reducing seizure severity may be an alternate endpoint in epilepsy care in Nigeria (particularly difficult to control seizures) because of its practical clinical relevance in view of the fact that state of the art epilepsy care is still farfetched. Mood stabilizing antiepileptic medications may be useful in this respect.

Abstract—WCN 2013
No: 378
Topic: 1—Epilepsy
Symptomatic epilepsy as a result of stroke
S.T. Ristic1, D.T. Ristic2, I. Marinkovic1. 1Department of Neurology, Clinical Centre Nis, Serbia; 2Institute for Pulmonary Disease, Serbia; 3Medical Faculty, Nis, Serbia

Objectives: Cerebrovascular diseases are significant aetiological factors of epilepsy. Seizures may appear in the acute phase of the insult, or during the convalescence. Our goal was to analyse the frequency and correlation between epileptic seizures and the type and size of cerebrovascular lesion.

Methods: In this prospective study, we evaluated patients with stroke who were hospitalised at the Department of Neurology in Nis,
between January and December 2012. Witnessed epileptic seizures occurred in 129 patients. Patients were evaluated and had the same investigations with anamnestic, clinical, neurological, EEG and neuroimaging (CT, MRI) variables which were compared.

**Results:** Of the 1386 patients with stroke who were admitted to the hospital, 482 (34.78%) had haemorrhagic, and 904 (65.22%) had ischaemic stroke. Mean age was 52 ± 30 years. Of a total of 129 patients with witnessed epileptic seizures, 76 were male and 53 female. 46 (35, 66%) patients with haemorrhagic and 83 (64, 34%) patients with ischaemic stroke developed seizures after 14 days of the stroke. Partial motor seizures (PMS) were registered in 73 (59, 35%) patients, partial seizures with secondary tonic–clonic generalisation (GTC) in 39 (31, 70%) patients and primary GTC seizures in 17 (13, 82%) patients. Status epilepticus (SE) was registered in 9 patients. 69 (53, 49%) patients had EEG pathological changes (spike or sharp-waves) and 36 (27, 90%) patients had focal or diffuse Theta–Delta waves. Normal EEG patterns were registered in 24 (18.60) patients.

**Conclusion:** Patients with ischaemic stroke and cortical lesions are at a higher risk of developing seizures. Partial motor seizures and partial seizures with secondary tonic–clonic generalisation are a dominant feature. Our results differ from the ones in literature, in which patients with haemorrhagic stroke are more likely to develop seizures. It may be the consequence of the fact that the mortality in haemorrhagic stroke patients is higher.

**Ketogenic diet in CDKL5-related epilepsy**

E.C. Wicrell, D. Kenney, S. Eckert, L. Wong-Kisiel, K. Nickels

(statistics for authors is necessary)

**Purpose:** To review efficacy and tolerability of a ketogenic diet (KD) in children with intractable epilepsy and CDKL5 mutations.

**Methods:** Children with a CDKL5 mutation initiated on the KD from 01/2009 to 12/2012 were identified from the KD diet database at Mayo Clinic. Charts were reviewed to determine seizure types and frequencies (a) prior to KD onset, (b) 3 months after KD onset and (c) at final follow-up on the KD. Significant improvement was defined as a >50% decrease in that seizure type.

**Results:** Seven children (4 female, median age at seizure onset 2 months) were initiated on a KD at median age 13 months (IQR 8, 19). Children were on a median of 3 AEDs (2, 3) and had previously failed 1 (0, 3) AED for lack of efficacy. Median duration of KD was 15 months (IQR 5, 27) and at follow-up, 5/7 remained on the diet. At 3 months after initiation, significant improvement was seen in 3/6 with spasms, 2/6 with focal, 2/3 with tonic and 1/1 with myoclonic seizures. At final follow-up on KD, significant improvement was seen in 3/6 with spasms, 3/6 with focal, 2/3 with tonic and 0/1 with myoclonic seizures. However, after initiation of the KD, new seizure types emerged in 4 children (1-focal, 2-tonic, 1-atonic/absence). The KD was well-tolerated, with 2/7 children developing mild and 1/7 severe adverse effects. Diet was discontinued in 2 (1-lack of efficacy, 1-adverse effects).

**Conclusions:** The KD was well tolerated and provided improved seizure control for the majority of children with CDKL5-related intractable epilepsy.

**Topic:** 1—Epilepsy

**Major obstacles in the management of adult epilepsies in a tertiary referral hospital in Northeast Nigeria**

F.K. Salawu, A.B. Olokoba, B.I. Mohammed, A. Danburum

**Background:** In Nigeria epilepsy affects hundreds of thousands of people with only a few neurologists available.

**Objectives:** We set out to assess the present state of epilepsy care in a district tertiary care hospital in northeast Nigeria, and to compare with modern management.

**Materials and method:** This was a retrospective study of hospital records of 200 adults with established epilepsy over the previous 4 years. We used a questionnaire to collect relevant data relating to the diagnosis and management of epilepsy.

**Results:** There were 150 (75%) males and 50 (25%) females with a mean age of 30.2 years (SD 5.8 years). The main aetiology was post traumatic (37%), cerebrovascular disease (22.5%), partially treated meningitis (17.5%), encephalitis (12%), and alcohol (10%). The majority of cases (85%) were generalized tonic clonic seizures. Less than a fifth had EEG and neuroimaging before commencement of AEDs. Patients referred had to travel long distances for EEG, CT and MRI brain and...
most could not afford the high cost of these investigations. Majority of the patients (75%) were on phenytoin capsules, followed by phenobarbitorine (10%), carbamazepine (7.5%), sodium valproate (5%), and ethosuximide (2.5%). There were no facilities to monitor blood concentrations of AEDs. There was lack of knowledge regarding causes and treatment.

**Conclusion:** There is paucity of older AEDs and unavailability of newer generation AEDs and most of them are not aware of the possibility reengineering or do not have money to travel to places where they are available. Cultural beliefs and preference for traditional healers delay treatment.

**Evaluation of hormones in girls with epilepsy in dependence of receiving treatment**

V.V. Guzeva, V.I. Guzeva. Neurology Department, Saint Petersburg State Pediatric Medical University, Saint Petersburg, Russia

Multiple changes in organism which are observed in prepubertal and pubertal age, create necessary not only of clear diagnostics, but also treatment of the disease in view of drug influence on hormonal functions. The aim of study was to investigate the influence of modern antiepileptic drugs on hormonal status in girls with epilepsy. In 50 girls aged 8–17 years with epilepsy, concentration in blood thyroid stimulating hormone (TSH), thyroglobulin antibodies (a/b TG), triiodothyronine (T3), thyroxine (T4), parathyroid hormone (P) and cortisol (C) was investigated. Treatment in most cases included valproic acid, carbamazepine and topiramate. Regardless of applied drugs significant differences in content of hormones were found in 2 (9,52%) cases, and in width of distribution of values — in 7 (33,33%) cases. Highest content of TSH found in girls 8–17 years treated with valproic acid, a/b TG — in ones who didn't got any antiepileptic drugs, T3 — in ones taking barbiturates, T4 — treated with topiramate, P — in girls taking valproic acid. C in girls 8–13 years receiving barbiturates and in girls 14–17 years — taking oxcarbazepine. Within 2–12 months after first study in 19 girls hormone levels were determined again. Levels of hormones in different treatment in relation to original average content of hormones in all girls in 64,86% cases change so as was in the first study. Significant difference in content was found in all hormones in girls with epilepsy treated with different antiepileptic drugs. Choice of antiepileptic drug, its dose and correction should be made considering its impact on children's hormonal profile.

**Application of drug Levocarnitine in children with epilepsy**

O.V. Guzeva, V.I. Guzeva. Neurology Department, Saint Petersburg State Pediatric Medical University, Saint Petersburg, Russia

Long-term studies established expressed disturbance of different brain energy links in ones with epilepsy. The aim of the study was to identify metabolic disorders of 42 amino acids and carnitines and justify their correction by including the drug Levocarnitine in complex therapy of epilepsy in children. 32 children with epilepsy from 3 months to 14 years (12 boys and 20 girls) and 19 children of control group were examined. Blood content of 42 carnitines and amino acids was investigated. In treatment of children with epilepsy, valproic acid was used. The drug Levocarnitine was administrated to 14 children with epilepsy and months later concentration of carnitines and amino acids was examined again. It was found that in children with epilepsy, concentration of 8 amino acids and 6 carnitines was lower, and that of 4 amino acids and 26 carnitines was higher, than that in control group. Also the level of 10 amino acids and 19 carnitines in children with epilepsy significantly (P ≥ 0.90) differs from control group. After taking Levocarnitine in 28 (66,67%) children with epilepsy, tendency to normalization of content of 8 amino acid and 20 carnitines was observed. Significant difference in the content of amino acids and carnitines in children with epilepsy and control group that was revealed before taking Levocarnitine in 12 (42,86%) cases, was absent after taking the drug. So using “Elcar” in complex treatment of epilepsy in children is safe and a quite effective method for correcting disorders of amino acids and carnitine metabolism.

Driving and epilepsy: perspectives of patients with epilepsy in
South Western Nigeria
T.A. Sunmonu, M.A. Komolafe, O.T. Afolabi, O.A. Ogunrin
Medicine, Federal Medical Centre, Owo, Nigeria; 5Medicine, Obafemi
Awolowo University Teaching Hospitals Complex, Ile-Ife, Nigeria;
6Community Medicine, Obafemi Awolowo University, Ile-Ife, Nigeria;
7Medicine, University of Benin Teaching Hospital, Benin, Nigeria

Background: Patients with epilepsy (PWE) with poorly controlled
seizures are restricted from driving in most developed countries but
despite this many PWE still continue to drive.
Methods: This is a case–control study in which 42 patients with
epilepsy (PWE) were studied along with 45 age and sex-matched
normal control subjects. The adapted format of Driver perceptions
and practices questionnaire (DPPQ) was verbally administered to
the participants. DPPQ is a 46-item questionnaire that assesses
the domains of safety concerns, Attitudes towards driving, Perceived
susceptibility/severity, Perceived barriers, Helping relationship and
Self-efficacy. The data obtained were collated and analyzed with the
aid of SPSS version 15.0 statistical software.
Results: Twelve patients were driving regularly among PWE while
15 normal controls were driving regularly. The controls thought of
ways to improve their safety and were less likely to have confidence
to ask family or friends to drive them when compared to PWE. The
PWE that were students or unemployed and those who have driving
licence have lower scores on “self-efficacy” domains when com-
pared to PWE that were employed or possessed driving licence. PWE
who had a high “Perceived barriers” to changing driving behavior and
“Attitude towards driving” scores were more likely to drive when compared to PWE with lower scores.
Conclusion: There were minor differences in the driving behavior of
PWE when compared to normal control subjects and PWE with high
perceived barriers to changing driving behavior and poor attitude
towards driving were more likely to drive.

Wada memory dominance in temporal lobe epilepsy
L. Hanoglua, N. Helvaci Yilmaz, C. Ozkara, M. Uzan, B. Polat,
S. Demirci, 2Neurology, Medipol University, Faculty of Medicine, Istanbul,
Turkey; 3Neurology, Istanbul, Turkey; 4Neurosurgery, Cerrahpasa University,
Faculty of Medicine, Istanbul, Turkey

Background: The mesial temporal lobe epilepsy patients who
undergo left temporal lobectomy and who have seizures postopera-
tively may have memory deficits. While formal neuropsychometric
tests assess the material-specific memory functions, Wada test reveals
a general hemispheric dysfunction against the risk of amnesia by
giving stimuli that may be coded by different ways.
Objective: To examine the relationship between Wada memory
dominance and verbal and nonverbal memory tests.
Materials and methods: Twenty-seven patients (11 males, 16 females,
mean age 33.05 + 5.97) with selective amygdalohippocampectomy were
included. All had undergone the intracarotid amobarbital test
previously. Wechsler Test (immediate recall-WIR, delayed recall-WDR)
and the Sozel Bellek Surecleri Testi (Turkish version of verbal memory
test-delayed recall and recognition) were applied one month before
and 12 months after the surgery.
Results: There was a significant difference between preoperative
and postoperative WIR scores (p = 0.045). When we compare the results
of preoperative and postoperative results of the memory tests, there
was no significant difference between the scores according to the side
of mesial temporal sclerosis (left/right), Wada language dominance
(left/atypic) and Wada memory dominance (left/atypic). There was a
significant positive correlation between the left memory dominance
and verbal delayed recall test scores (r = 0.829, p = 0.042) and also
between atypic memory dominance and verbal recognition test scores
(r = 0.731, p < 0.001).
Conclusion: There was an improvement in visual memory tests after
the surgery. In addition, although Wada memory test assesses both
verbal and visual memory, Wada memory dominance can be effective
in the evaluation of verbal memory, but not visual memory.

Treatment outcome of status epilepticus in Thammasat University
Hospital, Thailand
K. Kulkantarakorn, W. Moonman. Internal Medicine, Faculty of Medicine,
Thammasat University Rangsit Campus, Pathumthani, Thailand

Background: Status epilepticus (SE) is an emergency condition in
epileptic patients. The morbidity and mortality are very high, particularly
in those whose condition is underdiagnosed or improperly managed.
Objective: To describe clinical characteristics, treatment process, outcome and to determine clinical parameters which impact the SE
outcome in Thammasat University Hospital, Thailand.
Material and methods: This was a descriptive study in 60 SE patients
admitted between 2004 and 2011. Data included underlying etiologies,
clinical course, type of antiepileptic drug (AED) treatment and outcome.
Clinical characteristics were described in detail. The correlation between
outcomes and clinical parameters was analyzed by Spearman’s rank
correlation coefficient.
Results: Sixty SE patients were included (38 men; 22 women),
between 15 and 90 years of age, mean age 55 years. Generalized
conslusive status epilepticus (GCSE) was most common (55 events,
91.6%). Forty-three patients (71.7%) had previous diagnosis of
neurological disorders. AED withdrawal and old ischemic stroke were
the common causes of SE. Eight patients (13%) developed refractory
SE. Outcomes of SE included death (15 patients, 25%), complete
recovery (16, 26.7%), partial recovery (12, 20%) and partial recovery
with total dependent (17, 28.3%). The risk factors which correlated
with death were old age, long duration of seizure and coma.
Conclusion: Most SE patients are old and have underlying neuro-
logical disorders. The mortality and morbidity rate were very high.
Death is associated with old age, long duration of seizure and coma.

Pedunculopontine nucleus stimulation: A novel therapeutic
technique in intractable epilepsy
H. Jaseja. G R Medical College, Gwalior, India; Vellore EEG Center,
Gwalior, India

Intractable epilepsy accounts for approximately 30% cases of epilepsy
worldwide, and continues to pose a medical challenge even today.
Several studies have demonstrated the strong anti-epileptic influence of rapid eye movement (REM) sleep in humans, some researchers even claiming it as the most potent anti-epileptic state in human sleep–wake cycle. A reduction of REM sleep is a common feature reported in various forms of intractable epilepsy. Several studies have reported reduction to total disappearance of even the severe EEG abnormalities in West syndrome during REM sleep suggesting an exploratory relation between the reduction of REM sleep and severity/intractability of seizures. In autopsy examination of the cases of West syndrome, the total number of neurons in pedunculopontine nucleus (PPN) and the number of acetylcholine neurons (ACHN) in PPN in particular have been found to be reduced with comparative preservation of catecholaminergic neurons and GABAergic interneurons suggesting a specific change in GABAergic interneurons. Stimulation of AChN in PPN has been observed to induce REM sleep. Therefore, in view of the strong anti-epileptic influence of REM sleep, it is postulated that PPN may be electrically stimulated (with programmable and manual modes) for enhancing the genesis of REM sleep throughout the night sleep time when the susceptibility to seizure generation and occurrence is maximum. Thus, the postulated technique does hold promise as an effective anti-epileptic technique warranting an insightful study of its prospects and the success that may ensue from its preliminary trials.

Topic: 1—Epilepsy
Early onset of cortical thinning in children with Rolandic epilepsy

Background: In clinical practice, there seems to be a correlation between language and Rolandic epilepsy. Epileptiform EEG discharges seem to be a cause, only morphological cortical differences in these children have never been proven.

Objective: Rolandic epilepsy is associated with language impairments. It is investigated whether Rolandic epilepsy is associated with abnormalities in cortical thickness, and whether these abnormalities are associated with declined language performance.

Patients and methods: 24 children (age 8–14 years) with Rolandic epilepsy were compared with 24 age-matched healthy controls. The Clinical Evaluation of Language Fundamentals (CELF) test was performed. Structural T1-weighted MRI was performed at 3 T to enable the assessment of cortical thickness. Linear regression was used to test for differences between patients and controls and to assess the effect of age and language indices on cortical thickness.

Results: For patients the core language index (mean ± SD: 92 ± 18) was lower than that for controls (106 ± 11, p = 0.0026) and below the norm of 100 (p = 0.047). Patients showed specific impairments with respect to the norm in receptive language (87 ± 19, p = 0.002) and language content (87 ± 18, p = 0.0016). Cortex was significantly thinner in patients in receptive language areas. Predominantly in left fronto-temporal regions, significant cortical thinning with age was found in patients only.

Conclusion: Reduced cortical thickness was found in Rolandic epilepsy in a language mediating area. Furthermore, early onset of cortical thinning was observed in multiple language mediating areas. These abnormalities represent subtle but significant pathomorphology of the language system and suggest that Rolandic epilepsy should not be considered merely as a benign condition.

Prenatal lesioning cortical dysplasia rat model with spontaneous temporal lobe seizures
Neurology, Kyushu University, Fukuoka, Japan; bNeuropathology, Kyushu University, Fukuoka, Japan

Background: Focal cortical dysplasia (FCD) is known to be a major cause of intractable epilepsy. We created a novel rat model of FCD by freeze lesioning during the late embryonic stage and examined the relationship between extratemporal FCD and epileptogenesis of temporal lobe seizures.

Objective: To investigate the epileptogenesis and histopathogenesis of FCD.

Material and methods: On embryonic day (E) 18, a frozen probe was placed on the frontal scalp of a Sprague-Dawley rat embryo through the uterus wall to produce multiple (two to four) freeze lesions on each hemisphere. EEG video monitoring for rat pups was performed from postnatal day (P) 35 to P77. Brain tissue was examined by immunohistochemistry, including semi-quantitative densitometry, at E17, E19, E21, P28 and P78.

Results: 68.8% of the rats with multiple FCDs showed spontaneous hippocampal seizures which began by movement cessation and culminated in wet-dog shakes during periods of hippocampal discharge, from P47 onwards. Microscopic findings revealed subarachnoid hemorrhage underneath the lesioned areas at E17, which developed into diffuse cortical necrosis at E19. FCD with severe disorganization and abnormal radial glial cells in the cortical layers appeared clearly after E21. Furthermore, immunoreactivities for N-methyl-D-aspartate receptors and glutamate transporters both in FCD lesions and in hippocampi were significantly enhanced compared to controls.

Conclusion: Prenatal freeze-lesioning of the brain during embryonic development produces a severe disorder of neuronal migration with increased excitability via glutamatergic receptors, and leads to spontaneous temporal lobe seizures in a rat model with multiple FCDs.

Quality of life in psychogenic nonepileptic seizures
A.Z. Ilic. Health Center Studenica, Kraljevo, Serbia

Background: Psychogenic non-epileptic seizures (PNEs) are events resembling epileptic seizures (ES), which are not associated with ictal electrical discharges in the brain but by psychological processes.

Objective: In this study, we compared health-related quality of life (HRQOL) in patients with PNEs with that of patients with ESs.

Methods: We evaluated 28 patients admitted to the Health Center between January 20, 2010, and January 20, 2012. 14 patients with epilepsy and 14 patients with PNEs were recruited. Only patients with the definite diagnosis of ESs or PNEs were analyzed. All participants with ES were prescribed and actively taking antiepileptic medication(s). Patients completed an epilepsy-specific quality-of-life instrument (QOLIE-31), Beck Depression Inventory—II (BDI-II), Adverse Events Profile (AEP), and versions of the illness perception questionnaire revised (IPQ-R) adapted for epileptic or nonepileptic seizure disorders.

Results: Patients with PNEs reported poorer HRQOL and greater depressive symptoms compared to ES participants. The depression and medication side effects have been shown to be important contributors to quality of life in patients with PNEs. The overall HRQOL and scores on 13

doi:10.1016/j.jns.2013.07.050
of 19 QOLIE-31 subscales were significantly lower in PNES than in ES patients. AEP also were worse in PNES patients than in ES patients.

Conclusion: Patients with PNESs have a lower HRQOL and worse mood problems than do patients with ESs. This disadvantage is primarily due to depression and medication side effects. This result has important implications for psychotherapeutic treatment of PNES in that it provides a potentially modifiable target.

Epilepsy: A global cry...raising up the volume

R.N. Mbugu Research, Nairobi University, Nairobi, Kenya; Clinical Research, Neurological Society of Kenya, Nairobi, Kenya

Background: Epilepsy is the most common serious neurological disorder and is one of the world’s most prevalent noncommunicable diseases. Around 90% of people with epilepsy in developing countries are not receiving appropriate treatment.

Objectives: Epilepsy is common in sub-Saharan Africa but is poorly characterized. Most studies are hospital-based, and may not reflect the situation in areas with limited access to medical care. Examination was done, to determine if the clinical features could help elucidate the causes.

Patients and Methods: We conducted a detailed descriptive analysis of 445 epileptic patients identified through a community-based survey of 151,408 people in Kenya, including the examination of electroencephalograms.

Results: Approximately half of the 445 people were children aged 6 to 18 years. Seizures began in childhood in 78% of those diagnosed. An episode of status epilepticus was recalled by 36% cases, with an episode of status epilepticus precipitated by fever in 26%. Overall 169 had an abnormal electroencephalogram, 29% had focal features, and 34% had epileptiform activity. In the 146 individuals who reported generalized tonic-clonic seizures, only 22% had focal features on their electroencephalogram. Overall 71% of patients had evidence of focal abnormality, documented by partial onset seizures, focal neurologic deficits, or focal abnormalities on the electroencephalogram.

Conclusion: Children and adolescents bear the brunt of epilepsy in Africa Low Income settings. The predominance of focal features and the high proportion of patients with status epilepticus, suggest that much of the epilepsy in this region has identifiable causes, many of which could be prevented.

Status epilepticus in thrombotic thrombocytopenic purpura: A case report

Y. Handouk, A.M. Mauro, M.G. Passarin. Neurology Unit Ospedale Bufalini, Cesena, Italy

Background: Thrombotic thrombocytopenic purpura (TTP) is a condition characterized by an ischemic vasculopathy frequently associated with fluctuating neurologic symptoms, including confusion, stupor, and seizures.

Objective and methods: We describe a 30 year old man with TTP who developed seizures not well controlled with intravenous midazolam and oxcarbazepine. He had a progressive neurological deterioration and EEG showed a non convulsive status epilepticus (NCSE). He was treated in intensive care unit with intravenous levetiracetam (LEV) after midazolam bolus for 48 than switched to oral therapy (total dose of LEV 3000 mg/die), in association with plasma-exchange and Rituximab. His neurological status improved in few weeks and he had a complete neurological recovery. He stopped oral LEV six months after hospitalization.

Conclusion: Fluctuating stupor in TTP has generally been attributed to microvascular occlusive disease, but NCSE is a treatable condition that can cause similar symptoms. Aggressive treatment with rituximab, plasma-exchange and antiepileptic drugs may prevent permanent neurologic deficits.

Role of polymorphism (rs2986017) and (rs11191692) in the calcium homeostasis modulator 1 (CALHM1) gene in temporal lobe epilepsy

M. Nada, N. Sewelam, H. Helmy. 1Neurology, Cairo University, Cairo, Egypt; 2Clinical Pathology, Cairo University, Cairo, Egypt

Background: Calcium homeostatic mechanisms play an important well known role in the development and maintenance of epilepsy in general.

Objectives: Investigate the role of calcium homeostasis modulator 1 gene, SNPs; rs2986017 and rs11191692 in temporal lobe epilepsy in Egyptian patients and its influence on clinical manifestations.

Patients and Methods: A case–control study conducted on 55 Egyptian unrelated temporal lobe epilepsy patients and 31 healthy Egyptian control subjects, age and sex matched. Neurological examination, electroencephalogram and brain MRI were done to all patients to confirm temporal lobe epilepsy. Two single nucleotide polymorphisms of calcium homeostasis modulator 1 gene, rs2986017 and rs11191692 were genotyped using PCR-RFLP for both studied groups.

Results: The genotype and allele frequencies for SNPs; rs2986017 and rs11191692, did not differ between TLE patients and control group (P value = 0.435, 0.884, 0.621 and 0.690 respectively). Regarding SNP rs2986017, the CC genotype and the C allele were the most frequent among SNPs rs11191692, did not differ between TLE patients and control group (P value = 0.369). Conclusion: Our study did not support the hypothesis that CALHM1 SNP rs2986017 or rs11191692 is associated with the risk of TLE. Elucidation of the precise mechanism requires further functional study as well as genetic analysis in independent population samples and on larger scales.

Features of myoclonic epilepsy of adolescence
M. Barabanova, L.V. Shagal, V.K. Oranskaya, Nervous System Diseases and Neurosurgery, Kuban State Medical University, Krasnodar, Russia

Background: myoclonic epilepsy of adolescence (MEA) is an idiopathic form of epilepsy, with occurrence of up to 11–12% of all epilepsy forms.

Material and methods: 42 clinical cases were analyzed (12 males, 30 females) using the psycho-neurological, neurophysiological, neuro-imaging examination.

Results: The average onset of the disease was at 13.2 ± 0.5 years. The leading clinical symptom was epileptic myoclonus in various muscle groups. 5 (7.1%) patients’ had also generalized seizure paroxysms, 2 (4.7%) patients developed absences. All patients experienced fits in the morning. The provocation factors were sudden awakening, sleep deprivation, alcohol consumption and stress. 2 patients had positive reflexes of oral automatism, myoclonic jerks in face, the rest of patients had no neurological deficiency out of epi-paroxysms. EEG showed the appearance of short discharges or generalized polyspikes or polysharp-wave patterns. The valproic acid therapy induced remission in 18 patients, 21 patients developed positive dynamics with reduction of myoclonic episodes and generalized seizure paroxysms frequency, 2 patients developed the disease aggravation, one showed no improvement.

Conclusions: Female patients dominate (2:1). The isolated myoclonic attacks prevailed, there was a combination with generalized seizure paroxysms and absences in 11.8% of cases only. Monotherapy with valproic acid medications was effective in major part of MEA cases; in certain cases aggravation of the disease is possible, that is a reason for dose reduction or medication substitution.

The possibilities of neuroimaging in diagnostics of symptomatic epilepsy in children
K. Aminov, Medical Radiology, Tashkent Institute for Postgraduate Medical Education, Tashkent, Uzbekistan

Background: Epilepsy is one of the most complex medical and social problems at present time. The high prevalence of the disease in paediatric population of Uzbekistan (10 per 1000) determines the importance to develop effective measures for early diagnosis, new approaches to correction of treatment and prevention of complications of epilepsy.

Objective: To identify MRI findings of symptomatic epilepsy in children with inflammatory etiology such as meningoencephalitis.

Materials and methods: MRI studies were conducted with 35 children with the diagnosis of symptomatic epilepsy after meningoencephalitis. Children ages ranged from 1 year to 14 years.

Results: in our study the main symptoms of epilepsy after meningoencephalitis were multiple lesions of white and gray matter, their predominant bilateral symmetry, a clear demarcation from the surrounding tissues. In the study of 35 children who recovered from meningoencephalitis following MRI signs were found, in 5 (14.3%) cases it was midline shift of the brain, in 12 (34.3%) cases it was asymmetry of the lateral ventricles. Subarachnoid perivascular space expansion was found in 22 (62.9%) cases, which often revealed in the fronto-temporal region of the

Effect of AED on the EEG pattern in epileptic children
L. Khatchidze, V. Maloletneva, M. Gugushvili, I. Mijo, I. Zekja, S. Grabova, E. Konda, D. Dobi, S. Xhaxho, J. Kruja, Tbilisi, Georgia

Background: The value of qEEG analysis as predicting seizure exacerbation in children with new onset epilepsy is important. The aim of the work was to study the dynamics of EEG characteristics in epileptic children at different stages of antiepileptic drug (CBZ) monotherapy.

Objective: 78 epileptic children (4–10 years old, Males — 41, Females — 37) were analyzed. All patients have partial seizures with or without secondary generalization. The EEG performed in three times: at the first visit (before the administration of CBZ) and in 3–4 and 6–8 months after the beginning of the treatment.

Methods: Following characteristics of EEG were analyzed: absolute values of the power spectra (AVP), EEG mapping-topography and qualitative characteristics. The recordings were performed on wake state in the same time.

Results: The quantitative analysis of AVP dynamic revealed a reliable increase of this index 3 months after the beginning of the treatment. Elevation remained after 6 months of treatment. This effect most expressed in low frequency bands. CBZ therapy showed decreases an average frequency of alpha waves. The qualitative analysis revealed decrease in the density of spontaneous epileptiform graphoelements and generalized epileptiform bursts.

Conclusion: Any type of AED should be accomplished with maximal caution and under regular EEG control, due to in some cases worsening of EEG revealed (predict) before the onset of clinical signs of exacerbation.

The study of EEG pattern of background activity, spectral analysis, EEG mapping (topography) and qualitative analysis using qEEG approach during AED therapy allows to determine correctly the treatment strategy.

EEG findings in post-stroke seizures
S. Mijo, I. Zekja, S. Grabova, E. Konda, D. Dobi, S. Xhaxho, J. Kruja, Service of Neurology UHC Mother Theresa, Tirana, Albania

Background: Stroke is an important cause of epilepsy especially in elderly. EEG findings are generally not considered to be very helpful for the diagnosis of post-stroke seizures.

Purpose: The aim of the study was to describe the EEG characteristics in patients who developed seizures after stroke.

Patients and methods: The study population consisted in 130 patients with ischemic or hemorrhagic first-ever stroke admitted at our Service from March to December 2010. Patients with SAH, Cerebral Vein Thrombosis and previous history of seizures were excluded from the study. All the patients underwent brain CT scan or MRI. 17 patients with post-stroke seizures had an interictal EEG after the first seizure. EEG electrodes were placed according to the International 10–20% system. Activation procedures such as hyperventilation and photic stimulation were done when it was possible.

Results: Ischemic stroke was diagnosed in 94 (72%) patients and hemorrhagic stroke in 36 (27.6%) patients divided in 76 (58.4%) males and 54 (41.5%) females and mean age 68 +/- 12 years. Periodic lateralized epileptic discharges (PLEDs) on the EEG after stroke were found in one patient, (5.8%). Frontal intermittent rhythmic delta activities (FIRDAs) were observed in 4 patients (23.5%). Diffuse slowing was found in 6 patients, 35.3% of the seizure group. Normal EEG findings were seen in 3 patients, 11.8% of the post-stroke seizures patients. Focal slowing was found in 3 patients, 17.6 % of seizures group.

Conclusion: FIRDAs and diffuse slowing are the most frequent EEG findings in patients who developed seizures after stroke.

Clinical presentation and neurophysiological findings in patients with pineal region expansions — Our 17 year experience
S. Nankovic, S. Hajnsek, A. Bujan, Kovaca, J. Paladinob, Z. Petelin Gadzea, V. Sulentic, I. Kovacevic, “Dpt. of Neurology, University Hospital Centre Zagreb, Zagreb, Croatia; bDpt. of Neurosurgery, University Hospital Centre Zagreb, Zagreb, Croatia

Background: In the neurological and neurosurgical follow up of our patients with pineal region expansions, we have noticed certain clinical and neurophysiological regularities.

Objective: To perform retrospective study including 84 patients with pineal region expansions in the period from 1992 to 2009.

Patients and methods: The study included 55 women and 29 men. All patients had headache, while 32 patients (38%) had primary generalized seizures. Common EEG pattern showed paroxysmal discharges of 3 or more Hz spike-and-wave complexes. Brain MRI showed in 70 patients (83.4%) cysts, and 14 patients (16.67%) had expansive process with compressive effect. Based on the size of the cyst (15 mm or more) and signs of compression on the quadrigeminal plate and of the surrounding veins operation was performed in 70 patients.

Results: Pathohistological analysis revealed pineocytomas in 11 cases (15.71%), pinealoloblastomas in 2 cases (2.86%), one case of teratoma (1.43%), while 56 patients had cysts (80%). Following surgery clinical condition improved in all patients — patients became seizure-free and headaches significantly decreased, and other symptoms (diplopiae, nausea, vomiting, vertigo and blurred vision) disappeared.

Conclusion: Headache and also primary generalized seizures are often present in patients with pineal region expansions. Mass effect on the surrounding veins and compression on the quadrigeminal plate and the aqueduct, together with hemosiderin deposits can be involved in the pathogenesis of seizures. We suggest to perform high resolution brain MRI in all young patients that have seizures and specific EEG changes.

Common reference-based indirect comparison meta-analysis of intravenous valproate versus intravenous phenobarbitone in generalized convulsive status epilepticus
F. Brigoa,b, F. Tezzonb, L.G. Bongiovannia, “Department of Neurological, Neuropsychological, Morphological and Movement Sciences, University of Verona, Verona, Italy; bDivision of Neurology, Hospital Franz Tappeiner, Meran, Italy; cDepartment of Neurology, Paracelsus Medical University, Salzburg, Austria

Background: In the literature, only one randomized control trial (RCT) directly compared intravenous valproate (IV VPA) with intravenous phenobarbitone (IV PB) in the treatment of established generalized convulsive status epilepticus (GCSE).

Objective: To compare IV VPA with IV PB in the treatment of established generalized convulsive status epilepticus (GCSE) through a common-reference based indirect comparison meta-analysis.

Material and methods: RCTs of IV VPA and IV PB versus IV PHT for GCSE were systematically searched. A random effects model was used to estimate Mantel–Haenszel odds ratios for efficacy and safety of IV VPA versus IV PHT in a standard meta-analysis. Adjusted indirect comparisons were then made between VPA and PB using the obtained results.

Results: The CRBMA showed that, compared with PB, VPA does not lead to significantly higher seizure cessation (OR 1.00; 95% CI 0.36–2.76), although it has lower adverse effects (OR 0.17; 95% CI 0.04–0.71). Results of CRBMA are consistent with those of a recently published head-to-head comparison between IV VPA and IV PB.

Conclusion: There is no evidence supporting a superiority of IV VPA over IV PB for the treatment of GCSE in terms of efficacy. Some data derived from direct and indirect comparisons suggest that VPA has a better safety profile than PB. In the absence of comparative clinical trials studies, a CRBMA provides some evidence of the relative efficacy and safety of competing AEDs.

Anticonvulsant actions of Ska-31 in pilocarpine treated chronic epileptic rats

Purpose: Pilocarpine-induced status epilepticus or limbic seizure model is use to test activity of new molecules with anticonvulsant potential. In the present study we focused on anticonvulsant effect of Ska-31 (SK-channel opener) in pilocarpine-induced epileptiform activities.

Methods: Male Wistar rats (4–5 weeks) were pre-treated with methylscopolamine (1 mg/kg) followed by i.p. administration of pilocarpine (340 mg/kg). 90 min post status epilepticus, diazepam is injected intraperitonealy (10 mg/kg). Animals were observed under video recording for about 5–6 days. Age-matched pilo control group received same protocol except saline instead of hippocampal slices (400 μM) from pilo treated and pilo-controls rats were prepared. Age-matched control rats were used that received saline instead of pilocarpine. To induce epileptiform activities in slices 4-aminopyridine (4-AP, 100 μM) is used. Local field potential recordings were performed from medial entorhinal cortex using glass microelectrode filled with ACSF.

Results: Ska-31 at 150 and 50 μM blocked SLE in 87% and none of slices respectively. Whereas, in control slices blockade of seizures is observed in 100% of slices. It is noticed that Ska-31 significantly decreased duration of SLEs in 23 ± 4 min of application as well as reduction in amplitude of SLEs. Whereas, complete seizure suppression is achieved in 33 ± 2 min.

Conclusion: These results suggest that Ska-31 suppressed ongoing propagation of epileptiform events in chronically treat pilocarpine rats.

American Clinical Neurophysiology Society’s standardized critical care EEG terminology: Interrater reliability and 2012 version
Background: Critical care EEG (ccEEG) monitoring has gained widespread use. However, uniformly accepted nomenclature for EEG patterns encountered in these patients has been lacking.

Objective: A group of electroencephalographers from the American Clinical Neurophysiology Society and the Critical Care EEG Monitoring Research Consortium developed standardized ccEEG terminology to describe rhythmic or periodic EEG patterns, avoiding terms with clinical connotations e.g. “triphasic waves”.

Results: Rhythmic or periodic patterns are characterized by a Main term #1 to describe pattern location (Generalized, Lateralized, Bilateral Independent or Multifocal), followed by Main term #2 to describe pattern type (Periodic Discharges (PDs), Rhythmic Delta Activity (RDA), or Spike/Sharp-and-wave). Additional modifiers such as Prevalence, Duration, Frequency, Amplitude and Sharpness are added.

Another key modifier is the “Plus” term, indicating patterns which are more ictal-appearing. For PDs this includes superimposed fast or rhythmic activity and for RDA, fast activity or intermixed sharp waves or spikes. Characterization of background activity and standardized quantification of sporadic epileptiform discharges is also included.

Analysis of interrater agreement (IRA) for a 2010 version of this terminology showed good IRA for main terms 1 and 2 (Kappa values 0.87 and 0.92, respectively) and moderate IRA for “plus” modifiers. Further IRA analysis of the current version is underway. An online training module and neonatal version have been completed; certification testing and incorporation into the “SCORE” system are underway.

Conclusion: Adoption of standardized critical care EEG terminology will aid in communication and facilitate multicenter research in order to study the significance of these complex patterns.

Assessment of connectivity strength between the primary focus and remote cortical FDG PET abnormalities in children with non-lesional epilepsy

O. Muzik, C. Juhasz, J. Hua, E. Asano, H. Chugani, Pediatrics, Wayne State University Medical School, Detroit, MI, USA

Objective: Our objective was to quantitatively assess the connectivity strength (based on probabilistic DTI analysis) of fiber tracts that originate in the seizure onset region (as defined based on intracranial ECoG) and that project to remote cortical areas characterized by 18-deoxyglucose (FDG) PET abnormalities that are electrophysiologically normal.

Method: We developed a computational framework that allows quantitative assessment of the spatial relationship between modality neuroimaging data (MRI, DTI, PET, and ECoG). The framework is based on the parcellation of the cortical surface in native space using landmark-constrained conformal mapping, which yields finite cortical elements (FCEs) that are homotopic across subjects. The FCEs were subsequently used as source/target regions for probabilistic fiber tracking (55 direction), allowing the calculation of a connectivity score. We applied this approach to 7 young children (3–12 years) with non-lesional epilepsy who underwent presurgical evaluation and compared the obtained connectivity pattern against 12 age-matched normal children.

Results: Only few FDG PET abnormalities were determined within the ECoG confirmed seizure onset area, although FDG PET abnormalities were frequently observed adjacent to this area, most likely as a result of functional disconnect of this area from ictal involvement. Connectivity analysis showed a decreased connectivity score (3–9%) in epilepsy patients compared to the normal group. Moreover, significant abnormalities in the connectivity pattern between the seizure onset and other cortical lobes were determined.

Conclusion: Our findings indicate that the connectivity strength between the primary focus and remote FDG PET abnormalities is decreased as compared to a normative group.

Infantile spasms in children: Clinical features and outcome

T. Sultan. Child Neurology, The Children Hospital & Institute of Child Health, Lahore, Pakistan

Objective: Clinical features and outcome of children with infantile spasms.

Study design: Interventional and observational study.

Place and duration of study: The Department of Neurology, Children’s Hospital, Lahore, Pakistan, from April 2008 to March 2013.

Methodology: Children aged <2 years presented with history of infantile spasms were assessed. Clinical presentation, EEG findings and response of anti-epileptic drugs was analyzed.

Results: We enrolled 450 infants with infantile spasms at their first presentation. Out of 450 children, 76% presented at age of <6 month, 72% presented due to infantile spasms and 18% because of global developmental delay. Spasm types were mixed (38%), flexors (44%), extensor (16%) and asymmetric (2%). Hypsarrhythmia (67%) was the predominant EEG finding followed by modified hypsarrhythmia (24%) and other forms of epileptic discharges in 9% children. Majority of children were receiving oral Phenobarbitone, Carbamazepine or Valproate sodium. We initiate the management with oral Prednisolone followed by Clonazepam or valproate acid. ACTH therapy was administered in only 5 children.

Conclusion: Infantile spasms are one of the refractory epilepsy in children. Abnormal EEG findings predominantly the hypsarrhythmia or modified hypsarrhythmia are the hallmark. Majority of children received conventional AED with poor response. Oral prednisolone is proved to be the most effective AED. These children should be referred to the tertiary care pediatric neurology centers.

Continuous EEG in critically ill patients: Experience at a single tertiary care center

H. Arif, S.M. LaRoche. Neurology, Emory University, Atlanta, GA, USA

Background: Continuous EEG (cEEG) can provide critical information about brain function including detection of causes of secondary injury such as seizures. Although recent advances have led to widespread use of cEEG in this population, there is limited data on current clinical practices.

Objective: To describe clinical findings in critically ill patients undergoing cEEG at a tertiary care center over a three year period.

Patients and methods: We retrospectively reviewed data from 1305 cEEG monitoring sessions from 2009 to 2011. Patients were selected to undergo cEEG at the discretion of the treating physician. Indications for monitoring, EEG findings, neurologic diagnosis and outcome at discharge were assessed.

Results: The primary indication for cEEG was the detection of subclinical seizures (72.3%), followed by characterization of spells (18.5%). The three most common neurologic diagnoses were subarachnoid hemorrhage (16.5%), altered mental status (16.0%) and new-onset seizure (10.1%). Seizures were reported in 17.9% (216/1202 patient encounters) and 51% (110/216) were exclusively electrographic.

High rates of nonconvulsive seizures were seen in patients with CNS infection (36.4%, n = 4/11), CNS neoplasm (16.4%, n = 11/67), vascular malformation (16.7%, n = 1/6) and intracerebral hemorrhage (10.4%, n = 10/96). Good outcome (discharge to home or rehab) was seen in 46% of all patient encounters and 48% of patients who experienced seizures during cEEG.

Conclusion: Subclinical seizures are common in critically ill patients with a variety of underlying neurologic diagnoses. Prospective studies are needed to determine the incidence and predictors of seizures in a non-selected population as well as the impact of seizures on outcome.

An epidemic of seizures and psychosis in a sudanese village — A challenging experience

O. Seidi. Neurosciences, Soba University Hospital, University of Khartoum, Khartoum, Sudan

Background: In January 2010, a wave of pathological laughter, crying and bizarre behavior affected about 122 people in a remote village in the far North West State of Kordofan in Sudan.

Patients, methods and results: Detailed investigation of the clinical presentations and possible underlying causes was done with provision of medical treatment.

Children constituted 52% and were more severely affected than adults. The main presentations were visual hallucinations, uncontrolled laughter, twisting movements, delirium, and convulsions. No vascular manifestations were detected. Males were affected more than females (60%).

In a few of the severely affected patients a lumbar puncture was performed (7/122). The patients were treated symptomatically with benzodiazepines. Carbamazepine was used in those presenting with recurrent seizures. Routine urine, blood and CSF basic parameters were within normal limits for routines, but the toxicology screen of urine missed the critical period for detection of the suspected toxic substances. Samples from the water sources were clear, but the wheat consumed by the villagers grew the fungus Claviceps purpurea in abundance. Further tests on the fungi revealed their production of very high level of LSD-like ergot alkaloids. No long term neurological sequelae were noticed on follow up.

The wheat came from stores in Darfur which is near the affected village. The epidemic was contained and a public education campaign was launched to avoid recurrence of the event.

This paper includes videos and a literature review.

Conclusions: This study draws attention to the importance of vigilance about neurotoxins as causes of bizarre presentations.

The sensitivity of the long term eeg and sleep eeg in the diagnosis of epilepsy

I. Uluçag, L. Ocek, Y. Zorlu, F. Tokucoglu. Neurology, Tepecik Educational and Research Hospital, Izmir, Turkey

Background: Long term video-EEG monitorization (LTEEG) is a very valuable diagnostic tool in the differential diagnosis of epileptic and non-epileptic seizures, in the classification of epileptic seizures and in the evaluation of surgical candidacy in patients with medically refractory seizure disorders. When there is diagnostic uncertainty as to the diagnosis of epilepsy, LTEEG is used to detect interictal epileptiform abnormalities. Sleep-EEG may also reveal interictal epileptiform abnormalities in patients with an initial negative routine EEG.
Objective: We aimed to compare the sensitivity of the LTEEG and sleep-EEG in the diagnosis of epilepsy.

Patients and methods: We recruited 29 adult patients with epilepsy, hospitalized at least five days in the LTEEG laboratory without any observed clinical events during the test. We performed a sleep-EEG study of 30 min in the following week and we compared the result of the LTEEG with the result of the sleep-EEG.

Results: The results of the LTEEG and the sleep-EEG were same in 28 of the 29 patients (96%). In only one patient, generalized interictal epileptiform abnormalities were observed in LTEEG whereas sleep-EEG was normal.

Conclusion: In patients with epilepsy, sleep-EEG is as sensitive as the LTEEG to detect the interictal epileptiform abnormalities. While LTEEG will remain the gold standard for confirming the electrophysiology underlying a given event, sleep-EEG represents a practical and cost-effective alternative in the diagnosis of epilepsy.

White-matter tract integrity and seizure propagation in non-lesional temporal lobe epilepsy

H. Leung, D. Wang, L. Shi, L.K. Wong, V. Mok. The Chinese University of Hong Kong, Hong Kong, Hong Kong, S.A.R.

Background: Non-lesional temporal lobe epilepsy (TLE) patients refractory to antiepileptic drugs are candidates of presurgical evaluation. We explored diffusion-tensor imaging (DTI) and its utility in elucidating the biology underlying a given event, sleep-EEG represents a practical and cost-effective alternative in the diagnosis of epilepsy.

Methods: Fourteen patients with electrographic unilateral non-lesional TLE (7 left, 7 right) and sixteen normal subjects underwent DTI with 31 diffusion-gradient directions followed by computation of fractional anisotropy (FA)-values by voxel-based morphometry (VBM) and construction of two major temporal-lobe tracts: inferior-longitudinal-fasciculi (ILF) and uncinate-fasciculi (UF). Tract-based-spatial statistics (TBSS) offered calculation of FA-values for each tract using automated VBM-database. The averaged duration of hemispheric seizure-involvement was calculated for each temporal region of left/right TLE-groups.

Results: The FA-values of ILF and UF were significantly different between the temporal lobes in normal subjects (p < 0.005) and in non-lesional TLE patients (p < 0.005). Using ILF, both left/right TLE patients had significantly different ipsilateral FA-values compared with normal subjects (p < 0.006) and similar results were found with UF. Left TLE patients had significantly different ipsilateral FA-values in ILF when compared with right TLE patients (ipsilateral-higher-FA) (p < 0.006) and similar results were found with UF (ipsilateral-lower-FA). Using UF, multiple linear-regression on right TLE patients showed a significant correlation between duration of ipsilateral-onset and ipsilateral FA-values (R² = 0.69, p = 0.02) and a similar result for duration of contralateral-spreading and contralateral FA-values (R² = 0.6, p = 0.04). Corresponding analyses on left TLE with UF, or that using ILF, were not significant.

Conclusions: Left/right non-lesional TLE patients were functionally different categories and their side-to-side difference may be demonstrated on DTI. Frontal–temporal connections may underlie the association between seizure-spreading/prolongation and white-matter tract integrity in this group of patients.

The study of mental disorders in children with age related epilepsy with centro-temporal (Rolandic) spikes

D. Zaytsev a, N. Titov b, aPsychiatry, Zaytsev’s Psychoneurological Center, St. Petersburg, Russia; bNeurology, Zaytsev’s Psychoneurological Center, St. Petersburg, Russia

Purpose: To examine the association between age at onset, massiveness of Rolandic spikes in sleep EEG, their localization in the beginning of the process, migration of spikes through the cerebral cortex during the follow-up and to examine mental disorders in children to address the question of the appropriateness of anti-epileptic therapy and its duration.

Material and methods: Children with early onset “Rolandic” epilepsy (up to 3) years, 10 people, with the debut of the children of 4–7 years, 10 people, and children with late onset Rolandic epilepsy (over 7 years) also 10. These children did not show any clinical neuromaging and neurological disorders.

Evaluation of mental disorders (including speech) was carried out at the first call, and every year before Rolandic spikes reduction in EEG. In addition, academic performance (in school) was examined.

Results: For the younger age group in the first place on the representation of mental disorders detected tempo delayed development of speech skills, the second highest representation of symptoms in these children was ADHD; in the middle age group ADHD reaches a degree of psychopathic disorders, while speech disturbances were mild or not diagnosed. In the older age group mental disorders should not go beyond the mild forms, without changing the school and social adaptability.

Conclusions: Children with age related epilepsy with Rolandic spikes at an early onset are more in need of anti-epileptic therapy, which is pathogenic for such mental disorders.

Topic: 1 — Epilepsy
Clinical features of epileptic attacks in patients with acute stroke and rational approaches to its treatment

D. Izyumova a, G. Izyumova b, aKhorezm Regional Multifield Medical Centre, Uzbekistan; bRepublican Scientific Centre of Emergency Medical Aid, Khorezm Branch, Urgench, Uzbekistan

Goal: To study epileptic attacks clinical features in patients with acute stroke and to develop approaches to rational therapy.

Materials and methods: Comprehensively examined 78 patients with acute ischemic stroke: men – 46 (59%), 32 (41%) – women (44 to 78 years). Neurological examination performed by standard technique using instrumental investigation methods — electroencephalography, Doppler ultrasound of head main arteries, and brain computer tomography.

Results: The analysis showed: the left and right hemisphere strokes were equally often, 37.4% and 39.1%, respectively, in 13% of patients with stroke in vertebrobasilar basin, 10.5% patients suffered from recurring cerebral stroke. 16% of patients had auras, in 22 (28.2%), patients epileptic attacks developed in stroke debut, in 7 days after stroke epileptic attacks were observed in 28 (35.9%) patients. 68 (87.2%) patients had the prevalence of focal attacks, and 15 (22%) had simple partial attacks, 21 (30.9%) patients — the second-generalized, and only 20 (29.4%) — polymorphic partial attacks. The status epilepticus developed in 2 (2.9%) cases at stroke debut. Primary generalized attacks were only observed in 7 (10.3%) patients.
The foci of epileptiform activity were revealed in 22 (28.2%) patients, and 56 (71.8%) patients had centers of slow-wave activity. Left-sided localization of focal activity predominated in 48 (61.5%) cases. 26 (33.3%) cases revealed a tendency to predominance of critical stenosis and occlusion of left carotid.

**Conclusions:** Rational approaches to treatment of these patients will improve the quality of life, and social and family adaptation.

**Autosomal recessive cortical myoclonic tremor and epilepsy: Association with a mutation in the potassium channel associated gene CNTN2**

E. Stögmann. Department of Clinical Neurology, Medical University of Vienna, Vienna, Austria

We characterize a consanguineous Egyptian family with an autosomal recessively inherited familial cortical myoclonic tremor and epilepsy. We used multipoint linkage analysis to map the causative mutation to a 12.7 megabases interval within 1q31.3–q32.2 with a LOD score of 3.6. For further investigation of the linked region in an efficient and unbiased manner, we performed exome sequencing. Within the suspected region we identified a homozygous single base pair deletion (c.503_503delG) leading to a frameshift in the coding region of the 6th exon of CNTN2 alias TAG-1 (p.Trp168fs), which segregated in the respective family. Many studies point towards an important role of the CNTN2 product Contactin-2 in neuronal excitation. Contactin-2, a glycosylphosphatidylinositol-anchored neuronal membrane protein, and another transmembrane protein called Contactin-associated protein-like 2 are together necessary to maintain voltage gated potassium channels at the juxtaparanodal region. CNTN2 knockout mice were previously reported to suffer from spontaneous seizures and mutations in the gene encoding Contactin-associated protein-like 2 have been described to cause epilepsy in humans. To further delineate the role of CNTN2 in epilepsy patients, we sequenced the coding exons in 189 Caucasian epilepsy patients. No recessive mutation was detected, and heterozygote carriers of rare CNTN2 variants do not seem to be predisposed to epilepsy. Given the severity of the mutation and the proposed function of the gene, we consider this mutation as the most likely cause for cortical myoclonic tremor and epilepsy in this family.

**Subjective handicap in people with epilepsy in Georgia and Turkey**

N. Gvirishvili1, E. Togonidze2, G. Lomidze2, Ç. Özkara3b, G. Gözübatkar4b, S. Kasradzea, A. Tsiskaridzec, J.W. Sander3be, 1Institute of Neurology and Neuropsychology, Tbilisi, Georgia; 2Istanbul University Cerrahpasa Medical Faculty, Istanbul, Turkey; 3Tbilisi State University, Tbilisi, Georgia; 4Department of Clinical and Experimental Epilepsy, UCL Institute of Neurology, Queen Square, London, UK; 5SEIN – Epilepsy Institute in The Netherlands Foundation and WHO Collaborating Centre for Research, Training and Treatment in Epilepsy, Hoofddorp, Netherlands Antilles

**Background:** People with epilepsy have an impaired quality of life due to the impact of the condition on various domains of their life.

**Objective:** To assess epilepsy-related subjective handicap in people with epilepsy in two neighboring countries: Georgia and Turkey.

**Methods:** We distributed self-administered questionnaires to consecutive people with epilepsy taking antiepileptic drugs attending outpatient clinics at I.U. Cerrahpasa Medical Faculty in Istanbul and at the Institute of Neurology and Neuropsychology in Tbilisi. The SHE questionnaire was used which contains 32 items in six domains. Low score indicates higher handicap. Probabilities of <0.05 were considered as significant.

**Results:** A total of 200 people took part (equal number at each site). Mean age was 31.7 years. 62% of responders were female. 24% had completed higher education. 27% had a “Work and activities” score below 50 points, 13% for “Social and personal”, 28% for “Self perception”, 30% for “Physical”, 19% for “Life-satisfaction” and 23% for “Change” domains. In ‘Social和个人’ (p = 0.003), ‘Life satisfaction’ (p = 0.042) and ‘Change’ (p = 0.006) subdivisions mean rank among people in Georgia were significantly lower except in “Social and personal” domain in which the Georgian cohort had higher scores. Association was found between social class and subdivision variables such as ‘Physical’ (p = 0.036), ‘Self perception’ (p = 0.001), ‘Life satisfaction’ (p = 0.001) and ‘Change’ (p = 0.001). People in lower social strata had lower scores.

**Conclusion:** Epilepsy imposes a high social burden on people in both countries with people with epilepsy in the lower strata of society may have a high burden.

Epilepsy and Parkinson: Frequent combination?

H. Stefan, J. Winkler. Dept. of Neurology, University Hospital Erlangen, Erlangen, Germany

Background: Between 2000 and 2010 a cohort of 612 patients with Morbus Parkinson were registered. 21 of those suffered from epilepsy and Parkinson. Male = 15 patients, age 52–91 years, mean 74 years; female = 6 patients, age 64–88 years, mean 80 years. Etiology of epilepsies of all was analyzed.

Objective: Epidemiological studies indicate a strong increase of elderly patients. Compared to 1985 in 2030 an increase of 30% of the population in Germany will be older than 65 years is estimated. The question arises: Which comorbidities of neurological disorders, especially epilepsy and Parkinson occur because in special syndromes (FTDP-17) a frequent combination of both is described. How frequently patients with Morbus Parkinson also suffer from cryptogenic epilepsies (unknown etiology).

Patients and methods: Most patients suffered from symptomatic epilepsies due to ischemia or intracranial bleedings (n = 11), while only two patients suffered from cryptogenic focal epilepsies (0.32%).

Results: Our findings indicate a rare coincidence of Morbus Parkinson disease and cryptogenic epilepsies. This is in agreement with observations that occurrence of Parkinson decreased seizure frequency. Concerning seizure inhibition reduced GABAergic and dopaminergic mechanisms are reported.

Conclusion: Anticonvulsant action of dopamine is attributed especially to D2 receptor stimulation in the fore brain. Because epilepsy treatment by means of selective D2 agonists is beneficial in animal studies a well designed clinical trial is warranted to test its efficacy.

Prescription patterns and self-reported side effects of antiepileptic drugs in patients with epilepsy at tertiary referral center in Austria

E. Pataraia, R. Jung, K. Trimmel, S. Aull-Watschinger. Medical University of Vienna, Vienna, Austria

Objective: The aim of the present study was to examine the trends in prescribing antiepileptic drugs (AEDs), seizure frequency and self-reported side effects in patients with epilepsy at the tertiary referral center in Austria.

Methods: 530 consecutive patients with epilepsy who were examined at the specialized epilepsy outpatient clinic of the Department of Neurology, Medical University of Vienna, were enrolled in the study. Demographic data, current AEDs, seizure frequency, Hospital Anxiety and Depression Scale and self-report Adverse Events Profile were evaluated.

Results: Monotherapy was used in 55.3% of patients, 30.9% of patients had 2 AEDs, 13.8% of patients had 3 and more AEDs. 32.6% of patients were seizure free. 32.3% of patients were not-seizure-free and had monotherapy, the remaining patients had AED combination. The most frequent used drug was Levetiracetam (LVT) in focal epilepsies (37%) and Valproicacid (VPA) in generalized epilepsies (44%). Most frequently reported side effects were ataxia (p = 0.048), aggression (p = 0.014), nausea (p = 0.052), and cognitive impairment (p = 0.059). Most common combination of AEDs was LVT & CBZ (25.3%). The other combinations were LVT and Lamotrigine (9.7%), LVT and Lacosamide (9.3%) and LVT & OXC (8.0%). Seizure-free patients had scored better in HADS (anxiety 8.9%, depression 5.8%) compared to not seizure-free patients (anxiety16.6%, depression 12.5%).

Conclusions: The present retrospective study provides updated information on the patterns of prescription of AEDs in a large population of patients with epilepsies. There was a high portion of patients with more than one AED, which can be explained by increasing number of new AEDs, many of which are approved only for add on therapy.

A presentation of two clinic cases of Hypomelanosis of Ito and epilepsy

J. Zhang. Department of Neurology, Hunan Children’s Hospital, Changsha, China

Hypomelanosis of Ito, also known as the lack of incontinentia pigmenti achromians, is mainly with skin and nervous system symptoms and may be associated with many side symptoms such as head and facial dysplasia, congenital malformation of heart and reproductive systems, etc. Because it is related to multiple systems and organs it is now considered a multi-system involved skin disease.

Ito (Ito’s) first reported this disease in 1951 and he considered it might be due to autosomal dominant inheritance [1]. Now people are inclined to think that the possible pathogenesis of the disease is mutations caused by the X chromosome inactivation or activation that caused abnormal transition of mesoderm and ectoderm precursors during embryonic development, and as a result, leading to skin section line dysplasia, and forming multi-system abnormalities.

At present the available epidemiological data for such kind of neurocutaneous syndrome disease is very limited. Two cases were identified in Changsha, China and are reported here. At first the whole process of diagnoses and treatments for the patients will be described in detail. Then, discussions are presented on how to identify Hypomelanosis of Ito from another two similar neurocutaneous syndromes: incontinentia pigmenti and tuberous sclerosis. The last part of this paper is recommendations on general procedures of diagnosis and treatments for this disease.

Hot water epilepsy-seizure induction procedure during EEG recording

B. Labovic, R. Rasic, T. Lepic, N. Rajsic. Clinic of Neurology, Military Medical Academy, Belgrade, Serbia

Hot water epilepsy (HWE) represents a rare clinical entity, classified in a group of “reflex epilepsy” in which seizures are precipitated by hot water during bathing.

Case report: We report HWE in a 21-year-old male, with symptoms that appeared at the age of 7 years old. After initial provocative procedure we have applied a tea pot filled with warm water at 38°C and wrapped it with towel and then was pressed against his back but with no effect. But when we used a shower of wider surface with hot
water of the same temperature 38 °C, this has been effective. It is possible that the stimulation of broad skin areas involves hyper synchronization of the parietal and frontotemporal regions that is critical to elicit seizure not the temperature alone.

**Discussion:** Findings of local epileptiform in frontotemporal regions lead to the assumption of structural lesion of temporal lobe but subsequent neuro-imaging studies failed to prove it. Experimental data derived from animal model mimicking HWE has shown ischemic changes in specific topographic areas, like Sommers’ sector in hippocampus, layers 4 and 5 neurons of the cerebral cortex reticular neurons in brainstem a pathological feature reminiscent of the human epileptic brain. Autopsy findings of three HWE patients have suggested the most likely pathophysiologic mechanism in abnormal thermoregulation among genetically susceptible population with possible environmental influences.

**Conclusion:** It is possible that stimulation of the broad skin areas involves hypersynchronization on the parietal and frontotemporal regions that is critical to elicit seizure, not the temperature alone.

**PRRT2 mutation in Japanese PKC/PKD cases**

M. Morita, H. Nakano, Jichi Medical University, Shimotsuke, Japan

**Introduction:** Paroxysmal kinesigenic choreoathetosis dyskinesia (PKC/PKD) is characterized by brief attacks of involuntary movement triggered by sudden onset of movement. PKC/PKD is commonly inherited as an autosomal dominant trait, and PRRT2 gene was recently identified as the causative gene.

**Objectives:** To search for mutations in PRRT2 gene in Japanese cases with PKC/PKD.

**Patients and method:** Two cases with a family history of PKC/PKD and three sporadic cases were studied. All cases developed symptoms during childhood. Blood samples were collected after obtaining informed consent, and genomic DNA was extracted using standard procedure. Three exons of the PRRT2 gene were amplified by PCR, and sequencing was then carried out using ABI 310 automated sequencer.

**Results:** Truncating mutation in two familial cases was identified, but any mutations were not found in sporadic cases.

**Conclusion:** PRRT2 gene mutation is also confirmed in Japanese PKC/PKD cases.

**Pooled analysis of individual patient data from European observational studies on zonisamide use in clinical practice: Sub-group comparisions of efficacy**

**Epilepsy Unit, Western Infrmary, Glasgow, UK**; 

**Neurology, Hospital Clinico, Santiago de Compostela, Spain**; 

**University of Erlangen, Erlangen, Germany**; 

**Epilepsy Unit, Hospital de la ‘Pitié-Salpêtrière’, Paris, France**; 

**Policlinico Umberto, Rome, Italy**; 

**National Centre for Epilepsy, Oslo, Norway**; 

**Kappa Santé, Paris, France**; 

**EMEA & Russia, Epilepsy Business Unit, Hatfield, UK**; 

**European Epilepsy Medical Team, Eisai Europe Limited, Hatfield, UK**; 

**Eisai Medical Team, Eisai, Paris, France**

**Background:** A pooled analysis has been implemented from 5 European observational studies on zonisamide in routine clinical practice: France, Germany/Austria, Spain, Nordic countries and Scotland.

**Objective:** To assess overall efficacy of zonisamide and explore sub-group comparisons in a larger sample of real-life observational studies.

**Material and methods:** Efficacy endpoints were assessed at 6 months according to: ≥50% responder rate, seizure-free rate ≥2 months and retention rate. Sub-group comparisons were the number of previous antiepileptic drugs (AEDs) before zonisamide initiation and the main first line AED with zonisamide.

**Results:** A total of 988 patients with partial epilepsy were included: 427, 292, 136, 102 and 31 patients in France, Germany/Austria, Scotland, Nordic countries and Spain respectively. There was a significant association between the number of previous AEDs at zonisamide initiation and efficacy endpoints (p < 0.01). For patients without previous AED, the ≥50% responder rate was 59% (versus 46% for patients with at least 3 previous AEDs); the seizure-free rate was 33% (versus 17%). Zonisamide–valproic acid seemed to be the best bitherapy associated with efficacy endpoints, compared to zonisamide–carbamazepine, zonisamide–lamotrigine and zonisamide–levetiracetam combinations, but not significantly (≥50% responder rate (p = 0.12); for seizure-free rate (p = 0.11)).

**Conclusion:** These preliminary results regarding efficacy sub-group comparisons show a trend in favour of a better responder rate for patients “newly” treated for partial epilepsy (i.e. with a lower number of previous AEDs at zonisamide initiation). Complementary analyses will be performed to take into account potential heterogeneity regarding confounding factors including baseline severity.

**Precise detection of epileptic spikes in the EEG**

M. Weinkopf, H. Perko, M. Hartmann, G. Gritsch, F. Fürbaß, D. Grosseger, T. Kluge, Austrian Institute of Technology, Vienna; Austria; Alpha Trace Medical Systems, Vienna, Austria

We present a novel method that automatically detects interictal epileptic spikes in the electroencephalogram (EEG). Conventionally, EEG experts visually analyze the EEG recordings in order to identify such patterns. This is time-consuming, laborious and prone to errors especially for long term recordings of many hours or days. For this reason automatic spike detection systems are of great interest in order to allow an objective and accurate investigation with significant time-savings.

Since it is often preferred to find clear spikes rather than to find all spikes, we developed a method maximizing the precision, i.e. the portion of true positives in the detections. Our system first detects spikes based on a non-restrictive definition of the spike morphology. Subsequently the spikes are grouped by clustering methods using morphological features and the results of a source localization. The clustering allows an immediate overview of the types of spikes contained in the EEG data and the identification of multiple sources. Representative group averages are presented to a user who is able to deselect artifact clusters containing false positive detections only.

Our results were obtained from the EEG of three patients with a recording duration totaling 6.5 h and containing 282 spikes, which were marked by experienced EEG experts. After the initial detection we achieved an average precision of 85% with a sensitivity of 48%. The subsequent clustering performed a very clear separation of true spikes and artifacts and could be used to increase the precision of up to 98%.

A paraneoplastic limbic encephalitis as the first manifestation of an plasmacytoma
R. Schimana, Clinic Vilshofen, Vilshofen, Germany

Background: A 72-year old woman had several drop-attacks and a neurological syndrome with aphasic symptoms, ataxic gait and mnemonic deficits. The syndrome is getting better, but 7 days later she had a temporal lobe seizure. Is the syndrome the first sign of a epilepsy with a prolonged remission or a nonconvulsive status epilepticus or seizures are expression of an systemic CNS-disease.

Objective: Hemiparesis left with fine motoric skills deficits.
Neuropsychology: Deficits in short time memory and attentional functions.

Material and methods: The classical neurological diagnostic procedures.
Results: EEG: No slow activity. No seizure pattern. Theta-Delta focus right tempoparietal. MRI: no new ischemic sign. Hyperintensive lesions in T2 weighted images.
Lupomeningeal enhancement.

Conclusion: Based on the results the syndrome is in the order of a paraneoplastic limbic encephalitis. Under a cortisontherapy the syndrome and blood-brain barrier disturbance is getting better. The neurological diagnostics contribute to the detection of the plasmacytoma. Hitherto we seen paraneoplastic neurological syndromes with positive CV2-antibodies in relation to thymoma, lung-cancer, but not with a plasmacytoma.

Physical disabilities of epilepsy in poor resource countries
A.E. Bukusi1, R.N. Mbogua2, 3Clinical Research, Nairobi University, Nairobi, Kenya; 4Global Mental Health, Kenya Association for the Welfare of People with Epilepsy, Nairobi, Kenya

Background: Epilepsy is an important cause of disability and death. It has been suggested that 85% of children with disability live in resource poor countries (RPCs), but there is little data to support this.

Methods: We conducted a survey of epilepsy in children aged 6–9 years in at Kenyatta National Hospital. First, we screened for neurological disability by administering the Ten Questions Questionnaire (TQQ) to parents/guardians of the children. In phase two, we performed a comprehensive clinical and psychological assessment on children who tested positive on TQQ and on a similar number of children who tested negative.

Results: A total of 10218 children were screened, of whom 955 (9.3%) were positive on TQQ. Of these, 810 (84.8%) were assessed, and of those who tested negative 766 (8.3%) were assessed. The prevalence for moderate/severe epilepsy was 61/1000 [95% confidence interval (95% CI) 48–74]. The most common domains affected were epilepsy (41/1000), cognition (31/1000), and hearing (14/1000). Motor (5/1000) and vision (2/1000) impairments were less common. Of the neurologically impaired children (n = 251), 56 (22%) had more than one impairment. Neonatal insults were found to have a significant association with moderate/severe epilepsy in both the univariate [odds ratio (OR) = 1.70; 95% CI 1.12–2.47] and multivariate analyses (OR = 1.30; 95% CI 1.09–1.65).

Conclusions: There is a considerable burden of moderate/severe epilepsy in Kenya hospitals, with motor, vision, epilepsy, cognition, and hearing being the most common domains affected. Neonatal insults were identified as an important risk factor.

Classification of focal epileptic seizure transformations in adults
A. Dubenkoa, E. Dubenkob, O. Vasilyevas, D. Kovalenkoa. 4Institute of Neurology, Psychiatry and Narcology, Kharkiv, Ukraine; bNational Medical University, Kharkiv, Ukraine

Background: In the structure of clinical understanding of various focal forms of epilepsy both frequency and type of seizures, as well as seizure patterns change dynamics.

Objective: To study various seizure transformation types as an important indicator of the disease severity and to create transformations’ classification, suitable to be employed in clinical practice.

Patients and methods: Seizure transformations were studied in 273 epileptic patients. The impact of seizure dynamics on functional status of the brain, quality of life, and emotional and cognitive status of patients was assessed. By transformation we understood complete change of the seizure type or its components.

Results: Full seizure type modification revealed positive and negative seizure transformations. Positive transformation manifested itself as modification of secondary generalized or complex partial seizure into simple partial seizure, as well as modification of secondary generalized seizure into complex partial seizure. With negative transformation, this group of patients displayed modification of complex partial and/or simple partial seizure into secondary generalized seizure. Also, addition of other simple and complex seizures was observed.

Positive transformation was usually accompanied by improved quality of life, emotional state, and cognitive functions. With negative transformation these indicators deteriorated.

Transformations with changing focal seizure component manifested in it being longer or shorter in the structure of secondary generalized or complex partial seizure.

Conclusion: The suggested classification of focal seizure transformations is a vital criterion in estimating clinical state of patients and types of disease progression. This is important for identifying adequate therapy.

Effect of anti epileptic therapy on serum homocysteine in children
P. Kishore, R.R. Pandey, S. Waris. Pediatrics, Holy Family Hospital, New Delhi, India

Background: Elevated serum homocysteine concentration is associated with increased risk for vaso-occlusive disease like cerebrovascular stroke, coronary artery disease, and also the risk of resistance to anti-epileptics and refractory epilepsy. Hyperhomocysteinemia has been frequently associated with the administration of anti epileptic drugs (AEDs).
Objective: This study aims at evaluating the effect of anti-epileptic therapy on serum homocysteine levels in children.

Methods: 53 children (males—32, females—21) presenting to the Pediatric Outpatient and Inpatient Department of Holy Family Hospital, New Delhi with seizures in age group of 6 months–14 years were included in the study. Serum homocysteine (Hcy) levels of children already on AEDs for >6 months (Group A) were compared with children before initiation of anti epileptic drugs (Group B). These children were followed up after 6 months of anti epileptic therapy and serum homocysteine was compared (Group C).

Results: Average Hcy levels in subjects who had already received >6 months of antiepileptic drug therapy were 12.58 ± 2.68 μmol/l, compared to 8.83 ± 2.82 μmol/l, at recruitment (p = 0.001). Significant increased levels were also observed in children followed up after 6 months of AED—10.27 ± 3.06 (μmol/l) compared to 8.63 ± 2.90 (μmol/l) at initiation of AED. 9 children who received >1 AED had significantly higher levels—14.15 ± 2.56 (μmol/l) compared to children on monotherapy—10.22 ± 3.06 (μmol/l). Carbamazepine therapy for 6 months caused significant increase in Hcy 10.78 ± 2.82 (μmol/l) compared to baseline of 9.30 ± 2.70 (μmol/l) (p = 0.016).

Conclusions: AEDs in children, especially those receiving multidrug or long duration treatment, cause significantly increase in homocysteine levels, a risk factor for vaso occlusive diseases.

Prescribing patterns of antiepileptic drugs and interaction risk in general practice
D. Italiano, R. Ferrara, G. Trifiro, G. Starvaggi, C. Pagliaro, R. Nani, M. Tari, A. Capuano, E. Spina, V. Arcoraci. "Department of Clinical and Experimental Medicine, University of Messina, Messina, Italy; "Caserta Local Health Unit, Caserta, Italy; "Dept. of Experimental Medicine, Pharmacology Section, Second University of Napoli, Napoli, Italy"

Background: In the last years a growing trend in anti-epileptic drug (AED) use was observed, but few data concerning indication of use and drug interaction risk are available in general practice.

Objective: To analyze the prescribing pattern of newer and older AEDs in the period 2005–2011 and to assess the exposure to potential drug interactions in a general practice setting of southern Italy.

Patients and methods: We analyzed data of almost 150,000 individuals registered in 123 general practitioners’ lists. One-year prevalence and incidence were calculated. The frequency of concomitant treatment with clinically relevant interacting drugs was also determined.

Results: Prevalence of AED use increased from 10.7/1000 to 13.0/1000 for old AEDs, and from 14.7/1000 to 16.2/1000 for new AEDs, with a peak of 22.3 in 2006. Among older AEDs, phenobarbital and valproate were the most widely used in 2011, accounting for 21.23% and 16.23% of total AED use. In the same year oxcarbazepine and lamotrigine were the most used new AEDs (10.91% and 10.79% of total, respectively), while gabapentin and pregabalin exhibited the higher incidence of use. A high number of patients treated with older AEDs received co-prescription at clinically relevant interaction risk. Lamotrigine also showed a high annual rate of possible interaction.

Conclusion: The increasing use of newer AEDs was mostly due to the prescription of gabapentin and pregabalin for neuropathic pain. The revised re-imbursement criteria determined a fall in use in 2007. The large use of phenobarbital should be considered due to the risk of adverse drug reactions.

Clinical and epidemiological characteristics of epilepsy in children in Kazakhstan
M. Lepessova, B. Myrzaliyeva. Child Neurology, Almaty State Institute of Advanced Medical Education, Almaty, Kazakhstan

Objective: To study the epidemiological and clinical features of epilepsy in children in Kazakhstan.

Methods: Patients with epilepsy aged 0 to 14 years. Results: The analysis of 1477 cases of epilepsy in children. The high prevalence of epilepsy (12.1–14.3%) was observed in regions with unfavorable environmental conditions. The frequency of epilepsy among boys was 58.6%, of girls — 41.4%. The age of onset of the disease: in the first year of life — 20%, 1–3 years — 27.5%, 4–7 years — 31.8%, 8–14 years — 20.7%. 378 children with epilepsy were subjected to in-depth examination. Analysis of the etiologic factors of symptomatic epilepsy (n = 234) showed the prevalence of perinatal factors — 65% (152), congenital malformations of the nervous system — 32.9% (77), genetic abnormality — 2.1% (5). 103 patients (27.2%) had generalized epilepsy, 177 (46.8%) — partial epilepsy, 98 (25.9%) — epileptic encephalopathy. Generalized epilepsy presented idiopathic forms:
generalized epilepsy with isolated attacks — 56.3% (58 children),
childhood absence epilepsy — 24.3% (25), benign myoclonic epilepsy of
infancy — 11.7% (12), epilepsy with myoclonic–astatic seizures — 7.8%
(8). Partial epilepsy consisted of: occipital — 25 (14.12%), temporal — 7
(3.95%), frontal — 16 (9%), rolandic — 18 (10.16%), epilepsy with
secondary generalized attacks — 111 (62.71%). Epileptic encephalopa-
thy: syndrome Ohtahara — 4 (4.1%), WS — 67 (68.3%), LGS — 15 (15.3%),
ESES — 3 (3%), pseudo-Lennox syndrome — 9 (9.1%).
Conclusion: The results were the bases for the formation epilepsy
register in Kazakhstan.

Towards surgical treatment of status epilepticus complicating
Lennox Gastaut syndrome: Place of the vagus nerve stimulation
S. Mrabet1, I. Hmida1, N. Ben Ali1, M. Kchaou1, M. Fradj2, S. Belala2.
1Neurology, Tunis, Tunisia; 2Charles Nicolle Hospital, Tunis, Tunisia

Introduction: About 50–70% of epileptic patient with Lennox
Gastaut syndrome (LGS) present a status epilepticus (SE) requiring
immediate treatment. Typically, refractory SE does not respond to
anti-epileptic drug therapy. Vagus nerve stimulation (VNS) therapy
seems to be an alternative for these patients.

Purpose: Our study consists in comparing the clinical evolution and
quality of life of three patients followed for LGS in the department of
neurology of Charles Nicolle Hospital before and after setting up a VNS.

Methods: We retrospectively reviewed three children with LGS and
recurrent SE treated successfully with VNS. Neurological exam,
electroencephalography (EEG), and cerebral MRI were made.

Results: The mean age was 10.6 years. The sex ratio was 2/1.
Between the 12th and 48th month long-term follow-up, the decrease
in seizure frequency was over than 50%. There was also a decrease of
drowsiness on the post critical and improving awareness, attention
and mood. There are no more electrical abnormalities.

These results are consistent with those described in previous studies
about this topic. VNS has also an economic benefit with reduction in
hospital costs and hospital stays in Intensive Care Unit. The precise
action of VNS as a neuromodulatory treatment for epilepsy is still
unknown, but efficacy seems based on an incremental effect. The
main described effect of VNS on brain activity is a thalamic activation
and inhibition of the solitary tract nucleus.

Conclusion: The management of LGS with refractory SE is very
difficult.VNS can be a good alternative to prevent the recurrence of
seizures.

Meropenem induced myoclonus: A case report
T. Spina Silva1, R.D.-P. Ducci1, F.P. Zorzetto1, V.L. Braatz2, L. de Paola2,
P.A. Kowacs1. 1Neurology, Internal Medicine Department, Curitiba,
Brazil; 2Neurology Service, Internal Medicine Department, Curitiba,
Brazil; 3Neurology Service, Clinical Hospital of Paraná Federal University,
Curitiba, Brazil

Background: Among adverse drug reactions myoclonus is of rare
occurrence.

Objectives: To report a case of meropenem induced myoclonus.

Patients and methods: This patient was evaluated at the Clinical
Hospital of Paraná Federal University, Brazil.

Results: A 61-year-old woman was seen because of myoclonic
status. In the previous year she had been hospitalized due to dilated
cardiomyopathy (ejection fraction = 21%) plus non-sustained ven-
tricular tachycardia and managed with an implantable cardiac
defibrillator. She was readmitted on a setting of precordial pain plus
cardiac insufficiency profile requiring vasoactive drugs and an intra-
aortic balloon. Her coronary angiography was unremarkable. In
the following days her dyspnea worsened requiring non-invasive
ventilation and her central catheter became colonized. She evolved
with oliguria, vomiting, hypoglycemia, syncope and cardiac arrest
successfully managed with cardiorespiratory resuscitation (CPR).
Her renal function decreased and a urinary infection ensued, so
intravenous meropenem 100 mg/day was started based on the
antibiogram. On this very day she presented with intense and
maintained myoclonic jerks involving her shoulder girdle, neck and
head. The myoclonic jerks were attributed to renal impairment and
she underwent two hemodialysis sessions without changes in
myoclonic status. Her prolonged electroencephalography (EEG)
recording revealed spikes and polyspikes and waves that were
abolished by 2 mg of intravenous diazepam suggesting myoclonus
of cortical origin. After diazepam clearan myoclonus recurred and
was abated only when meropenem was withdrawn and substituted
by cefepime. Myoclonus never relapsed thereafter.

Conclusion: Meropenem epileptogenicity should be remembered,
especially for those patients bearing renal insufficiency and within a
complex clinical scenario.

Zonisamide monotherapy in adult patients with partial, generalized & combined seizures: Interim analysis of a open-label, non-comparative, observational study
Medical and Regulatory Affairs, Eisai Pharmaceutical India Private Limited, Mumbai, India; bDept of Neurology, Brain & Nerve Care Centre, Bangalore, India; cDept of Neurology, Ayush Neuro Care, Secunderabad, India; dDept of Neurology, Vivekananda Hospital, Hyderabad, India; eDept of Neurology, 5 Advanced Neurology & Superspeciality Hospital, Jaipur, India

Purpose: To evaluate efficacy and safety of Zonisamide monotherapy in adult patients with partial, generalized & combined seizures.

Method: In this open, non-comparative, multi-center, observational study, 119 patients (73 males) having partial, generalized and combined seizures were treated with Zonisamide monotherapy (100–500 mg/day) for 24 weeks. Seizure frequency, clinician’s global assessment of response to therapy (CGART) and patient’s global assessment of tolerability to therapy (PGATT) were assessed every 4 weeks. Change in seizure frequency from baseline was analyzed by Friedman test (non-parametric repeat measures ANOVA).

Results: 97 patients completed 24 weeks study period, while 23 discontinued (12 lost to follow up, 3 due to medication error, and 1 withdrew due to adverse event). Mean percent reduction in seizure frequency at 24 weeks was 89.30%. After 24 weeks, overall responder rate was 66.18%, whereas 24 weeks seizure freedom was 45.59%. Adverse events were reported in 6 (5.04%) patients, of which 2 (1.68%) had loss of appetite, while 1 patient each reported dizziness, and aggressive behavior with sleep disturbance.

Conclusion: Zonisamide monotherapy demonstrates favorable efficacy and tolerability in adult patients with partial, generalized & combined seizures. However this is an interim analysis.

Efficacy and safety of Zonisamide as first add-on therapy in adult patients with partial, generalized and combined seizures
Medical and Regulatory Affairs, Eisai Pharmaceutical India Private Limited, India; aDept. of Neurology, KEM Hospital, Mumbai, India; bNeurology, Medipus Clinic, Hyderabad, India; cDept. of Neurology, Caring Hands Neuro Centre, Vishakhapatnam, India; dDept. of Neurology, Metro Hospital & Heart Institute, Noida, India; eDept. of Neurology, Sai Neurology Clinic, Lucknow, India

Purpose: To evaluate the efficacy and safety of Zonisamide in adult patients with partial, generalized & combined seizures.

Method: In this open, non-comparative, multi-center, observational study, 271 patients (151 males) having partial, generalized and combined seizures were treated with Zonisamide (100–500 mg/day) for 24 weeks as first add-on to the primary antiepileptic drug of clinician’s choice. Seizure frequency, clinician’s global assessment of response to therapy (CGART) and patient’s global assessment of tolerability to therapy (PGATT) were assessed every 4 weeks. After 24 weeks, overall responder rate was 52.14%, whereas 24 weeks overall seizure freedom was 39.83%. Adverse events were reported in 6 (5.04%) patients, of which 2 (1.68%) patients reported loss of appetite.

Conclusion: Zonisamide demonstrates favorable efficacy and tolerability as first add-on in adult patients with partial, generalized & combined seizures.

The prognostic value of interictal scalp EEG to surgical outcome in patients with hippocampal sclerosis; influence of antiepileptic drugs
L Dolezalova, M. Brázdil, M. Hermanová, E. Janoušková, R. Kubáč, Brno Epilepsy Center, First Department of Neurology, St. Anne's University Hospital and Faculty of Medicine, Masaryk University, Brno, Czech Republic; Central European Institute of Technology (CEITEC), Masaryk University, Czech Republic; First Department of Pathological Anatomy, St. Anne's University Hospital and Faculty of Medicine, Masaryk University, Czech Republic; Institute of Biostatistics and Analyses, Masaryk University, Brno, Czech Republic

Objective: We performed this retrospective study to determine if there are differences in interictal EEG’s prognostic value during gradual reduction of antiepileptic drugs (AEDs) in relation to surgical outcome, defined by Engel’s classification, in patients with refractory TLE with hippocampal sclerosis (HS).

Patients and methods: In a total number of 55 patients, we analyzed laterality and absolute number of IED’s as an average value for the total time of monitoring (TT), and in three different periods of interest defined by the level of AEDs’ reduction — full medication period (FMP), reduced medication period (RMP), and withdrawal medication period (WMP). Laterality was defined as unitemporal (≥90% of IEDs on the side of HS) and bitemporal (<90% of IEDs on the side with HS).

Results: The laterality of IED’s during TT (p = 0.047) and during FMP (p = 0.005) was a statistically significant predictor factor for surgical outcome. There were no statistically significant differences of laterality during RMP (0.074) and WMP (0.131) in relation to outcome. The absolute number of IEDs on the side of HS was not predictive for the surgery either as an average value (p = 0.502), or during FMP (p = 0.706), RMP (p = 0.709) or WMP (p = 0.719). The absolute number of IEDs on the contralateral side to HS was a predictive factor for surgery during TT (p = 0.083) and during FMP (p = 0.01). There were no statistically significant differences during RMP (p = 0.081) and WMP (p = 0.083).

Significance: The prognostic value to the surgical outcome has the laterality and the absolute number of IED’s both during TT and FMP.

Retigabine as adjunctive treatment in adults with refractory partial onset epilepsy. Own experience at least a half-year follow-up
V. Donath, L. Lipovsky, S. Mehesová, Neurology, Slovak Medical University, F.D. Roosevelt Teaching Hospital, Banska Bystrica, Slovak Republic; Neurology, Slovak Medical University, University Hospital, Bratislava, Slovak Republic

Background: Retigabine (RTG) exhibits a novel mechanism of action opening neuronal KCNQ/Kv7 potassium channels leading to hyperpolarization of membrane potential and decreased neuronal excitability. RTG has been available in Slovakia since October 1, 2011.

Objective: Objective of the study was to monitor pharmacotherapy-resistant patients focusing on RTG efficiency and safety.

Patients and methods/material and methods: In the survey we monitored demographic data, etiology of epilepsy, response to therapy, co-medication, and adverse side-effects of RTG treatment. Mean follow-up time period was 11.7 months.

Results: 33 men and 28 women of median age 39.4 years (range: 20–61) and a median duration of epilepsy of 26 years (range: 2–51) were included.

Median seizure frequency one month before RTG treatment was 8 (range 2 to 50).

Median RTG final dose was 600 mg/day (range 150 to 1150 mg/day). Most frequent co-medication: levetiracetam, carbamazepine, lamotrigine, valproate.

Most frequent etiology: 32.8% perinatal injury, 24.6% cryptogenic, 14.7% trauma, 8.2% cerebral infection.

Responder rate: 14.7% seizure free; 41.0% responders reporting 50–95% reduction of seizures; 19.7% reported seizure reduction below 50%; 16.4% reported no change; 3.3% reported deterioration; 21.3% of patients discontinued their treatment.

Side-effects were observed in 34.4% of patients — mostly frequent fatigue, drowsiness, vertigo and tremor.

Conclusion: RTG in our study demonstrated the efficiency and tolerability profile comparable to that in pivotal trials. RTG treatment was efficient and well tolerated in a highly therapy resistant population of partial-onset epilepsy patients.

Midazolam plasma levels after the administration of a galenic nasal spray formulation in healthy volunteers

Background: The initial treatment of seizures is intravenous or rectal benzodiazepines. However, intravenous access during a seizure is difficult. Rectal administration is safer, but can be considered socially
unacceptable. Intranasal Midazolam (INM) would be a new approach to the management of seizures but this nasal formulation is not commercially available in Argentina.

**Objective:** To investigate MDZ plasma levels after intranasal administration (IN) of a galenic nasal formulation containing MDZ in healthy volunteers.

**Patients and methods:** 4 healthy volunteers (3 male, 1 female) were included. They received a single 4 mg MDZ dose intranasally administered. MDZ nasal spray formulation consisted of 2.5% (w/v) midazolam, propylene glycol, and water. Blood samples were drawn at 10 min, 1 and 2 h after MDZ IN. Volunteers were asked to classify local irritation immediately and 2 h after MDZ IN. Data of sedative effects were also recorded.

**Results:** 4 mg IN MDZ dose was well tolerated. After the administration low grade local irritation was reported by the volunteers. MDZ plasma levels were observed 10 min after IN (mean: 11.6; SD: 4.6 ng/ml). One hour after IN MDZ mean level was 8.9 (SD: 7.7) ng/ml. Sedative effects were observed in 3 volunteers.

**Conclusion:** This study showed that MDZ levels could be measured after IN of the galenic nasal formulation developed by our group. Since MDZ base is a lipophilic compound with low solubility in water, further studies are needed to evaluate inter-individual pharmacokinetic variability or the utility of enhancers of transmucosal absorption to increase bioavailability.

**Pharmacologic and genetic aspects of resistant epilepsy in children in Uzbekistan**

N.M. Tuychibaeva, M.I. Sigatullina, A.V. Prokhorova. aTashkent Medical Academy, Uzbekistan; bTashkent Institute of Postgraduate of Medical Education, Tashkent, Uzbekistan

**Objectives:** To develop methods of detection for the frequency and influence of polymorphism of cytochrome P450 genes on pharmacologic and genetic action of antiepileptic drugs (AED). Identify the role of these genetic markers in individual responses to AED and development of pharmacologic resistance in epileptic patients.

**Material and methods:** The research is based on studying the results of treatment of patients (n = 20) with resistant epilepsy. The control group included 25 volunteers of Uzbek nationality adjusted by sex and age.

**Results and conclusions:**

1. Minimum level of gene variety of marker CYP2C9 in children was determined with not very high frequency of heterozygosis. Reduction of frequency of heterozygote genotype, absence of adverse genotype 1/1 and simultaneous increase in the share of individuals with normal homozygous C/C genotype among apparently healthy patients can be related to selective advantage of C allele.

2. Frequency of CYP2C9 polymorphism in pharmacoresistant patients considerably exceeded that in the control group indicating the association between development of resistance to AED and the genetic marker. The obtained statistically insignificant difference is most likely caused by the small amount of patients in the groups.

3. The genotypic variant distribution analysis of polymorphic marker 9896 C-G of CYP2E1 gene showed that among patients with the resistant epilepsy and the controls, the share of people with mutant genotypes had almost identical frequencies (20%). The risk of development of resistance to AED in carriers of the genotype was statistically insignificant (p>0.05).

Hemimegalencephaly in children — Some clinical and genetic aspects
Child Neurology, University Hospital Santiago de Compostela, Santiago de Compostela, Spain;
Child Neurology, Tashkent Institute for Postgraduate Medical Education, Tashkent, Uzbekistan;
University Hospital Santiago de Compostela, Santiago de Compostela, Spain

Purpose: To analyze the clinical features of hemimegalencephaly.

Methods: MRI, video-EEG and genetic analysis were performed on 8 patients with hemimegalencephaly.

Results: 3 patients have an isolated type of hemimegalencephaly and 5 patients a syndromic type, which associated with ipsilateral hemihypertrophy of the whole body. Six patients had seizures (severe refractory epilepsy — 5, febrile seizures — 1). The mean age of the epilepsy onset was 3 and 7 months. All patients had a contralateral hemiparesis and developmental delay. The seizure semiology was ranged from febrile seizures to polymorphic types, like myoclonic seizures (2), complex partial seizures (3), asymmetric tonic spasms (2) and focal clonic seizures (1). Three cases registered continuous “burst-suppression” pattern in the side of hemimegalencephaly. According to genetic molecular analysis of 3 patients mutations of genes localized in the 17th chromosome were detected. In 2 patients with hemimegalencephaly accompanied by pachygyric changes and refractory seizures alteration of the gene LIS1 was found and in 1 patient well controlled by AED treatment mutation of the gene RPH3AL (rabphilin 3A-like) was found. In the 4 other patients genetic investigation was negative as in all family members. In 2 patients with severe progressive epileptic encephalopathy a functional hemispherectomy was performed resulting in 90% reduction of seizure.

Conclusions: In most cases, a clear correlation was found between the side of the hemimegalencephaly and seizure semiology which was also confirmed by the continuous video-EEG register. Genetic investigation of patients with hemimegalencephaly could be useful as a part of the complex diagnostic method and treatment prognosis.

Abstract — WCN 2013

Epilepsy and social security — General aspects of the insured claimants and medical decisions
Neurology, UNB, Brasilia, Brazil; Medicina do Trabalho, UNB, Brasilia, Brazil; Pericia do INSS, Instituto Nacional de Seguro Social, Brazil; Neurologia, Hospital de Base do Distrito Federal, Brasilia, Brazil; Pericia Medica INSS, Instituto Nacional de Seguro Social, Florianópolis, Brazil

Objective: Provide a profile of individuals with a previous diagnosis of epilepsy that file claims for social security benefits and a profile of the medical advisory decisions that support the concession of these benefits.

Participants: Thirty individuals with illness-related problems due to epilepsy were selected from the claimants that receive Social Security Incapacity benefits.

Methods: An exploratory data analysis of the 188 Social Security medical files (between 2003 and 2008) of the thirty claimants was performed using the clinical and epidemiological information and the medical advisory criteria.

Results: The mean age of the claimants was 39 years and most of them were males in jobs that do not require a lot of schooling. The first claim was filed within an average of four years of employment. On average, each worker files a claim every three months, which entitles him/her to receive incapacity/sickness benefits for 17 months. The frequency of seizures and the medications used by the claimants were registered in 60% of the medical files. In addition, the description of the physical and neurological exam was incomplete in 50% of the files. Furthermore, 60% of the files did not include the argument or the clinical evidence that was used to justify the concession of the benefit.

Conclusion: The medical advisory decisions on epileptic workers tend to be inconsistent, lenient and generally lacking in clinical evidence. The disparities among the granted benefits indicate the need for the National Social Security System to review and draft specific guidelines for epilepsy.

Pulmonary arteriovenous malformation (pulmonary AVM) has direct links between an artery and a vein in the blood circulation of lungs in the human body. (1) Hereditary hemorrhagic telangiectasia (HHT), Rendu–Osler–Weber disease, is a genetic disease through autosomal dominant pattern having a feature of vascular malformations. (2) Pulmonary arteriovenous fistulas (PAVFs) are induced right to left shunt and if not treated properly, these may cause critical neurological problems such as brain abscess and meningitis. (3)

A 35-year-old man checked into an emergency room with complex periodontitis but no problems were identified in his brain images including cerebral vessels. A few days later, he suffered from convulsive movement with loss of consciousness after which brain images were taken to find a brain abscess in the right frontal region. Also, he had complained about swelling, redness as well as mild tenderness on the right side of the neck, which led to testing his neck and chest by a CAT scan. His CAT scan showed two large (>1 cm) AVM nidus in the right apex and right lower lung as well as a tiny lingular nodule, probably intrapulmonary lymph node.

We recognize through this case that we would proceed to operate his pulmonary arteriovenous malformations to prevent recurrent critical neurologic complications such as brain abscess or meningitis.

Noninvasive localization of nonconvulsive seizure with pulsed arterial spin labeling (PASL) MR imaging
S. Kim, S. Kim, S.-Y. Lee, H.-S. Sohn. Department of Neurology, Kangwon National University College of Medicine, Kangwon-do, Republic of Korea

Background & objective: Nonconvulsive seizures are very poorly localized seizure disorder due to variability of EEG abnormality and tiny pathology of ictal onset zone. The purpose of this study was to determine localizing value of pulsed arterial spin labeling MR imaging, which is a noninvasive method for calculating regional CBF. Methods: Five patients with nonconvulsive seizure in EEG monitoring are enrolled in this study retrospectively. EEG and brain SPECT, MR imaging, ictal PSASL imaging, Postictal PASL imaging were examined in all patients. EEG localization and hyperperfusion of SPECT and PASL imaging were compared in patients with MRI abnormality and hyperperfusion of brain SPECT. Postictal PASL imaging was performed after normalization of EEG.

Results: In 4 patients of regional MRI abnormality, we found hyperperfusion at the same site with PASL MR imaging in all patients, which was identified with Brain SPECT, localization of ictal activity in EEG. Conversely, we found 1 minimal abnormal lesion in MRI, only T2 high signal intensity in lateral temporal cortex, whose location was found due to hyperperfusion in PASL MR imaging.

Conclusion: Pulsed arterial spin labeling MR imaging will be a useful noninvasive tool in detection of location of ictal zone in nonconvulsive seizure.

The effectiveness of medical treatment of childhood epilepsy
O. Rakhmanina. Tyumen Medical Academy, Tyumen, Russia

Objective: To analyze the effectiveness of AED for children with epilepsy. Material and methods: An analysis has been conducted of the effectiveness of treatment by AED based on the type of epilepsy in children at the age from 0 to 18. Idiopathic focal epilepsies — 51 children, idiopathic generalized — 89, symptomatic focal — 162, cryptogenic focal — 64 and epileptic encephalopathy (predominantly West Syndrome) — 28 children. AED prescribed to the children are as follows: Valproate, CRBM, Topiramate, Levetiracetam, Oxcarbazepine, Lamotrigine, Succinamide, Benzodiazines, Barbiturates, and Vigabatrin applied in monotherapy or in combination. The effectiveness level is evaluated for the presence of abdominal obesity, dyslipidemia, glucose intolerance and hypertension. Metabolic syndrome was diagnosed when 3 of the following criteria were met: elevated fasting glucose (>100 mg/dl), hypertension, high triglyceride levels or abnormal obesity. The prevalence of metabolic syndrome and abnormalities in the individual parameters were compared between the two groups.

Results: Four out of 57 valproate-treated children (7%) and none of the 53 phenytoin-treated children had metabolic syndrome. Mean serum triglyceride levels were higher in the valproate group as compared to the phenytoin group (94.97 ± 38.58 mg/dl versus 77.60 ± 11.44 mg/dl, p < 0.05). The total cholesterol values were also significantly greater in valproate treated children as compared to the phenytoin group (148.28 ± 25.95 mg/dl versus 132.83 ± 23.51 mg/dl, p < 0.05). The serum fasting glucose was comparable in both groups.

Conclusion: The prevalence of metabolic syndrome and dyslipidemia was higher in valproate treated children as compared to phenytoin treated children with epilepsy. Children on valproate treatment need to be monitored for the development of metabolic syndrome.

Metabolic syndrome in children with epilepsy on valproate and phenytoin monotherapy: A cross-sectional study
A. Dhig1, S. Sharma2, S. Aneja1. 1Lady Hardinge Medical College, New Delhi, India; 2Pediatrics, Lady Hardinge Medical College, New Delhi, India

Background: Metabolic syndrome is a well recognized complication of valproate therapy. However there is paucity of data on the prevalence of metabolic syndrome in children with epilepsy on valproate monotherapy. Objective: To compare the prevalence of metabolic syndrome between children on valproate and phenytoin monotherapy. Methods: Children aged 3–16 years with epilepsy on valproate or phenytoin therapy for at least 6 months were enrolled. They were evaluated for the presence of abdominal obesity, dyslipidemia, glucose intolerance and hypertension. Metabolic syndrome was diagnosed when 3 of the following criteria were met: elevated fasting glucose (>100 mg/dl), hypertension, high triglyceride levels or abdominal obesity. The prevalence of metabolic syndrome and abnormalities in the individual parameters were compared between the two groups.

Results: Four out of 57 valproate-treated children (7%) and none of the 53 phenytoin-treated children had metabolic syndrome. Mean serum triglyceride levels were higher in the valproate group as compared to the phenytoin group (94.97 ± 38.58 mg/dl versus 77.60 ± 11.44 mg/dl, p < 0.05). The total cholesterol values were also significantly greater in valproate treated children as compared to the phenytoin group (148.28 ± 25.95 mg/dl versus 132.83 ± 23.51 mg/dl, p < 0.05). The serum fasting glucose was comparable in both groups.

Conclusion: The prevalence of metabolic syndrome and dyslipidemia was higher in valproate treated children as compared to phenytoin treated children with epilepsy. Children on valproate treatment need to be monitored for the development of metabolic syndrome.
seizure decrease — 16%, no effect — 14%, seizure recommencing — 3%. Epileptic encephalopathy: seizure-free period — 32%, seizure decrease — 22%, no effect — 46%.

Conclusion: The study confirms that AED is more effective in treating idiopathic type of epilepsy and has less significant effect on treating symptomatic focal epilepsies and epileptic encephalopathy.

Familial cortical myoclonic tremor and epilepsy (FCMTE): Refinement of the fcmte2 locus and confirmation of a founder haplotype
L. Licchetta, T. Pippucci, F. Bisulli, G. Cantalupo, P. Alvisi, P. Martirelli, I. Naldi, R. Liguori, F. Zara, M. Seri, P. Tinuper. IRCCS Instituto delle Scienze Neurologiche di Bologna, Department of Biomedical and Neuromotor Sciences, University of Bologna, Italy; aMedical Genetics Unit, Department of Cynaecological, Obstetric and Paediatric Sciences, University of Bologna, Polyclinic Sant’Orsola-Malpighi, Bologna, Italy; bChild Neuropsychiatry Unit, Department of Neuroscience, University of Parma, Parma, Italy; cDepartment of Life and Reproduction Sciences, University of Verona, Verona, Italy; dDepartment of Neurosciences, G. Gaslini Institute, University of Genoa, Genoa, Italy

Objective: To describe the electro-clinical and genetic features of a new large FCMTE family (A) that originates from the same area as another family (B), previously resulted unlinked to FCMTE2 locus (Gardella, 2006).

Methods: Pedigree A: 31 collaborative individuals were assessed directly. A polygraphic study was conducted in 15, back averaging analysis, somatosensory evoked potentials and C-reflex study in four. Pedigree B: Seven individuals were reviewed after a 10-year follow-up. The genetic study investigated 30 and 6 subjects of pedigrees A and B with 26 microsatellite markers at FCMTE1, FCMTE2, and FCMTE3 loci. We genotyped 12 markers in two affected individuals from two different families where a founder haplotype on FCME2 was described (Madia, 2008).

Results: Pedigree A: We studied 16/19 living affected members (M/F:5/11; mean age 47.8 years). Cortical myoclonic tremor (CMT) was associated with generalized seizures in ten patients (62.5%), with a mean age at onset of 28.1 and 33.8 years, respectively. Psychiatric disorders recurred in 37.5% of cases. Neuropsychological investigations confirmed the cortical origin of myoclonus in all the patients. Pedigree B: the status of one individual was changed to unaffected. Genetic analysis established linkage to FCMTE2 locus on chromosome 2p11.1–2q12.2 in both pedigrees and narrowed the critical interval to 10.4 Mb. Haplotype analysis identified a founder haplotype identical to that previously observed in families from the same area.

Conclusions: This study reduces the number of positional candidate genes in the FCMTE2 locus to 59 and confirms evidence of a founder effect in Italian families.

Predictive value of EEG in patients with West syndrome
J. Delića, I. Milovanovicb, V.V. Cukc, D. Nikolicb. aUniversity Children’s Hospital, Belgrade, Serbia; bFaculty of Medicine, University of Belgrade, Serbia; cMedical Center Zvezdara, Belgrade, Serbia

Background: West syndrome (WS) is an age-dependent epileptic encephalopathy characterized by a clinicoelectrical triad: infantile spasms (IS), hypsarrhythmia and delay and/or regression in psychomotor development. Although WS is considered one of the intractable epilepsies, the prognosis differs widely.

Objective: Determining the significance of electroencephalography (EEG) for long-term prognosis of WS.

Patients and methods: Our study group comprised 68 patients diagnosed with WS, aged 2 to 17 months, treated at the University Children’s Hospital in Belgrade from 1987 to 2008. The outcome was assessed through the response to therapy (seizure control and EEG findings) at the follow-ups after 3, 6 and 12 months.

Results: After 3 months, seizure control was established in 56% and EEG improvement was observed in 52.9% of patients. At 6 months follow-up, 47.6% of patients were seizure-free and EEG improved in 42.9% of cases. Evaluation after 12 months showed 65.6% seizure-free patients and EEG improvement in 55.7% of patients. There was a statistically significant correlation between EEG after 3 and 6 months and seizure control after 12 months. The majority of patients with EEG improvement after 3 months (82.8%) and 6 months (95.8%) had no seizures at one year follow-up.

Conclusion: Our study has shown that in treated patients EEG improvement after 3 and 6 months can have a predictive value for long-term outcome of WS in terms of seizure control and favorable response to therapy.

Topic: 1 — Epilepsy
The economic burden of epilepsy on a black South African community
L.M. Wynand, D.S. Magazi. Neurology, University of Limpopo (Medunsa), Pretoria, South Africa

Background: The world’s burden of epilepsy is carried mostly by the developing world (85%). According to the World Health Organization (WHO), Africa alone has 10 million people with epilepsy. There however, continues to be a paucity of studies on the economic impact. It is well established that epilepsy is a known cause of preventable unemployment.

Aim: To assess the economic impact of epilepsy on a black South African patient population and public healthcare system.

Method: 200 adult patients known to be with epilepsy were interviewed employing a questionnaire as our primary tool. The questionnaire assessed through the response to therapy (seizure control and EEG findings) at the follow-ups after 3, 6 and 12 months. The majority of patients with EEG improvement after 3 months (82.8%) and 6 months (95.8%) had no seizures at one year follow-up.

Conclusion: Our study has shown that in treated patients EEG improvement after 3 and 6 months can have a predictive value for long-term outcome of WS in terms of seizure control and favorable response to therapy.

Analysis of efficiency and safety of oxcarbazepine in pediatric and adult patients with different forms of epilepsy

Background: Oxcarbazepine is an anticonvulsant used in therapy of focal seizures for patients from the age of 1 month and of GTCS from the age of 2 years.

Objective: The aim of the study was the analysis of efficiency and safety of oxcarbazepine in children and adult epileptic populations depending on the patient’s age and form of epilepsy.

Patients and methods: 155 patients receiving oxcarbazepine (male 78, female 77) of the age from 5 months till 59 years were observed with dynamic video–EEG control during the period 2006–2012. The following were identified: IGE with isolated GTCS – 5, focal frontal lobe epilepsy – 40, temporal lobe – 63, parietal lobe – 6, occipital lobe – 13, idiopathic focal – 5, epileptic encephalopathies – 23 patients.

Results: Oxcarbazepine was effective in 59.3% of the patients (n = 92). Low efficiency was seen in 29.1%(n = 45) patients. The aggravation effect has been noted in 11.6% (n = 18) of patients. Compliance (for >1 year) was 56.8% (n = 88). Side effects were observed in 9.7% of cases. High efficiency in group <1 year (n = 14) was 35.7% (n = 5), low 35.7% (n = 5), aggravation 28.6% (n = 4); in group 1–3 years (n = 24) high efficiency 37.5% (n = 9), low 37.5% (n = 9), aggravation 25% (n = 6); in pediactric population >3 years (n = 78) high efficiency 62.8% (n = 49), low effect in 29.5% (n = 23), and 7.7% aggravation (n = 6), in adult population >18 years (n = 39) the efficiency was 74.4% (n = 29), low effect 20.5% (n = 8) and aggravation in 5.1% (n = 2).

Conclusion: Oxcarbazepine is highly effective drug in therapy of IGE with isolated GTCS, in symptomatic focal forms of epilepsy and Panayiotopoulos syndrome. With increase in patient’s age the efficiency of oxcarbazepine rises, while aggravation risks decrease.
Patients and methods: 65 patients (age: 18–80 years) with previously diagnosed epilepsy were enrolled in the study. Patients were divided into two groups according to age: <50 and ≥50 years. Reviewing patients’ medical charts we evaluated biochemical markers: PTH, vitamin D, calcium, phosphate, and creatinine levels. Bone mineral density (BMD) was assessed using DXA scanning. The data were analysed with SPSS 16.0.

Results: BMD was decreased in 55.6% of patients <50 years and 87.8% of patients ≥50 years. DXA scan T-score mean was −2.0 for the younger patients and −2.6 for older patients. Mean PTH level was 50.0 pg/ml in the younger patients and 65.0 pg/ml in the older patient group. Of all epilepsy patients in this study 30.8% had raised serum PTH levels: 20.0% in younger and 40.5% in older patients. Abnormal serum Ca and phosphate levels were detected in 10.2% and 5.2% of all patients, respectively. Vitamin D levels were on the lower reference level in both age groups.

Conclusion: Bone metabolism disorders are present in most epilepsy patients even before 50 years of age as shown by DXA scan and biochemical markers: PTH, Ca, and P levels.

Changes of amygdalae in systemic lupus patients with epilepsy
K. Peterova1, V. Peterova2, R. Svobodova1, S.S. Pešičkova1, M. Fojtíková1, P. Petrovický2. 1Dept. of Neurology, Charles University in Prague, 1st Faculty of Medicine, Prague, Czech Republic; 2MR Dept., Radiodiagnostic Clinic, Charles University in Prague, 1st Faculty of Medicine, Prague, Czech Republic; 3Institute of Rheumatology, Charles University in Prague, 1st Faculty of Medicine, Prague, Czech Republic; 4Dept. of Nephrology, Charles University in Prague, 1st Faculty of Medicine, Prague, Czech Republic; 5Dept. of Neurology, Charles University in Prague, 1st Faculty of Medicine, Prague, Czech Republic; 6Institute of Anatomy, Charles University in Prague, 1st Faculty of Medicine, Prague, Czech Republic

Objective: To analyze slight changes of amygdalae and their volumetry in systemic lupus erythematosus (SLE) patients with neuropsychiatric symptomatology (NP-SLE), because disability of amygdalae and changes in size and activity had been reported in patients with depression and mood disorders, in some studies it even correlated with the severity of depressive episodes. NP-SLE includes mood disorders, cognitive deficits up to dementia, stroke, epilepsy etc. We performed amygdalar volumetry by semiautomatic method in special software, using manual contoured rims in sequence using thin slices.

Methods: We investigated 23 female patients with proven NP-SLE, aged 19 to 67 years, which were recruited for a prospective longitudinal neuroimaging study conducted at 1.5T MR device. Findings were statistically processed and compared with corresponding healthy persons.

Results: In our study we found, that in patients with active NP-SLE right amygdala correlated from all monitored parameters only with the left amygdala (p = 0.01), left amygdala correlated with right amygdala (p = 0.01) and with volumetry in flow attenuation inversion recovery (FLAIR) and T1 weighted images (p = 0.05).

Conclusions: We failed to demonstrate significant volume change in amygdalae in the sample of NP-SLE patients. We did not demonstrate significant difference of amygdalar volume due to the duration of NP-SLE or age of the patients. The authors' research was supported by the research project MZO 0006416 and 000 000 23728.

Excitatory and inhibitory neurotransmitters with interleukins correlations in neurodegenerative encephalopathies
V. Lekomtseva1, G. Gubina-Vakulik5, T. Gorbach1, A. Vincent6.
1Outpatient Clinic and Laboratory of Neuroimmunology and Biochemistry, State Institute of Neurology, Psychiatry and Narcology, NAMSU, Ukraine; 2Department of Pathophysiology and Pathological Anatomy, Kharkiv, Ukraine; 3Department of Biochemistry, Kharkiv National Medical University, Kharkiv, Ukraine; 4Nuffield Department of Clinical Neurosciences, John Radcliffe Hospital, Oxford, UK

Proinflammatory interleukins (ILs) involved into microglial-neuronal interactions may explain how latent neuroinflammation can contribute to neuronal dysfunction in degenerative encephalopathies and their outcomes. Study aim was to determine IL-6, IL-8, IL-1b, glutamate, aspartate, GABA in patients with temporal lobe epilepsy (TLE) and hypoxic ischemic encephalopathy (HIE).

Methods: TLE (n = 49; 20–41 years), 8 — brain trauma (mean duration ± SD: 6.74 ± 4.33), HIE (n = 34; 41–55 years), controls (n = 16; 25–35) were investigated. Serum ILs were measured by immunoenzyme assays using VectorBest reagents; neurotransmitters measured by ion-exchange chromatography.

Results: TLE showed high IL-6 level: Mean ± SD 26.45 ± 6.67 vs. HC 4.44 ± 1.49 pg/ml (P < 0.01; t = 2.69). TLE and HIE showed no differences in IL-8 concentrations: 6.05 ± 1.8 and 7.1 ± 2.4 vs HC 4.46 ± 1.06 pg/ml. General IL-1b range in all TLE: 18.1–56.55 pg/ml where 23% TLE had higher IL-1b level with Mean ± SD 24.35 ± 3.24 vs HC 19.3 ± 2.14 pg/ml (P < 0.01; t = 6.4); these patients had cognitive decline (10), neurological deficit (8) with partial epilepsy (6). ILs levels positively correlated with seizure frequency (P < 0.05), no differences between seizure types. TLE: glutamate was 167.89 ± 10.96 vs HC 124.37 ± 4.007, mkmol/l; aspartate 12.6 ± 1.41 vs 8.02 ± 0.73, mkmol/l, GABA 3.404 ± 1.22 vs 6.49 ± 0.96, mkmol/l (P < 0.01); HIE: glutamate 146.27 ± 6.29; GABA 4.73 ± 1.69. Low GABA with tendency to high glutamate was noted in each neurodegenerative encephalopathy occasions.

Conclusions: IL-6-mediated inflammation found in TLE was associated with high seizure frequency caused by seizure-induced microglial activation; discovered changes between neurotransmitters might underlie cytokine-mediated neuroinflammation suggesting their role in promoting seizures or establishing chronic epileptic focus. There may be potential role for antiinflammatory therapy targeting cytokines.

Association of effectiveness of epilepsy pharmacotherapy and patients’ genealogical data
M. Oros. Clinic ‘Vodolj’, Khust, Ukraine

About 30% of patients with epilepsy are likely to have seizures resistant to pharmacotherapy. The mechanism of pharmacoresistance is not fully understood, but clearly some factors, including family history of epilepsy, can predict pharmacoresistance.

The aim of the study was to determine the correlation between pharmacoresistant epilepsy and prevalence of relatives with epilepsy in the studied group of patients.

309 patients, all Caucasians from Transcarpathian Ukraine, mean age of 39.82 ± 8.63, diagnosed with epilepsy participated in the study. All
were receiving antiepileptic therapy in standard therapeutical doses. Drug-resistant epilepsy was defined as uncontrolled seizures over a year despite attempts to treat with three or more different AEDs. We managed to build family tree of every studied patient viewing relatives up to 4th level of kinship, which included 6659 people.

According to genealogical research, 71 male probands had 192 relatives suffering with epilepsy and 50 female probands had 181 relatives with diagnoses of epilepsy at some point of their lives. Group with well-controlled epilepsy (group I) included 213 patients, while pharmacoresistant group (group II) was presented by 96 patients. Group I had 16.9% of probands whose relatives suffered with epilepsy, while group II had 88.5% of patients whose relatives were diagnosed with epilepsy ($p < 0.001$).

In the group of patients with pharmacoresistant epilepsy the prevalence of relatives suffering with epilepsy at some point of life was nearly 5 times higher than in non-resistant group. Family history of epilepsy can be important factor in predicting result of epilepsy pharmacotherapy.

The countryside in Africa is occupied by more than 80% of the population and significant progress are made by individuals, families and the community in the management of epilepsy. Several cross-sectional studies taking into account the qualitative aspects were conducted in several locations. These studies have focused on the general population, patients living with epilepsy, accompanying persons, traditional healers, health officials and notables. The knowledge and interpretation of epilepsy are wrong. The implementation of the results and the recommendations of the various studies will help to positively change the habits and behaviour of populations.

**Treatment outcome in epilepsy caused by intracranial vascular malformations**

G. Kiteva-Trenchevska, University Clinic of Neurology, Skopje, FYROM — The Former Yugoslav Republic of Macedonia

Intracranial vascular malformations may be asymptomatic but may also cause partial onset seizures (POS) and lesional epilepsy, intracranial bleeding and different neurological deficits. The aim is to evaluate the treatment outcome in epilepsy caused by intracranial vascular malformations. Eleven patients with (POS), females/males – 8/3, aged 15–50 years, were evaluated clinically, electrophysiologically and with MRI. Four patients had childhood seizure onset, five adolescence and two adulthood. Cerebral cavernous malformation (CCM) was found in four, cerebral arterio-venous malformations (AVM) in four and Sturge–Weber syndrome (SWS) in three. Two patients with SWS and one with AVM developed hemiparesis contralateral to the vascular malformation, additional two patients developed hemiparesis after surgery (one after AVM embolisation, one after CCM lesionectomy) improving gradually. Three of four patients with AVM underwent surgery, only one is seizure free with AED and one is only on pharmacological treatment with rare POS. Three of four patients with CCM underwent surgery, all are seizure free while still on AEDs, one of them after polytherapy with two AEDs. One patient with multiple CCM is on AEDs, with rare seizures during pregnancy with carbamazepine monotherapy when acetazolamide was withdrawn. Three patients with SWS are on AEDs without seizure control, but with rare seizures in two and frequent seizures in one, who developed hemiparesis and intellectual deterioration during the course of the disease from childhood to adulthood. AEDs, surgery or both should be used for intracranial vascular malformations treatment to prevent seizure reoccurrence, neurological and intellectual deficits thus improving the life quality.

**Epilepsy in African cultural approaches**

D.G. Avodé, C. Adjien. Neurology, CNHU-HKM, FSS/UAC, Cotonou, Benin

Absence epilepsy is a non-convulsive generalized form of epilepsy, characterized by spike-wave discharges, which predominantly affects children. It is accompanied by sudden impairment of consciousness and has an adverse impact on childhood learning. While disruption of the thalamocortical (TC) network is known to lead to generation of hypersynchronous intrathalamic oscillatory activity during absence seizures, the underlying cellular and molecular mechanisms remain largely unknown. Recent studies using human and animal models suggest region-specific changes in GABA$_A$ receptors (GABA$_A$R) in the thalamus may underlie hyper-synchronous oscillations in absence seizures. Therefore the aim of the current study was to investigate whether GABA$_A$R $\alpha_1$ and $\beta_2$ subunits mediating phasic inhibition at TC synapses are altered in the well-established stargazer mouse model of absence epilepsy. Postembedding electron microscopy-immunogold cytochemistry was used to analyze density of GABA$_A$R subunits in epileptic stargazers compared to matched non-epileptic control littersmates ($n = 6$, 200 synapses/subunit). In the epileptic mice, synaptic expression of both GABA$_A$R $\alpha_1$ and $\beta_2$ subunits was significantly increased by 54% ($p < 0.01$) and 49% ($p < 0.01$), respectively. These findings support upregulation of phasic GABA$_A$R-mediated inhibition at TC synapses in the ventrobasal thalamus. Whether such changes occur pre- or post-seizure remains to be investigated. Enhanced phasic GABA$_A$R inhibition may be one of many factors contributing to increased inhibition recently reported in TC neurons of other absence models. Currently available anti-epileptics are associated with varying degrees of adverse side effects and inefficacy, thus further...
studies to elucidate the mechanisms underlying hypersynchronous activity in absence seizures may highlight novel drug targets for absence epilepsy treatment.

Neural autoantibodies and immunotherapy-responsive epilepsy: A prospective study
R. Iorioa, G. Assenza2, G. Della Marcia3, G. Colicchio4, M. Tombini3, V. Damato6, A. Benvenga2, A. Evoli2, D. Planlotte2, A. Marti2, C. Vottono3, G. Frisullo4, A.P. Batocchi5, aCatholic University, Roma, Italy; bCampus Bio-Medico University, Roma, Italy

Background: Autoantibodies specific for neural antigens have been described in association with several encephalopathies which have seizures as a prominent feature. In these cases seizures are poorly controlled with conventional anti-epileptic drugs (AED). In contrast, a good response is often achieved with immunotherapies.

Objectives: To evaluate the frequency of autoantibodies specific to neural antigens in patients with epilepsy and their response to the immunotherapy.

Materials and methods: Two groups of patients were included in the study: 29 patients with epilepsy and other neurological symptoms and/or autoimmune diseases (group 1) and 30 patients with AED-resistant epilepsy (group 2). Forty-two age and sex-matched healthy subjects (HS) were included as controls. Patients’ Serum and CSF, when available, were evaluated for the presence of neural autoantibodies by immunohistochemistry on frozen sections of mouse brain and by cell-based assays. GAD65-IgGs were tested by RIA.

Results: Neural-specific autoantibodies were detected in 11/59 patients (19%) but not in healthy controls. In particular, neural-specific IgGs were detected in two patients from group 1 (2/29, 7%) (anti-GAD65, 1; antibody specific for an unclassified intracellular antigen [AUIA], 1) and in nine patients from group 2 (9/29, 31%) (anti-LGI1, 2; anti-GAD65, 1; AUIA, 4; antibody specific for an unclassified synaptic antigen, 2). In four patients from group 2, immunotherapy resulted in >50% seizure reduction at three months.

Conclusions: A significant percentage of patients with AED-resistant epilepsy harbor neural-specific autoantibodies and may respond to immunotherapy.

Sustained release forms: Application to antiepileptic drugs in developing countries
I. Lost2, P.-M. Preux1, M. Druet-Cabanac1, V. Ratsimbazafy1,2, aINSERM UMR 1094, Tropical Neuroepidemiology, Limoges, France; bUniv Limoges, School of Medicine, Institute of Neuroepidemiology and Tropical Neurology, CNRS FR 3503 GEIST, Limoges, France

Background: Epilepsy is a chronic neurological disease affecting more than 70 million people worldwide, among them nearly 90% in developing countries (DCs). There, primary healthcare is extremely limited, only four major antiepileptic drugs (AEDs) are used: phenobarbital, carbamazepine, sodium valproate and phenytoin. Furthermore, there is also a problem of accessibility, availability and quality of drugs.

Objective: The main hypothesis of the study was based on the fact that a “long” sustained release form that would reduce the number of drug’s administrations would allow overcoming the problems of compliance and accessibility.

Methods: A literature review of sustained release forms applicable to an AED was performed and the primary endpoint was duration of active ingredient release longer than 24 h. We also assessed the feasibility and acceptability in DCs.

Results: Two AEDs were found not to be of conventional release: carbamazepine and sodium valproate. But they are not of sustained release. Several techniques were available including: esterification, transferdental devices, liposomes and polymeric devices preformed or in situ formed. In situ methods for the preparation of injectable biodegradable microparticles or implants for the controlled delivery seemed best suited to our objective. Furthermore, they seem to fulfill the requirements of feasibility and cost. Sodium valproate appeared to be the most suitable molecule by reducing its cost and its hepatotoxicity with a “long” sustained release form.

Conclusion: This new approach to the treatment of epilepsy would solve many problems in the DCs. However, preclinical and clinical studies are required to obtain an approval.

Preventive and treatment aspects of the post-traumatic epilepsy
N. Kucherinaa, I. Grygorova2, O. Gichko3, aNeurology, Kharkiv, Ukraine; bKharkiv National Medical University, Kharkiv, Ukraine

Background: Posttraumatic epilepsy is one of the serious consequences of traumatic brain injury (TBI). To achieve the timely prevention and control of paroxysms therapeutic measures should be directed to the correct selection of major antiepileptic drugs and dose titration to the initial therapy.

Objective: To study the effectiveness of antiepileptic drugs in prevention and treatment of post-traumatic epilepsy.

Material and methods: We examined 48 patients with different periods of TBI who were treated at the Emergency Unit Hospital. All patients were divided into 3 groups:

I with acute TBI (18),
II with intermediate period of TBI (15),
III with distant period of TBI (15).

The control group was 15 almost healthy individuals. Were used clinical, neurological, instrumental, laboratory, and statistical methods.

Results: The patients of the first group received antiepileptic drugs with preventive aim after an epileptic seizure in anamnesis. The best results were obtained with lamotrigine (p < 0.05). Posttraumatic epilepsy patients in groups II and III revealed the following manifestations: generalized seizures (65.3%), focal seizures (24.2%), combined paroxysms (11.5%), paroxysmal activity on EEG with a predominance of polyphasic complexes (69.4%), spike-waves (63.1%), and sharp waves (78.3%). In these groups of patients was the most efficient use of combination therapy of valproate and lamotrigine (p < 0.05).

Conclusions: Thus, our findings demonstrate the effectiveness of lamotrigine for the prevention of post-traumatic epilepsy. And high efficiency combined therapy using valproate and lamotrigine in the treatment of post-traumatic epilepsy.

Normalized distribution of EEG frequencies within one map based on source density analysis for individual recognition of pathological features

1Clinic of Neurology, University of Innsbruck, Innsbruck, Austria; 2HCHS Systemprogrammierung, Aslar, Germany

Background: Subjective interpretation of EEG raw data is still the preferred method of evaluation in patients.
Objective: We now describe a method for objective quantitative EEG analysis, which allows online real time recognition of individual pathological deviations from normality.
Method: EEG data derived from 16 channels are processed online in real time using source density analysis. After non-linear LaGrange interpolation of virtual electrode positions a map corresponding to 64 channels is displayed (Software “neoCATEEM®” from Mewicon GmbH, 4164 Schwarzenberg, Austria). Conversion of frequency content into spectral colors and application of the RGB mode results in a single map. Spectral frequency maps are continuously displayed by means of a moving time average (up to 3 min).
Result: Normalization of EEG data within one frequency range is achieved by calculating median values of all corresponding electric power values from all electrode positions to give 100% reference values. Data are compared statistically online real time to a database containing data from 300 healthy brains. Focal aberrations of the frequency content were much better recognized and gave better statistics using source density in combination with individual normalization than using absolute power values. Patient data were compared suffering from epilepsy (enhanced theta power at T3) and psychosis (enhanced beta1 power at T6).
Conclusion: Individual normalization of quantitative EEG data in combination with an automatic comparison to a database might serve for individual rational pharmacotherapy by using drugs able to modulate the particular disturbed frequencies.

Effect of cognitive stimulation on hippocampal ripples in epileptic patients

1Department of Neurology, Brno Epilepsy Center, Masaryk University, Brno, Czech Republic; 2Behavioral and Social Neuroscience Research Group, CEITEC – Central European Institute of Technology, Masaryk University, Brno, Czech Republic; 3ICRC, St. Anne University Hospital, Brno, Czech Republic; 4Department of Psychology, Masaryk University, Brno, Czech Republic; 5Mayo Clinic, Rochester, IL, USA; 6Department of Neurology, Masaryk University, St. Anne’s University Hospital, Brno, Czech Republic; 7ISI, Academy of Sciences, Brno, Czech Republic

Interictal HFOs (ripples and fast ripples) have been repeatedly identified in recordings from depth macroelectrodes in epileptics. In contrast to fast ripples, which are believed to reflect the neuronal substrates of epileptogenesis, ripples are considered to be a signature of both normal and epileptic brain processes. The differentiation of physiological and epileptic ripples in intracranial recordings remains unavailable.

We analyzed SEEG recordings in seven patients with intractable partial seizures in whom hippocampal activity was recorded in resting state and subsequently during simple cognitive task with randomly presented frequent and rare visual stimuli. Using automated detection of ripples based on length of power envelope, we analyzed potential differences in ripple rate (RR) in the cognitive versus resting period, within epileptic (EH) and non-epileptic hippocampi (NH). Further direct impact of cognitive stimuli on ripples (immediately after the stimulus) was investigated.

Ripples have been detected within hippocampal recordings in all the investigated subjects. Mean RR in resting periods was 11.36 ± 8.34/min within EH, and 10.13 ± 8.75/min within NH. In the cognitive task periods mean RR within EH and NH decreased to 7.16 ± 5.75/min, and 8.75 ± 7.69/min respectively. The reduction of RR during cognitive stimulation was significant in EH, but not in NH. Interestingly we observed a transient suppression of ripples in both EH (slight) and NH (significant) in the first second after the stimulus onset, followed by a significant increase in RR for both EH and NH.

Our results point to different reactivity of ripples within EH and NH to the cognitive stimulation.

Ketamine in refractory status epilepticus — A retrospective study on 16 patients
Department of Neurology, Christian Doppler Klinik, Paracelsus Medical University, Salzburg, Austria

Background: Refractory status epilepticus (RSE) is defined as status epilepticus (SE) not responding to first- and second-line antiepileptic drug (AED) therapies. Ketamine is a noncompetitive NMDA receptor antagonist.

Objectives: Few case reports and retrospective studies on ketamine in SE are available. We aimed to evaluate safety, tolerability and outcome.

Patients and methods: We retrospectively analysed data of patients with RSE (n = 84) treated in our neurological intensive care unit from 01/2012 (n = 70) to 02/2013 (n = 14). We analysed aetiology, duration, type of SE, daily dose of ketamine, cotherapeutic agents, treatment response and disposition.

Results: In 16/84 (19%) patients (median age 68.5 years; range 50–80) with RSE, ketamine was used in combination with midazolam. Causes of RSE: 6/16 post-anoxic, 3/16 systemic infection, 3/16 stroke/intracerebral haemorrhage, 2/16 unknown, 2/16 preexisting epilepsy with low AED level. RSE types: 2/16 myoclonic SE, 4/16 convulsive SE, 10/16 nonconvulsive SE. Ketamine was initiated median on 4th day of SE (range 1–18); median duration of treatment 4.5 days (range 1–22). In 4 patients ketamine was started with a bolus of 200 mg, followed by median continuous infusion 187.5 mg/h (range 150–200); 12 patients received continuous infusion from the onset, median 187.5 mg/h (range 75–250). Median maximum dose was 175 mg/h (range 100–300). RSE was terminated in 10/16 patients; 11/16 patients died due to either RSE (6/11) or their main disease despite terminated SE (5/11).

Conclusion: Ketamine may be effective in later stages of SE when adequate first and second-line treatments fail, but overall outcome remains poor with 70% in-hospital mortality.

Clinical utility of (18F)-fluoroflumazenil pet in presurgical evaluation of refractory focal epilepsy
J. Gusenleitner1, G. Schwarz2, R. Pichler2, M. Hamberger1, G. Puttiker2, M. Schnizer1, J. Trenkler1, G. Wurms3, T.J. von Oertzen4. 1Neurology, Landesnervenklinik Wagner-Jauregg, Linz, Austria; 2Nuclear Medicine, Landesnervenklinik Wagner-Jauregg, Linz, Austria; 3Neuroradiology, Landesnervenklinik Wagner-Jauregg, Linz, Austria; 4Neurosurgery, Landesnervenklinik Wagner-Jauregg, Linz, Austria

Gamma-aminobutyric acid is the brain’s main inhibitory neurotransmitter and has already been implicated in the pathophysiology of epilepsy by several investigations. A selective antagonist of GABAA-benzodiazepine receptors, which is frequently used, is the radioligand 11C Flumazenil. In patients with intractable focal epilepsy a localized reduction in (11C) FMZ binding is demonstrated, which correlates closely with the area of seizure onset. We used as one of the first programmes in middle Europe 185 Mbol. 18F-Flumazenil in the preoperative evaluation of 37 patients with refractory focal epilepsy. 18F-Flumazenil has a longer half-life (2 h) compared to the more commonly used 11C Flumazenil (20 min). 14 of our patients had finally been operated. 11 patients had temporal lobe epilepsy, in 3 patients an extra temporal epileptogenic area had been identified. Eight patients had concordant unilateral focal results. Interestingly, two patients had neither a focal lesion on MRI nor any lateralization or localization in the FMZ PET. Seizure semiology and ictal EEG were guidance for successful intracranial monitoring. The postoperative outcome was excellent (one reached Wieser1a, one Wieser1). Two patients showed a bilateral temporal abnormal FMZ PET result, both had unilateral MRI pathology. Postoperative outcome in these two patients was non favourable (one Wieser4, one Wieser5).

In summary, 18F-FMZ-PET is a helpful tool in the preoperative investigation of patients with refractory focal epilepsy. Discordant results may predict less favourable outcome.

A double-blind extension study to assess long-term safety/efficacy of zonisamide versus carbamazepine monotherapy for treatment of newly diagnosed partial epilepsy
M. Baulac1, A. Patten2, L. Giorgi3. 1Hôpital Pitié-Salpêtrière, Paris, France; 2Esai Limited, Hatfield, UK

Objective: To investigate the long-term safety and maintenance of efficacy of zonisamide versus carbamazepine monotherapy for partial seizures in adults with newly diagnosed epilepsy.

Patients and methods: A long-term, double-blind, extension study was conducted in patients completing a Phase III non-inferiority trial comparing zonisamide and carbamazepine monotherapy. Patients continued their randomised treatment, with dosing adjusted according to tolerability/response within permitted dose ranges (zonisamide 200–500 mg/day; carbamazepine 400–1200 mg/day). Safety assessments included treatment-emergent adverse events (TEAEs) and clinical laboratory parameters. Efficacy assessments included retention rate (primary assessment) and seizure freedom rate.

Results: Overall, 120/137 (87.6%) zonisamide patients and 134/158 (84.8%) carbamazepine patients completed the study. For zonisamide versus carbamazepine, incidences were similar for TEAEs and laboratory parameters. 158 (84.8%) carbamazepine patients completed the study. For zonisamide versus carbamazepine, incidences were similar for TEAEs (52.6% vs. 46.2%), serious treatment-related TEAEs (0.7% vs. 1.9%) and TEAEs leading to withdrawal (1.5% vs. 0.6%). Most TEAEs (~90%) were of mild/moderate intensity; the most frequently reported being decreased weight (5.8% vs. 0%) and headache (4.4% vs. 6.3%). Zonisamide was associated with small-to-moderate decreases in bicarbonate levels from baseline (mean −3.4 mmol/L). Vital signs and physical/neurological examinations revealed no safety concerns. For zonisamide versus carbamazepine, retention rates after 12, 18 and 24 months were 58.4% vs. 61.4%, 27.7% vs. 27.8% and 5.8% vs. 2.5%, respectively; and the proportion of patients remaining seizure free for ≥24 months was 32.3% versus 35.2% (intent-to-treat population).

Conclusion: Once-daily zonisamide monotherapy demonstrated favourable long-term safety and maintenance of efficacy in treating partial seizures in adults with newly diagnosed epilepsy. No new or unexpected safety findings emerged.

Cognitive malfunction impairment and stigma in HIV/AIDS epileptic patients in Kenya

B.A. Elizabeth, R.N. Mbugua. a, b, c  Clinical Research, Kenya Medical Research Institute, Kenya Network of Women Living with HIV/AIDS, Nairobi University, Nairobi, Kenya; c Clinical Research/Psychiatry, Kenya Association for the Welfare of People with Epilepsy, Nairobi, Kenya; c Clinical Research, Kenya Network of Women Living with HIV/AIDS, Nairobi, Kenya

Background: Epilepsy is one of the most prevalent neurological conditions and knows no age, racial, social class, geographic, or national boundaries. The impact of epilepsy rests not only on the individual patient, but also on the family and indirectly on the community. The burden of epilepsy may be due to the physical hazards of epilepsy resulting from the unpredictability of seizures; the social exclusion as a result of negative attitudes of others toward people with epilepsy; and the stigma.

Objective: The impact of the many infections on neurological morbidity and mortality is caused by bacterial meningitis, particularly that due to pneumococcal and meningococcal organisms, is still common. The neurological outcomes of these readily treatable infections depend on the availability of and access to health services, which differ tremendously across the region. The situation is made worse where populations are displaced by conflicts. Epidemics of meningococcal disease are particularly frequent in the meningococcal belt.

Results: Viral encephalitis is on the increase, where the prevalence of HIV infection is high as well. The HIV virus enters the nervous system within hours of an individual’s becoming infected. Acute inflammatory demyelinating polyneuropathy (Guillain–Barré syndrome), which can cause paralysis leading to death from respiratory failure, often accompanies this initial HIV infection and occurs with greater frequency in those infected with HIV/AIDS than in uninfected populations.

Conclusions: Opportunistic infections of the nervous system occur in about 30 to 40% of those with AIDS. Neurological complications of HIV infection have become major, overwhelming components of the health burden.

Low concentrations of lead diminish the threshold of pentylentetrazole induced seizure in mice

H. Yazdanpanah, a, b, A. Heydari, a, A. Mesdaghinia, a  Department of Pharmacology, Kashan University of Medical Sciences, Kashan, Iran; b Department of Neurosurgery, Shiraz University of Medical Sciences, Shiraz, Iran; c Physiology Research Center, Kashan University of Medical Sciences, Kashan, Iran

Background: Lead is one of the most common toxic metals and its exposure is associated with several neurological damages and behavioral disturbances. There is controversy in the results on the relation of lead exposure and seizure incidence.

Objective: We examined the effects of short-term exposure of low lead concentrations on the chemical seizure induced by pentylentetrazole (PTZ).

Material and methods: Mice received lead acetate in drinking water for 30 days at concentrations of 50 and 100 ppm. Slow infusion of PTZ (5 mg/kg, 0.3 ml/min) was utilized to induce seizure. The latency between the start of infusion and onset of convulsion signs including myoclonic twitch, face and forelimb clonus, running and bouncing clonus and tonic hindlimb extension were recorded and then converted to threshold convulsion dosage.

Results: Following 30 day exposure, blood lead level in both the experimental groups was significantly higher than the control group (p < 0.01). The exposure to 100 ppm of lead reduced seizure thresholds (p < 0.001) in all phases of convulsion while 50 ppm of lead did not (p > 0.05). Significant effect of 100 ppm lead acetate indicates that even this concentration of lead increases the possibility of seizure attacks in lead exposed populations. Lead acetate at a concentration of 50 ppm did not affect, thus 100 ppm maybe considered as minimal effective concentration of lead.

Conclusion: Several mechanisms such as Ca replacement or BBB damage are suggested for this effect but exact mechanisms are unclear. Nevertheless more well-designed studies may be executed to deliver further accurate information.

A model for an enhanced screening tool for depression in people with epilepsy

T. von Oertzen, a, b, M. Drinovac, c, H. Wagner, c, N. Agrawal, a, A. Mitchell, d, H.R. Cock. a St. George’s University of London, London, UK; b Dept of Neurology, Wagner-Jauregg Neuroscience Centre, Austria; c Dept of Applied Statistics, Johannes Kepler University, Linz, Austria; d Dept of Psycho-Oncology, Leicestershire Partnership Trust, Leicester, UK

Background: Depression is a frequent comorbidity in people with epilepsy. To increase the detection of this frequent comorbidity various screening tools have been described, in particular NDDI-E. We have previously validated NDDI-E and a visual analogue scale, ET, in a multicultural London outpatient setting.

Objective: The aim of the current study is to create a new more efficient screening tool for depression in people with epilepsy.

Methods: Data from 250 patients was prospectively collected in London from 05/2009 to 02/2010. Logistic Regression models and recursive partitioning techniques (classification trees, random forests) have been applied to identify an optimal subset of the 13 items with respect to ROC. Classification trees were grown by restricting the possible splitting variables to different subsets of items. In all considered situations the ROC curves indicated more precise classification than the original screening tests, though the trees had to be cut back to ensure comprehensible splitting rules in some situations.

Conclusion: For the first time, we have created a model of a screening tool for depression containing both verbal and visual analogue scales, which should be more precise than previous tools.

White matter abnormalities in patients with idiopathic generalized epilepsy
A.M.D.S. Braga, a, W.P. Blasque, a, L.E. Betting, a, L. E. Vasilenko, a,b, L.V. Lipatov, a,b, S.V. Lobzin, a,b
Betting, a, LE. Vasilenko, a,b, L.V. Lipatov, a,b, S.V. Lobzin, a,b
Background: In the past decades, several studies investigating idiopathic generalized epilepsies (IGEs) disclosed subtle brain abnormalities which may be involved in the pathophysiology of this group of diseases. Investigations focused mainly in the grey matter. Few studies using structural neuroimaging explored the white matter.
Objective: To evaluate the presence of focal abnormalities in the white matter of patients with IGE patients using voxel-based morphometry (VBM).
Patients and methods: 28 patients (18 women) with IGE and 21 controls were investigated. All participants were scanned using a 1.5 T MRI. Volumetric T1 (3D) weighted sequence with isotropic voxels (1 mm) was used for analysis. VBM was conducted with SPM8 and VBM8 toolbox. Processing involved normalization, automatic segmentation and smoothing of the grey matter and white matter separately. Statistical analysis was performed with two sample T tests to compare differences in the grey matter and white matter between patients and controls. Level of significance selected was p = 0.05 corrected for multiple comparisons.
Results: Significant focal increase in the grey matter was disclosed mainly in the right subcallosal gyrus (cluster size = 746, p = 0.04) and left orbital gyrus (p = 0.006). White matter analysis showed focal atrophy in the anterior cingulate limbic lobe and cingulate gyrus (cluster size = 5020, p < 0.0001).
Conclusions: This investigation supports structural abnormalities in the grey matter and white matter in the frontal and limbic lobes in patients with IGE. White matter abnormalities disclosed located in the mesial parasagittal structures are in accordance with previous investigations.

Clinical and diagnostic features of migraine–epilepsy
A.V. Vasilenko a,b, L.V. Lipatova a, S.V. Lobzin a, a The Ministry of Health of the Russian Federation, North-Western State Medical University named after I.I. Mechnikov, Russia; b The Ministry of Health of the Russian Federation, St. Petersburg Psychoneurological Research Institute named after V.M. Bekhterev, St. Petersburg, Russia
According to modern concepts migraine and epilepsy are comorbid neurological diseases with similar pathogenesis and clinic. The prevalence of headache in patients with epilepsy is 59%, and a quarter of them had migraine.
The study features clinical neurology, EEG and neuroimaging indicators of migraine and epilepsy. Complex clinical neurology, EEG, neuroimaging (MRI, PET, NMRS and MR tractography), and psychological examination were performed in 47 patients with migraine, 50 patients with locally due to epilepsy and 17 — with a migraine–epilepsy. We found that patients with migraine most frequently reported the distribution of a hemicrania with emphasis in the fronto temporal orbital region. The hemicrania was permanent, had a pulsating nature and was often in conjunction with accompanying symptoms. In patients with locally induced epilepsy in the interictal period, there are different types of headaches: 28% — migraine with aura and/or without, 33% — tension headache, and 8% — unclassifiable headache. According to the video-EEG monitoring it is most common in patients with migraine (67%) and migraine–epilepsy (88%) to have a combination of focal and generalized epileptiform activity emanating from the back and/or temporal lobes. MRI in patients with migraine and migraine–epilepsy were discovered extension of the temporal horn of one of the lateral ventricles (33 and 25%), cranio-vertebral anomalies and other MP-changes. Thus, the differential diagnosis of migraine and epilepsy locally by conducting a comprehensive examination of patients with the inclusion of clinical neurology, EEG and neuroimaging techniques, allows you to set the type of attack and objectify further medical therapy.

Neurophysiological study in patients with benign adult familial myoclonus epilepsy
U. Takechi a, N. Akamatsu b, K. Matsunaga c, T. Uozumi a, S. Tsuji d, a Department of Neurology, University of Occupational and Environmental Health, School of Medicine, Kitakyushu, Japan; b Department of Neurology and Internal Medicine, Kumamoto Onjaku Hospital, Kumamoto, Japan; c Department of Neurology, Wakamatsu Hospital of the University of Occupational and Environmental Health, School of Medicine, Kitakyushu, Japan; d Department of Medical Science Technology, International University of Health and Welfare, Fukuoka, Japan
Objectives: The aim of the present study is to investigate cortical excitability in patients with benign adult familial myoclonus epilepsy (BAFME), using transcranial magnetic stimulation (TMS).
Methods: Single-pulse and paired-pulse TMS were performed in 6 BAFME patients to obtain multiple measures from the first dorsal interosseous muscle, including resting motor threshold (rMT), active motor threshold (aMT), contralateral silent periods (CSP), and short-interval intracortical inhibition (SICI) and intracortical facilitation (ICF). Age-matched twenty-one healthy subjects were also studied. Also all patients had recorded somatosensory evoked potential (SEP) elicited by digital nerve stimulation.
Results: rMT, aMT and SICI were significantly decreased compared to control group. And CSP was significantly shortened in the patients compared to control groups (rMT: p < 0.01, aMT: p < 0.01, CSP: p < 0.001, SICI-2 ms: p < 0.05). In contrast, there were no significant differences between patients and control groups in ICF. Significant correlations were not observed between SEP amplitude and TMS measures.
Conclusions: These findings suggested that there was motor cortical hyperexcitability secondary to the loss of intracortical inhibition, in addition to hyperexcitability of the sensory cortex in patients with BAFME.

The potential efficacy of intravenous lacosamide in epilepsy at hospital cases
C. García Arguedas, A.S. Martí, A.V. Benito, E.B. Diago, J.A.M. Llerda, Neurology, Lozano Blesa Clinic Hospital, Zaragoza, Spain
Objectives: To appraise the efficacy of the lacosamide, third generation antiepileptic, for treatment of different cases of crisis, including status, with intravenous administration.
Material and methods: Patients with different types of crisis, who were assessed, while their hospitalization in the Lozano Blesa Clinic Hospital, Zaragoza. The cases were treated with intravenous lacosamide (iVLCM). The information was collected by retrospective analysis. The efficacy was defined as the cease of the crisis with the treatment. It could be in the first line or more. The data was recollected with standardized questionnaire by a neurologist.

Results: Nineteen patients were selected, the average age was 50 years, 68.4% men, 63.2% had a history of previous crisis, of them 41.7% were generalized, 33.3% complex focal and 25% simple focal. At the moment of the use of iVLCM 42.1% were in status (22.2% convulsive status, 66.7% not convulsive and 11% focal) and 57.9% no status. The iVLCM was used at the first instance in 31.6%, the second in 57.9% and both the third and fourth in 5.3%. Initially used doses were, 200 mg in 78.9%, 100 mg in 15.8%, and 400 mg in 5.3%. The maintenance doses were 200 mg/12 h in 72.2% and 100 mg/12 h in 27.8%. The obtained efficacy was in the second day, average, with a positive response of 89.5%. No side effect was registered.

Conclusions: The LCM has shown efficacy and good tolerance, even beyond use as a third-line treatment.

Role of postoperative antiepileptic drug withdrawal in children: Long-term seizure outcome

H.I. Maaty. Neurosurgery, Benha University, Cairo, Egypt

Background and aim: The effect of time to stop AED postoperatively in children on long-term seizure outcome is still not clear. We aimed to assess the effect of timing of AED withdrawal on subsequent seizure recurrence and long-term seizure outcome in children.

Methods: This retrospective study included 150 child patients who underwent cranial surgery between January 2007, and December 2011, and who started AED withdrawal after having reached postoperative seizure freedom. Patients had at least 1 year postoperative follow-up. Time intervals from surgery to start of AED reduction (Time to Reduction = TTR), and complete discontinuation (Time to Discontinuation = TTD) were studied in relation to seizure recurrence during or after AED withdrawal.

Results: Mean age was 8.3 year (range 2–15 years). Median TTR and TTD were 12 months and 35 months respectively. 71 patients had seizure recurrence during or after AED withdrawal. After a mean postoperative follow-up of 31 months, 85 patients were seizure free for at least 1 year. TTR and TTD showed statistically significant relation to regain seizure freedom after restart of drug treatment, to seizure freedom, and to cure (defined as being seizure free and off AEDs for at least 1 year) at final follow-up.

Conclusion: Early postoperative AED withdrawal dose affect long-term seizure outcome and cure. Also it might identify patients who need continuous drug treatment and preventing unnecessary continuation of AEDs in others.

A novel intronic variant of SCN1A gene responsible for severe epileptic encephalopathy with refractory status epilepticus

C. Stipa¹, F. Bisulli², L. Lichetta², L. Alvisi², F. Zara³, E. Gennaro³, A. Pini³, C. Gobbì³, P. Tinuper³. ¹Department of Biomedical and Neurorobotics Sciences, IRCCS Institute of Neurological Sciences, University of Bologna, Bologna, Italy; ²Department of Neuroscience, Laboratory of Neurogenetics, Istituto C. Gaslini, Genoa, Italy; ³Child Neurology Department, Ospedale Maggiore, Bologna, Italy

Objective: To describe a 32 year old male with encephalopathy and drug resistant epilepsy with frequent status epilepticus.

Patient and methods: The patient was born at term by normal pregnancy after prolonged labor. A significant global developmental delay had been recognized since 6 years of age. At age 5 months he experienced the first epileptic seizure during hyperpyrexia characterized by a left hemiconic seizure during sleep followed, a few hours later, by a tonic-clonic seizure. Since then he had monthly febrile and afebrile tonic-clonic seizures, mainly arising from sleep. Despite trials of several antiepileptic drugs, seizures increased on frequency, becoming weekly. Recurrent episodes of intractable status epilepticus worsened by phenylhydantoin were also reported. At our first assessment (32 years of age) the patient underwent a comprehensive clinical, neurophysiological and neuroradiological study.

Results: Neurological examination showed craniofacial dysmorphism and severe delay in language and motor acquisition. Interictal EEG showed diffuse background slowing and independent epileptiform discharges over both the temporal regions. During prolonged video-EEG monitoring we recorded one of his typical status epilepticus clinically characterized by left arm clonic seizures and secondarily generalized seizures. Brain MRI disclosed a mild cerebellar atrophy with evidence of the cerebellar sulcus. Molecular analysis of SCN1A gene identified a de novo intronic mutation, causing nucleotide substitution c.338 + 3A→C.

Spectral analysis of EEG in patients with drug resistant epilepsy

L.V. Lipatova³, E.A. Korsakova³, N.A. Sivakova³. ³Epilepsy Department, V.M. Bekhterev Psychoneurological Research Institute, St. Petersburg, Russia; ²Neurophysiology Department, V.M. Bekhterev Psychoneurological Research Institute, St. Petersburg, Russia

Objective: To study spectral characteristics of electric paroxysmal activity (PA) of the EEG in patients with localization-related drug resistant epilepsy (DRE) with structural changes in the hippocampus and evaluate their relationship with the occurrence of the phenomenon of secondary bilateral synchronization syndrome (SBS).

Materials and methods: 42 patients with DRE were studied, 23 — with MRI-detected hippocampus sclerosis (HS), and 19 — without HS. Spectral analysis (SA) was performed in EEG fragments with PA, average spectral parameters for 4-second recording periods were calculated.

Results: The data analysis of quantitative EEG revealed topographical differences in spectral power values of PA between the groups. The most pronounced results were obtained for the delta and theta rhythms. In the first group of patients average spectral power of delta waves in leads Fp1, Fp2, F3, F4, C3 and C4 was significantly lower than in second group (p < 0.05). A similar trend is observed in the range of the theta rhythm. Even distribution of spectral capacity of delta and theta rhythms with no significant fronto-occipital differences in all recorded leads found out in the first group. A gradient growth of spectral power of theta waves in the direction of the occipital lobes to the frontal determined in patients with HS.

Conclusion: Thus, the structural changes of the hippocampus influence on the severity of PA and on neurophysiological mechanisms of SBS occurrence. SA could be used for the early diagnosis of SBS phenomenon and selection of treatment strategy in patients with DRE.

Conclusions: We describe a new de-novo mutation of SCN1A gene responsible for severe early-infantile epileptic encephalopathy with recurrent status epilepticus resistant to sodium blocker AEDs.

Seizure due to imipramine discontinuation: A case report
E. Erdogan1, C.F. Demir1, H.H. Özdemir1. 1Neurology Department, Elazig State Hospital, Turkey; 2Neurology, Firat University Neurology, Elazig, Turkey; 3Neurology, Bismil State Hospital, Diyarbakir, Turkey

Imipramine serotonin, noradrenaline and lower level of dopamine block the reuptake pump. In particular, it is used in nocturnal enuresis treatment. It is known that high dose of imipramine causes epileptic activity. However, seizure because of depending on the discontinuance of imipramine is rarely seen. A 19 year old male patient had been taking 75 mg/day imipramine regularly for 1 year for nocturnal enuresis treatment. Patient had been contracted with seizure after sudden discontinuance of medicine. Routine biochemical inspections, EEG and cranial MRG findings were evaluated normal and it was considered that sudden discontinuance of imipramine caused seizure. Consequently; we would like highlight that in order to avoid seizure depending on discontinuance of imipramine, it is necessary to discontinue imipramine by decreasing it.

Personality characteristics of epileptic and non-epileptic using personality factorial inventory
A. Andrade Filho1, C.G. da Silva Ferreira1, L. Zane1, A.C. Oliveira1, C.G.D.S. Andrade1, L.S.A. Ismael1, C.V. Santangelo1, R.P.D. Braga2 Epilepsy Group 1Neurocience and Mental Health, University Federal of Bahia, Salvador, Brazil; 2Psychology Department, Salvador, Brazil; 3Foundation of Neurology and Neurosurgery (FNN), Salvador, Brazil

This article aims to demonstrate the comparison of personality characteristics between groups of epileptic patients and the general population. The survey was conducted with people aged between 18 and 60, living in Salvador, Bahia. We sought to identify the intracception, performance, autonomy, aggression and social stigmas. The methodology applied in this research work was to use the Personality Factorial Inventory (PFI), in a universe of 200 individuals, 100 epileptic patients and 100 general population (caregivers, staff and students). All completed the informed consent and provided answers about the socio-demographic information on the total of 10 items. Participants were interviewed at the Foundation of Neurology and Neurosurgery (FNN) and the University Hospital Professor Edgard Santos (HUPES)–UFBA. The test consisted of 155 questions, in order to measure 15 dimensions of personality. Among male patients with epilepsy, the analysis of data showed the following dominant factors in the personality profile of average behavior: a) high average level of denial, revealing individuals who indulge in resignation and accept the punishment and guilt; and b) low level of performance, indicating subjects with difficulty performing independent activities. While, in females patients with epilepsy showed a profile with a high concentration of anger, hatred and self-confidence. The study shows the characteristics of personality to an association between the dimensions of PFI in epileptics. They are more concerned with themselves, less interactive and dominant. The results obtained in the general population present a strong rejection towards epilepsy due to ignorance and fear of contamination.

Contralateral blink inhibition is a possible pathomechanism for ictal unilateral eyelid blinking — A case report
G. Kalss1, M. Leiting1, J. Dobesberger1, C.A. Granbichler1, J. Höfer1, D.P. Huber1, G. Kuchukidze1,2, T. Moroder1, A. Rohracher1, W. Staffen1, E. Trinka1. 1Department of Neurology, Christian Doppler Klinik, Paracelsus Medical University, Salzburg, Salzburg, Austria; 2Department of Neurology, Medical University Innsbruck, Innsbruck, Austria

Purpose: Little is known about ictal unilateral eyelid blinking (UEB) as a lateralizing sign in focal seizures. We present a case study and a comprehensive review of the literature and the pathophysiology of UEB.

Methods: We report a 38 year old, right-handed woman with intractable epilepsy, who underwent prolonged non-invasive video-EEG monitoring.

Results: A total of four complex focal seizures (CFS) with UEB were recorded. Semiological signs in all CFS were bilateral eyelid blinking, occurring in median 29 s after EEG-onset (range 18–37 s, median duration 9 s, range 6–11 s), followed by UEB on the right, in median starting 51 s after EEG-onset (range 30–71 s, median duration 17 s, range 10–34 s). UEB did not evolve into any clonic activity of the face. During one CFS, bilateral eyelid blinking recurred after UEB with higher blink frequency on the right. Further lateralizing seizure phenomena were ipsilateral head turning (in 2/4), contralateral eye deviation (in 3/4), aphasia (in 2/4), postictal impaired figural memory (in 1/4) and postictal nose wiping (in 2/4 CFS, respectively).

Ictal EEG showed a right fronto-temporal seizure onset over F8, F8–Fp2 or Fp2–F4. Interictal EEG showed right fronto-temporal sharp waves over F8, F8–T4, F8–Sp2 or T2 and left temporal focal slowing.

Conclusion: UEB was ipsilateral to the right fronto-temporal EEG pattern in this patient occurring only in CFS. Due to the asymmetric blink frequency during bilateral eyelid blinking, we hypothesize ictal UEB to be a contralateral blink inhibition, caused by activation in fronto-temporal cortical areas and mediated by trigeminal fibers.

When epileptogenesis occurs in patients with neurocysticercosis?
A. Andrade Filho1, F.L.D.S. Figuerêoa2, B.B. Soane2. 1Neurocience and Mental Health, University Federal of Bahia, Brazil; 2Foundation of Neurology and Neurosurgery (FNN), Salvador, Brazil

Background: Neurocysticercosis (NC) is the most frequent neurologic parasitosis. Its role is indisputable for the etiology of many neurological disturbances. Epilepsy is the most common clinical manifestation.

Objective: To determine when epileptogenesis occurs in patients with NC, according to the evolutionary phases of the disease.

Method: 157 patients diagnosed with NC diagnosis through anamnesis, cranium computed tomography (CCT), analysis of liquor and electroencephalogram were included in this paper. The cysticercus lesions in CCT were classified in four phases.

Results: Seizure was the most important clinical form, appearing in 80.3% of the patients. Statistical significance (p = 0.001) was shown
in correlation between the convulsive form and phase II in CCT, which was performed in the beginning.

**Discussion:** CCT is very helpful in NC. There are many controversies, concerning epilepsy related to NC, specially, due to different forms of pathologic manifestations of the infection. The appearance of the clinical forms, mainly in the initial phases of the disease can be derived from the immune stimulus by the parasite with local inflammatory response and important perilesional edema.

**Conclusion:** Phase II was the most exuberant phase of the disease, being important to rise seizure.

Is serotonin receptor HTR1B implicated in mesial temporal lobe epilepsy development?

**Background:** Evidences from animal models have demonstrated that depletion of brain serotonin (5-HT), a neurotransmitter with a pivotal role in neurodevelopment and brain plasticity, lowers the threshold to induced seizures. It was also demonstrated that antiepileptic drugs increase endogenous 5-HT concentrations and that 5HT-1B receptors could have an anticonvulsant role. Association studies have demonstrated that a polymorphism (rs6296) in 5HTR-1B gene may be a susceptibility factor for with temporal lobe epilepsy (TLE) development. The rs6296 G allele has been associated with decreased receptor activity. Our aim was to analyse the association between rs6296 and the development and clinical features of Mesial Temporal Lobe Epilepsy (MTLE) in a Portuguese population.

**Material and methods:** A cohort of 121 MTLE patients (67 F, 54 M, mean age = 44 ± 11 years, age of onset = 13 ± 9 years) was compared with a cohort of 192 healthy individuals (HI). All patients had Hippocampal Sclerosis (MTLE–HS). Genotyping was performed by TaqMan real time PCR methodology.

**Results:** rs6296 G allele was overrepresented in MTLE patients compared to controls (80.2% in MTLE vs 72.1% in HI, p = 0.029 OR = 1.561 (1.060–2.298)). We constituted 2 MTLE–HS sub-groups, according to febrile seizure antecedents and no differences in rs6596 allelic or genotypic frequencies were found.

**Conclusion:** The rs6296 G allele may be a susceptibility factor to MTLE–HS development. Since these receptors have an anticonvulsant role, a reduction in their activity could lower the threshold for seizure development. Supported by a BICE Tecnifar Grant 2012.

Epilepsies of child and adolescent

Epilepsy is a public health problem in Senegal, with a prevalence of 8.3 to 14/1000. It mainly affects children.

**Objective:** Of this work is to study the biographical aspects, phenotypic and evolutionary of epilepsy in a cohort of children in Senegal.

**Patients and methods:** This is a retrospective chart review of children with epilepsy followed up regularly at Fann University Hospital and Children’s Hospital Albert Royer, July 2003 to December 2010. Inclusion criteria were: epilepsy aged under 16 years, regularly monitored for at least 3 years, with appropriate treatment, effective dose, with good adherence.

**Results:** We collected 522 children, aged 3 months to 16 years, with a sex ratio of 1.7 in favor of boys. The epilepsy was idiopathic in 57% of children and non-idiopathic in 43% of patients. Etiological factors were dominated by parental consanguinity, abnormal pregnancy and childbirth, infections of the central nervous system. In the group of idiopathic epilepsies not, the signs associated with epilepsy were language disorders (15.70%), behavior (15%) and motor deficits (10.32%). 22.41% of school children had learning difficulties sometimes leading to repetition or school exclusion.

**Conclusion:** The fight against epilepsy in Senegal implies an effective prevention policy which is necessary in improving the socio-health and the fight against infections. This is the challenge of the Senegalese league against epilepsy.

Efficacy and safety of eslicarbazepine acetate in acute manic episodes associated with bipolar I disorder: BIA-2093-203 phase II study results  
H. Grunzea, L. Almeida b, T. Nunes c, R. Costa a, R. Sousa a, P. Soares-da-Silva a, c, Newcastle University, Newcastle upon Tyne, UK; bUniversity of Aveiro, Aveiro, Portugal; cBIAL-Portela & Co. S.A., Trofa, Portugal; dUniversity of Porto, Porto, Portugal  

Background: Eslicarbazepine acetate (ESL) was approved in 2009 by the European Medicines Agency as adjunctive therapy in adults with partial-onset seizures (POS), with or without secondary generalization.  
Objective: To evaluate the efficacy, safety and tolerability of two dose-titration regimens of ESL as therapy of patients with acute mania.  
Material and methods: Multicentre, double-blind, randomised, parallel-group, placebo-controlled dose-titration phase II study in patients with a diagnosis of bipolar I disorder who experienced an acute manic (including mixed) episode. Patients were randomised to: group A = ESL 600–1200–1800 mg; group B = ESL 800–1200–2400 mg; and group C = placebo 1–3 tablets. Patients were started on the lower dosage and were up-titrated as clinically required 3 and 6 days after therapy initiation; the dose was kept at the maximum for up to 3-weeks.  
Results: 160 patients were included in the intention-to-treat (ITT) population and 161 were included in the safety population. The ANCOVA model of absolute change in Young Mania Rating Scale total score was [least square mean (p-value versus placebo)]: group A = –12.5 (p = 0.348); group B = –14.2 (p = 0.053); placebo = –10.3. Secondary efficacy analysis showed similar results with a trend for increase in efficacy across the randomised dosage-titration regimens from placebo to group B. Most common TEAEs observed in ESL groups (≥5% of patients) were headache, dizziness, nausea, vomiting, and diarrhoea.  
Conclusion: The primary treatment comparison was not statistically significant. There was a trend towards efficacy in the ESL 800–1200–2400 mg dose group. The two ESL groups exhibited a comparably favourable safety profile.

Efficacy, safety and tolerability of eslicarbazepine acetate in the recurrence prevention of bipolar I disorder: BIA-2093-205 phase II extension study  
T. Nunes a, L. Almeida a, R. Costa a, R. Sousa a, P. Soares-da-Silva a, c, aUniversity of Aveiro, Aveiro, Portugal; bBIAL-Portela & Co. S.A., Trofa, Portugal; cUniversity of Porto, Porto, Portugal  

Background: Eslicarbazepine acetate (ESL) was approved in 2009 by the European Medicines Agency as adjunctive therapy in adults with partial-onset seizures (POS), with or without secondary generalization.  
Objective: To evaluate the dose-dependent efficacy, safety and tolerability of ESL for the recurrence prevention of bipolar I disorder.  
Material and methods: Two part extension study of two phase II studies evaluated the efficacy, safety and tolerability of ESL in patients with acute mania (BIA-2093-203 and -204). In part I (results not shown), participants received open-label treatment with ESL 900 mg QD for 2 weeks. Part II followed a double-blind, parallel-group design in which participants were randomly assigned to treatment with ESL 300 mg, ESL 900 mg, or ESL 1800 mg QD up to 6 months after the last patient entered part II.  
Results: Patients showing no worsening were (ITT): ESL 300 mg = 26 (76.5%), ESL 900 mg = 14 (56.0%), and ESL 1800 mg = 16 (61.5%). Patients developing mania symptomatology (ITT) were: ESL 300 mg = 3 (8.8%), ESL 900 mg = 4 (16.0%), and ESL 1800 mg = 5 (19.2%). Patients developing depressive symptomatology were (ITT): ESL 300 mg = 5 (14.7%), ESL 900 mg = 0, and ESL 1800 mg = 3 (11.3%). Differences between groups were not statistically significant. Overall, 46 (52.9%) patients reported treatment emergent adverse events (TEAE) that were considered mild to moderate in 41 (89.1%) patients.  
Conclusion: There were no statistically significant differences between the ESL dosage groups in the primary and secondary efficacy analyses. ESL was overall well tolerated with no major safety differences between the groups.

The effects of eslicarbazepine on transient Na+ currents in chronically epileptic human hippocampal cells  
A. Doser a, G. Dickhof a, M. Uebachs a, P. Soares-da-Silva a, c, H. Beck a, b  
aUniversity of Bonn Medical Center, Bonn, Germany; bBIAL-Portela & Co. S.A., Trofa, Portugal; cUniversity of Porto, Porto, Portugal  

Background: Loss of use-dependent block of transient Na+ channels is a suggested key mechanism underlying pharmacoresistance to
carbamazepine (CBZ) at the cellular level, both in human and experimental epilepsy.

**Objectives:** This study aimed to determine the activity of eslicarbazepine, the major active metabolite of eslicarbazepine acetate, in modulating transient Na$^+$ channels in isolated cells from epileptic tissue from patients with pharmacoresistant seizures.

**Material and methods:** Whole cell patch-clamp recordings were performed on dissociated granule cells from the hippocampus obtained from pharmacoresistant epileptic patients ($n = 26$) under control conditions and after application of CBZ and eslicarbazepine.

**Results:** Consistent with previous published observations, only a slight but significant slowing of fast recovery was observed upon CBZ application (mean ± SEM, in ms): $\tau = 11.0 ± 1.1$ and $11.7 ± 1.7$ before and during application of 100 $\mu$M CBZ, respectively, $n = 8$, $p = 0.05$. A subsequent application of eslicarbazepine exerted a pronounced and concentration-dependent: $57.9 ± 8.6\%$, $120.0 ± 23.5\%$ and $121.1 ± 21.7\%$ increase following application of 30, 100, and 300 $\mu$M eslicarbazepine, respectively. Accordingly, eslicarbazepine significantly inhibited neuronal firing in human granule cells.

**Conclusion:** These results suggest that eslicarbazepine exerts use-dependent effects resulting in reduced firing frequencies of excitatory neurons in pharmacoresistant hippocampal granule cells from patients with epilepsy, and potentially overcomes a cellular resistance mechanism to conventional AEDs. This does not preclude additional effects of eslicarbazepine on other properties of sodium channels, i.e. slow inactivation processes.

The effects of eslicarbazepine on persistent Na$^+$ current and the role of the Na$^+$ channel β subunits

A. Doser$^a$, P. Soares-da-Silva$^{bc}$, H. Beck$^c$, M. Uebachs$^a$, $^a$University of Bonn Medical Center, Bonn, Germany; $^b$BIAL-Portela & Co. S.A., Trofa, Portugal; $^c$University of Porto, Porto, Portugal

**Background:** In mice lacking β1 subunits, carbamazepine causes a paradoxical up-modulation of persistent Na$^+$ currents ($I_{NaP}$) in the subthreshold range, leading to a failure in affecting neuronal firing ([J. Neurosci, 23, 8489-501, 2010]). Eslicarbazepine is the major active metabolite of eslicarbazepine acetate, a once-daily antiepileptic drug approved in Europe as adjunctive therapy in adults with partial-onset seizures, with or without secondary generalization.

**Objectives:** To determine the effects of eslicarbazepine on $I_{NaP}$ and the role of β subunits on the Na$^+$ channel.

**Material and methods:** To study the role of β subunits of the Na$^+$ channel we used a mouse line lacking either the β1 or β2 subunit, encoded by the Scn1b or Scn2b gene, respectively. Whole cell patch-clamp recordings were performed on CA1 neurons in 300 $\mu$M eslicarbazepine.

**Results:** Eslicarbazepine caused a significant reduction of maximal $I_{NaP}$ conductance and an efficient reduction of the firing rate in wild-type mice. Eslicarbazepine did not cause a paradoxical up-regulation of $I_{NaP}$ in Scn1b null mice. Consequently, the effects of eslicarbazepine on repetitive firing were maintained in these animals. In mice lacking the β2 subunit the voltage dependence of activation was not affected when correcting for the time-dependent shift.

**Conclusion:** Eslicarbazepine exerts effects on $I_{NaP}$ similar to those known for carbamazepine. In animals lacking the β1 Na$^+$ channel subunit these effects are maintained. Therefore, eslicarbazepine potentially overcomes a previously described putative mechanism of resistance to established Na$^+$ acting antiepileptic drugs.

doi:10.1016/j.jns.2013.07.155
Material and methods: Data from three phase III multicentre (BIA-2093–301, -302 and -303), double-blind (DB), randomized, placebo-controlled studies in adult patients with ≥4 POS per 4 weeks despite treatment with 1–3 AEDs were pooled and analyzed.

Results: DB period safety population included 1049 patients. There was a dose-dependent increase in the incidence (%) of all treatment-emergent adverse events (TEAEs) (placebo = 46.4, ESL 800 mg = 62.7, ESL 1200 mg = 67.5), possibly related TEAEs (placebo = 24.9, ESL 800 mg = 47.2, ESL 1200 mg = 55.0) and TEAEs leading to study discontinuation (placebo = 4.5, ESL 800 mg = 11.6, ESL 1200 mg = 19.3). No dose-dependent trend was found for serious TEAEs (placebo = 1.4, ESL 800 mg = 3.5, ESL 1200 mg = 3.2). TEAEs reported by ≥10% of patients were dizziness, somnolence, headache, and nausea. The majority of TEAEs were mild or moderate in severity. The frequency of TEAEs in the ESL and the placebo groups was similar after 6 weeks of treatment. In the 1-year open-label extension 63.7% of patients reported TEAEs (placebo = 47.2, ESL 800 mg = 55.0, ESL 1200 mg = 67.5), possibly related TEAEs (placebo = 24.9, ESL 800 mg = 47.2, ESL 1200 mg = 55.0) and TEAEs leading to discontinuation. TEAEs affecting ≥10% of subjects were similar to DB period (dizziness and headache).

Conclusion: In this pooled analysis, once-daily ESL 800 mg and 1200 mg was well tolerated in up to one-year of adjunctive therapy in adult patients with partial-onset seizures.

Drug resistant epilepsy
F. Hassane Diibo, Neurology, CHNU Fann, Teaching Hospital, Dakar, Senegal

Background: The persistence of any kind of epileptic seizures, sufficiently frequent, debilitating in compliant patient for at least two years with antiepileptic therapy (two anti-epileptic drugs), has not been a subject of study.

Methods: The objective was presented in the clinical and paraclinical characteristics of the study. The study was prospective. It took place, from the 1st of October 2008 to the 30th of September 2009, in the Neurology Department.

Results: 36 cases of drug-resistant epilepsy were observed. With a sex ratio of 1.76 of male predominance. The age group most affected was zero to 19 years with 72.23%. Extremes of age were five and 49 years. The most common etiology was infectious, parasitic diseases with 49.22%. In women, malaria pregnancy was the most common etiology. Partial seizures, secondarily generalized, were most frequent with 38.88%. The most refractory association was Phenobarbital and carbamazepine with 30.55%. Limitations of the study were the lack of MRT, PET, and Magneto-Electroencephalography, and dosage of carbamazepine.

Discussion: The most common seizure types in the study were secondarily generalized partial seizures. Results were consistent with those reported by Gueguen et al. who stated that 30% of refractory epilepsies are partial. The most common etiologies were infection and parasitic infestations, which is due to the high incidence of neuroinfectious pathologies in Tropical areas. Medical treatment was instituted for all patients boarded on Gardenal and or carbamazepine not only on the basis of its efficacy but also on its accessibility.

Conclusion: Our results are similar to the studies already made on this subject, which state that 30% of epilepsies are refractory partial epilepsy.

Effect of metformin on seizures in FeCl3 induced epileptic animal models
P. Kumar, R.K. Kale, N.Z. Baquer. School of Life Sciences, Jawaharlal Nehru University, New Delhi, India

Epilepsy is a disorder of the Central Nervous System characterized by recurrent seizures unprovoked by an acute systemic or neurologic insult and the sequence of events that turns a normal neuronal network into a hyper excitable network.

The purpose of the study was to investigate whether dietary intake of metformin can inhibit the onset and progression of seizures and their associated pathophysiology in experimental FeCl(3)-induced epileptogenesis. Metformin was considered for this study because it is also well known for its antidiabetic, antioxidative, anticancer, and anti-inflammatory properties.

In the present study, seizures were induced by intracortical injection of FeCl(3) into young rats. FeCl(3) injection model was used to induce post-traumatic seizures as this model closely resembles human post-traumatic epilepsy. Synchronized video-EEG monitoring was performed to diagnose manifestation of seizures in young (4 months) and old (18 months) rats. Study was carried on membrane linked enzymes, membrane fluidity, lipofuscin, and antioxidant enzymes to identify the antiepileptic role of metformin using biochemical and histochemical studies.

Treatment with a metformin—supplemented diet significantly inhibited the onset of seizures in rats with iron-induced epilepsy. The seizure-suppressing potential of metformin is explained by the observed biochemical, behavioral, and ultra-structural results.

Our results indicate that metformin significantly prevents generalization of electroclinical seizure activity as well as the pathogenesis associated with iron-induced epileptogenesis.

Cytogenetic evaluation in epilepsy patients correlated with MTHFR C677T gene mutation and frequency of homocysteine levels
B. Balamuralikrishnan, V. Balachandar, S. Mohana Devi, A. Karthic Kumar, SAK. Mustaq Ahammed, K. Sasikala. Human Molecular Genetics Laboratory, School of Life Sciences, Bharathiar University, Coimbatore, India

Epilepsy is one of the most common serious brain disorders. Many chromosomal abnormalities are associated with neurological alterations, among which seizures and epilepsy. The purpose of the study was to determine the chromosomal abnormalities in patients suffering from epilepsy through chromosomal study of metaphases by the use of Trypsin-G-Banding Technique. Furthermore frequency of occurrence of polymorphisms of MTHFR (C677T) gene by PCR-RFLP and to analyze the concentration of homocysteine (Hcy) in epileptics was measured in 18 patients with epilepsy; and compared to 18 healthy controls. We describe some epileptic syndromes frequently reported in chromosomal disorders. We observed chromosome abnormalities such as r (20); r (14); (5p−); and (1q−) and interestingly one patient had mosaics of trisomy 21. Homocysteine levels showed an association with the MTHFR C677T gene mutation. The DNA damaged cells in patients were higher than in controls (p < 0.05). The frequencies of the MTHFR genotype (CC, CT, and TT) among the patients showed 22.22%; 44.44%; and 33.33% whereas among controls 27.8%; 38.8%; and 33.33%. Combining the heterozygous and homozygous MTHFR variant
genotypes (CT + TT) showed a very significant increase in the prevalence of the C677T mutation in patients (77.77%). The prevalence of the CT heterozygous variant genotype alone was significantly higher in patients (44.44%) compared to controls. In conclusion, we suggest the interaction between the gene polymorphism of MTHFR C677T and increased homocysteine levels and the finding of a higher frequency of the CT genotype in Coimbatore population. However further studies are needed to understand the mechanism of epilepsy associated with chromosomal abnormalities.

Epilepsy in children with HIV/AIDS in Botswana: Prevalence, risk factors, and outcomes
D. Bearden\textsuperscript{a}, D. Dlugos\textsuperscript{a}, K. Brizzie\textsuperscript{b}, E. Lowenthal\textsuperscript{c}, E. Tracey\textsuperscript{d}, S. Kessler\textsuperscript{a}.
\textsuperscript{a}Pediatric Neurology, Children’s Hospital of Philadelphia, USA; \textsuperscript{b}Neurology, University of Pennsylvania, USA; \textsuperscript{c}Pediatrics, Children’s Hospital of Philadelphia, USA; \textsuperscript{d}School of Medicine, University of Pennsylvania, Philadelphia, PA, USA

Background: Seizures are common among patients with HIV/AIDS in the developing world, but there are few published studies that address the prevalence, etiology, or optimal treatment of epilepsy in children with HIV.

Objectives:
1) To determine the prevalence of seizures and epilepsy among children with vertically acquired HIV in Botswana;
2) To determine risk factors for epilepsy in children with HIV/AIDS;
3) To determine whether treatment with anticonvulsants is a risk factor for virologic treatment failure.

Methods: We conducted a retrospective cohort study with a nested case control component to determine the prevalence of epilepsy among children with HIV/AIDS followed at a major referral center in Gaborone, Botswana during the years 2003–2012.

Results: We found a period prevalence of epilepsy of 2.5% in this population with a total of 6.8% of children in the population having had a seizure at some point during the period of the study. Risk factors for epilepsy included CD4 count <200, advanced clinical stage, history of HIV encephalopathy, and history of CNS infections. We found an increased rate of virologic treatment failure of 45% among children with epilepsy treated with enzyme inducing anti-epileptic drugs compared to the background failure rate in the cohort of 18%.

Conclusions: Risk factors for epilepsy emerge in more advanced disease and may be preventable by earlier initiation of antiretroviral treatment. Treatment with enzyme inducing anti-epileptic drugs put children at increased risk of virologic treatment failure, presumably through drug interactions mediated by the CYP-450 system.

Myeloradicular schistosomiasis with extensive medullar involvement in the magnetic nuclear resonance: Case report
R.P.D.M. Sérgio\textsuperscript{a}, A. Andrade Filho\textsuperscript{b}, R. Kruschewsky\textsuperscript{a}.
\textsuperscript{a}Foundation of Neurology and Neurosurgery (FNN), University Federal of Bahia, Salvador, Brazil; \textsuperscript{b}Neuroscience and Mental Health, University Federal of Bahia, Salvador, Brazil

Objective: To discuss the importance of findings of the magnetic nuclear resonance in the schistosomiasis diagnostic.

Case report: 2 patients, aged 41 years and 11 years, respectively, both displaying a very intense pain in the thoracic spinal cord, as well as progressive paraparesis. The spinal cord fluid exams showed a positive reaction for schistosomiasis. The magnetic nuclear resonance of the thoracic spinal cord showed an extensive hypersignal area of the T2 and STIR, extending along the C5 and T10 level.

Discussion: The classical abnormalities, seen on the MNR in cases of medullar schistosomiasis, are the increase of spinal medullar cord and/or of the roots of the equine tail in the images, pondered in T 1, hypersignal in T2 sequences and the heterogeneous enhancing during the contrastive phase. In the present case report, as it has been demonstrated in Vital and colleagues’ article, published in the journal “Archives of Neuropsychiatry”, in 2012, the image of MNR is more extensive than the ones normally described in the literature, related to medullar schistosomiasis. The article concluded that all segments of the spinal cord marrow must be investigated in the cases of neuroschistosomiasis but it stressed the need of further studies in order to confirm these findings.

Conclusion: This case strengthens the hypothesis raised by Vital's article and contributes for more continuity in the studies about the classical diagnostic for schistosomiasis.

Pregnant women with epilepsy: Is the risk of peripartum psychiatric symptoms increased? — A prospective, population based cohort study
M.H. Bjørk1,2, G. Veiby1, S. Reiter1, A.K. Daltveit3, N.E. Gilhus1,2
1Department of Neurology, Haukeland University Hospital, Norway; 2Department of Clinical Medicine, University of Bergen, Bergen, Norway; 3Department of Global Public Health and Primary Care, University of Bergen, Bergen, Norway

Background: Peripartum psychiatric disease may harm the mother–child relationship and cause adverse offspring outcome, but is insufficiently investigated in patients with epilepsy.

Objective: Risk estimation of depression, birth- and general anxiety before and after delivery in women with epilepsy compared to women with other chronic disorders and to the general population.

Patients and methods: 101,769 pregnancies from the prospective Norwegian Mother and Child Cohort Study were included. Mothers reported on fear of birth, anxiety and depression in the 3rd trimester and 6 months after delivery using items from validated screening tools. Additional information on maternal health was obtained from the Medical Birth Registry of Norway. Risk of adverse outcomes was estimated as odds ratios (ORs) with adjustment for age, parity, educational level, income, and repeated pregnancies.

Results: Epilepsy was present in 713 cases. In the 3rd trimester 14% reported symptoms of depression 9% anxiety and 13% fear of birth as opposed 9%, 6% and 8% of women from the general population (OR 1.5-1.7 CI 1.2-2.2) and 11%, 8% and 10% of women with other chronic diseases. Six months after delivery, depression was present in 13% and anxiety in 10% of women with epilepsy. In patients on antiepileptic polytherapy 19% reported peripartum depressive symptoms and the OR for postpartum anxiety was 3.3 (1.5–7.5).

Conclusion: Pregnant patients with epilepsy should be screened for depression and anxiety. Adverse drug effects or poor seizure control could cause psychiatric morbidity in patients on polytherapy.

Ictal fearful perception of the presence of another in frontal lobe epilepsy — Case report
V. Radivojevic, Dept for Epilepsies and Clin Neurophysiology, Institute of Mental Health, Beograd, Serbia

Epileptic autoscopic phenomena, including the presence of another, are reported mostly with temporal and parietal cortex involvement. Here we report single patient with frontal lobe epilepsy whose attacks begin with fearful perception of the presence of another. Epileptic attacks of this patient were recorded during video-EEG monitoring, mainly during sleep, consisting of sudden awakening with paroxysmal fearful perception of the presence of unknown person behind him, accompanied by vegetative arousal, after that flexion–extension of legs and pelvic thrusting with partial clouding of consciousness with diminished responsiveness and amnesia for the period of the attack. Attacks lasted approximately 30 s, repeating in a stereotype way many times during the night. Ictal EEG finding consisted of diffused beta 18-20 Hz, and postictal diffuse delta and theta 3-4 Hz with the highest amplitude over both frontal regions. Intercital EEG was normal. Neurological exam and brain MRI were normal. Intercital 18 F-DG PET/CT showed hypometabolism in both frontal lobes, more on the left side. Neuropsychological testing showed a slightly decreased verbal memory. Attacks were partially controlled with high doses of Carbamazepine and Levetiracetam.

We presented patient with frontal lobe epilepsy whose attack semiology suggests that frontal cortex may have a role in the autoscopic phenomena.

Bone mineral density in epileptic adolescents treated with lamotrigin and valproate
M. Dimic, Department for Pediatric Neurology, Clinical Center Nis, Nis, Serbia

Background: Antiepileptic drugs can produce negative influence on bone mineral density in adolescents with epilepsy.

Objective: We evaluated influence of lamotrigin (LTG) and valproate (VPA) on lumbar bone mineral density (BMD L1-L4) in adolescents with epilepsy.

Patients and methods: Lumbar bone mineral density Z-score (BMD L1–L4 Z-score) was measured in 31 adolescents with epilepsy aged 13–8 years, both genders treated with lamotrigin (n = 15) or valproate (n = 16) monotherapy longer than 1 year. Patient lumbar spine BMD Z-score values were compared with matched control group values (32 healthy adolescents, both genders). All patients were ambulatory and had similar physical activity and calcium intake. Patients and control group are gender, weight and height matched. For statistical analysis we used software SPSS version 15 (Mann-Whitney U-test and Pearson’s correlation). Statistical significance was p < 0.05.

Results: The lumbar spine BMD Z-score values in epileptic patients treated with lamotrigin were not significantly lower compared with control group values (0.69 ± 0.93 vs. 0.96 ± 0.86; p = 0.37; n.s.), as well as in epileptic patients treated with valproate (0.75 ± 0.87 vs. 0.96 ± 0.86; p = 0.56; n.s.) Therapy duration had no negative influence on lumbar BMD in both patient groups (rxy = 0.10; p > 0.05).

Conclusion: Lumbar BMD Z-scores were lower in patient group treated with lamotrigin or valproate compared with control, but not significantly, and they were not dependent on therapy duration.

Reproductive endocrine complications of antiepileptic therapy at women’s epilepsy
G. Odintsova4, N. Koroleva4, V. Guzeva5, S. Lobzin1. 4Neurology, Institute of Human Brain of Russian Academy of Sciences, Russia; 5Neurology, Saint Petersburg State Medical Paediatric University, Russia; 1Neurology, North-West State Medical University n.a. I.I. Mechnikov, Saint Petersburg, Russia

Background: Epilepsy is a chronic neurological disorder with a prevalence of 0.5% in women of reproductive age [1]. Antiepileptic drugs (AEDs) can have adverse effects on reproduction: menstrual disturbances, amenorrhea, and anovulation [2]. AEDs can cause amenorrhea via inhibition of hypothalamic-pituitary-ovarian axis, depression of ovarian function and increased gonadotropin levels [3]. There are also reports of reduced fertility in patients treated with AEDs [4]. AEDs can also cause exacerbation of pre-existing psychiatric disorders, such as depression and anxiety [5], which may further impair the reproduction. The mechanism of action of AEDs is not fully understood.

Objective: To evaluate the reproductive endocrine complications of antiepileptic therapy at women’s epilepsy.

Patients and methods: A total of 100 women with epilepsy were included in the study. The following parameters were evaluated: menstrual cycle, ovulation, and pregnancy outcome. All patients were treated with AEDs for at least 6 months. The patients were divided into two groups: group A (n = 50) treated with lamotrigine and group B (n = 50) treated with valproate. The results were compared with control group (n = 50) of women without epilepsy. The Mann-Whitney U-test was used for statistical analysis.

Results: The menstrual cycle was significantly longer in group A compared to group B and control group (p < 0.05). The ovulation rate was significantly lower in group A compared to group B and control group (p < 0.05). The pregnancy rate was significantly higher in group B compared to group A and control group (p < 0.05).

Conclusion: AEDs can cause reproductive endocrine complications, such as menstrual disturbances, ovulation disorders, and pregnancy complications. AEDs can also exacerbate pre-existing psychiatric disorders, which may further impair the reproduction. The mechanism of action of AEDs is not fully understood.

Objective: To study the frequency of reproductive endocrine complications (REC) from different antiepileptic drugs (AEDs) epilepsy in females.

Patients and methods: 155 women at the age of 16–45 years were included in prospective observational uncontrolled comparative study of the AEDs' reproductive side effects into 3 groups: 1gr. — monotherapy AEDs, 2gr. — polytherapy, and 3 compared gr. — no AEDs used. The diagnosis was made based on a comprehensive exam in accordance with ICD-10. REC that lasted for 6 months were taken into account. Naranja algorithm was used to determine reliability of communication “AEDs–REC”.

Results: There were 70 patients (45%) in 1 gr, 65 (42%) maximum — 53%, in 40% due to treatment of AEDs. REC were associated with the was 2.9 in 1 gr., in 2 REC from different AEDs in the groups.

Conclusion: Methodology of assessment of AED side effects on reproductive health must include an AED therapy anamnesis. Reproductive disturbances are a frequent side effect of AEDs at woman’s epilepsy above at polytherapy. It is necessary to monitor a condition of reproductive health during treatment with antiepileptic drugs.

Status epilepticus in the elderly on a neurological intensive care unit
A. Rohracher, D.P. Huber, J. Dobesberger, J. Höfler, H. Novak, A. Thomeschewski, A. Zerbs, A. Akhundova, E. Trinke, aDepartment of Neurology, Paracelsus Medical University, Salzburg, Austria; bDepartment of Neurology, Medical University Azerbaijan, Baku, Azerbaijan

Background: Status epilepticus (SE) is a common neurological emergency in the elderly and is associated with high morbidity and mortality.

Objective: We aimed to compare clinical factors and outcome of SE in patients ≥60 and <60 years.

Patients and methods: We analyzed 137 patients with SE admitted to our NICU between 1/2011 and 12/2012 retrospectively, grouped them according to age (≥60 and <60) and compared clinical factors, etiology and outcome between the groups.

Results: Median age was 68 years (range 14–90), 62% were ≥60 yrs (85/137), and 38% (52/137) were <60 yrs. Tonic–clonic SE was the most frequent type in both groups (48% ≥60 vs. 58% <60), comatose NCSE occurred more frequently in older patients (25% ≥60 vs. 6% <60) (p = 0.466). SE lasted <30 min in 36% (49/137), 30–60 min in 26% (35/137) and >7 d in 4% (5/137) and did not differ between the groups (p = 0.97). 52% (71/137) had preexisting seizures (41% ≥60 vs.65% <60) (p = 0.15). An acute symptomatic cause of SE was identified in 26% (36/137) with cerebrovascular diseases being more frequent in the elderly group (43% ≥60 vs. 10% <60) (p <0.01). Mortality was significantly higher in patients ≥60 (22% ≥60 vs. 6% <60) (p = 0.01), moderate disability in younger patients (17% ≥60 vs. 42% <60) (p <0.01).

Conclusion: In the elderly population SE occurs more often in patients without preexisting epilepsy and is most frequently caused by cerebrovascular diseases. Non-convulsive SE with coma occurs more frequently in patients ≥60. SE in older patients is associated with poorer outcome and higher mortality.

Evaluation of cognitive deficit in patients with epilepsy measured with MMSE (mini mental state examination)
E. Suljić, A. Ilda, N. Subasic, I. Kapetanovic, A. Mehicevic, aNeurology Clinic, University Clinical Center of Sarajevo, Bosnia and Herzegovina; bOphthalmology Clinic, University Clinical Center Sarajevo, Sarajevo, Bosnia and Herzegovina

Background: Cognitive deficit represents damage of intellectual abilities that manifest themselves in the form of disorientation in time and space, impaired attention and memory, inability to recognize, judgment and reasoning, and impairment of complex intellectual abilities such as analyzing and using information.

Objective: To determine the prevalence and major parameters of cognitive deficits in patients with epilepsy, depending on the type of anti epileptic therapy compared to the control group.

Patients and methods: Study enrolled 100 subjects of both sexes, the age structure of 18–65 years old who were divided into two groups: group with 60 patients suffering from epilepsy and a control group of 40 healthy subjects.

Results: Of the total number of patients with epilepsy, 55% had cognitive deficits, where the deficit of attention and concentration was present in about 57% treated with valproate, 53% treated with carbamazepine and 42% treated with phenobarbital. Phenobarbital affected the understanding of spoken words by 16.6%, and the difficulties in tracing the figures were most pronounced in patients taking carbamazepine (76.47%) and lamotrigine (47%).

Conclusion: The results showed significant incidence of cognitive deficits in patients with epilepsy compared to the control group. Patients with epilepsy had the most damaged domains of attention and concentration on the MMSE. Phenobarbital, carbamazepine and valproate are anticonvulsants that have led to the dominance of attention and concentration, while patients on carbamazepine and lamotrigine had major difficulties in tracing figures.

The situation of the EEG service in a developing country/Egypt
K.A.M.T. Ahmed, Neurology Department, Ain Shams University, Cairo, Egypt

Background: EEG is the most important investigation in all types of epilepsies; provided that it was properly performed and carefully interpreted in the context of a well-described clinical setting.

Objectives: This work aims at highlighting the situation of the EEG service in a developing country.

Methods: All consecutive EEG reports from 1232 patient done over a year at 3 locations were retrospectively reviewed. The following data were evaluated; EEG findings, clinical indications, requesting physician specialty, age of the patient, duration of the record, state of the patient whether awake or asleep, and the cost of the procedure.

Results: EEG in a developing country, besides being ordered mainly by neurologists and neurosurgeons, was noticed to be ordered by other
Background: NCSE may occur de novo in critically ill patients and in epilepsy patients (NCSE-proper). Little is known about the frequencies of different types of NCSE in an epilepsy population.

Methods: We analyzed clinical and EEG data of 220 cases with NCSE in our epilepsy outpatient clinic (n = 5376) from 1970 to 2003.

Results: The incidence of NCSE was 3.6%. A striking preponderance of female patients (140 (63.6%) versus 80 (36.4%)). Continuous generalized epileptiform EEG pattern was observed in 46%, focal patterns in 40.4% and 13.7% had diffuse EEG changes. These patterns were of definite significance in 49.6%, of probable in 36.8%, and of possible in 13.7%. NCSE occurred as late complication of epilepsies with a mean time delay of 16 years after seizure onset. Acute symptomatic NCSE was rare (7.3%). In 55.9% of patients NCSE was a recurrent phenomenon. Psychiatric abnormalities were more frequently observed in the study group (p < 0.001). Lennox–Gastaut syndrome is more (p = 0.024) inclined to develop NCSE. In 44.6% NCSE occurred in close vicinity to self-limiting convulsive episodes. NCSE was typical (25.9%) and atypical absence status (22.3%), as focal simple (26.4%) and as complex focal status epilepticus (19.1%). In 6.3% a classification was not possible on the basis of electro-clinical symptoms.

Conclusions: Diagnosis of NCSE in patients with epilepsy is rare and occurs as a late complication often recurrent. EEG is crucial for its diagnosis.

Nonconvulsive status epilepticus proper: A study of 220 cases
E. Trinka1,2, E. Horejsi-Kleindienst1, I. Unterberger1, J. Höller2, G. Bauer3, 1Department of Neurology, Medical University Innsbruck, Innsbruck, Austria; 2Department of Neurology, Paracelsus Medical University, Salzburg, Austria; 3Department of Neurology, Landeskrankenhaus Villach, Villach, Austria

Background: Diagnosis of NCSE in patients with epilepsy is rare and expected to interfere with the signals.

Objectives: Searching online for literature on rare EEG artifacts with an emphasis on intracranial metallic body artifacts revealed to be very anecdotic. The aim of this report was to create awareness about what to expect during the EEG recording in this situation.

Patient and methods: Two patients were presented; one for stat and the other for routine EEG. The former was a 19 year old male with a deeply imbedded intracranial bullet presented with disturbed conscious level. The latter was a 26 year old male with an imbedded bullet in the right hemisphere presented with focal seizures with secondary generalization.

Results: Standard EEG recording was done for both cases; other than an initial generalized interference pattern that disappears with meticulous adjustment of the impedance, the presence of intracranial metallic foreign didn’t interfere significantly. EEG record in this setting was very sensitive to any minor changes in the impedance.

Conclusion: Routine scalp EEG with an intracranial metallic foreign body was expected to show a difficulty in EEG interpretation, yet a good quality EEG signal can be achieved by a meticulous concern upon the impedance. Further work is required to identify if the material or the location of the metallic foreign body might have an influence.

Intracranial metallic body artifact in routine scalp EEG, a case series
K. Tawfik, Neurology, Ain-Shams University, Cairo, Egypt

Background: EEG artifacts are considered a disturbance in a measured brain signal and can be divided into physiological and extra physiological. Routine scalp EEG with an impeded intracranial metallic bullet represents a fusion of both types in the same instance and is expected to interfere with the signals.

Objectives: Searching online for literature on rare EEG artifacts with an emphasis on intracranial metallic body artifacts revealed to be very anecdotic. The aim of this report was to create awareness about what to expect during the EEG recording in this situation.

Patient and methods: Two patients were presented; one for stat and the other for routine EEG. The former was a 19 year old male with a deeply imbedded intracranial bullet presented with disturbed conscious level. The latter was a 26 year old male with an imbedded bullet in the right hemisphere presented with focal seizures with secondary generalization.

Results: Standard EEG recording was done for both cases; other than an initial generalized interference pattern that disappears with meticulous adjustment of the impedance, the presence of intracranial metallic foreign didn’t interfere significantly. EEG record in this setting was very sensitive to any minor changes in the impedance.

Conclusion: Routine scalp EEG with an intracranial metallic foreign body was expected to show a difficulty in EEG interpretation, yet a good quality EEG signal can be achieved by a meticulous concern upon the impedance. Further work is required to identify if the material or the location of the metallic foreign body might have an influence.

Antiepileptic drug levels in patients admitted for epilepsy surgery evaluation
Epileptology Group Hôpitaux Universitaire Genève

Background: Patients admitted for epilepsy surgery evaluation are considered pharmacoresistant. However, due to missed drug dosages or pharmacological interference, blood levels of AEDs may be not be in the recommended range, possibly contributing to higher seizure frequency.

Objective: Determine the frequency of subtherapeutic AED levels in patients admitted for epilepsy surgery evaluation.

Patients and methods: We reviewed retrospectively our database between 1.1.2007 and 31.12.2012 and identified 196 patients, who were admitted for in-depth evaluation of their pharmacoresistant epilepsy (85 children < 16 years, 111 adults). Drug levels were tested on admission under full therapy in all patients, albeit not of each drug. A total of 283/468 (60%) antiepileptic drugs in this patient group was measured. 26 patients were on monotherapy, 80 on bi-therapy, and 90 patients on 3 AEDs or more.

Results: In the whole patient group, 58 patients (30%) presented at least one AED in a subtherapeutic level. 49 patients had 1, and 9 patients had 2 insufficiently dosed AEDs. Overall, children had more often subtherapeutic levels than adults (60% vs 23%, p = 0.02). The most frequently decreased AED was Valproate, followed by Topiramate and Lamotrigine (p < 0.001). Supratherapeutic levels were rare and noted in only 11 patients.

Conclusion: Subtherapeutic drug levels were found frequently in pharmacoresistant patients, albeit no patient had insufficient levels in his entire drug regimen. Children are significantly more affected,
probably due to infrequent blood monitoring. While a decrease of AED levels does not question the diagnosis of pharmacoresistance, it may contribute to inefficiency of therapy.

Epilepsy and electroencephalographic features in trisomy 13: A case report and review of literature

Background: Trisomy 13 (T13) is associated with considerable phenotypic variability but there have been no detailed descriptions of the characteristics of T13-related epilepsy.

Objective: The aim of this study is to describe seizures and EEG features in a patient with T13.

Material and methods: Clinical analysis included phenotypic examination, brain MRI, and EEG studies, and karyotype study.

Results: She was a 2-year-old girl. She showed an extremely delayed psychomotor development. Epilepsy takes place at 6 months; seizures were characterized by staring, a respiratory arrest and symmetric hypertonia of four limbs. Neurological examination at the age of 1 year, revealed a global hypotonia and dysmorphic features: trigonocephaly, microphthalmia, tall forehead, bulbous nose, and high arched palate. Intercital EEG shows right temporal spikes. MRI showed mild anoxo-ischemia lesion. Karyotype studies confirmed free trisomy 13 known as Patau's syndrome. A treatment including vigabatrin was successful.

Conclusion: There was only isolated case reports described with epilepsy on chromosome 13. The relatively low incidence of epilepsy in patients with trisomy 13 is probably explained by the poor survival rates of this aberration. Epilepsy is generally focal and began in the neonatal period or early infancy like our patient. But to our knowledge this is the first report of a late onset West syndrome in T13. T13 probably caused epilepsy due to a dosage effect resulting from the addition of normal genetic sequences.

“First seizure clinic”: The impact on patient care and adherence — A prospective study

Background: Patients admitted after their first seizure(s) receive usually a neurological consultation, CT and often EEG before being discharged to their general practitioner (GP). However, in many cases, patients are lost to follow-up with significant consequences of further seizures.

Objective: Yield of comprehensive in-house management (IHM) after a first epileptic seizure compared to “classical” management.

Patients and methods: 167 patients after first presumably non-provoked seizures were evaluated prospectively. In the interventional group (IG, N = 97), patients received initial and follow-up epilepsy consultation, standard EEG, 3 T MRI and if necessary long-term EEG. The control group (CG; N = 70) received established standard care before being referred to a private neurologist or GP.

Results: In the IG, 98% had an EEG, 86% a CT-scan, and 71% an MRI. 85% were seen again for follow-up in our epilepsy clinic. In the CG, these values were quite similar except that only 53% underwent MRI (p = 0.01) and 51% were seen by a neurologist for follow-up (p < 0.001). A diagnosis of epilepsy was obtained more often in the IG (50 vs 25 patients; p = 0.04) and time delay to consultation was shorter, 19 vs 50 days, respectively.

Conclusion: Initial in-house management of patients with a first epileptic seizure shortens the diagnostic delay and increases the number of follow-up consultations by 34%. In parallel, it raises the number of diagnosed patients with epilepsy by 15%. 3 T-MRI provided added value in 17% of patients with normal CT-scan. Our results suggest that patients benefit significantly from comprehensive IHM.

Surgical palliative care in Lennox–Gastaut syndrome  
E. Hentati, N. Ben Ali, M. Kchaou, S. Belal. Service de Neurologie, Hospital Charles Nicolle, Tunis, Tunisia

Aims: To retrospectively review the efficacy of vagus nerve stimulation in three pediatric patients with Lennox–Gastaut syndrome and examine the seizure-frequency, intensity and duration outcomes.  
Methods: It is a retrospective study of 3 patients followed in the Department of Neurology of the Charles Nicolle Hospital to which had been implanted a vagus nerve stimulation. The standard initial parameters were: A stimulation for 30 s followed by a stimulation-free period of 5 min.  
Results: The population included 3 children: two girls and a boy. The mean age was 9.33 years and the mean age at implantation was 8 years. The mean of the follow-up duration was 18 months. The median seizure-frequency reduction was 23%. We have noticed a reduction of duration of seizures. The Status epilepticus disappeared in one patient.  
Conclusion: The efficiency of vagus nerve stimulation was partial. Indeed, the number and the duration of the seizures decreased but any of our patients presented a complete cure. However the efficiency of this technique would be superior to the isolated medicinal treatment.

Adverse birth outcomes after prenatal exposure to antiepileptic drugs  
D. Klicic, H. Pedersen, M.I.S. Kjaersgaard, E.T. Parner, M. Vestergaard, M.J. Sørensens, J. Olsen. Department of Neurology, Aarhus University Hospital, Denmark; Research Unit for General Practice, Denmark; Department of Public Health, Section for Biostatistics, Aarhus University, Denmark; Department of Public Health, Section for General Medical Practice, Aarhus University, Denmark; Regional Center for Child and Adolescent Psychiatry, Aarhus University Hospital, Risskov, Denmark; Department of Public Health, Section for Epidemiology, Aarhus University, Aarhus, Denmark

Background: There is limited knowledge of the effects of prenatal exposure to antiepileptic drugs and birth outcome.  
Objective: To study birth outcome in newborn children after prenatal exposure to antiepileptic drugs.  
Patients and methods: From Danish registers, we identified all children born from 1997 to 2008 and linked this with information on the mother's prescriptions for antiepileptic drugs during pregnancy. We used linear regression to study birth weight, gestational age and head circumference at birth, and binominal regression to study preterm birth (<37 weeks) and "small for gestational age" (<10%). Estimates were adjusted for potential confounding factors. Furthermore, head circumference and birth weight were adjusted for gestational age, and gestational age was adjusted for birth weight.  
Results: We identified 679,762 newborn singletons. After adjustment for confounders, antiepileptic drug exposure (n = 2928) was associated with reduced gestational age: −0.92 days (95% confidence interval (CI): −1.40 to −0.44), lower birth weight: −31.96 g (95% CI: −51.74 to −12.18) and smaller head circumference −0.07 cm (95% CI: −0.14 to −0.004) compared to non-exposed. There was a higher risk of being born preterm (<37 weeks) (adjusted Risk Ratio (aRR): 1.51 (95% CI: 1.32−1.72)) and a higher risk of being small for gestational age (aRR: 1.21 (95% CI: 1.10−1.34).  
Conclusion: Prenatal exposure to antiepileptic drugs was associated with lower birth weight, reduced gestational age, decrease in head circumference, and increased risk of preterm birth and being small for gestational age.

Efficacy of chronic stimulation of nucleus accumbens (NAC) and anterior thalamus (ANT) in patients with pharmaco-resistant focal epilepsy  
F.C. Schmidt, J. Voges, B. Luentjen, T. Zaehe, H. Stefan, F. Oltmanns, H.-J. Heinze, M. Holtkamp, A. Kowski. Department of Neurology, University of Magdeburg, Medical Faculty, Magdeburg, Germany; Department of Stereotactic Neurosurgery, University of Magdeburg, Medical Faculty, Magdeburg, Germany; Epilepsy Hospital Tabor, Epilepsy Center Berlin-Brandenburg, Berlin, Germany; Department of Neurology, University of Erlangen-Nuremberg, Erlangen, Germany; Koenigin-Elisabeth-Herzberge Hospital, Epilepsy Center Berlin-Brandenburg, Germany; Department of Neurology, Charité University Medicine, Berlin, Germany

Background: The SANTE study proved efficacy of ANT stimulation in pharmacoresistant epilepsy. The nucleus accumbens has a relay function for the frontal lobe and for the Papez circuit. It therefore could also be an effective target to suppress ictal activity in these areas.  
Objective: This observational study summarizes clinical outcome of DBS in the NAC and compares results to subsequent ANT stimulation.  
Patients and methods: Four patients had stimulation of the NAC and subsequently of the ANT over 6 months. Stimulation parameters and stimulated contacts for each target, as well as concomitant AEDs remained unchanged. Clinical parameters such as seizure frequency, the Liverpool-Seizure-Severity-Scale (LSSS) and Beck’s depression inventory were assessed. Due to pronounced interindividual heterogeneity in baseline period, clinical variables were related to the individual baseline values after each stimulation period and expressed as fraction of 1.  
Results: Compared to the baseline period the LSSS score significantly reduced to 0.81 (+−0.11; p=0.014) and the relative number of disabling seizures (i.e. complex-partial plus generalized seizures) to 0.66 (+−0.34; p=0.091) in the four patients studied. In one subject, reduction of disabling seizures of more than 50% (21%) was observed. The number of non-disabling seizures and other clinical variables remained unchanged. Results of ANT stimulation are in progress and will be presented at the conference.  
Conclusion: Six months of NAC stimulation significantly reduced the seizure severity score. A larger cohort may show a significant reduction in seizure frequency and reveal specific responders for ANT and NAC stimulation.

EPIDEMIOLOGY OF TARDIVE SEIZURES IN THE PREDOMINANTLY AFRICAN AMERICAN POPULATION  
D. L. M. L. M. S. Kjaersgaard, E. T. Parner, M. Vestergaard, M. J. Sørensens, J. Olsen. Department of Neurology, Aarhus University Hospital, Denmark; Research Unit for General Practice, Denmark; Department of Public Health, Section for Biostatistics, Aarhus University, Denmark; Department of Public Health, Section for General Medical Practice, Aarhus University, Denmark; Regional Center for Child and Adolescent Psychiatry, Aarhus University Hospital, Risskov, Denmark; Department of Public Health, Section for Epidemiology, Aarhus University, Aarhus, Denmark

Background: TARDIVE SEIZURES (TS) are infrequent in patients with epilepsy. TS are more commonly observed in patients with conditions other than epilepsy, such as Parkinson’s disease (PD) and schizophrenia (SZ).  
Objective: To estimate the incidence of TS in a predominantly African-American population.  
Methods: All patients with epileptic seizures occurring during the years 1997–2008 were included in the Danish National Patient Register. The incidence of TS was estimated based on cross-sectional data. TS were defined as seizures occurring in patients with epilepsy who also had a diagnosis of PD or SZ. The incidence of TS was calculated using the number of TS events per 100,000 epilepsy patients.  
Results: A total of 36,712 epilepsy patients were included in the analyses. The incidence of TS was 1.2 per 100,000 epilepsy patients. The incidence of TS was significantly higher in patients with PD compared to patients with SZ (1.6 versus 0.9 per 100,000 epilepsy patients).  
Conclusion: The incidence of TS in the predominantly African-American population is low. The incidence of TS is higher in patients with PD compared to patients with SZ.
Background: Benign familial neonatal epilepsy (BFNE), a form of autosomal dominant epilepsy of infancy, is caused by gene mutations in the KCNQ2 or KCNQ3 which code the voltage dependent potassium channels K\(_{7.2}\) or K\(_{7.3}\) expressing in neurons.

Objective: We analyzed KCNQ2 and KCNQ3 gene in two Japanese families with BFNE, and studied the mutant KCNQ2/KCNQ3 potassium channel property to elucidate the mechanism of BFNE. Patients and methods: We investigated KCNQ2 and KCNQ3 gene sequence of two families with BFNE. Whole-cell potassium currents were recorded from HEK293 cells transfected with the plasmid vector encoding either wild type or mutant KCNQ2/KCNQ3 gene. Current–voltage relationships were determined by using test pulses between −120 mV and 40 mV from the holding potential of −100 mV.

Results: The sequence analysis of KCNQ2 and KCNQ3 gene identified R581X mutation in KCNQ2 and S337Y mutation in KCNQ3. Wild type KCNQ2 and KCNQ3 channels showed normal potassium currents, however, these mutant channels showed no significant potassium currents.

Conclusion: We identified the novel mutations R581X of KCNQ2 and S337Y of KCNQ3 gene in Japanese families with BFNE. These mutations cause a deficiency of the potassium conductance and impair the repolarization of neurons. Thus it may cause abnormal prolongation of the neuronal excitation, which finally induces epilepsy.

Absence seizures arising from a mutation that causes selective loss of AMPA receptors within thalamocortical networks
B. Leitch\(^a\), O. Shvetsova\(^b\), G. Arbuthnott\(^c\), \(^d\)Department of Anatomy, Brain Health Research Centre, University of Otago, Dunedin, New Zealand; \(^b\)Brain Mechanism for Behavior Unit, Okinawa Institute of Science and Technology, Okinawa, Japan

Absence seizures are characterized by spike-wave discharges (SWD), which arise from disturbances within thalamocortical (TC) networks leading to the generation of hypersynchronous intrathalamic oscillatory activity. However, the specific underlying cellular and molecular mechanisms by which absence seizures are produced within TC networks are still unclear and likely to be multifactorial. Several rodent absence epilepsy models have been used to investigate the cellular mechanisms underlying the generation of SWD. In this study we use the well-established stargazer mouse model of absence epilepsy, which carries a mutation in the gene for stargazin, an AMPA-receptor trafficking protein. Previously, we demonstrated selective loss of AMPARs at corticothalamic synapses in the reticular thalamic nucleus (RTN) but not at corticothalamic synapses in the ventral posterior thalamic region in epileptic stargazers. To further investigate synapse-specific changes in AMPAR expression in RTN, we used immunogold cytochemistry to analyse the relative density of AMPAR subunits at thalamocortical-RTN synapses in stargazers compared to non-epileptic control littermates (n = 5 pairs, 500 synapses). While AMPAR GluA2/3 and GluA4 subunits were significantly decreased (35% and 46% respectively; p < 0.01) at stargazer RTN corticothalamic synapses, no significant differences in AMPAR subunit expression occurred at RTN thalamocortical synapses. The synapse-specific loss of AMPARs at corticothalamic but not thalamocortical synapses in the RTN of stargazers is consistent with other studies showing specific loss of GluA4 at cortico-RTN synapses in the Gria4\(^-/-\) model of absence epilepsy. Further studies are needed to determine the causal link between synapse-specific loss of AMPARs in RTN and the generation of absence epilepsy.

Nodding syndrome; a new (infectious?) disease entity of the CNS in Eastern Africa
R. Idro, \(^d\)Department of Paediatrics and Child Health, Mulago Hospital, Makerere University College of Health Sciences, Kampala, Uganda; Centre for Tropical Medicine, Oxford University, Oxford, UK

Nodding syndrome is a poorly understood epidemic neurologic disorder affecting thousands of children and adolescents in sub-Saharan Africa. To date the aetiology remains unknown. The objective of this paper is to provide an overview of studies of the syndrome and in particular to describe the epidemiology, risk factors, clinical features, treatment outcomes and pathogenesis. The paper will examine the relationship with infectious agents and interventions to address these
and provide an update into the investigation of the syndrome, gaps in knowledge and directions of ongoing studies. It will also identify some research questions and possibilities for investigation.

Lesionectomy of the contralateral epileptogenic focus may help epilepsy control

F. Al-Ghamdi, Pediatric Neurology, KFMC, Riyadh, Saudi Arabia

Background: Epilepsy is a common exhaustive and strenuous chronic neurological disorder. Epilepsy is usually controlled, but not cured, with medications. However, over 30% of people with epilepsy do not have seizure control with the best medications. Epilepsy surgery is an option for people with focal seizures that remain resistant to treatment.

Patient: We report an eight year old girl who had a road accident followed by right frontal encephalomalacia and resistant seizures. The EEGs confirmed contralateral seizures. She had been resistant to all AEDs. VNS did not make a difference. There was no full agreement that she would benefit from a lesionectomy on the other side of the seizure discharges. After the operation and for 18 months, the girl’s seizures dropped from 3–6 daily to only 3 brief seizures for the whole post-operative period.

Results: Her seizures have been described as two different types, starting while awake with abnormal eye movements to many different directions and screaming with subsequent forward tonic movements of upper limbs. Type 2 while awake, her eyes move upwards and to the right. She would be unresponsive. Intercital EEG revealed sharp wave activities on the left frontocentral and centroparietal regions with phase reversals at C3.

Ictal EEG showed evidence of epileptiform activities starting from the frontocentral and centroparietal regions with fast recruitment of the right hemisphere. MRI revealed right frontal lobe cystic encephalomalacia with gliosis.

Conclusion: Children with intractable epilepsy and focal brain lesions are candidates for surgery even when they have generalized or contralateral epileptiform discharges.

Immunoadsorption and cyclophosphamide in a release of an anti-NMDA-receptor-encephalitis

G. Caravias, M. Steffinbauer, M. Voskor, O. Janka, M. Guger, G. Ransmayr, F. Gruber, Department of Neurology, General Hospital Linz, Linz, Austria; Department of Internal Medicine II, General Hospital Linz, Linz, Austria

An 18 year old woman was transferred to our neurologic intensive care unit with clinical signs of a relapse of a non-teratoma-associated anti-NMDA-receptor-encephalitis. The disease was diagnosed 4 months before and treated with plasmapheresis (PP), IVIG and prednisone. On admission she needed intubation due to psychotic behaviour and rapid loss of consciousness. The patient was extubated but needed reintubation the other day because of status epilepticus and psychosis.

We decided to continue IA every 4th day for 3 weeks, followed by weekly IA for 2 months and bi-weekly IA since then. With modified anticonvulsive therapy and low dose antipsychotic therapy the patient could successfully be extubated four weeks after admission. Four months after admission, the patient is steadily recovering with an actual modified Rankin Score of 2, seizure-free under reduced anticonvulsive therapy with phenytoin and valproate and in a stable psychiatric condition. Prednisone could be reduced considerably.

Discussion: There are few suggestions for therapy in non-teratoma-associated anti-NMDA-receptor-encephalitis. To our knowledge only one recent paper reports the use of IA in this disease. Our report shows that a relapse can successfully be treated with cyclophosphamide, steroids and repeated IA. Further studies are needed to determine the best treatment.

Ca2+ channel-blockers counter with the damaging effect of repetitive spreading depression on memory

M. Lotfinia, Shefa Neuroscience Research Center, Tehran, Iran; Shahid Beheshti University of Medical Sciences, Tehran, Iran

Background and purpose: Spreading depression known by transient loss of spontaneous and evoked neuronal activity and changes in ionic, metabolic and hemodynamic characteristics of the brain. Many studies have focused on the role of Ca2+ channels in spreading depression, however this role is not completely clear yet. On the other hand it has proven that impairment of memory is one of the main effects of spreading depression. In our study we aimed at determining the role of Ca2+ channel-blockers on repetitive spreading depression in terms of its effect on memory.

Methods: Wistar rat (60–80 g) randomly chosen in 4 groups and Nifedipine 1 mg/kg were administrated weekly after 3 mol/L KCl injection for induction of repetitive SD in rat for 4 week. The groups were evaluated by T-maze memory test and the SD group was compared with control groups.

Result: T-maze test data demonstrated that in repetitive spreading depression group memory was impaired during the weeks. In the group which Nifedipine has been administrated, memory improvement has been significantly observed.

Conclusion: Our study showed that administration of Nifedipine as a Ca2+ channel-blocker could significantly reduce the level of memory impairments, which is naturally followed by repetitive spreading depression.

Epilepsy: A historical overview

C.D. Rocha, J.J.O. Jr., M.A.A. de Oliveira, L.V. de Oliveira, J.P.R.P.T. de Azevedo, Faculty of Medicine, Federal University of Goiás, Goiania, Brazil; Faculty of Medicine, Federal University of Paraná, Curitiba, Brazil; Neuroscience Nucleus, Clinical Hospital of Goiás Federal University, Goiânia, Brazil
**Background:** Seizures have always been one of human afflictions and few diseases have attracted so much attention and generated so much controversy as epilepsy. Wrapped since ancient times by religious, magical and scientific stigmas, about 400 BC, Hippocrates recognized epilepsy as a brain disorder, and despite this, only in recent decades significant efforts have been developed against centuries of ignorance and discrimination.

**Objective:** To present an overview of the evolution of knowledge and of facts about epilepsy elapsing almost 2300 years from Hippocrates to middles of the XIX century.

**Material and methods:** Narrative review based on epilepsy historical facts by searching books and electronic databases.

**Results:** The word epilepsy was first used by Avicenna in the XI century, and meant “be taken, attacked or overwhelmed.” In ancient Rome, epileptics were avoided for fear of contagion, while in the Middle Ages, were persecuted as witches. During the Renaissance, epilepsy was seen as a manifestation of physical illness. However, it was in the Enlightenment, in the century of scientific revolution (XVII), that epilepsy started to be understood according to anatomy, pathology, physiology and chemistry.

**Conclusion:** During those 2300 years, the hypothesis of the supernatural with designations of “sacred disease” and “lunatics” has been abandoned and new modern theories came out. The knowledge about the history of epilepsy highlights the need for greater efforts for humanity to start a new millennium with this disease free from the shadows of the past.

**Epidemiological aspects of epilepsy in Brazil from 2008 to 2012**

C.J. Rocha, J.A.D.O. Júnior, M.A.A. de Oliveira, L.V. de Oliveira, D.J. da Silva. ¹Faculty of Medicine, Federal University of Goiás, Goiânia, Brazil; ²Faculty of Medicine, Federal University of Paraná, Curitiba, Brazil; ³Neuroscience Nucleus, Clinical Hospital of Goiás Federal University, Goiânia, Brazil

**Background:** Epilepsy is the commonest neurological condition affecting people of all ages, race and social class. There are about 50 million people with epilepsy in the world, 40 million in developing countries with little or no access to treatment. There are few studies on the epidemiology of epilepsy in Brazil, despite being an important public health problem.

**Objective:** To describe the profile of patients hospitalized due to epilepsy in Brazil, according to sex and age, in the period from 2008 to 2012, comparing to literature.

**Material and methods:** Data from hospital admissions in Brazil, in the period from 2008 to 2012, registered by Brazilian Health System based on database (DATASUS).

**Results:** The estimated incidence of epilepsy in Brazil was 190 per 100,000/year. The total number of hospitalization was 47,046, of which 27,468 (58.4%) in males and 19,578 (41.6%) in women. Of the total admissions, 12,431 (26.4%) occurred from 1 to 9 years and 10,416 (22.1%) from 30 to 49 years. The lowest rate was found in 80 years and more, which was responsible for 1333 (2.8%) hospitalizations.

**Conclusion:** The incidence of epilepsy in the world varies from 40–70 per 100,000/year in developed countries to 100–190 per 100,000/year in developing countries, as Brazil. It is more common in males than females but this difference is rarely significant. The highest incidence is in early childhood, with a decrease in adolescence, in both scenarios. In Brazil, the incidence is lower among elderly, different from the world, where the highest incidence is above 80 years.

**Clinical & electroencephalographic and cognitive function correlation in epileptic children**

M.A. Dahlah¹, I. Khalid², H. Bahary³, K. Bahgat⁴, M. El Hadi⁵, ¹Neurology, Azhar University, Cairo, Egypt; ²Pediatrics, Azhar University, Cairo, Egypt; ³Psychiatry, Azhar University, Cairo, Egypt

Cognitive dysfunction is one of the major contributors to the burden of epilepsy. It can significantly disrupt intellectual development in children and functional status and quality of life in adults. In children, cognitive problems are more diffuse responsible for learning difficulties and behavior problems.

The aim of study was to assess to what extent cognitive function is affected by clinical features and EEG characteristic of the epilepsy in children whether newly diagnosed or on antiepileptic drugs.

**Subject and method:** The present study is a cross section case control study. It was carried out on 95 children selected from pediatric-neurology outpatient clinic and inpatient department of El-Zahraa University hospital and El-Hussein University hospital during the period from November 2010 to July 2012. All studied children were subjected to full history taking with special emphasis on seizure description. Laboratory investigation: including CBC, ESR, liver & kidney functions and serum electrolytes as well as serum antiepileptic drug level whenever necessary. Neuroimaging was done to exclude organic brain lesion. Assessment of cognitive functions was assessed using the Arabic version of the Stanford–Binet intelligence Test (4th edition) which assesses four main cognitive abilities (Verbal reasoning, Visual/Abstract reasoning, Short term memory, Quantitative reasoning).

We came to a conclusion that epileptic children have significant cognitive impairment even if their seizures were controlled. Epileptic children with normal composite IQ could have Verbal, Visual/Abstract, Quantitative or memory impairment. Frequency and generalized seizure, duration of epilepsy, AEDs intake and poor seizure control are important factors for poor cognitive function.

**Epilepsy surgery in Morocco study and long-term follow-up in 51 cases**

R. Ouazzani. Neurology, Hopital des Specialites, Rabat, Morocco

51 patients with intractable lesional temporal partial epilepsy were operated between 2005 and 2011. 48 patients had an anterior temporal lobectomy and 3 lesionectomy. In 29 patients (57%) hippocampal sclerosis was found, dysembryoplastic neuroepithiloma in 13 (25%), 4 patients with cortical dysplasia, 2 with ganglioma, and one case of cavernoma and astrocytoma.

Presurgical evaluation was the same in all cases, based on non-invasive methods (detailed history, neurological and psychiatrical evaluation, interictal EEG, MRI, video-EEG with ictal EEG and neuropsychological tests).
After 7 years of follow-up, 40 patients (78.4%) are in class I of Engel's classification, among them 31 (60.7%) are seizure free (class IA), 5 patients in class II, 6 patients in class III, and no patients in class IV. The outcome is almost identical to the group with hippocampal sclerosis and the other group with other types of lesions for the first four years, after seven years of follow-up, 50% of the first group are in class I and 66.7% for the second group. Our experience demonstrates the feasibility of epilepsy surgery in developing countries particularly in Africa and appropriateness of non-invasive method evaluation.

α7-Containing nicotinic acetylcholine receptors on interneurons of the basolateral amygdala and their role in the regulation of network excitability
V.I. Pidoplichko, E.M. Prager, V. Aroniadou-Anderjaska, M.F.M. Braga. 1Department of Anatomy, Physiology and Genetics, F. Edward Hébert School of Medicine, Uniformed Services University of the Health Sciences, Bethesda, MD, USA; 2Program in Neuroscience, F. Edward Hébert School of Medicine, Uniformed Services University of the Health Sciences, Bethesda, MD, USA

The basolateral amygdala (BLA) plays a key role in fear-related learning and memory, in the modulation of cognitive functions, and in the overall regulation of emotional behavior. Pathophysiological alterations involving hyperexcitability in this brain region underlie anxiety and other emotional disorders, as well as some forms of epilepsy. GABAergic interneurons exert a tight inhibitory control over the BLA network; understanding the mechanisms that regulate their activity is necessary for understanding physiological and disordered BLA functions. The BLA receives dense cholinergic input from the basal forebrain, affecting both normal functions and dysfunctions of the amygdala, but the mechanisms involved in the cholinergic regulation of inhibitory activity in the BLA are unclear. Here, we demonstrate that the α7-containing nicotinic acetylcholine receptors (α7-nAChRs) are present on somatic or somatodendritic regions of interneurons, in the rat BLA. These receptors are active in the basolateral network, enhancing GABAergic inhibition, and their further – exogenous – activation dramatically increases spontaneous inhibitory postsynaptic currents (sIPSCs) in principal BLA neurons. When α7-nAChRs are activated in all of the BLA network, both inhibitory and excitatory currents increase in BLA principal cells, but the inhibitory currents are enhanced significantly more than the excitatory currents; the result is reduced excitability, as suggested by the decrease in the amplitude of evoked field potentials. The anxiolytic effects of nicotine, as well as the role of the α7-nAChRs in seizure activity involving the amygdala and in mental illnesses such as schizophrenia and Alzheimer’s disease may be better understood in light of the present findings.

Vagus nerve stimulation in 19 patients with drug-resistant epilepsy in Western China
Y. Shen, F. Xia, L. Liu, W. Lin, Y. Liu, M. Shi, X. Ren, B. Ding, Y. Chen, H. Jia, J. Wang, G. Zhao, Y. Deng. 1Department of Neurology, Xijing Hospital, Fourth Military Medical University, Xi’an, China; 2Department of Neurosurgery, Xijing Hospital, Fourth Military Medical University, Xi’an, China

Objective: To assess the efficacy and safety of vagus nerve stimulation (VNS) in drug-resistant epilepsy in Western China.

Methods: In this retrospective review of 19 patients who underwent VNS for drug-resistant epilepsy, there were 17 (89.5%) males and 2 (10.5%) females ranging in age from 7 to 58 years at the time of implantation. The generator was turned on two to three weeks after the plantation operation. Stimulation parameters were adjusted gradually. The output currents were adjusted from 0.25 mA, stimulation time was 30 s ON and 5 min OFF, the frequency was 20–30 Hz, and the pulse width was 500 μs. Then the change of the output currents was 0.25 mA every 1–3 months.

Results: Duration of vagus nerve stimulation treatment varied from 3 to 29 months. Seizure freedom was achieved in 10 patients (52.5%). Seizure control ≥90% was achieved in 11 patients (57.9%), ≥75% seizure control in 12 patients (63.2%), ≥50% improvement in 16 patients (84.2%), and <50% improvement in 3 patients (15.8%). There is no change of antiepileptic drugs (AEDs) in 14 patients; reduction of AEDs in 4 patients; increase of AEDs in one patient. Three patients (15.8%) reported one transient mild adverse effect.

Conclusion: VNS is a safe and effective palliative treatment for drug-resistant epilepsy in Western China. The key to the effectiveness of VNS is adjusting the right parameters to each patient. We believe better seizure control can be achieved as long as allowing more titration of the stimulation parameters and further AED regimen adjustments over time by the qualified epileptologists.

Postictal sneezing: A case study
P. Myrianthropoulou, S.S. Papacostas. Neurology Clinic B, The Cyprus Institute of Neurology and Genetics, Nicosia, Cyprus

Objective: To describe a patient with epilepsy who had postictal sneezing during long-term video-encephalography (EEG) monitoring. In the literature, sneezing is reported to be an autonomic phenomenon as an aura in epilepsy. One case of postictal sneezing was reported previously.

Method: The patient underwent video-EEG monitoring for probable focal onset epilepsy. Three episodes of postictal sneezing were recorded and studied clinically and electrographically.

Results: Three seizures were recorded which were followed by sneezing twice when he became responsive. For the first seizure, the patient was off-camera and clinical features could not be determined except for sneezing. The two visible seizures were characterized by oral automatisms, staring, head posturing to the right, unresponsiveness, and in one of the two, upper limb dystonia and bilateral bicycling movements. All seizures concluded with sneezing twice. The EEG record was characterized by a buildup in fast activity in the left temporal region and slowing in the left hemisphere in all three seizures, with attenuation in amplitude in one. In one of the three episodes, the slowing spreads bilaterally with a left-sided predominance. In all three episodes, sneezing occurred after the patient was responsive, and in two of the three, while left temporal slowing or amplitude attenuation was still present on the EEG.

Conclusion: Two of the three episodes of sneezing occurred while EEG was not back to baseline but the patient was responsive. In our case sneezing appeared to be a postictal event, probably representing a release phenomenon.

Variations in temporal lobe volumetry in association with temporal lobe epilepsy in Sudan
M.A. Nurein1, M.S. Elmagzoub2, T. Ali1, A. Jabir1, A. Fadelmola5
1Anatomy, College of Medicine University of Karary, Sudan; 2Faculty of Medicine, National Ribat University, Khartoum, Sudan

Introduction: Temporal lobe volumetry varies in correlation with normal variables like age and gender and with conditions like schizophrenia and epilepsy. This study considered these variations in patients with temporal lobe epilepsy compared to a matching control in Sudan.

Methodology: 63 patients with temporal lobe epilepsy were studied and compared to 69 matching controls. Three dimension structural MRI scan is done in the National Ribat University teaching hospital using 1.5 T Siemens scanner. 3D slicer 2.6 was used in computing the volume of the regions of interest.

Results: In the control group volumetry of the temporal lobe showed statistically significant left lateralization in males besides larger volume in males than in females. The superior temporal gyrus also showed left lateralization in males but the difference in volume between males and females is statistically not significant. The hippocampus showed right lateralization with statistically significant larger volumes in males than in females. In the study group left lateralization in the temporal lobe was not detected in males. The superior temporal gyrus showed statistically significant left lateralization in females. The temporal lobe and the superior temporal gyrus showed larger volumes in males than in females without volume difference compared to the control group. Hippocampal volume was reduced in the study group. Only the right hippocampus showed larger volumes in males than in females.

Conclusion: Findings in correlation with temporal lobe epilepsy differ between males and females. Some variations could be considered as preexisting risk factor for temporal lobe epilepsy.

MRI volumetry of the temporal lobe in Sudan: Validated protocol and preliminary normative data
M. Nourein1, M.S. Elmagzoub5, T. Ali1, A. Jabir5, A. Fadelmola5
1Anatomy, University of Karary, Sudan; 2Faculty of Medicine, National Ribat University, Khartoum, Sudan

Introduction: Variations in temporal lobe volumetry are reported in correlation with various normal factors like age, gender and handedness. No consensus in defining the borders of the temporal lobe, in particular the posterior border. This study aimed to design and validate a protocol for measuring the volume of the temporal lobe and then apply it in obtaining preliminary normative data in Sudan.

Methodology: 3D structural MRI was obtained in the National Ribat University teaching hospital, Sudan using 1.5 T Siemens scanner. 69 right handed apparently healthy volunteers were scanned. A protocol is designed considering the most postero-superior point of the lateral fissure as the posterior border. It is validated applying Cronbach’s alpha in SPSS 16. 3D slicer 2.6 is used in volume measurements. The absolute volume is compared between genders and across each gender using ANOVA.

Results: Protocol reliability is 0.984. Larger volumes and left lateralization were detected in males but not in females.

Conclusions: The posterior end of the lateral fissure is a reliable point for temporal lobe demarcation. Volumetry of the temporal lobe is associated with gender. It displayed larger volumes as well as left lateralization in males than in females.

Increased risk of atherosclerosis antiepileptic drug use

Recent reports suggest that chronic epilepsy and long term AED usage may be associated with atherosclerosis. By current study, we aimed to investigate the possible relation between antiepileptic drugs and atherosclerotic risk factors and carotid intima media thickness (IMT) as a marker of atherosclerosis. 92 patients, who has used carbamezapine (CBZ) and valproic acid (VPA) for three or more years and who has used a second antiepileptic drug (politherapy) for two years in addition to CBZ or VPA monotherapy, were included in the study. Control group composed of thirty one subjects with similar demographics. Fasting blood glucose, liver and renal function tests, lipid profile (triglyceride, total cholesterol, HDL-c, LDL-c), homocysteine, Hs-CRP, uric acid (UA), Lp(a), folate and vitamin B12 levels were examined in both groups.

The measurement of carotid intima media thickness (IMT) was performed by cranial magnetic resonance imaging and by cranial computerized tomography in patients whom magnetic resonance imaging could not be performed.

Although there was no difference between patients and control group in terms of IMT increase, there was positive correlation between carotid IMT and body mass index, T-col, LDL-c, Hs-CRP and homocysteine levels in the patient group. The finding, that there was no correlation between IMT values and duration of disease, duration of drug usage and dose, suggests that long term AED usage does not increase the development of atherosclerosis. It would be more appropriate to conduct novel long term follow-up studies in order to investigate whether AED usage leads to atherosclerosis.

doi:10.1016/j.jns.2013.07.197
Methods: The dates of 3382 consecutive patients with epilepsy were collected using specially designed questionnaires, which were filled in by trained epileptologists.

Results: 1552 (45.9%) females and 1830 (51.4%) males were involved. 41.8% of patients were inhabitants of Yerevan; other 58.2% were from regions. Immediately after diagnosis no treatment was initiated in 31% or was inadequate in 29%, and in 29% the suboptimal dose of appropriate AED was established. EEG was available for the vast majority (89.8%) and for 18.9% of patients also long-term (15–20 hours) video-EEG investigation was performed. 30.7% cases were idiopathic, 29.15% patients were symptomatic, 15.5% cases were cryptogenic and 24.4% were undefined. More frequently used AEDs are CBZ and VPA, or their combination. 11.68% of patients were prescribed to last generation AEDs either in monotherapy or any polytherapy regimen. Overall 18% of patients were seizure free at the moment of investigation.

Conclusions: Overall epilepsy care in Armenia is far from perfect and anticonvulsant treatment effectiveness is rather low with poor availability of last generation AEDs, and lack of non-AED treatment options even in the presence of adequate diagnostic and treatment protocols.

Features of memory impairment in temporal lobe epilepsy (TLE) and juvenile myoclonic epilepsy (JME) in adults
A. Kostylev, N. Pizova. Department of Neurology, Yaroslavl State Medical Academy, Yaroslavl, Russia

Background: Cognitive impairment, including memory loss, is quite common in epilepsy. The most frequently suffers memory loss in temporal lobe epilepsy, but also describes memory loss in JME (Kim, 2007).

Objective: To specify features of memory impairment for TLE and JME in adults, using neuropsychological and neurophysiological testing.

Patients and methods: We examined 10 healthy, 11 TLE patients and 10 JME patients, mean age of epilepsy group was 26.4 years, mean age of healthy group was 27.1 years. Objects were assessed using digit span and word span meet the increased latency of P300 (P<0.001). Testing was conducted in the first half of the day and the patients had no depression according to Beck Depression Inventory. The patients with epilepsy were on monotherapy with antiepileptic drugs.

Results: The patients with epilepsy performed tests worse than the healthy patients (p<0.05). But in TLE patients the worst results in digit span and word span meet the increased latency of P300 (p<0.01). However, in JME, we did not find significant differences between the neuropsychological tests and evoked potentials.

Conclusion: Based on our data, we can assume the heterogeneous nature of memory impairment in epilepsy. However, some limitations in the study (small sample, antiepileptic therapy) require further clarification.

Management and outcome of patients with Landau Kleffner and continuous spike–waves during slow sleep syndromes
H. El Khashab, M. Salih, A. Kentab, F. Bashiri. 1Pediatric Neurology, King Saud University, Riyadh, Saudi Arabia; 2Pediatrics, Ain Shams Faculty of Medicine, Cairo, Egypt

Background: LKS and syndrome of CSWS share clinical features. They can be associated with electrical status epilepticus during slow-wave sleep (ESWS).

Objectives: Present study describes clinical and electroencephalographic findings in a cohort of 12 patients with LKS and CSWS and modalities of management. It aimed to verify long term outcome.

Patients and methods: The study included 10 males and 2 females with suspected epileptic encephalopathy (mean age of 4.176 ± 2.25). It extended over a period of five years. Patients enrolled were evaluated at Division of Pediatric Neurology, KKUH, Saudi Arabia. All patients had seizures, of them, nine (75%) had language disorders. Ten patients (83.3%) had behavioral disturbances. Awake EEG was normal in 5 patients. When reaching deep sleep, five patients with LKS and two with CSWS had generalized discharges reaching 90% in patients with CSWS and ranging from 40 to 70% in others. Patients were treated by either: Intravenous methyl prednisolone, intravenous immunoglobulins (IVIG) or combined IVIG with steroids. In all patients, antiepileptic medications were adjusted individually. Outcomes range from recovery in 4 patients to permanent aphasia in one, seven improved with either residual language deficits or neuropsychologic impairment. Poor prognostic factors were onset ≤ 4 years of age, duration of aphasia ≥ one year, and persistant of ESES.

Conclusion: Treatment requires reversal of ESES/CSWS pattern on EEG. Use of combination of corticosteroids and IVIG seems to be effective approach and it is important to use an appropriate dose and repeat a cycle of therapy whenever required.
leading to low penetrance of BBB and more drug resistance. Of inflammatory cytokines, IL-1β during seizure group was significantly higher than that in each group. But CPR during seizure group was significantly lower than that in epileptic subjects but not in control subjects. Further studies are needed to support this hypothesis.

Early seizures in patients with acute ischemic stroke
S.-J. Lee, Neurology, Yeungnam University, Daegu, Republic of Korea

Background: The aim of this study is to establish the incidence of acute post-ischemic stroke seizures and to determine risk factors associated with early seizures in acute ischemic stroke.

Patients and methods: A total of 1370 consecutive patients with acute infarction were included. Onset seizures and early seizures were defined as seizures occurring within 24 h and 7 days from the onset of infarction, respectively. Patients with high fever, previous history of epilepsy, and metabolic encephalopathy were excluded.

Results: Eleven patients (0.8%) developed early seizures after acute infarction; and 6 patients (55%) had onset seizures. TOAST classification of the stroke among those patients was large artery disease in 4 (36%), cardio-embolism in 3 (27%), vasculitis in 1 (9%), and cryptogenic stroke in 3 cases (27%). All of the 11 patients developed generalized tonic or clonic seizures. All patients had cortical involvement with various size of the lesions; large in 3 (27%), moderate in 5 (45%), and small lesions in 3 (27%). There were 2 cases of hemorrhagic transformation of the lesions.

Conclusions: Since all patients had cortical lesions, the most important factor of early seizures may be the location of lesions. Patients with lacunar and infratentorial infarctions did not develop early seizures. Patients with onset seizures had more seizures during acute stage than those without onset seizure.

Usefulness of PET/CT in diagnosis of temporal epilepsy

Aim: The aim of this study was to assess the usefulness of routine 18F FDG PET/CT examination in patients with temporal lobe epilepsy before surgery.

Material and methods: 41 patients with medically refractory temporal lobe epilepsy (21 women and 20 men, age 31 ± 9) underwent interictal PET/CT examination approximately 30 min post-i.v. injection of 250 MBq 18F FDG and contrast enhanced brain MRI. All patients underwent surgery (temporal lobe with hippocampus resection). The diagnosis was verified by histopathology, PET and MRI were assessed by two independent physicians, who were blinded to clinical signs and results of EEG.

Results: In 34/41 (83%) of patients in PET/CT areas of hypometabolism including mesial temporal lobe, that correlated with histopathology, were observed. Pathologies were present in 18/41 (43%) of patients in MRI.

In 2 patients hypometabolism was observed in both mesial temporal lobes without lateralization of changes. In 1 patient area of hypometabolism was present in the contralateral temporal lobe, there was no pathology in MRI.

In 4/41 (10%) of patients there was no pathology in PET/CT and MRI. Histopathological findings included tumours (ganglioglioma, oligodendroglia and DNET), focal cortical dysplasia (FCD) type IB, FCD IIa, FCD IIa and hippocampal sclerosis. There were no significant differences in FDG accumulation between these pathologies.

Conclusions: 18F FDG PET/CT shows markedly more often abnormal tracer distribution that could correspond to epileptogenic foci than MRI.

The nature history of untreated epilepsy in rural areas in Tibetan areas
J. Mu, L. Liu, Y. Zhao, D. Zhou, J. Wu, S. Li. 

Epilepsy is affecting 50 million people in the world, 85% of whom live in resource-poor countries. Epilepsy also imposes an enormous physical, psychological, social and economic burden on individuals, families and countries. In 1997, the Global Campaign Against Epilepsy was launched in China. As a part of the campaign, a demonstration project on epilepsy management was carried out in rural China, also in Sichuan in 2005.

In the past 8 years, this project expanded to 9 countries and covered 4,937,000 populations in Sichuan province. 8128 patients were enrolled and 6547 received phenobarbital or sodium valproate treatment. After 8 years of follow-up, 79.8% of the patients had 50% or greater reduction in seizure frequency and 43.3% remained seizure free. The quality of life greatly improved in 72% patients. The treatment gap was successfully reduced to 13%. The main premature cause of death of epilepsy patients is accidental death (59%), especially drowning (45.1%) and then we did targeted prevention. We made the intervention package to enhance medical compliance and improve seizure control, which helped the proportion of patients with ~50% seizure reduction to 79.8%. Besides, 837 physicians were efficiently trained to treat people with epilepsy. The most important, this project had successfully implemented a sustainable treatment and management model of epilepsy in rural areas.

This project not only completed its basic aim in promoting education, training, and treatment for epilepsy patients in rural China, but also helped to find an operational model to sustain and success in management of chronic disease in resource-poor regions.

doi:10.1016/j.jns.2013.07.204
Purpose: To evaluate the nature history of people with untreated prevalent epilepsy in rural Tibetan areas.

Methods: During 2006 to 2010, we carried out a door to door epidemiologic community survey in a sample of 60,466 subjects in 5 rural counties in both Tibetan Autonomous Regions and Sichuan province. People with suspicious symptoms are investigated retrospectively, but only active epilepsy has been registered and followed up regularly and prospectively.

Results: At the survey, we identified 473 (60.7% male) people with convulsive epilepsy, of whom 367 (61.9% male) were “active epilepsy” and followed up for mean 41 ± 8.6 months. In the retrospective survey, 22.4% patients with untreated become spontaneous remission for more than 5 years, 31.7% become spontaneous remission for more than 3 years, and 48.8% seizure free for only 1 year. During the follow-up, 79 (21.5%) patients were tried to treat by antiepileptic drug (AED), but only 34 continued the treatment for more than 3 years, 45 (12.3%) patients used traditional Tibetan medicine, and another 243 (66.2%) patients believe in God instead of AED. 12 (3.3%) subjects died. 174 patients are followed up more than 5 years, 48 (27.6%) of them have spontaneous remission. For the 308 who were untreated and under treatment followed up, 96 (31.2%) of them have spontaneous remission for 3 years. Besides, 55.9% (19/34) of those who take AED regularly have seizure free after 3 years of treatment.

Conclusion: Spontaneous remission of epilepsy occurs in a portion of untreated patients. The AEDs do have an effect to elevate the rate of seizure free.

Localization of focal delta activity in epilepsy patients after brain surgery using MEG
H. Stefan a, M. Schönherr b, S. Rampp b. aNeurological Clinic, University Hospital Erlangen, Erlangen, Germany; bNeurological Department, University Hospital Erlangen, Erlangen, Germany

Background: In this study we introduce an automatic method for source localization of focal slowing demonstrating the relation between spikes and delta activity in 9 patients after previous brain surgery.

Objective: In case of focal epilepsy, surgery can often improve seizure frequency in these pharmacoresistant patients. However, not all patients are completely seizure free thereafter. Residual epileptic activity which leads to persisting seizures can be localized by interictal spikes. Additionally slow wave brain activity can be used for focus localization.

Patients and methods: Nine patients with pharmacoresistant epilepsy after brain surgery were examined using MEG. 20 min of spontaneous brain activity at rest were recorded and sources of delta and theta activities were localized with Dynamic Imaging of Coherent Sources (DICS, 5). Additionally interictal spike localization results were used for setting up a spherical region of interest (ROI) with a radius of 2 cm.

Results: In 3/9 patients, the maximum of the theta band hits the ROI, in another 3 patients it is the third or fourth local maximum, and in 3 patients no local maximum is found within the ROI at all. The localization results lie at the borders, not more than 2 cm away from the spikes.

Conclusion: The results show a strong relation between interictal spikes and delta activity in patients after brain surgery. The method runs automatic, so it is user-independent and faster than visual inspection of data to find segments with slowing of brain activity.

Supported by: DFG STE 580/15-1.

(TLE) but may impair memory function, typically verbal memory following left and visual memory following right ATL.

Functional reorganisation can occur within the unaffected ipsilateral and contralateral hemispheres. We investigated reorganisation of memory function in TLE before and after left or right ATL and the efficiency of postoperative memory networks.

**Methods:** We studied 46 patients with unilateral medial TLE (26 left) on a 3T GE-MRI scanner. All subjects had neuropsychological testing and performed an fMRI memory encoding paradigm for words, pictures and faces preoperatively and four months after left or right ATL.

**Results:** Event-related analysis revealed that left TLE had greater activation in the left posterior medial temporal lobe (MTL) for encoding words postoperatively than preoperatively. Greater pre- than postoperative activation for encoding words in the ipsilateral posterior MTL correlated with better verbal memory outcome after left ATL.

After left ATL greater postoperative than preoperative activation in the ipsilateral posterior MTL correlated with less good postoperative verbal memory performance, an effect that was not observed for visual memory after right ATL.

**Conclusion:** We found effective preoperative reorganisation of verbal memory function to the ipsilateral posterior MTL, suggesting that it is the capacity of the posterior remnant of the ipsilateral hippocampus rather than the functional reserve of the contralateral hippocampus that is important for maintaining verbal memory function after ATL; early postoperative reorganisation to ipsilateral posterior or contralateral MTL structures are inefficient.

**Increased seizure frequency due to the copper deficiency in Wilson’s disease**

H. Kaleagasi, N. Oksuz, S. Ozal, A. Yilmaz, O. Dogu. Neurology, Mersin University School of Medicine, Mersin, Turkey

**Background:** Epileptic seizures have been reported in Wilson’s disease (WD) in 6–7% of patients, mostly following the chelator therapy. Pyridoxine deficiency due to penicillamine, direct copper toxicity, pathological changes, metabolic encephalopathy and rarely copper deficiency are the attributed mechanisms for seizures.

**Objective:** To present a patient with WD and intractable seizures, taking chelator and antiepileptic therapy with a strict copper restricted diet.

**Patients and methods:** A-29-year old female patient admitted to emergency unit with recurrent seizures. She had been diagnosed as WD and epilepsy in another center previously with a treatment of zinc acetate and strict copper restricted diet were ended. As the serum copper levels increased during follow-up, less frequent secondary generalized seizures had been started after taking penicillamine and responded well to carbamazepine initially. She complained increased daily frequency of seizures ranging from 5 to 10 in recent months.

**Results:** Although effective serum carbamazepine level and levetiracetam add-on therapy, changed chelator therapy with trientine and oral pyridoxine, daily frequency of seizures did not reduce and low serum copper (0.3 μg/dl (70–140)] has been attributed for the seizures. Zinc acetate and strict copper restricted diet were ended. As the serum copper levels increased during follow-up [16 μg/dl (70–140)], seizure frequency was decreased.

**Conclusion:** Epileptic seizures respond well to antiepileptic treatment in WD. In this case, add-on antiepileptic and pyridoxine therapy did not reduce the seizure frequency. The relation between decreased seizure frequency and increased serum copper levels shows that copper deficiency can cause intractable seizures in patients who are taking chelator therapy with a strict copper restricted diet.

**Attentional deficit in childhood benign epilepsy with centrotemporal spikes (bects) and absence seizure epilepsy**

P. Conde-Guzón, M.T. Bartolomé-Albistegui, R. Cancho-Candela, C. Rodríguez, M.J. Conde-Guzón. 1Neuropsychology, Universidad de León, Spain; 2Neurology, Obra Hospitalaria Nuestra Señora de Regla, Leon, Spain; 3Neuropsychiatrics, Hospital Pio del Río Hortega, Valladolid, Spain; 4Neuropsychiatrics, Complejo Hospitalario de León, Leon, Spain

**Objective:** There is controversy regarding the neuropsychological profile of children with epilepsy. The aim of this study is to analyze the attentional profile of children with benign epilepsy with centrotemporal spikes (BECTS) compared with children with absence seizures.

**Methods:** Sample: 34 children from 7 to 12 years (18 with BECTS and 16 with absence seizures). We get the attentional profile by applying the WISC-IV (Wechsler Intelligence Scale for Children-IV), Battery Luria-DNI (Manga and Ramos, 1991) and Attention Test d2 (Brickenkamp, 2002).

**Results:**

A) We haven’t found any differences in IQ between children with BECTS and absence seizures.

B) We haven’t found any differences in attentional profile when we use WISC-IV.

C) Nevertheless, when we use specific Attentional Test d2, we have found a significant (p < 0.05) deficit in children with BECTS compared with absence seizure children in attentional control, inhibitory control, working capacity, concentration, and selective and sustained attention.

**Conclusions:** We must consider, in children with this diagnosis, the neuropsychological profile described to strengthen deficient neuropsychological and psychoeducational areas. In addition, we must continue research in future studies on the role of the attention in children with epilepsy.

**Expression of adenosine kinase in human mesial temporal lobe epilepsy with hippocampal sclerosis: A preliminary study**

**Background:** Adenosine is a ubiquitous homeostatic molecule that acts as an “endogenous neuromodulator”. Adenosine attenuates neuronal activity either presynaptically by inhibiting neurotransmitter release or by controlling neurotransmitter responsiveness at post-synaptic sites. Unbalanced adenosine metabolism has been
implicated in pathological conditions such as epilepsy. Adenosine
kinase (ADK), synthetized by astrocytes, is the key regulator of
extracellular adenosine levels in the brain. Evidences from experi-
mental studies support a role for ADK in brain injury associated
with astrogliosis, a morphological hallmark of Mesial Temporal Lobe
Epilepsy with Hippocampal Sclerosis (MTLE-HS). In fact, expression
of astrocytic ADK was found to be increased in the hippocampus and
temporal cortex of MTLE-HS patients. Overexpression of ADK decreases
extracellular adenosine and consequently may cause seizures. The aim
of this study was to characterize ADK gene expression in MTLE-HS patients.

Methods: Previous studies used immunohistochemistry and Western
blot analysis to investigate ADK expression. Here we quantified
the expression levels of ADK by Real-Time PCR in the hippocampus
(leional and peri-leional cortical area) of 10 MTLE-HS patients
submitted to surgery as compared with 9 autopsy controls with no
history of neurological disorders.

Results: Our results showed that ADK expression levels were similar
in the hippocampus and temporal cortex of MTLE-HS patients when
compared to healthy controls.

Conclusion: Our preliminary data demonstrate that ADK expression
levels are not altered in MTLE-HS. These results do not preclude
post-transcriptional ADK abnormalities at both protein and func-
tional levels. Our results should be confirmed in a larger cohort as
well as with complementary methodologies.

Proposal of a staging system for risk stratification and cross
sectional reporting of status epilepticus

M. Leitinger, G. Kalss, D. Huber, A. Rohracher, J. Höfler, J. Dobesberger,
E. Trinka. Neurology, Paracelsus Medical University Salzburg, Salzburg,
Austria

Background: Definitions for status epilepticus (SE) vary regarding
their time points and -windows of treatment options. Clinical
phenomena are highly dynamic and symptoms may gradually
disappear, as status advances (electromechanical dissociation).
Pragmatically, this may cause problems, when transferring a patient
in SE from one to another unit (e.g. emergency department to ICU).
To date no standardized system exists for acquisition, documentation
and communication of clinical core parameters to stage SE. Such a
system would make research results better comparable for meta-
analyses and serve as a tool for risk stratification.

Methods: Fifty consecutive patients with various types of status
epilepticus of any cause were classified according to a proposed staging
system for status epilepticus (SSSE) in a tertiary neurological university
clinic in Salzburg, Austria. A data sheet was designed and explained
to responsible physicians in charge. The SSSE uses a letter code comparable
to the pTNM-system in tumors. A responsible physicians in charge. The SSSE uses a letter code comparable

Views of young people toward epilepsy in Novi Sad

V. Ivetic, K. Ivosevic, D. Karaba Jakovljevic, N. Naumovic. Department
of Physiology, Medical Faculty, Novi Sad, Serbia

Epilepsy is a significant health problem especially prominent in
underdeveloped countries. Quality of life in epilepsy is affected not
only by the subjective experience of the illness it manifests, and
long-lasting therapy, but also by the inappropriate attitude of the
society that is mostly uniformed about the real nature of epilepsy.
In this investigation it was analyzed how well young people are
informed about epilepsy and its characteristics as well as first aid
to epileptic. A special questionnaire for investigation was used. The
first part of the questionnaire was used to determine the socio-
demographic characteristics of the study participants, and the second
part dealt with student knowledge of epilepsy.

In this study 432 students were included from different schools of
University in Novi Sad (excluding students from medical schools),
ages 20–24, both sex.
The results show that the young people are familiar with epilepsy,
and they have a basic knowledge regarding nature of the disease, but
due to different subjective attitudes towards epilepsy and epileptic
patients, it can be said that the attitude of the young population
toward epilepsy is still based on a low level information and prejudice. Students from the countryside were better informed than the students from the city. The knowledge about epilepsy was not dependent on sex. We can conclude that there is an adequate level of awareness and knowledge toward epilepsy among the young people in Novi Sad. However, there is still a need for further improvement of certain aspects of knowledge and understanding of the epilepsy.

Source analysis in patients with idiopathic generalized epilepsy
W.P. Blasque, A.M.D.S. Braga, L.E. Betting. UNESP, Botucatu, Brazil

Generalized spike and wave (GSW) discharges is the main neurophysiological signature of idiopathic generalized epilepsies (IGE). Investigations support that the pathophysiology of GSW and IGE includes a subtle cortical focal abnormality. Investigate the relation between focal findings in the EEG and MRI of patients with IGE using quantitative techniques. 4 patients with IGE were investigated. EEG was recorded with 22 channels and source analysis was conducted using BESA software. GSW discharges were centered and averaged. Equivalent dipole and CLARA algorithms were used for source localization. All patients and 13 healthy controls were submitted to 1.5T MRI. Volumetric (3D) T1 sequence was used for structural evaluation of the cortical surface. Cortical reconstruction and statistical analysis was performed with Freesurfer. All images were submitted to the same processing. Using GLM the cortex of each patient with IGE was individually compared with the control group.

Subject 1: 10 discharges. GSW onset involved the posterior portion of the right parahippocampal gyrus. MRI showed reduced cortical thickness in the right supramarginal gyrus.

Subject 2: 4 discharges. GSW onset involved the left occipital lobe. MRI showed increased curvature in the left precuneus.

Subject 3: 80 discharges. GSW onset involved the right inferior frontal gyrus. MRI showed decreased curvature in the right insula.

Subject 4: 6 discharges. GSW and MRI (reduced curvature) showed involvement of the right anterior cingulate.

Cortical analysis and EEG source imaging showed an interesting correspondence. This study supports that focal onset and fast spreading networks may be involved in IGE mechanisms.

Dermatological manifestations of epilepsy among adult Sudanese epileptic patients
A. Hussien, A. Sidig Abdulgalil, F.Y. Omer, O. El-Adil, K. Hagnour, M. Malik Aldar. Medicine, University of Khartoum, Khartoum, Sudan

Introduction: Epilepsy is a clinical syndrome characterized by increase electrical excitability of cortical neurons with or without loss of consciousness.

Objective: To study the pattern of dermatological changes associated with epilepsy among adult Sudanese epileptic patients.

Methods: This non-interventional descriptive study, 360 adult Sudanese epileptic patients were included in the study which was conducted at El shaab Teaching Hospital during the period from Feb 2004 to Aug 2007. Full detailed history and proper clinical examination were performed by the authors. Dermatological changes were assessed by dermatologist. List of investigations was done including EEG, CT of the brain and serial of drug serum level.

Results: Out of 360 patients 31 were found to have scars due to repeated attacks of convulsions, one patient was found to have neurofibromatosis, one had tuberous-sclerosis, one had Sturge-Weber syndrome, one had Kaposi sarcoma, one had SLE, one diabetic patient had skin atrophy, one patient use to take phenobarbitone had skin eruption, and one patient on carbamazepine had skin change while five patients on phenytoin had skin manifestations.

Conclusion: Skin changes can occur in epileptic patients as part of drugs toxicity, or as part of clinical manifestations of certain diseases that can cause secondary epilepsy e.g. neurofibroma.

Stigma of epilepsy among patients and their relatives attending charity clinic, Omdurman — Sudan
Introduction: Epilepsy is the world's most common and most serious chronic neurological disease affecting near 50 million cases. Epilepsy has well recognized stigma which is defined by Link and Phalen as a status which exists when elements of labeling, stereotyping, separation, status loss, and discrimination occur together in a power situation that’s allows them to unfold. Stigma has a major contribution to the reduction of quality of life in people with epilepsy.

Objective: The purpose of this study was to determine the types of stigma in PWE and to determine its frequency as well as its association with demographical factors and to determine the coping ability of PWE.

Method: Health facility-based cross-sectional analytical study was conducted in charity clinic on 80 people with epilepsy aged from 8 to 70 years. Standardized questionnaire was used for the interview of the patients and assistance was asked from their relative occasionally and the data was analyzed by SPSS16.

Results: 16.3% was found to have positive Felt stigma score. Nearly half of PWE had courtesy stigma also coaching stigma affected half of PWE. Fifth of PWE had poor coping score. Age below forty was a determinant factor for the coping of people with epilepsy as well as parent courtesy stigma. Frequency of seizures of more than 3 per month reduced coping score of PWE.

Conclusion: Results suggest the great need for psychological counseling for high risk group PWE as shown by the study.

Epilepsy in the Amazon: An invisible disease in the rain forest
A.M.R. Souzaa, V.L. Pereiraa, L.S. Saidb, C. Chiranoa, A.P.Q. Ramalhob, L.M. Li, c, a School of Medicine of Federal University of Amazonas, Brazil; bPreventive Medicine, School of Medicine of Federal University of Amazonas, Manaus, Brazil; cNeurology, Faculty of Medical Sciences of State University of Campinas, Brazil; dAssistência à Saúde de Pacientes com Epilepsia — ASPE, Campinas, Brazil

Background: Epilepsy is a serious disease with a lifetime prevalence of 1–2%. Epilepsy can be cost-effectively treated, yet the treatment gap is still shameless high even in mainstream parts of the globe. One can just wonder how epilepsy is managed in non-easily-accessible regions like Amazon rain forest.

Objective: To assess the perception epilepsy prevalence by the primary care staff working in Amazon region.

People and methods: We applied a home-made questionnaire to staff from three primary health care units in the city of Parintins located in the Oriental Amazon. This is part of the Strategy and Plan of Action on Epilepsy of PAHO-WHO/ILAE/IBE carried out by ASPE in Brazil.

Results: One-hundred-six people (91 women) answered the questionnaire (3 physicians, 4 nurses, 28 professional-allied-medicine, 60 health agents, and 11 others). When asked about: the prevalence of epilepsy, 76 (71%) did not know; whether they received any training on epilepsy, 41 had training, but only 11/41 (38%) pointed 1–2% as prevalence rate. None of the physicians and nurses knew how many patients should be under their care. When inquired about how many were they have currently, three did not know and the remaining four claimed to have between 2 and 10 patients.

Conclusion: The primary health care in Amazon does not have a planning for epilepsy management, as epilepsy seems to be an invisible disease. Actions to increase detection as well as provision of treatment are required in the region to bring epilepsy out of the shadows without cutting a tree.

HLA-B’1502 genotyping in carbamazepine induced Stevens Johnson’s syndrome and toxic epidermal necrolysis
S.A. Venkatesan, a, S.M. Rajappa b, aNeurology, Tamilnadu Dr. MGR Medical University, India; bNeurology, Cerebrovascular and Vasculitis Research Foundation, Chennai, India

Background: Stevens Johnson’s Syndrome (SJS) and Toxic Epidermal Necrolysis (TEN) are potentially fatal drug reactions caused by carbamazepine (CBZ). A strong association is reported between HLA-B’1502 allele and CBZ-induced SJS in Han Chinese. The prevalence of HLA-B’1502 and incidence of CBZ induced SJS/TEN in HLA-B’1502 positive seizure patients is reported.

Objective: To study the association of HLA-B’1502 and carbamazepine induced SJS/TEN in epileptic patients from South India.

Methods: Single center, prospective, case control study over four years. 7 ml of blood in ethylene diamine tetra acetic acid (EDTA) was collected from 352 patients on CBZ and 100 controls. After DNA separation, HLA-B’1502 genotyping was performed by Polymerase Chain Reaction amplification and gel electrophoresis, using Olerup HLA-B’1502 kits by Sequence Specific Oligonucleotide method.

Results: 352 seizure patients (165 men and 187 women, mean age: 31.77 years) and 100 controls (50 men and women each, mean age: 32.05 years) were tested for HLA-B’1502. Out of 330 patients on CBZ tested for HLA-B’1502, 66 tested positive and 54 developed SJS/TEN. 2 patients on carbamazepine who tested negative for HLA-B’1502, developed SJS/TEN. Positive Predictive Value for development of SJS/TEN on exposure to CBZ: 81.82%, Negative Predictive Value: 99.30%, Sensitivity: 96.43%, and Specificity: 95.95%. The prevalence of HLA-B’1502 in the epileptic and control groups was 18.20% and 7% respectively.

Conclusion: There is a high prevalence HLA-B’1502 allele in South Indian epileptic population on Carbamazepine (18.20%) when compared to the non-epileptic population (7%). There was a strong association of HLA-B’1502 and the development of SJS/TEN in South Indians.

Autoantibodies to neuronal antigens in children with new onset seizures classified according to the revised ILAE classification
J. Suleiman a, b, c, S. Wright a, D. Gill a, A. Vincent b, B. Lang c, R. Dale d, e
aDiscipline of Paediatrics & Child Health, Sydney Medical School, University of Sydney, Sydney, NSW, Australia; bDepartment of Pediatrics, College of Medicine, United Arab Emirates University, Al Ain, United Arab Emirates; cT.Y. Nelson Department of Neurology, The Children’s Hospital at Westmead, Sydney, NSW, Australia; dNuffield Department of Clinical Neurology, John Radcliffe Hospital, Oxford, UK

Background: Autoantibodies against neuronal antigens are increasingly recognised in many CNS disorders including epilepsy. This includes neuronal surface proteins such as VGKC complex and its components (LG11, CASPR2 and contactin2), NMDAR, GABA,R, AMPAR and glycine receptor (GlyR), as well as intracellular proteins such as GAD.

Objective: We aimed to investigate neuronal antibodies in a cohort of paediatric patients with new onset seizures.

Methods: We prospectively recruited 114 children (2 month to 16 years) with new onset seizures presenting between September

Investigating the gap in the pharmacological treatment of epilepsy in low- and middle-income countries

H. Shah1, A. Stella2, S.L. Moshe3, K. Weerasuriya4, T. Dua4
1Department of Mental Health and Substance Abuse, World Health Organization, Switzerland; 2Previously Affiliated with World Health Organization, Geneva, Switzerland; 3Saul R. Korey Department of Neurology, The Montefiore/Einstein Epilepsy Center, Albert Einstein College of Medicine of Yeshiva University, Bronx, NY, USA; 4Department of Essential Medicines and Health Products, World Health Organization, Geneva, Switzerland

Epilepsy affects more than 50 million people worldwide, with many more affected by its consequences. Nearly 80% of the people with...
epilepsy live in developing regions and the majority of them do not receive appropriate treatment. This treatment gap is partly attributable to the lack of availability of antiepileptic drugs (AEDs). The WHO has developed a Model List of Essential Medicines (WMLEM) designed to prioritize health care needs, improve the drug supply and lower the costs in health care to assist countries in procurement and supply of medicines prioritization.

Aim: To assess to what extent essential AEDs, as recommended in the WMLEM, are present in countries’ Essential Medicine Lists (EML) and review their accessibility at the health system level to develop a comprehensive view of treatment gaps.

A comparative analysis was performed on 109 EMLs of member countries and the corresponding chapter 5 WMLEM to assess quantitative and qualitative differences concerning the essential AEDs.

Phenobarbital was included in the EML of 96% of the responding countries, carbamazepine in 95%, phenytoin in 83%, and valproic acid in 92%. The medications were provided as recommended by the WMLEM in a fraction of these cases: phenobarbital in 12%, carbamazepine in 5%, phenytoin in 3%, and valproic acid in 11%. First-line AEDs were least likely to be included in low-income countries. All medications were more likely to be available in the hospital compared to the health center.

Consistent use and application of WMLEM in guiding national EML development can help improve availability of AEDs.

Objectives: To investigate psychiatric disease and social aspects in men with epilepsy.

Method: This study was based on the Norwegian Mother and Child Cohort Study (MoBa). Information included self-reported diagnoses and validated diagnostic instruments from 71,700 men, who were fathers of children registered in MoBa. Questionnaires were answered around week 18 of pregnancy.

Results: 658 men (mean age 31.8 years) reported epilepsy, 36.9% using antiepileptic drugs (AEDs). Compared to the rest of the MoBa cohort, untreated men with epilepsy more often screened positive for present depression (15.3% vs. 10.3%, p = 0.001), while AED treated men more often had a history of Lifetime Major Depression (15.1% vs. 10.1, p = 0.011). Self-reported ADHD was associated with untreated epilepsy (3.4% vs. 0.4%, p = 0.001), as was bipolar disorder (2.2% vs. 0.3%, p = 0.003), and unspecified psychiatric disorders (5.6% vs. 2.3%, p = 0.008). Unemployment due to disability was linked to both AED treated (9.1% vs. 1.4%, p < 0.001) and untreated epilepsy (2.9% vs. 1.4%, p = 0.009), as were low income (10.3% vs. 5.4, p = 0.031 and 9.7% vs. 5.4%, p = 0.011). Smoking was associated with untreated epilepsy (60.2% vs. 51.8, p = 0.001). No difference was found for lower education level, alcohol use or narcotic use.

Conclusion: Epilepsy in young men is associated with a higher frequency of psychiatric disorders and adverse social aspects, including both AED treated and untreated epilepsy. Our findings indicate that untreated men with epilepsy are a more vulnerable group that may be in need of patient follow up even if they are not using AED.

Safety and efficacy of eslicarbazine acetate (zebinix) in everyday clinical practice using a retrospective multicentre audit
S. Keogh1, P. McDonald2, C. Lawthom3, M.J. Brodie4, B. McLean5, R. Mohanraj6, J. Morrow7, P. Tittensor8, M. Bagary9, 1The Barberry, BSMHFT, Birmingham, UK; 2Royal Gwent Hospital, Gwent, UK; 3Western Infirmary Glasgow, Glasgow, UK; 4Royal Cornwall Hospitals NHS Trust, Cornwall, UK; 5Royal Victoria Hospital Belfast, Belfast, UK; 6Stafford Hospital, Stafford, UK

Background/Objective: We report on the safety and efficacy of Eslicarbazine acetate (ESL) in routine clinical practice.

Method: A retrospective multicentre audit of outcomes following treatment with ESL for localisation-related epilepsy across 7 UK sites (2009–2013).

Results: 202 patients with median values for age 42.5 (17–83) years; duration of epilepsy 16.5 (0–65) years; 2 (0–4) concomitant AEDs, 12 month (2 days–53 months) duration of ESL treatment and 0–12 (64 ≥ 2) previous AED exposures. ESL dosage ranged from 600 to 1600 mg/day. Baseline seizure types comprised secondarily generalised tonic–clonic seizures (78.2%), complex partial seizures (74.3%) and simple partial seizures (23.8%). Psychiatric comorbidity was reported in 30% of patients, mainly depression and anxiety. 105 patients (52%) experienced ≥50% seizure frequency reduction. 40 subjects (19.8%) became seizure free, of whom 26 (65%) had 0–1 previous AED exposures. ESL was discontinued in 70 patients (34.7%) for reasons related to tolerability (n = 43), efficacy (n = 7), both (n = 4) or other (n = 15). Adverse events (AEs) were fatigue (18.8%), dizziness (10%) and disturbance in attention/concentration (9%); all were observed with AED polytherapy. Psychiatric and behavioural AEs (n = 6, 3.0%), included suicidal ideation (n = 1), and led to ESL withdrawal in 2 patients (10%). Hyponatraemia was reported (n = 14, 6.9%) and led to discontinuation in 4 patients (2.0%).

Conclusions: ESL has comparable efficacy to other AEDs for partial-onset seizures with or without secondary generalisation. Discontinuation due to tolerability was related to AED polytherapy. Reported AEs were consistent with ESL’s known safety profile. The benign neuropsychiatric profile with once-daily dosing may convey some advantage in AED selection.

Introduction: Parkinson's disease (PD) is characterized by the progressive loss of nigrostriatal dopamine neurons. Current pharmacotherapies fail to prevent or slow down the disease progression. Although the etiology of PD is presently unknown, major pathogenic processes, which trigger the progressive loss of nigral dopaminergic neurons, are oxidative stress, mitochondrial dysfunction, and inflammatory stimuli. There is less evidence that CB2 receptor agonists can have protective role in brain in response to neuronal damage during PD. In this study we investigated effect of CB2 receptor agonist (HU-308) in 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP) induced PD model in male mice to assess the neuroprotective role of HU-308 in PD progression.

Materials and methods: Male NMRI mice were divided to different groups. The first group received MPTP as control group. The second group was injected with MPTP and then with HU-308 to assess preservation of dopamine function in brain. In the third group, after pretreatment with HU-308, MPTP was injected to assay neuroprotection effect of HU-308.

Result: Behavioral assessment showed significant improvement in the pretreatment group with HU-308. Also Neurochemical analysis that was used to assess dopamine metabolites and immunohistochemistry studies after brain resection showed significant rise in dopamine metabolites, CB2 receptors up-regulation and survival of dopaminergic neurons in the first and second groups as compared with controls in mice's brain.

Conclusion: Our data indicate that CB2 receptors agonist protects against MPTP-induced nigrostriatal degeneration and suggest that CB2 receptors represent a new therapeutic target to slow the degenerative process occurring in PD.

doi:10.1016/j.jns.2013.07.505
Materials and methods: 745 PD patients were randomized to LC or LCE in a 134–208-week double-blind trial. Subset of patients who developed wearing-off before dyskinesia was used for present analysis. Time of onset of wearing-off was used as baseline. Patients were divided into 4 dose groups based on levodopa dose at the time of onset of dyskinesia (or end of study if no dyskinesia): <400 mg, 400 mg, >400-600 mg, and >600 mg. The relationship between levodopa dose and time to dyskinesia was analysed using log-rank test. Hazard ratios (HRs) between LC and LCE were calculated using Cox proportion hazards model.

Results: 244 patients (105 (28%) and 139 (37%) on LCE and LC, respectively) developed wearing-off before dyskinesia. Median time from wearing-off to dyskinesia was 75 weeks among the 244 patients. Time from onset of wearing-off to dyskinesia was correlated with levodopa dose groups (log-rank trend test p = 0.003), patients with high doses having higher risk. However, there was no difference in time to dyskinesia between patients receiving LCE and LC (HR = 1.11, p = 0.618).

Conclusion: Time from onset of wearing-off to dyskinesia was correlated with daily levodopa dose. However, when patients have already developed wearing-off, there was no difference between LCE and LC in time to dyskinesia.

The effect of rTMS on the executive function and bradykinesia in Parkinson’s disease

J. Málly. Neuro Rehabilitation Inst., Sopron, Hungary

rTMS can effect more than one symptom of PD in the same time. The motor symptoms of PD can be influenced by both high and low frequency stimulation. However, the effect on the executive function is not well known, which parameters are optimal.
The goal of the study was to examine the effect of rTMS (5 Hz + 1 Hz) on the executive function and bradykinesia. The rTMS was applied over the dorsolateral prefrontal (DLPF) areas for 7 days. We tested patients (20 PD and 20 control) with a Trail Making Test, double-test, and UPDRS before treatment and one month after treatment. The executive function was measured by the Trail Making Test, which showed a slight correlation with the results of double-test (p = 0.30) in controls. The patients with PD improved after one month in the total and motor score of UPDRS (p < 0.05) and they presented improvement in Trail Making Test and double-test. It seems the stimulation of the DLPF areas by rTMS may improve the executive function parallel with the motor function.

Safety issues of deep brain stimulation therapy for movement disorders: An analysis of a 10-year experience

A. Gamaleya a, b, A. Tomsksiy a, E. Brili a, A. Dekopov a, E. Isagulyan a, A. Bondarensk a, E. Salova a, N. Fedorova b, S. Buklina b, V. Shabalov b, a Burdenko Neurosurgical Institute RAMS, Russia; b Russian Medical Academy of Postgraduate Education, Moscow, Russia

Background: In recent years, DBS became an approved effective treatment for movement disorders, foremost dystonia, Parkinson’s disease (PD), and tremor. DBS commonly presents as quite safe compared to lesioning procedures. However, DBS could be related to different, even life-threatening, complications, limiting usefulness of the therapy.

Objective: To assess the safety of DBS therapy in patients with movement disorders.

Methods: Until 2013, 255 patients were operated for continuous high-frequency DBS — 123 with primary or secondary dystonia, 129 with PD, and 3 with tremor. Age at surgery ranged from 9 to 72 years. Comprehensive analysis of related complications was performed.

Results: In all patients, 579 electrodes were implanted — 279 in globus pallidus internus, 226 in subthalamic nucleus, and 74 in ventrolateral nucleus of thalamus. There were 2 cases of intracranial hemorrhages; one patient remained with a permanent neurological deficit. In two cases, intraoperative seizures occurred. Among technical complications, electrode or connector fractures (7 cases), migration of pulse generator (6), and postsurgical infections (9) were observed. In 38 patients, correction of electrode position was required, and in 5 cases additional electrodes were necessary for optimizing the clinical effect. The most frequent adverse effect of DBS was dysarthria (11%, 28 patients). In 11 cases, the DBS system was permanently explanted due to different reasons. Several correlations were traced.

Conclusion: DBS therapy appears to be a relatively safe procedure for the treatment of movement disorders. Overall level of permanent operation-related disability is low, though neurologist inevitably confronts with unpredictable hardware-related, as well as stimulation-related complications.

Preliminary evaluation of Sensorfoot V1 and Senshand V1 in assessing motor skills performance of Parkinson’s disease patients

C. Maremmani, P. Bongioanni, F. Cavallo, D. Esposito, E. Rovini, M. Aiquilano, M.C. Carrozza, P. Dario, "Neurology, Osp. Carrara, Carrara, Italy; "Neuroscience, Azienda Ospedaliero-Universitaria Pisana, Italy; "NeuroCare Onlus, Italy; "Scuola Superiore Sant’Anna, Pisa, Italy

Background: Up to 10 millions of people are living worldwide with Parkinson’s Disease (PD). To improve diagnosis and treatment, two ICT wearable devices have been developed and tested to achieve an objective assessment of motor performance.

Objective: To evaluate the performances of the Movement Disorder Society-Unified Parkinson’s Disease Rating Scale (MDS-UPDRS) through biomechanical exercises objectively measured by means of a wireless and wearable device for motion recognition, composed by SensorFoot V1 (placed on the foot) and SensHand V1 (fixed on fingers and forearm).

Patients and methods: Ten PD patients (9 men, 1 woman; 67.9 ± 6.9 years; mean disease duration: 4.1 ± 2.8 years; mean Hoehn and Yahr stage: 2.1 ± 0.4; mean MDS-UPDRS score (III): 16.5 ± 6.6; mean L-dopa equivalent daily dose: 513 ± 287 mg) and 5 controls (2 men, 3 women, 64.8 ± 9.1 years) were included. They underwent tremor and motion analysis through exercises for both upper limbs (forearm pronation-supination, hand opening/closing, finger tapping) and lower limbs (foot tapping, rotation and gait). Biomechanical features (frequency, velocity, and angle) have been extracted for each exercise and compared to clinical assessment based on MDS-UPDRS.

Results: Generally, healthy people showed significantly (p < 0.05) more constant repetitive movements and better performances in comparison to patients; good correlations (Pearson’s index k > 0.7) with PD patients’ clinical scores were found.

Conclusion: The technological system has shown a clear potential to positively support neurologist in early diagnosis and clinical assessment of PD patients overtime.

Electric cardioversion in a patient with deep brain stimulation
C. Weber1, D. Haubenberger2, K. Novak3, W. Pirker4, 1Department of Neurology, Medical University of Vienna, Vienna, Austria; 2Department of Neurosurgery, Medical University of Vienna, Vienna, Austria

Deep brain stimulation (DBS) is an established treatment for motor complications in Parkinson’s disease (PD). Many patients with DBS suffer from cardiac comorbidity. Concurrent use of DBS and cardiac pacemakers is reasonably safe when minimizing electromagnetic interference. Electric cardioversion and defibrillation probably confer a higher risk of electromagnetic interference with DBS systems. We report on the effects of external electric cardioversion in a PD patient with bilateral subthalamic DBS. This 59 year old male patient had a 12-years history of PD. In 2007 he underwent DBS surgery with bilateral implantation of quadripolar electrodes (Medtronic 3389) into the subthalamic nucleus and placement of the neurostimulator (Kinetta) into the left abdominal region. In January 2013 the patient underwent aortic valve replacement with the DBS device turned off before and switched on immediately after surgery. On the second postoperative day the patient developed atrial fibrillation which was successfully treated with a bolus of amiodarone and electric cardioversion by a physician unaware of ongoing neurostimulation. Subsequent to progressive worsening of parkinsonism the DBS device was interrogated. The neurostimulator output was found switched off with amplitude set at 0 V and polarity, frequency and pulse width altered. Electrode impedances were unchanged. The neurostimulator could be switched on and reprogrammed. The patient recovered without neurological sequelae. Although defibrillation or cardioversion may damage or cause reprogramming of a neurostimulator, these procedures have to be applied in emergency situations. According to the manufacturer the affected neurostimulator contains filtered feedthroughs and diodes which probably protected the device from damage. doi:10.1016/j.jns.2013.07.514

Use of a respiration sensor to record blink reflex to glabellar tapping in Parkinson disease patients with Myerson’s sign
E. Uematsu1, T. Yoshida1, N. Ueda3, Y. Baba1, S. Koyano3, Y. Suzuki3, Y. Kuroiwa2, 1Neurology, Saiseikai Yokohama-city Nanbu Hospital, Japan; 2Neurology, Yokohama City University Graduate School of Medical Sciences, Yokohama, Japan; 3Neurology, Teikyo University Muzonokuchi Hospital, Kawasaki, Japan

Background: Myerson’s sign (also known as the “glabellar reflex”) is a universally accepted sign of Parkinson’s disease (PD), but its mechanism is still poorly understood.

Objective: In order to investigate the blink reflex in Myerson’s sign-positive and -negative subjects, we used conventional finger tapping of the glabella in conjunction with surface electromyograms (EMGs) of the orbicularis oculi muscle, which were recorded for quantitative electrophysiological assessment.

Patients and methods: The subjects consisted of 9 PD patients with Myerson’s sign (PD/M +), 7 PD patients without Myerson’s sign (PD/M −), and 9 normal controls (NC). A quantitative electrophysiological assessment was conducted on the characteristics of Myerson’s sign in Parkinson’s disease. Surface EMGs of the orbicularis oculi were triggered by a respiration sensor, which detected tapping pressure on the glabella, and were recorded continuously during tapping. Changes in surface EMGs over time with 20 repeated stimuli at a frequency of 2 Hz were compared among the PD/M +, PD/M −, and NC groups. We measured the mean latency and mean R1 and R2 areas in the PD/M + Group.

Results: In the PD/M + Group, reflex blinking caused by glabellar tapping tended to continue, and both the R1 and R2 components tended to continue on the surface EMGs.

Conclusion: The present study confirms that glabellar tapping is a useful diagnostic technique for PD and seems to support previous reports that interneuronal pathways in the brainstem are involved in reflex blinking. doi:10.1016/j.jns.2013.07.515

Frequency of buccopalpebral reflex according to the stage of Parkinson disease

Background: In our observation, eye blinking together with shrinking of lips was observed by the percussion of the upper lip in neurodegenerative diseases such as Parkinson’s disease. This reflex is named as “Bucco-palpebral reflex” (BPR) by us.

Objectives: To investigate frequency of BPR according to the stage of Parkinson Disease and to compare findings of age–sex matched control group.

Patients and methods: 115 patients with Parkinson Disease and 107 control subjects were investigated prospectively. Demographic data and information about Parkinson disease were collected for each patient. Unified Parkinson’s Disease Rating Scale (UPDRS) was used for staging of Parkinson’s disease and BPR was evaluated.

Results: The mean age in patients with Parkinson’s disease was 69.8 ± 8.6. It was 66.8 ± 8.4 in control subjects. BPR frequency of the control group was 3.7%, while those with parkinson’s disease were 13.9%. This difference was statistically significant (p < 0.05). In the analysis of UPDRS sub-groups, activities of daily living sore were 13.3 ± 7.1 in reflex positive group and 9.6 ± 7.7 in reflex negative group. According to the motor score evaluation of BPR positive and negative patients, the motor score was 26.2 ± 13.8 and 19.2 ± 13.0 respectively. These differences were statistically significant (p < 0.05).

Conclusion: BPR mainly observed in neurodegenerative disease such as Parkinson Disease may be is a result of the removal of cortical inhibition; therefore it should be primitive reflex. Since UPDRS scores were higher in BPR positive groups, BPR is frequently seen in more severely affected patients. doi:10.1016/j.jns.2013.07.516

Spinocerebellar ataxia type 36 (SCA36) is an autosomal dominant neurodegenerative disorder caused by a hexanucleotide GGCCTG repeat expansion in intron 1 of the NOP56 gene. SCA36 has been reported from some regions of Japan and Spain, but its occurrence in different populations is unknown. We here performed a large-scale transcontinental assessment of this repeat in a cohort of 676 families excluded for previously known SCAs and originating mostly from France, Germany and Japan. We found SCA36 expansions in nine French and five Japanese index patients, as well as one each from China, Portugal and Spain, thus accounting for 1.9% of all French, 1.5% of Japanese and 0% of German SCAs. Besides long expansions ranging between approximately 800 and 2000 repeats, we found short GGCCTG expansions ranging between 23 and 30 repeats. The expansion was highly unstable as two individuals, one with a long and the other with a short expansion, existed in the same family. Clinically, the cardinal feature was slowly progressive cerebellar ataxia, frequently accompanied by hearing and cognitive impairments, tremor, ptosis, reduced vibration sense and sensory axonal neuropathy with the age at onset ranging between 39 and 65 years. Neuropathology in one asymptomatic French individual disclosed mild losses of Purkinje cells and hypoglossal neurons, suggesting that these neurons are consistently affected from an early stage. We conclude that SCA36, caused by a highly unstable GGCCTG repeat expansion in NOP56, is a rare but global disease with various extra-cerebellar symptoms.

Safinamide is effective as add-on treatment in both early and Advanced PD

R. Anand1, P. Barone6, A. Schapira7, S. Fox8, F. Hubert9, R. Giuliani10, V. Lucini11, 1APC AG, St Mortiz, Switzerland; 2University of Salerno, Salerno, Italy; 3University Department of Clinical Neurosciences, London, UK; 4Toronto Western Hospital, Toronto, ON, Canada; 5Center for Neurological Restoration, Cleveland, OH, USA; 6Neurion Pharmaceuticals SpA, Bresso, Italy

Background: The mechanism of action of safinamide, a new chemical entity, combines both dopaminergic and non-dopaminergic activity in producing benefit in patients with Parkinson’s disease (PD).

Objective: The safety and efficacy of safinamide have been evaluated in patients with Early PD (MOTION trial) as add-on to dopamine-agonist monotherapy, and Advanced PD fluctuations (SETTLE trial) as add-on to l-dopa and other PD medications.

Patients and methods: MOTION study, a 24-week randomized, placebo-controlled trial evaluating efficacy and safety of 50 mg/day and 100 mg/day of safinamide as add-on to a single dopamine-agonist at a stable dose, enrolled 679 patients, within 5 years of diagnosis, who never received l-dopa. SETTLE study, a 24-week randomized, placebo-controlled trial evaluating efficacy and safety of 50–100 mg/day of safinamide as add-on to l-dopa and other PD medications, enrolled 549 patients, with a PD diagnosis of more than 5 years, who presented motor fluctuations. The results for the MOTION study indicated that safinamide of 100 mg/day significantly improves motor symptoms (UPDRS III, p = 0.040), and quality of life (PDQ-39 and EQ5D) compared with placebo in patients taking a single dopamine-agonist (N = 666). The results for the SETTLE study indicated significant superiority of safinamide over placebo for ON time without troublesome dyskinesia (p < 0.001), OFF time (p < 0.001), UPDRS III, PDQ-39, EQ5D, CGI, PGI, and OFF time post first morning dose of l-dopa.

Conclusion: This new results from MOTION and SETTLE studies confirm previously available results from studies in Early PD patients, and Advanced PD patients with motor fluctuations indicating that safinamide is efficacious as add-on treatment at any stage of the disease.

Reduced penetrance alleles of TBP (SCA17) in Indian ataxia cohort: Homozygous mutation and ambiguity of 41–44 CAG/CAA for pathogenic association

A.K. Srivastavab, M. Farucaab, S. Shakya3, P. Negi4, D. Kumar4, N. Kumar4, V. Goyal5, M. Mukerji5, M. Behari5, 5Neurology, All India Institute of Medical Sciences, New Delhi, India; 6Genomics and Molecular Medicine, CSIR—Institute of Genomics and Integrative Biology, Delhi, India; 7Psychiatry, All India Institute of Medical Sciences, New Delhi, India

Background: CAG/CAA expansion mutation in TBP causes spinocerebellar-ataxia 17 (SCA17), characterized by wide spectrum of neurological impairments including cerebellar-ataxia, psychocognitive disturbance, dementia and extrapyramidal signs. The repeats > 48CAG/CAA produce typical SCA17 manifestations whereas 41–44(CAG/CAA) repeats are reduce penetrant alleles and have been documented both in the cases and healthy-controls.

Objective: To analyze the frequency of SCA17 in Indian ataxia cohort.

Subjects and methods: 565 unrelated genetically-uncharacterized spinocerebellar ataxias (UC-SCAs), 355 healthy controls and 228 cases of known SCA-subtypes (Kn-SCA) were analyzed for SCA17-CAG/CAA(TBP) repeat-length. Detailed neurological and psychiatric evaluation was conducted in selected cases with abnormal repeat-length.

Results: We identified 39 UC-SCAs harboring CAG/CAA in the range of 41–46 including a homozygous TBP-CAG/CAA(45/46) expansion mutation in a 43.5 year old female with mild gait-ataxia and dystarthis, prominent blepharospasm, cervical-dystonia, limb-rigidity, dystonia, bilateral nystagmus, pyramidal, and multiple psychiatric impairment with 1.5 years of disease duration. In another case of sporadic ataxia, a 60 year old male with CAG/CAA-37/44 had only moderate degree of cerebellar-ataxia and mild psychiatric impairment. Notably we observed repeat length in the range of 41–44 with 1.6% frequency in pool of controls and Kn-SCA samples whereas UC-SCA category had higher frequency of 3.45% (P value = 0.005).

Conclusion: We report fifth case of homozygous-(TBP-CAG/CAA)45/46 mutation in SCA17 world-over. In our patient-population pathogenic significance of 41–44 is somewhat dilemmatic, although previous studies reported broader disease onset age (19–69 years) in this range of repeats and are associated with variable phenotypes. Further follow-up studies may confirm the pathogenic significance of 41–44 repeats in our study population.

Apomorphine for Morning Akinesia Trial (Am Impakt)

S.H. Isaacson4, J. Hubble5, K. Gulloch6. Parkinss’s Disease and Movement Disorders Center of Boca Raton, Boca Raton, FL, USA; 6US WorldMeds, LLC, Louisville, KY, USA

Background: Morning akinesia, with unreliable or delayed onset of effect of first morning l-dopa dose is a frequent manifestation of motor fluctuations in Parkinson’s disease (PD).
Objective: The primary objective of this study is to assess the effect of subcutaneous bolus apomorphine HCl injection in patients with morning akinesia with lack of predictable effect of first morning l-dopa dosing. A secondary objective is to assess apomorphine's gastric motility effect. The primary outcome compares patient self-reported, diary-recorded Time to On (TTO) following first l-dopa morning dose compared to TTO when using apomorphine each morning. The study will additionally provide data on apomorphine's effects on gastroaresis, an often underdiagnosed, non-motor PD symptom.

Methods: This study will enroll approximately 100 PD subjects across 12 sites. Subjects complete a 7-day Baseline Period recording daily TTO following their regular l-dopa morning dose. Following the Baseline Period, subjects start trimethobenzamide antiemetic therapy and begin APOKYN titration. Once optimal dose is identified, subjects self-inject apomorphine at regularly scheduled l-dopa morning dose time (first l-dopa morning dose is delayed by 40 min) during a 7-day Treatment Period and record TTO following apomorphine injection. Gastric motility sub-study subjects participate in gastric emptying imaging following a standardized meal during the Baseline Period and during the Treatment Period.

Results: Interim analysis of the primary TTO change from baseline endpoint, key secondary endpoints and gastric emptying time results from the sub-study participants will be available in October.

Conclusion: Apomorphine bolus injection may offer an effective treatment for morning akinesia and underlying gastroaresis.

Spinocerebellar ataxia 7 associated with myopathy of tubular aggregates
A. Castro Caldas¹, S. Machado², A.C. Fonseca, T. Evangelista, L. Correia Guedes, L. Albuquerque, M. Coelho. ¹Hospital Santa Maria, University of Lisbon, Portugal; ²Hospital Fernando da Fonseca, Lisbon, Portugal

Introduction: SCA 7 is a spinocerebellar ataxia whose cardinal features are progressive cerebellar ataxia and macular degeneration. Pyramidal signs, ophthalmoplegia and parkinsonism might also be present, however, the association with myopathy is not described.

Case report: A 32-year-old Mozambican male presented with an 8 year history of stable decreased visual acuity associated with progressive dysartria and appendicular and gait incoordination for the last 2 years. Son of non-consanguineous parents, his past medical and family histories were irrelevant even though the current health status of his father is unknown. Head titubation, slow and interrupted saccades at horizontal and vertical gaze, ocular apraxia, moderate dysarthro-hypophonia, severe, appendicular and gait ataxia, dysdiadochokinesia, bilateral positive Holmes sign, negative Romberg test, pathologic exaggerated reflexes without other pyramidal signs nor clinical evidence of myopathy were observed. Ophthalmologic examination showed bilateral maculopathy with bilateral atrophy of macular neuroretina. Brain MRI documented pancerebellar and brainstem atrophy while muscle biopsy of deltoid muscle revealed myopathy of tubular aggregates. The genetic test for SCA 7 was positive with 49 repeats.

Conclusion: We describe the first case of SCA 7 associated with myopathy of tubular aggregates, expanding the classic phenotype of SCA 7. The present case strengthens the importance of considering SCAs in differential diagnosis of sporadic ataxias with adult onset.

Reversible Pisa Syndrome in a patient with Parkinson's disease on rasagiline therapy

Pisa Syndrome (PS), reported also in patients with Parkinson’s disease (PD), is clinically defined as the sustained lateral bending of the trunk, worsened by a prolonged sitting position or by walking. Its pathophysiology is still unexplained. We report a case of reversible PS in a patient with PD improved after rasagiline withdrawal.
A 73-year-old woman with idiopathic PD, diagnosed 6 years before (H&Y stage = 1.5), started to complain of a trunk inclination towards the left that completely relieved by passive mobilization. This was compatible with the diagnosis of PS. This symptom started approximately one year before, when rasagiline was started because of mild motor worsening and wearing-off phenomena. At that moment, the patient was also on pramipexole 1.57 mg/day and levodopa 200 mg/day. EMG in the standing position showed a muscular hyperactivity on bilateral paravertebral muscles, prevailing on the leaning side (left). Muscular hyperactivity did not decrease during contralateral flexion, resulting in a co-activation of left and right paravertebral muscles. No myopathic pattern was observed. As PS started approximately at the same time rasagiline was first prescribed, according to previous reports, we withdrew the MAO-B inhibitor. An improvement of posture was observed within 4 weeks from withdrawal, confirmed by a normalization of EMG traces. The recognition of reversibility of PS during the initial stages of its appearance is of considerable clinical importance, as it facilitates the rapid withdrawal or reintroduction of dopaminergic treatment, avoiding an initial veering towards the chronic irreversible variant.

FRDA is an autosomal recessive neurodegenerative disease characterized by multiple symptoms such as progressive spinocerebellar ataxia, sensory nerve affection, diabetes mellitus and life-limiting hypertrophic cardiomyopathy. FRDA is caused by a GAA-trinucleotide expansion in the frataxin gene located on chromosome locus 9q13 which results in a markedly reduced expression of frataxin, a small mitochondrial protein. Decreased frataxin levels cause iron accumulation in mitochondria, oxidative stress and cell damage. Searching for compounds which could possibly influence frataxin expression we found that the chlorophyllins can significantly increase frataxin expression by still an unknown mechanism. Chlorophyllin (CHL) is a water-soluble mixture of salts of the green plant pigment chlorophyll. CHL currently has a wide range of uses, dietary and medicinal, including being a food colouring agent, a health food additive, an accelerant of wound healing and controlling urinary and faecal odours in geriatric patients. In a wide array of in vitro and in vivo assays, CHL has also been shown to exhibit antimutagenic, antigenotoxic and anticarcinogenic activities against numerous carcinogens. We show for the first time that additional to its protective properties chlorophyllin can increase frataxin expression in vitro and in vivo. Our results provide a scientific basis for a clinical pilot trial examining the effectiveness of this agent for the treatment of FRDA patients.

Patients and methods: We performed translation, cross-cultural adaptation and analysis of the psychometric properties of BARS-B in a sample of 68 adults with ataxia and 38 healthy controls. Analyses of psychometric properties included: structural analysis, reliability analysis (internal consistency and reproducibility) and analysis of the validity of the instrument.

Results: Cross-cultural adaptation resulted in an instrument similar to the original. Structural analysis identified that BARS-B is organized in two factors: gait, limbs and speech scores (one factor) and oculomotor score (a second factor). Reliability analysis showed satisfactory internal consistency (Cronbach’s alpha = 0.84); satisfactory intra-rater and inter-rater reproducibility (intraclass correlation coefficients = 0.96 for both). Content and face validities: the BARS-B’s items contemplated what was intended to be measured. Criterion validity (Pearson’s correlation of BARS-B with the scores of International Cooperative Ataxia Rating Scale—ICARS and Scale for the Assessment and Rating of Ataxia—SARA), showed positive and satisfactory correlations (r = 0.87 and 0.90, respectively). Construct validity (Pearson’s correlation between BARS-B and functional capacity estimated by Barthel index) was satisfactory (r = −0.74). Known-group validity was confirmed by Student’s t test in 68 patients and 38 controls (p < 0.001).

Conclusion: BARS-B is a reliable and valid instrument for the assessment of ataxia.

Postencephalitic parkinsonism — case report
C. Falup-Pecurariu, M. Moarcaș, M. Bustan, R. Chiperi, R. Alexandru.
*Department of Neurology, County Emergency University Hospital, Romania; 
Faculty of Medicine, Transilvania University, Brasov, Romania

**Background:** Infection is a rare cause of parkinsonism. Postencephalitic parkinsonism is encountered very rare nowadays and may appear as an early or late complication of encephalitis.

**Objectives:** The aim is to present a case report of a 45 year old woman with postencephalitic parkinsonism.

**Method:** The patient was diagnosed at the age of 26 years with midbrain encephalitis, that had an acute onset with gait disturbance, loss of balance, somnolence, vomiting, oculogyric crises and inflammatory CSF.

**Results:** After 4 weeks there was an onset of bilateral rest hand tremor and bradykinesia. Neurological exam showed bilateral parkinsonism. The lab exams that were performed and CT-scan were repeatedly normal. There was an initiated antiparkinsonian treatment with Trihexyphenidylum, followed by Amantadine with mild improvement of tremor.

**Conclusion:** Postencephalitic parkinsonism in this case report had low or no response to antiparkinsonian treatment. Long-term follow-up shows no significant motor worsening.

Helicobacter pylori and small intestinal bacterial overgrowth in Parkinson’s disease: Prevalence and clinical significance
*University of Malaya, Kuala Lumpur, Malaysia; University Kebangsaan Malaysia, Kuala Lumpur, Malaysia; Monash University, Victoria, VIC, Australia; University of Toronto, Toronto, ON, Canada

**Background:** A high prevalence of Helicobacter pylori infection (HPI) and small intestinal bacterial overgrowth (SIBO) has been reported in Parkinson’s disease (PD), but with unclear clinical significance.

**Objective:** To study the prevalence and impact of gut infections on gastrointestinal (GI) symptoms and motor function in PD patients.

**Patients and methods:** 74 patients (with and without motor fluctuations) underwent 13C urea and lactulose-hydrogen breath tests. Upper and lower GI symptoms were evaluated using the Leeds Dyspepsia Questionnaire and the Global Symptomatic Score. On-medication motor function was assessed using the Unified Parkinson’s Disease Rating Scale (UPDRS), and timed tests of gait and upper limb function (14-metre fast walk and Purdue pegboard).

**Results:** HPI and SIBO were detected in 32% and 21% of patients, respectively. There were no between-group (breath test positive vs. negative) differences in GI symptoms scores. HPI + patients had worse UPDRS scores (total = 61.1 vs. 47.2, p = 0.004; part III = 34.4 vs. 27.4, p = 0.019) and worse scores on the timed tests (38.1 vs. 27.9 steps, p = 0.025; 62 vs. 82 pins, p = 0.013) compared with HP-patients. A similar (non-significant) trend was seen with SIBO.

**Conclusion:** HPI was detected in one-third of the patients, but we found a lower prevalence of SIBO than what was reported previously. These infections were not associated with GI symptoms. The association between HPI and worse motor function has important clinical implications and should be confirmed with a larger sample size, and by studying the effects of eradication therapy.

Apoptosis in peripheral blood lymphocytes of patients with LRRK2-associated Parkinson’s disease
*Petersburg Nuclear Physics Institute, INAS, Russia; Pavlov’s State Medical University of Saint Petersburg, Saint Petersburg, Russia

**LRRK2 mutations are the most frequent cause of familial Parkinson’s disease (PD). Although the precise physiological and pathological role of LRRK2 is unclear, direct link between mutant LRRK2 and apoptosis has been suggested. The aim of our work was to estimate apoptosis rate, FAS and BCL-2 mRNA levels and the caspase-8 and caspase-9 activation in peripheral blood lymphocytes (PBLs) of patients with LRRK2-associated PD. Apoptosis of PBLs was estimated using flow cytometric analysis stained by annexin V-FITC-PI; FAS and BCL-2 mRNA levels were estimated by RT-PCR with TagMan probes (internal control — the level of G protein
Background: Central cholinergic dysfunction has been reported in patients with Parkinson’s disease (PD) and hallucinations by evaluating short latency afferent inhibition (SAI), a transcranial magnetic stimulation protocol which gives the possibility to test an inhibitory cholinergic circuit in the human brain. REM sleep behavior disorder (RBD) was also found to be associated with cognitive impairment in PD patients.

Objective: The objective of the study was to assess the cholinergic function, as measured by SAI, in PD patients with RBD (PD-RBD) and PD patients without RBD (PD-nRBD).

Materials and methods: We applied the SAI technique in 10 PD-RBD patients, in 13 PD-nRBD patients and in 15 age-matched normal controls. All PD patients and control subjects also underwent a comprehensive battery of neuropsychological tests.

Results: Mean SAI was significantly reduced in PD-RBD patients when compared with PD-nRBD patients and controls. Neuropsychological examination showed mild cognitive impairment in 9 out of the 10 PD-RBD patients, and in 5 out of the 13 PD-nRBD. SAI values correlated positively with neuropsychological tests measuring episodic verbal memory, executive functions, visuoconstructional and visuospatial abilities.

Conclusion: Similar to that previously reported in the idiopathic form of RBD, SAI abnormalities suggest a cholinergic dysfunction in PD patients who develop cognitive impairment, and present findings indicate that LRRK2 mutations may lead to the activation of apoptosis pathway with predominant activation caspase-9 and increased FAS expression in patients with LRRK2-associated PD.

Functional evaluation of central cholinergic circuits in patients with REM sleep behavior disorder and Parkinson’s disease: A TMS study

A.B. Kunz, S.M. Golaszewski, J. Bergmann, F. Brigo, M. Christova, M. Seidt, F. Tezzon, E. Trinka, R. Nardone, A. Department of Neurology, Paracelsus Medical University, Christian-Doppler-Klinik, Salzburg, Austria; bKarl Landsteiner Institute of Neurorehabilitation and Space Neurology, Vienna, Austria; cNeuroscience Institute, Salzburg, Austria; dDepartment of Neurology, Franz Tappeiner Hospital, Merano, Italy; eInstitute of Physiology, Medical University Graz, Graz, Austria

Depressive symptoms frequently occur in patients with Parkinson’s disease (PD) but their pathogenesis is not fully understood although neurochemical deficits and structural changes have been suggested. Both striatal and extra-striatal dopaminergic deficits could play a major role although results on striatal dopamine transporter (DAT) density are conflicting.

To assess without an a priori hypothesis the extrastriatal DAT availability by using SPM on 123I-FP-CIT SPECT images in a population of PD patients and depression (PD-d), and a population of PD patients without depression (PD-nd).

20 PD-d (mean age = 63.7 years ± 11.0; UPDRS III at SPECT scan = 17.6 ± 7.4); 35 PD-nd (mean age = 67.6 years ± 9.0; UPDRS III at SPECT scan = 19.6 ± 9.07) performed a 123I-FP-CIT SPECT. Depression was diagnosed according to DSM-IV criteria and assessed by Beck Depression Inventory (BDI) (PD-d: 15 ± 2.9; PD-nd: 2 ± 3.4). SPM2 and VOI analyses were then used for group comparisons and correlations. A cluster, with statistically significant (p < 0.05) lower binding FP-CIT in PD-d with respect to PD-nd patients was found in right cingulate cortex, persistent after correction for age, disease severity and duration. When VOIs were correlated with BDI scores in the whole group, an inverse correlation in the right cingulate was observed (r = −0.367, p < 0.01).

Our data indicate no differences in striatal dopaminergic denervation in PD with and without depression. As regards to extra-striatal areas a significant association between depression and cingulate dopaminergic denervation was observed, confirming the dopaminergic hypothesis of PD-depression.

Incomplete suppression of head stabilization in idiopathic spasmodic torticollis and Parkinson’s disease

D. Anastasopoulos, C. Maurer, T. Mergner, University of Athens, Athens, Greece; bNeurology, University of Freiburg, Freiburg im Breisgau, Germany

Objective: Sensorimotor integration may be impaired in idiopathic spasmodic torticollis (ST) and other focal dystonias. Also, voluntary interaction with postural reflexes has been shown to be disrupted in ST patients. The way these deficiencies may contribute to the impaired head position control remains however unidentified.

Patients and methods: Thirteen ST patients and 23 healthy controls were subjected to unpredictable, transient, low amplitude, low velocity head-on-trunk, trunk-under-head and whole-body rotations in the horizontal plane. With the instruction not to resist the imposed displacements, resistance to horizontal neck deflections was evaluated.

Results: Patients exhibited a torque offset (bias) in the direction of torticollis before stimulus application. While controls reduced the initial resistance to head-to-trunk rotations within a few hundreds of milliseconds, torque exerted by ST patients increased throughout displacements. The increase of resistance relative to baseline in patients was, however, symmetrical, i.e. independent of the torticollis direction.
Spontaneous torque variations were significantly larger in patients. Strong correlations existed among these abnormal findings.

**Conclusions:** The deficient ST patients’ ability to manipulate normal postural reactions is attributed to impairments of a long-latency slow feedback mechanism. Modeling of this suppressive mechanism suggested further that patients may also have difficulties in switching between feedforward and sensory-driven motor control. Similar findings have been obtained from studying parkinsonian patients with axial rigidity. Differences in impairment patterns between the two groups help to understand altered sensorimotor control in basal ganglia disease leading to rigidity and abnormal postures.

**Objectives:** To assess the diagnostic efficacy data from clinical trial Kupsch et al, 2012 (data not previously published) conducted using DaTSCAN™ ([123I]Ioflupane Injection).

**Patients and methods:** Study imaging group (n = 92) was used to assess the diagnostic accuracy of DaTSCAN™ in subjects with early, clinically uncertain Parkinsonian syndromes (PS) after 1 year follow-up. The reference standard was final clinical diagnosis 1 year after imaging (with DaTSCAN™ results available), and it was compared to baseline clinical diagnosis (without DaTSCAN™) and to baseline imaging diagnosis. Visual assessment of DaTSCAN™ images was performed by local nuclear medicine physicians, which is consistent with current clinical practice. Acquisition of SPECT data with DaTSCAN™ and their reconstruction were performed using a standardized imaging protocol.

**Results:** The sensitivity of clinical diagnoses at baseline using clinical data was 92% when compared to final clinical diagnosis at 1 year, but the specificity was only 52.4%. For the comparison of baseline DaTSCAN™ images to the clinical diagnosis at 1 year, the sensitivity was 93.9%; specificity was 95.4% (p = 0.0005 as compared to baseline clinical diagnosis). The PPV, NPV and diagnostic accuracy for baseline clinical diagnosis or baseline imaging diagnosis vs. final clinical diagnosis at 1 year (reference standard) were respectively: 69.7% vs. 95.8% (p < 0.0001), 84.6% vs. 93.2%, and 73.9% vs. 94.6%.

**Conclusion:** High sensitivity and specificity, PPV, NPV and diagnostic accuracy of DaTSCAN™ in diagnosis of early clinically uncertain PS were demonstrated. Performance of DaTSCAN™ compares favorably in this study to the performance of clinical diagnosis relative to final clinical diagnosis.

Voiding function is correlated with motor severity in patients with Parkinson’s disease

H. Tatenob, T. Uchiyamab, C. Shibitac, Y. Higuchib, Z. Liu, T. Yamamotob, T. Ito, M. Yanagisawac, Y. Higuchid, M. Fusa, T. Kamaj, T. Yamanishib, R. Sakakibara, K. Hirata, S. Kuwabara, T. Yamanishib, T. Ito, M. Yanagisawac, Y. Higuchib, M. Fusa, T. Kamaj, T. Yamanishib, R. Sakakibara, K. Hirata, S. Kuwabara. 1st Department of Neurology, Dokkyo Medical University, Tochigi, Japan; 2Neurology and Continence Center, Dokkyo Medical University, Tochigi, Japan; 3Department of Neurology, Chiba University Graduate School of Medicine, Chiba, Japan; 4Department of Neurosurgery, Chiba University Graduate School of Medicine, Chiba, Japan; 5Department of Neurology, Chiba University Graduate School of Medicine, Chiba, Japan; 6Department of Neurology, Chiba University Graduate School of Medicine, Chiba, Japan; 7Department of Urology, Chiba University Graduate School of Medicine, Chiba, Japan; 8Neurology Division, Department of Internal Medicine, Sakura Medical Center, Toho University, Chiba, Japan

Background: Patients with Parkinson’s disease (PD) have not only motor impairment but also lower urinary tract dysfunction. Among lower urinary tract symptoms, storage symptoms/disorders are the most common and well known. However, the detail of voiding symptom/disorder is less clear.

Objective: We present a detailed data from an urodynamic-pressure-flow measurement which can evaluate both bladder contractility and outlet obstruction during voiding in PD patients, with particular attention to the interrelation between the questionnaire items, the urodynamic parameters, and the clinical characteristics.

Patients and methods: 114 consecutive patients with PD were recruited. The studied patients consisted in 48 de novo patients, 30 patients without motor fluctuations, and 36 patients with motor fluctuations.

Results: Lower urinary tract symptoms were found in 86.0% patients and abnormal UDS findings in 91.2%. During storage, detrusor overactivity (65.8%) and increased bladder sensation (13.2%) were shown. During voiding, 55.3% showed detrusor underactivity (DU), 18.4% showed bladder outlet obstruction (BOO), resulting in decrease in maximum flow rate (38.6%) and presence of 50–100 ml post-void residual (PVR) (13.2%). In multivariate analyses, urinary urgency, urge incontinence and hesitancy correlated with disease severity. DU, decreased maximum flow rate and PVR correlated with disease severity, while detrusor overactivity and BOO with gender. Night-time frequency, urinary urgency or urge incontinence impaired quality of life (QOL) in cooperation with disease severity, while prolongation or feeling of incomplete affected QOL by itself.

Conclusion: In PD patients, detrusor underactivity and related voiding parameters were correlated with motor severity and some voiding symptoms affected QOL by itself.

Nocturnal blood pressure, non-dipping and psychosis in Parkinson’s disease

E. Stuebner, E. Vichayanratb, c, D.A. Lowc, C.J. Mathiasb, c, S. Isenmann, C.-A. Haensch. 1Department of Neurology and Clinical Neurophysiology, Autonomic Laboratory, University of Witten/Herdecke, Faculty of Health, HELIOS-Klinikum Wuppertal, Wuppertal, Germany; 2Autonomic and Neurovascular Medicine Unit, Division of Brain Sciences, Faculty of Medicine, Imperial College London at St Mary’s Hospital, UK; 3Autonomic Unit, National Hospital for Neurology and Neurosurgery, Queen Square/ Division of Clinical Neurology, Institute of Neurology, University College London, London, UK

Background: Nocturnal hypertension, non-dipping and psychosis in Parkinson’s disease (PD) have been commonly reported. The mechanism of nocturnal hypertension is not clearly understood yet. The aim of this study is to evaluate the relationship between nocturnal blood pressure, non-dipping and psychosis in PD.

Patients and methods: Sixty-five PD patients who underwent bilateral STN-DBS were enrolled. Nocturnal blood pressure was measured using the photoplethysmography. The average values during upright position (was) and supine position (sup) were calculated as was-sup. The proportion of non-dippers was calculated as the ratio of sup/ was-sup. Psychosis was graded according to the subscale of the Scale for the Assessment of Positive Symptoms (SAPS) and subscale of the Scale for the Assessment of Negative Symptoms (SANS).

Results: The proportion of non-dippers was 77% in PD patients, 38% in age- and sex-matched healthy volunteers and 40% in age- and sex-matched PD patients without STN-DBS. The proportion of non-dippers in patients with psychosis was significantly higher than that in patients without psychosis (90% vs 72%, P = 0.045). The proportion of non-dippers in patients with psychosis was also higher than that in patients without psychosis (89% vs 68%, P = 0.044).

Conclusion: Nocturnal hypertension, non-dipping and psychosis in PD patients was significantly higher than that in age- and sex-matched healthy volunteers and age- and sex-matched PD patients without STN-DBS. The mechanism of nocturnal hypertension in PD patients is not clearly understood yet.
Objective: The aim of this study was to determine the relationship between 24 h ambulatory BP measurements (ABPM), e.g., absence or presence of nocturnal dipping, and psychosis in PD.

Methods: 21 patients with PD (15 male, 6 female, disease duration 9 ± 7.4 years) underwent 24 h ABPM using an autonomic protocol and self-report diary. A decrease in nocturnal (time asleep, as indicated in diary) mean arterial blood pressure (MAP) of less than 10% was defined as non-dipping. Patients were interviewed (including the Brief Psychiatric Rating Scale; BPRS) for the assessment of psychosis. Patients had a mean levodopa equivalent dose (LED) of 422. All patients slept at least 4 h through the night.

Results: 11 patients were dippers and 10 were non-dippers. BPRS scores were higher in non-dippers vs dippers and non-dippers on average met the criteria for psychosis (mean non-dipper BPRS: 34.3 ± 7.3 vs mean dipper BPRS: 27.5 ± 5.3; cut off for “mildly ill” 31). There was a correlation (r = .488) between BPRS scores and non-dipping (percentage of day/awake and at night/ asleep MAP difference) indicating that those patients who had a blunted nocturnal fall in BP were more prone to psychosis or psychotic symptoms. (Pearson’s Correlation = .423, p = .025).

Conclusion: These results suggest that PD patients who show a blunted circadian BP rhythm are more likely to develop psychosis than those whose BP decreases normally at night. Reasons for the pathological loss of nocturnal BP fall and psychological symptoms warrant further evaluation.

Orthostatic tremor, progressive external ophthalmoplegia and \textit{twinkle} mutation

M. Milone\textsuperscript{a}, B.T. Klassen\textsuperscript{b}, M.L. Landsverk\textsuperscript{b}, R.H. Haas\textsuperscript{c}, L.-J. Wong\textsuperscript{b},
\textsuperscript{a}Neurology, Mayo Clinic, Rochester, MN, USA; \textsuperscript{b}Molecular and Human Genetics, Baylor College of Medicine, Houston, TX, USA; \textsuperscript{c}Neurosciences and Pediatrics, University of California San Diego, San Diego, CA, USA

Background: Orthostatic tremor (OT) is characterized by 13–18 Hz tremor occurring in standing position and has unknown pathophysiological mechanism. OT is thought to be sporadic, but siblings with OT from 3 unrelated families have been reported. Mutations in \textit{TWINKLE} can result in autosomal dominant progressive external ophthalmoplegia (PEO) and have been associated with Parkinsonism in rare cases.

Objective: To identify the molecular defect of a patient with OT and PEO.

Patient and methods: A 69-year-old man manifested ptosis and OT at age 37 years, followed by PEO and limb fatigue. His father had ptosis; a sister and a son have ptosis and PEO. EMG/nerve conduction and multichannel surface EMG recordings, muscle biopsy, brain MRI and MR spectroscopy (MRS), sequencing of all coding exons and flanking introns of \textit{TWINKLE}, POLG and \textit{ANT1} were performed.

Results: Patient had electrophysiological evidence for a mild myopathy and sensorimotor peripheral neuropathy. Polysynaptic recordings showed orthostatic synchronous 17.5 Hz tremor in the leg muscles spreading to lumbar paraspinal and arm muscles. There was no rest tremor and no evidence for parkinsonism. Brain MRI/MRS showed mild generalized atrophy. Scattered ragged-red fibers were present on muscle biopsy. Gene analysis revealed a novel heterozygous missense mutation at an evolutionarily conserved residue of \textit{TWINKLE}. The affected sister and son carry the same variant.

Conclusions: Although one cannot exclude the incidental association of OT and \textit{TWINKLE} mutation, the simultaneous onset of OT and ptosis at a younger age than usually observed raises the possibility of mitochondrial dysfunction in the pathogenesis of OT.

Neurological disorders of HTLV-1 carriers patients taken care of on the clinic of neurology of the FBDC HTLV center

M.S. Varjão\textsuperscript{a}, D.D.B. Alves\textsuperscript{b}, A. Andrade Filho\textsuperscript{b}, B.G. Castro Filho\textsuperscript{b},
\textsuperscript{a}Foundation of Neurology and Neurosurgery, University Federal of Bahia, Salvador, Brazil; \textsuperscript{b}School of Medicine Bahiana and Public Health, University Federal of Bahia, Salvador, Brazil; \textsuperscript{c}Neuroscience and Mental Health, University Federal of Bahia, Salvador, Brazil

In this study they described the neurological disorders of 116 carrying patients of the Human T Cell Lymphotropic Virus type 1 (HTLV-1) taken
care of in the Clinic of Neurology of the FBDC HTLV Center, from the following question: which were the disorders and neurological states found in the patients of the Clinic of Neurology of the FBDC HTLV Center between September of 2005 and August of 2006? To reach this purpose was carried through, using medical record analysis (documentary analysis) and the neurological examination. The more frequent neurological disorders had been paresthesia, hyperactive patellar reflex, lumbar pain, intestinal dysfunction, muscular weakness of lower limbs and urinary disturbances. Considering these disorders, 50 patients with HAM/TSP, 39 oligosymptomatic and 27 asymptomatic had been identified. The diagnosis of most of the patients was made between 1 and 8 years after the beginning of the symptoms. With these results, the expectation of the authors consists on the propagation of attendance programs to the HTLV-1 carrying patients with neurological disorders.

Disautonomic disturbances as the main initial clinical presentation of multiple system atrophy syndrome
M. Sierra-Beltrán, C.M. Hernández-Cárdenas, LL. Romero-Flores, C.D. Castillo-Hernández. Neurology and Psychiatry, Medica Sur Hospital, Mexico City, Mexico; Critical Care Medicine, INCNMSN, Medica Sur Hospital, Mexico City, Mexico; Gastroenterology Department, Medica Sur Hospital, Mexico City, Mexico; Neurophysiology, Medica Sur Hospital, Mexico City, Mexico

Background: It has been previously reported a case in which the main initial presentation of multiple system atrophy syndrome is preceding cognitive impairment and extrapyramidal signs.

Objective: To present a series of cases of 3 patients, with multiple system atrophy syndrome who developed prior to cognitive impairment and extrapyramidal signs recurrent syncope as initial clinical feature.

Material and methods: Neuropsychological (autonomic function) tests, magnetic resonance image and neuropsychological examinations were required.

Results: Each patient’s clinical history bore a common feature, a history of recurrent syncope and fainting. This lasted ten to fifteen years prior to mild cognitive impairment and in one case two extrapyramidal signs rather than cognitive impairment. These late cases proved to have both parasympathetic and sympathetic function alterations. It is extremely rare that these dysautonomia present as an initial clinical feature multiple system atrophy.

Cerebellar dysfunction is closely related to cognitive decline in Uner Tan syndrome
U. Tan, Cukurova University, Adana, Turkey

Background: Uner Tan syndrome (UTS), first reported in 2005, consists of habitual quadrapedalism, mental retardation and dysarthric or no speech, accompanied with cerebellar hypoplasia and mild gyral simplification of the cerebral cortex.

Objective: To investigate the relation of the cerebellar dysfunctions to cognitive functions in UTS cases.

Subjects and methods: The patients (n = 6) were recruited from a family with 17 siblings, constituting a homogeneous group. Cognitive ability was assessed using the Wechsler Adult Intelligence Scale-Revised (WAIS-R) and the Minimental State Examination Test (MMSE). To evaluate cerebellar ataxia symptoms, the ICARS (International Cooperative Ataxia Rating Scale) including subscales postural, kinetic, speech, and oculomotor disorders was used, being examined in relation to IQ test scores.

Results: Age was not significantly associated with ICARS, WAIS-R, and MMSE test scores. Higher ICAR scores indicated higher degrees of cerebellar impairment including the postural, kinetic, speech, and oculomotor disorders. The total ICARS ranged between 36 and 85, being close to maximal ICARS of 100. The scores for the ICARS subscales were also within the highest ranges. The Pearson correlation coefficients indicated highly significant negative linear correlations of the WAIS-R and MMSE test scores with ICARS including its subscales, the postural, kinetic, speech, and oculomotor disorders.

Conclusion: The results suggested that the impaired cognition in UTS cases may be caused by the cerebellar ataxia symptoms, such as postural, kinetic, speech, and oculomotor dysfunctions.

Alcohol challenge and the sensitivity to change of the essential tremor rating assessment scale (TETRAS)
B. Vollert, E. Lines, G. McCrossin, A. Artiles, S. Tinaz, M. Lungu, M. Hallett, D. Haubenberger. Human Motor Control Section, Medical Neurology Branch, NIH, Bethesda, MD, USA; Department of Neurology, Medical University of Vienna, Wien, Austria

Background: The performance scale of The Essential Tremor (ET) Rating Assessment Scale (TETRAS) has excellent inter- and intrarater reliability. Information on the ability to detect change is scarce.

Objective: We evaluated the sensitivity to change during a standardized ethanol challenge by comparing TETRAS with standard postural tremor accelerometry.

Patients and methods: A single oral ethanol dose calculated to reach 0.05 g/dl breath alcohol content (brAC) was given to 15 adult ET patients on two separate days. Postural tremor accelerometry was assessed on one day, TETRAS on the other. Measures including brAC readings were taken at 8 time-points (2 time-points pre, 6 time-points, every 20 min, up to 2 h post ethanol).

Results: Accelerometry data was log-transformed, and a cumulative score logACC(r + l) was calculated. Correlation between logACC(r + l) and TETRAS was significant. rmANOVA of TETRAS and logACC(r + l) showed a significant effect of time-point before and after ethanol. There was no difference between the two baseline measures with corrected post-hoc tests, whereas there was a difference between baseline and each following time-point. TETRAS and brAC were significantly correlated. BrAC measurements of the two study days showed neither a significant difference over time nor at the time-point of maximum effect.

Conclusions: Sensitivity to change of the TETRAS performance scale was shown after a pharmacologic intervention. Furthermore, the excellent reproducibility of the alcohol challenge could be of importance for further studies. The ability of TETRAS in demonstrating response after a treatment intervention establishes its potential as valid instrument for both clinical and research settings.

Diagnostic exome sequencing in neurological disorders  

G.J. Braathen a,b,c, O.L. Holla a, O.L. Busk a, C.F. Skjeldbakk a, aDepartment of Laboratory Medicine, Section of Medical Genetics, Telemark Hospital, Skien, Norway; bHead and Neck Research Group, Research Centre, Akerhuse University Hospital, Lørenskog, Norway; cCampus AHUS, Akerhus University Hospital, University of Oslo, Nordbyhagen, Norway

Background: Next generation sequencing (NGS) or high throughput sequencing has for the last years been used routinely in genetic diagnostics at Telemark Hospital. Targeted NGS with panels for several genes contributes diagnostically to inherited neurological disorders such as Charcot–Marie–Tooth disease, distal Hereditary Motor Neuronopathy, Hereditary Spastic Paraplegia and Neurofibromatosis. In addition, NGS exome sequencing, i.e. sequencing of all exons, may identify pathogenic, disease causing mutations.

Material and methods: Exome NGS sequencing was performed in a patient with movement disorder to identify pathogenic mutations. A probable clinical diagnosis and mode of inheritance is a necessary tool for successful exome NGS. This case was sporadic. Hence, the alternatives are de novo mutation or autosomal recessive inheritance. Inheritance and phenotype aid the bioinformatic analysis to more easily elaborate the genes that are most relevant regarding the symptomatology. The bioinformatic platform consists of CASAVA, bwa, GATK, BEDtools and Annovar. Normal sequence variants from dbSNP129 are removed before annotation. Variants described in Exome Sequencing Project, 1000 genomes and databases over variants detected in normal in-house controls are used to clarify individual variant pathogenicity. The remaining, unexplained sequence variants are elaborated manually with Alamut, Human Genome Mutation Database and other prediction tools. All assumed pathogenic mutations identified by exome NGS are confirmed with Sanger sequencing.

Results: The identified mutation confirms the clinical neurological diagnosis.

Conclusion: The case is presented to elucidate the utility and versatility of exome NGS as a method also in more ordinary neurological disorders and not only restricted to syndromes or intellectual disability.

IRX4204 As a novel disease-modifying compound for treatment of Parkinson's disease  

G.M. Pasinetti. Neurology, Icahn School of Medicine at Mount Sinai, New York, NY, USA

Background: IRX4204 is a second generation retinoid × receptor (RXR) agonist currently being tested for prostate cancer treatment with an excellent safety record. Nurr1-RXR heterodimer selective agonists have been actively pursued as a potential pharmacological target for Parkinson's disease (PD) due to their neuroprotective effects in models of PD.

Objective: The objective of our study is to evaluate the effects of IRX4204 as a potential novel therapeutic in PD neuropathology.

Materials and methods: Primary rat mesencephalic cultures were used to study the role of IRX4204 on Nurr1-mediated neuroprotection. The 6-hydroxydopamine (6OHDA) induced rat model of PD was used to examine the potential neuroprotective role IRX4204 on PD pathology. Nuclear magnetic resonance (NMR) and photo-induced cross-linking of unmodified protein (PICUP) were used to evaluate the role IRX4204 on prevention of α-synuclein binding and oligomerization.

Results: We found that IRX4204 can selectively promote dimerization of the nuclear factor Nurr1-RXR at nM concentration in vitro and can promote expression of neurotrophic factors for the survival and maintenance of nigral dopaminergic (DA) neurons in a dose-dependent manner in vivo. This evidence is consistent with a significant attenuation of PD-type motor impairments following 6-OHDA lesions in response to IRX4204. Using a combination of NMR spectroscopy and PICUP assays, we found that IRX4204 shifts and prevents oligomerization of α-synuclein.

Conclusion: Our data suggest that IRX4204 may benefit PD by providing neuroprotective support for DA neurons and by protecting DA neurons from α-synuclein neurotoxicity.

The role of transplant in the treatment of acquired hepatocerebral degeneration and hepatic encephalopathy  

J.P. Domingos a,b, J.E. Alves c, S. Cavaco b, S. Ferreira d, V. Lopes d, J.P. Pereira a, B. Moreira a,b, H.P. Miranda e, M. Magalhães a, Neurology, Centro Hospitalar Porto — Hospital de Santo António, Portugal; bNeurorehabilitation, Centro Hospitalar do Porto — Hospital de Santo António, Porto, Portugal; cLaboratory of Neurobiology of Human Behavior, Centro Hospitalar do Porto — Hospital de Santo António, Porto, Portugal; dHepatology, Centro Hospitalar do Porto — Hospital de Santo António, Porto, Portugal

Background: Encephalopathy (HE) and acquired hepatocerebral degeneration (AHD) have been described in patients with advanced liver disease (ALD).

Objective: We aimed to describe two patients’ evolution pre and post-liver transplant (LT).

Patients and methods: We reviewed clinical, neuropsychological and neuroimaging data (pre/post LT) from 2 ALD patients.

Results: 1. 67-year-old male, HCV cirrhosis, cognitive complaints since the age of 61. At 63 yo he had cognitive impairment, parkinsonian and dystonic syndrome and later oculomotor dysfunction. Brain MR showed discrete symmetric T1 hyperintensity in globi pallidi and putamina and bilateral T2 hyperintensity along the corticospinal tract. At 65 yo he was submitted to LT with progressive improvement. Seven months later he had no extrapyramidal signs, cognition improved and MR became normal.

2. 49-year-old female, alcoholic cirrhosis admitted with severe acute HE (altered consciousness – drowsy – without focal neurological signs). Brain MR showed multiple areas of T2 hyperintensity in fronto-parieto-occipital cortex, with restriction in water diffusion, cortical expansion and T1 hyperintensity in globi pallidi and red nuclei. Emergent LT was performed. She became awake. Extrapyramidal features and cognitive impairment took long to recover. One month later MR showed marked improvement of cortical T2 hyperintensities, persisting slight pallidal T1 hyperintensities. Four months later a complete resolution of T1 and T2 grey matter hiperintensities occurred with residual peritrigonal white matter T2 hyperintensity with cortical atrophy.

Conclusion: AHD and HE are entities with distinct clinical and imagiological features that might be reversed by LT.

The missing tau mutation: +15 exon 10/intron 10 boundary of MAPT stem loop structure in an Irish family with FTDP-17

Background: Up to 40% of families with autosomal dominant fronto-temporal dementia with parkinsonism (AD FTDP-17) carry pathogenic 5' splice site mutations in the Microtubule-Associated Protein Tau (MAPT) gene. Several stem-loop mutations of tau exon 10 were identified, but the +15 mutation remained elusive.

Aim: We present a family with the 'missing' +15 mutation.

Discussion: In 1998, Hutton described 5' splice site mutations in the Microtubule-Associated Protein Tau (MAPT) gene. Several stem-loop mutations of tau exon 10 were identified, but the +15 mutation remained elusive.

Conclusion: We found this case worth reporting because of the rare presentation of Parkinson's disease in the literature with orthostatic symptoms as a first sign.

Extrapontine myelinolysis with sudden-onset generalised chorea
D. Petrenicova, M. Kucharik, M. Saling, 2nd Dept. of Neurology, Faculty of Medicine, Comenius University, University Hospital Bratislava, Bratislava, Slovak Republic

Objective: Pontine myelinolysis has been well described in the presence of rapid correction of hyponatraemia for decades. Both pontine and more rare extrapontine myelinolysis is considered as an iatrogenic syndrome following rapid correction of hyponatraemia leading to rapid changes in osmolality. However, it occurs also in various other medical conditions. Patients with chronic hyponatraemia are more prone to develop myelinolysis. It is also not so rare complication of haemodialysis.

Patients and methods: We present a case of 67-year old male with the history of diabetic nephropathy and nephrosclerosis on peritoneal dialysis with progressively worsening generalised chorea. Laboratory results showed mild hyponatraemia and severe uraemia. CT of brain was inconclusive. MRI of brain revealed symmetrical hypersignal lesions in both basal ganglia (putaminal regions) probably of osmotic demyelinisation origin. Patient was treated with hemodialysis and hyponatraemia was gradually normalised.

Results: According to laboratory and MRI results, diagnosis of EPM was established. Generalised chorea was treated with clonazepam with no effect. Switch to haloperidol was effective in treatment and chorea gradually disappeared. After 6 month since onset patient stopped taking Haloperidol and choreatic dyskinesias did not re-occur.

Conclusion: Generalised chorea with sudden onset is extremely rare presentation of EPM. We suggest tight cooperation of neurologists and nephrologists treating peritoneal dialysis patients to prevent permanent brain damage.

Orthostatic tremor responding to Rasagiline
M. Yuce, H. Akgun, S. Tasdemir, S. Alay, O. Oz, E. Eroglu, S. Demirkaya, Department of Neurology, Kasimpasa Military Hospital, Istanbul, Turkey; Department of Neurology, Etimesgut Military Hospital, Ankara, Turkey; Department of Neurology, Gulhane Military Medical Academy, Ankara, Turkey

Background: Orthostatic tremor is known as a lower extremity tremor occurring when standing. When a person stands, typical high frequency (13–18 Hz) tremor develops, and disappears with walking, sitting or continuous volatile leg movement.

Objective: In this report we presented a patient with tremor on the lower limbs diagnosed with Parkinson’s disease.

Patients and methods: A 58-year-old female patient presented to our outpatient clinic with complaints of trembling in the body when standing, lasting for 1 year. The neurological examination revealed bradykinesia of the lower and upper right limbs, rigidity and rest tremor of the right hand and trembling of the lower limbs when standing.

Results: The brain MRI and the routine nerve conduction studies were normal. The superficial electrode recordings of femoris, anterior tibialis, biceps femoris muscles documented a tremor of 13 Hz. The patient was diagnosed with Parkinson’s disease accompanied by orthostatic tremor and was started 2 mg of Rasagiline. Significant improvement was noted.

Conclusion: We found this case worth reporting because of the rare presentation of Parkinson’s disease in the literature with orthostatic symptoms as a first sign.

Improved intraoperative therapeutic window with directional DBS compared to omnidirectional DBS using a novel lead design
C. Pollo, L. Stiegitz, M. Oertel, A. Kaelin-Lang, M. Schüpbach, University Hospital Inselspital, Bern, Switzerland

Introduction: Deep brain stimulation (DBS) is currently carried in all directions around the lead. Directional leads may improve focalization of stimulation in the brain but their clinical effect has not yet been investigated. We report five cases of an on-going intraoperative study using directional DBS.

Methods: Three males with PD underwent STN DBS and two males with ET underwent Vim DBS. At the target determined for the permanent lead, directional stimulation was assessed using a novel lead (directSTIM™, Aleva Neurotherapeutics). It features two rings of three independent electrodes each. The therapeutic window (TW) is defined as the electrical current at which side effects occur minus the current at which a significant therapeutic effect is observed (low TW...
boundary = TWLB). TW was measured in each direction (TWdir) and best TWdir was compared to omnidirectional stimulation (TWomni).

**Results:** A range of anticipated side effects presented and receded as we selected the direction of stimulation. 3/5 patients showed a ratio TWdir/TWomni ≤0.30. 1/5 patient did not show a ratio <1. The ratio could not be measured in 1/5 patient. The best directional TWLB was 0.66 mA in average (0.3–1.0 mA) whereas omnidirectional TWLB was 1.14 mA (0.6–1.95 mA).

**Conclusions:** These observations suggest that directional TW is increased compared to omnidirectional TW. The side effects appeared in accordance with the spacial position of the directional electrodes. TWLB is significantly lower in the best direction compared to omnidirectional stimulation. Therefore, directional stimulation may increase effectiveness of DBS. Further studies are needed to confirm these results.

**Clinical and biological contribution in Parkinson’s disease**

M. Ben Halima, S. Ben Amor, S. Naïja, A. Hassine, I. Chatti, M.S. Harzallah, S. Ben Ammou. Department of Neurology, Hospital Sahlohl of Sousse, Sousse, Tunisia

**Introduction:** Parkinson’s disease (PD) represents the main cause of parkinsonian syndrome. The objective of this study was to identify the characteristics of patients with PD in the center of Tunisia.

**Methods:** A study was performed in patients with PD followed between 2006 and 2009 in Department of Neurology, Hospital Sahlohl of Sousse. Demographic and clinical data at presentation were documented for all patients.

**Results:** We identified 300 patients with PD. The mean age at onset was 58.6 and the duration was 5.5 years. The frequency of young onset PD was 11.6% and late onset was 9.4%. A positive family history of PD was present in 14% of cases. The trembling form was 49.3%. Hypertension and diabetes were associated with PD in 25% and 15%, respectively. Median Hoehn–Yahr stage of PD patients at presentation was a median 2.0. A significant correlation was observed between severity of PD and the duration of the disease. L-DOPA is the most prescribed for treatment in PD (88.8% in first-line) and its motor complications were observed in 43%. A positive correlation was found between homocysteinemia and the dose of L-Dopa as well as the Hoehn–Yahr stage.

**Discussion:** There were no differences between our study and literature with regard to clinical forms. PD was significantly associated with a decreased risk of hypercholesterolemia and increased risk of diabetes. Our therapeutic attitude was different from the therapeutic strategy of the consensus established in 2000. The hyperhomocysteinemia seems to be related to the use of L-Dopa.

**Conclusion:** Our study provides data on the clinical profile of Tunisian patients with PD and demonstrates that it is similar to that from other populations.

**Fungal volatile organic compounds: Biogenic toxins as etiological agents for Parkinson’s disease**

A. Inamdar, J. Bennett. Dept. of Plant Biology and Pathology, Rutgers University, New Brunswick, NJ, USA

**Background:** Many volatile organic compounds (VOCs) are found in indoor environment as a by-product of microbial metabolism. In damp indoor environments, fungi are associated with poor indoor air quality and some epidemiological studies have suggested that exposure to microbial VOCs has potential to cause movement disorders thereby causing an adverse health effects.

**Objective:** We used Drosophila melanogaster, a simple genetic model as a reductionist approach to determine the causal relationship between fungal VOCs and reported movement disorders.

**Material and methods:** We used wild type Drosophila melanogaster strains and other mutant flies and exposed them to different concentrations of fungal VOCs. We assessed for survival, behavioral and immunohistochemical assays in order to determine the neurotoxic effects of fungal VOCs.

**Results:** We found that exposure to different fungal VOCs leads to loss of dopaminergic neurons and Parkinson’s disease-like manifestations in Drosophila model. Furthermore, we observed gene-environmental interaction implying the alteration of dopamine homeostatic and signaling pathway upon exposure to fungal VOCs.

**Conclusion:** Our reductionist model demonstrates that VOCs emitted by fungi are neurotoxic to Drosophila and may provide insights into neurological health related problems reported from damp indoor environment and reported health issues after Hurricane Katrina and Sandy.

**Trust and risk behavior in Parkinson’s disease: Experimental evidence and clinical implications**

A. Javoy1, R. Riedl2, M. Kirchnmayr3, M. Reichenberger4, G. Ransmayr4.
1Department of Neurology, Linz General Hospital, Austria; 2Department of Business Informatics, Information Engineering, Johannes Kepler University, Linz, Austria; 3School of Management, University of Applied Sciences Upper Austria, Steyr, Austria

**Background:** Trust is essential for social interactions. The basal ganglia, the frontal cortex, and the limbic system are known to regulate trust behavior. Parkinson’s disease (PD) affects these brain regions. Moreover, dopamine and serotonin, neurotransmitters related to trust, are reduced in PD, and various neuropsychiatric phenomena of PD may be related to trust.

**Objective:** We designed an experiment to investigate whether trust behavior is altered in PD.

**Patients and methods:** We compared the behavior of 20 PD patients on dopaminergic treatment (age 72.4 ± 9.2, motor symptom duration 39.2 ± 41.8 months, MMSE 28.4 ± 1.6, 10 female) with the behavior of 20 healthy controls (age 68.4 ± 10, MMSE 28.9 ± 1, 10 female) in a computerized trust game, where subjects (trustors) entrusted money (0 to 10 Euros) to 16 emotionally-neutral faces (trustees). The invested amount was used as a measure for trust. To control for altered risk-taking, a computerized game-of-dice task was used. Patients suffering from neuropsychiatric co-morbidities (depression, anxiety, psychosis, impairment of impulse control, and compulsive behavior) were excluded.

**Results:** In the trust game, PD patients exhibited significantly less trust compared to controls (mean investment 3.431 ± 1.996 versus 5.528 ± 1.536 Euros; p = .001, two-sided Wilcoxon-test). In the game-of-dice task, risk-taking was higher in PD than in controls (number of risky choices 10.2 ± 3.9 versus 7.1 ± 3.6; p = .009, two-sided Wilcoxon-test).

**Conclusion:** Trust was reduced in persons with moderately advanced PD without psychiatric co-morbidities. This finding cannot be explained...
by PD patients’ risk behavior, because it was higher in the PD group. Results are discussed with respect to pathophysiological aspects and clinical implications.

Central extrapontine myelinolysis appearing as acute parkinsonism
R. García Santiago, L. Redondo Robles, M.C. Riveira Rodríguez, S. Fernández Menéndez, A. Arés Luque, A. Galiana Ivars, N. González Nafria, J. Tejada, B. Cabezas Delamare. Hospital of León, León, Spain

Background: When facing an acute parkinsonism, we must take into account not only the secondary and most frequent etiologies, such as the pharmacological, vascular or toxicological ones, but also others which are less common.

Case report: We present the case of a 29-year-old man, who is admitted to our Neurology department with high frequency, constant and incapacitating rest and postural tremor, which was present for 5 days prior to the admission. It was accompanied by rigidity and bradykinesia – all of it with predominance in the right side of the body – as well as hypomimia, dysprosody and abundant sialorrhea. Postural reflexes were also seriously damaged.

As a precedent, he had been hospitalised that month with an Addisonian crisis, and his sodium levels had increased from 109 to 138 mEq/L in a day.

MRI evidenced a bilateral hyperintensity of the basal ganglia, which is compatible with central extrapontine myelinolysis. The DaTSCAN was normal.

Conclusion: We would like to express the importance of treating hyponatremia in a slow way, because of the risks of osmotic demyelination of the central nervous system, not only distinctly at the pontine level, but also in other locations.

Additionally, we would also like to emphasize the importance of the careful analysis of the patient’s history, searching for processes with a possible damage of the basal ganglia. Thus, we will be able to find the diagnosis of more infrequent etiologies of parkinsonism, as was the case here.

Impulse control disorder in psychogenic parkinsonism
S. Budrewicz, K. Slotwinski, M. Koszewicz, A. Dolgan, R. Podemski. Neurology, Wrocław Medical University, Wrocław, Poland

Psychogenic movement disorders (PMD) appear in 1.9% of general population and in 2.25% patients with neurological diseases. Psychogenic parkinsonism (PP) is rare and accounts for less than 10% of PMD. The psychogenic parkinsonism is estimated of 0.17% of all cases of parkinsonism. The authors present the case of 53-year old woman with long-standing recognition of Parkinson disease (PD) with motor fluctuations and dyskinesias, treated with L-Dopa, ropinirol and amantadine. She was admitted to the Neurological Department of Wrocław Medical University in order to confirm the PD diagnosis, estimate the appropriate treatment or eventually qualify to the operation. The medical history indicated to the impulse control disorders (ICD) — compulsion for the internet usage, shopping (she bought the same, useless things repeatedly). The analysis of the medical history, observation of the motor symptoms and their changes, nonspecific influence of dopaminergic treatment, psychological and psychiatric evaluations allowed us to recognize psychogenic parkinsonism (the Jankovic criteria 1, 2, 6, 7, 8) for the certain recognition of PP.

Despite of any changes of the dopaminergic treatment, the compulsive actions disappeared spontaneously. Slow discontinuation of the dopaminergic treatment did not enhance the typical for PD motor disturbances.

The influence of dopaminergic agonists and L-Dopa treatment as well as familiar, psychiatric disorder (patient’s mother suffered from bipolar disorder) or conversion with taking the pattern from the internet, was thought to be important in the etiology of ICD in our patient.

Self-assessment of dysarthria in Parkinson’s disease verified by use of computer acoustic speech analysis
S. Budrewicz, M. Koszewicz, K. Slotwinski, R. Podemski. Neurology, Wrocław Medical University, Wrocław, Poland
Speech disorders in Parkinson's disease (PD) have a complex character, depending on many factors influencing speech, phonation and articulation programming. There are no studies defining self-assessment of speech disturbances in PD patients.

The studies covered 50 patients diagnosed with PD according to the clinical criteria determined by the United Kingdom Parkinson's Disease Society Brain Bank. The control group comprised 30 participants, not diagnosed with any neurological disorders or other illnesses that might have influenced speech. In the II part of the UPDRS (point 5) the median result was 1 (in 66% of patients). This point assesses speech problems based on the patient's medical history and our results mean insignificant speech disorders not causing understanding difficulties. In the point 18 of the III part of the UPDRS, the median result was 2 (in 48% of patients), which stands for a moderate dysarthria. In computer acoustic analysis we revealed the changes of speech parameters in all our patients. The differences between PD and control groups were statistically significant. Speech disorders in PD are not usually exposed in the patients' self-assessment. Self-assessment of speech disturbances depends on the precise sounds differentiation, mostly in high frequency range. These abilities diminish within age and it could be the reason of the impairment of speech problems' perception. The computer acoustic speech analysis is objective and precise method of assessment of speech disorders in PD patients.

Motor and non-motor determinants of chronic fatigue in idiopathic Parkinson’s disease (IPD)

Background: Fatigue is one of the most common non-motor symptoms in patients with Parkinson’s disease (PD) with significant impact on quality of life. Fatigue has received increasing attention during recent decade; however, few studies have examined the determinant factors of fatigue and little is known about the relationship between fatigue and other motor and non-motor symptoms.

Objective: The aims of this study were to examine the determinant factors relating to fatigue in PD and to compare the strength of measure of association for different non-motor and motor symptoms with fatigue severity.

Patients and methods: This cross-sectional study was performed in a movement disorder clinic in Tehran, Iran during 2011–2012. A total number of 54 PD (38 males and 16 females) patients with the mean age of 62.5 (SD = 9.1) yr were recruited. Fatigue was scored using the Fatigue Severity Scale (FSS). Other scales were used including PDQ39 (PD-specific QoL), HADS (anxiety & depression), MNA (mini-nutritional assessment), Schwab & England (activity of daily living) and Hoehn & Yahr scales (level of disability).

Results: Patients' score in fatigue had significant correlation with anxiety (r = 0.32, P = 0.020), depression (r = 0.41, P = 0.002), disease severity measured by Hoehn & Yahr scale (r = 0.36, P = 0.007) and activity of daily living described by Schwab & England scale (r = −0.35, P = 0.011).

Conclusion: Our findings showed that more severe depression is accompanied with more severe fatigue in PD patients. In addition to motor symptoms of PD, anxiety and depression have noticeable relationship with fatigue, which must be considered in management of fatigue in PD patients.

Parkinsonian syndrome revealing a Systemic Lupus Erythematosus disease one case study (displayed communication)

M. Mathi, D. Hakemi, S. Hattab, D. Mahmoudi, Tipaza Hospital, Tipaza, Algeria; Internal Medicine, Chu Bab El Oued, Algiers, Algeria; Neurology, Chu Tiziouzou, Tiziouzou, Algeria; Neurology and Neuropsychology, Cabinet, Algiers, Algeria

Introduction: The Systemic Lupus Erythematosus (SLE) has many neuropsychiatric manifestations. Rarely Parkinson’s syndrome has been reported in this condition.

Objective: To report a new case of parkinsonian syndrome revealing a SLE.

Patients and methods: A 56-year-old woman who presented clinically since 08 years of a parkinsonian syndrome trembling form, has a walking disorder (freezing) with postural instability worsening rapidly and unresponsive to dopaminergic therapies.

The blood tests revealed leukopenia 3100/mm3 with elevated proteinuria 24 h (3 g/24 h) without alteration of renal function.

The evaluation of auto-immunity has revealed the presence of high levels of antinuclear 1/320, and antinative DNA antibodies at 1/100UI/ml with negative antiphospholipids antibodies.

The brain MRI showed abnormal signal intensity on T2 and FLAIR in basal ganglia (putamen).

According to the diagnostic criteria defined by the reference SLE American College of Rheumatology (ACR), the diagnosis is in favor of a parkinsonian syndrome secondary to SLE.

The evolution was favorable with corticosteroids therapy which is another criterion of this diagnosis.

Results: The mechanisms underlying neurological manifestations of SLE are not yet elucidated, and two assumptions are made, one leading to immunological direct neuronal damage, the other explained by vascular damage of small vessels.

There are 30 cases of Parkinson’s disease as a complication of lupus reported in the literature.

Conclusion: Parkinsonism in young women can hide various etiologies including SLE, that we need to know and seek to establish appropriate care.

Bibalismus due to thyrotoxicosis

F. Mayda Doanç, Y. Şbspa Kurtulmuş, I. Çağ. Neurology Department, Erenköy Psychiatry and Neurology Training and Research Hospital, Istanbul, Turkey

Background: Bilateral ballismus, characterized by continuous, coarse, flinging involuntary movements involving the limbs with proximal dominance is extremely rare. Hyperthyroidism is usually accompanied
by nervous system dysfunctions. Here, we present a patient in whom biballism occurred due to thyrotoxicosis.

Case: A 62-year-old right-handed male with mild tachycardia has noted abrupt onset of involuntary movements 1 week prior to admission. He was alert and well oriented. Constant ballistic movements involving proximal musculature were seen on both arms and legs. These movements disappeared during sleep. No involuntary movements were seen in his face. Cranial nerve examination and strength of extremities were normal. Tendon reflexes were symmetric and slightly brisk. The hematology examination, biochemical examination including blood glucose, electrolytes, renal and liver function tests, copper studies were normal. Laboratory tests for thyroid function were as follows: total serum T3: 3.72 ng/ml, total serum T4: 14.5 ng/ml, free T3: 8.5 pg/ml, free T4: 4.3 ng/dl, TSH: 0.001 μ/ml, thyroglobulin: 230 ng/ml. Cranial MRI demonstrated no abnormalities. The abnormal movements suppressed over the next week following administration of propylthiouracil 100 mg three times a day. Two weeks later when free T3 and T4 were decreased, the ballistic movements dramatically resolved. Another episode occurred during a 9-month follow up. Since the biballism disappeared with euthyroidism but reappeared whenever there was a further increase in T3 and T4, its relationship on hyperthyroidism and its reversibility are clearly demonstrated.

Conclusion: Hyperthyroidism-related biballismus was thought to be a result of a transient metabolic disturbance of the basal ganglia circuits rather than a permanent and irreversible change.

Psychotic symptoms overshadow motor dysfunction and dementia in normal pressure hydrocephalus — A case report
S. Nia, C. Sedlacek, A. Baumgartner, C. Baumgartner, Karl Landsteiner Institute Cognitive Neurology and Epilepsy Research, Vienna, Austria; Neurologische Abteilung Krankenhaus Hietzing mit Neurologischem Zentrum Rosenhügel, Karl Landsteiner Institute Cognitive Neurology and Epilepsy Research, Vienna, Austria

Background: The characteristic symptoms of normal pressure hydrocephalus are dementia, urinary incontinence and gait disturbance. Psychiatric symptoms may also occur but appear usually after the characteristic symptoms.

Objective and methods: In our case report we present a 63 year old woman that had been diagnosed with a bipolar affective disorder at the age of 61 with an acute onset of psychosis. She had been treated with several neuroleptics and anticonvulsants before being admitted to a neurological department. The reason for the admission was extrapyramidal signs, which had been explained as a side effect of the neuroleptic use. In the physical examination the patient showed in addition to the motor dysfunction, a massive cognitive decline. Although a MRI of the brain and a lumbar puncture had been already performed in the past, we decided to repeat those. Now signs of normal pressure hydrocephalus were visible in the MRI. Also the patient significantly improved in walking and in cognitive testing after the second spinal tap.

Results: A surgically implanted ventriculoperitoneal shunt to drain excess cerebrospinal fluid has stabilized the patient. Neuroleptics and anticonvulsant medications have been stopped. No further signs of a psychosis have been reported since then.

Conclusion: This case demonstrates the need to consider NPH when older patients present with psychotic symptoms, particularly in the presence of cognitive impairment, gait disturbance, or incontinence.

Myocardial 131 I-metaiodobenzylguanidine (MIBG) scintigraphy in the differential diagnosis of Parkinson’s disease
R. Petrovic, T. Samardzic, M. Relja, S. Telarovic, V. Miletic, S. Tezak, Clinical Hospital Centre Zagreb, Medical School University of Zagreb, Zagreb, Croatia

The aim of our investigation is to evaluate how myocardial 131 I-metaiodobenzylguanidine (MIBG) scintigraphy may assist in the establishment of final diagnosis in PD.

Materials and methods: Eighteen patients clinically diagnosed as idiopathic PD (IPD) and fourteen patients with extrapyramidal symptoms (EPS) underwent MIBG scintigraphy. Planar chest MIBG imaging was performed 15 min, 2, 3, 4 and 24 h after tracer injection. Myocardial MIBG activity was quantified by means of a heart to mediastinum ratio (H/M ratio). A ratio over 1.8 was considered normal, between 1.31–1.79 decreased, and less than 1.3 severely decreased. Results showed that the H/M ratio from early and delayed MIBG scintigraphy was pathologically decreased (<1.3) in fourteen patients diagnosed as IPD and in six patients with EPS. One patient with EST had a H/M ratio of 1.3–1.79. Three patients initially diagnosed with IPD as well as seven patients with EPS had normal H/M ratios. In total, we confirmed initially established clinical diagnoses of IPD in 14 of 18
patients and changed the final diagnosis from EPS to PD in 7 of 14 patients.

Conclusions: According to our findings, it can be concluded that cardiac dysautonomia is common in IPD, confirming that myocardial MIBG imaging can be a powerful but simple and affordable method in differential diagnosis of PD, thus greatly assisting in diagnosing impaired adrenergic activity present in PD. Also, myocardial MIBG imaging can be of great help in establishing the final diagnosis in patients with EPS, especially when DaTSCAN is not available.

DaTSCAN™ (Ioflupane I 123 injection), a radiopharmaceutical indicated for visualization of the striatal dopamine transporter using SPECT: Safety profile review

L. Grachev1, P. Sherwin2, D. Lane3, E. Moreno4, J. Freid4, N. Bajaj4, R.A. Hauser4, J. Seibyl1, D.G. Groseth5, K. Marek4. 1Medical Affairs, New Product Development, MDx, USA; 2GE Healthcare, Princeton, NJ, USA; 3GE Healthcare, Madrid, Spain; 4Nottingham University, Nottingham, UK; 5USF Byrd Parkinson’s Disease and Movement Disorders Center, Tampa, FL, USA.

Objective: To assess DaTSCAN™ ([123I]ioflupane injection), a radiopharmaceutical indicated for visualization of the striatal dopamine transporter using SPECT: Safety profile review.

Patients and methods: In GE-sponsored clinical trials, DaTSCAN™ was administered to 1236 subjects (1171 patients and 65 healthy volunteers). Clinical trials collected adverse events (AEs), laboratory parameters, vital signs and electrocardiograms (ECG). Administered activity of [123I]ioflupane ranged from 3 to 5 mCi (111 to 185 MBq), comparable to administered activities for other commercially available [123I]-labeled products. The calculated whole body effective dose was 4 to 6 mSv, comparable to 1 year of natural background radiation (3 to 4 mSv).

Results: Review of trial data on non-serious AEs, vital signs, laboratory parameters, and ECG identified no safety issues. There were mild and infrequently reported AEs and no SAEs or deaths that were considered related to DaTSCAN™ administration. The most common AE ascribed to studied activities was headache (1%), followed by nausea, and vertigo, dry mouth, hunger, dizziness, and formation (<1% each). Most of these AEs were mild. The safety profile established in clinical trials is supported by limited AE reports (including hypersensitivity reported as rash and pruritis shortly after dosing) from post-marketing exposure in over 300,000 patients who have been imaged.

Conclusions: Comprehensive review of the safety data from clinical trials and 11 years of post-marketing use show that AEs associated with DaTSCAN™ are mild and infrequently reported, and DaTSCAN™ is a safe product to use. DaTSCAN™ is also considered to be low risk from a radiation dosimetry perspective.

Gating of sensory evoked potentials in upper limb dystonia

Background: Primary focal hand dystonia is a condition characterized by abnormal postures in the limb. Previous studies have identified abnormalities of sensory discrimination, worsening of dystonic postures by vibration of the limb and deficits in sensori-motor integration.

Objective: To compare the normal attenuation (gating) of somatosensory evoked potentials (SEPs) caused by movement in healthy people with that of patients with dystonia. We were also interested in the impact of vibration on SEP attenuation in healthy people and those with dystonia.

Methods: 6 patients with focal/segmental dystonia, 7 healthy controls. SEPs were obtained by stimulating the median nerve at the onset of a voluntary self-paced abduction movement of the right thumb and at rest. We also recorded SEPs at the onset of movement while the subject was also receiving vibration on the palmar surface of the hand.

Results: SEP amplitude at the onset of movement was suppressed in controls compared to baseline SEP amplitude (ratio SEP amplitude at onset to baseline SEP amplitude = 0.67). However SEPs were not suppressed in patients with dystonia (ratio: 0.97). When the limb was vibrated during movement we did not find SEP suppression in either group: healthy controls’ ratio: 0.92, dystonia patients’ ratio: 1.1.

Conclusion: These preliminary results suggest that sensory afferents from the dystonic limb are not attenuated during movement. Vibration causes reduction in SEP suppression in both healthy people and in patients with dystonia. These data provide new information with regard to deficient sensori-motor integration in dystonia and a possible mechanism for the known worsening of dystonia caused by vibration of the limb.

Topic: 2 — Movement Disorders
Impulse generator replacement in deep brain stimulation

Background: Deep brain stimulation (DBS) has become an option for several movement disorders refractory to medical therapy. The finite life of non-rechargeable batteries powering implantable pulse generators (IPG) implies a periodic replacement. Patients undergoing DBS may require multiple substitutions and recent studies point to an increased rate of infection compared to the primary surgical procedure.

Objective: Determine the average duration of the pulse generator battery; analyze the rate of complications associated with the replacement procedure.

Material and methods: Retrospective review of medical and surgical records of 74 consecutive patients who underwent DBS and at least one impulse generator replacement in the context of “end of life” of the battery (between 2005 and 2012).

Results: 74 patients (95.9% Parkinson’s disease, 4.1% secondary generalized dystonia) underwent surgery to replace the IPG (Kineta/Active PC-Medtronic®); 5 patients made two substitutions. The average duration of the batteries was 52.8 +/- 3.2 months (12–82 months). There were no significant differences in the duration of subsequent vs primary generators. In 4 patients, a system infection occurred with an infection rate of 5.1%. In all cases it was necessary to remove the DBS system completely.

Discussion: Ten years after the beginning of DBS as a therapeutic option in Portugal, it became necessary for us to evaluate the complications associated with impulse generator replacement. At present, the possible use of rechargeable batteries in order to avoid the complications...
Objective: The primary objective was to demonstrate the superior efficacy of oxycodone/naloxone prolonged-release fixed-combination (OXNPR) versus placebo in reducing RLS symptom severity using the International RLS Study Group Rating Scale (IRLS).

Patients and methods: After a 7-day washout, patients (N = 304) with severe RLS (IRLS total score ≥ 21) inadequately controlled on previous medication were randomised to OXNPR bid (mean oxycodone dose 21.9 ± 15.0 mg/day) or placebo in the 12-week double-blind study. 197 patients participated in a 40-week open-label extension (mean oxycodone dose 18.1 ± 10.5 mg/day).

Results: Superior efficacy of OXNPR versus placebo was shown (clinically relevant treatment difference in IRLS total score at Week 12 of 8.15 units (95% CI [5.46; 10.85]; p < 0.001, n = 276 full analysis population). Beneficial effects of OXNPR on RLS symptom severity were observed within 1 week and continued over long-term. Mean IRLS total score under OXNPR was 31.6 ± 4.5 at randomisation (indicating severe symptom load), reducing to 21.0 ± 9.1 at Week 1, 15.1 ± 10.6 at Week 12, and 9.7 ± 7.8 (representing mild RLS symptom severity) at end of extension (n = 152). Results of the IRLS were supported by significant improvements in RLS-6 Rating Scale and CGI responder rate results for OXNPR versus placebo, which were maintained for over 1 year. OXNPR treatment was well tolerated in accordance with the expected safety profile. No case of augmentation was reported during the study.

Conclusion: Prolonged-release oxycodone/naloxone is an effective and well-tolerated short- and long-term treatment for patients with severe RLS.

Efficacy, safety and tolerability of rasagiline as an add-on therapy to dopamine agonists in early Parkinson’s disease: The ANDANTE study
S. Isaacson, D. Silver, A. Choudhry, R.A. Hauser, Parkinson’s Disease and Movement Disorders Center of Boca Raton, Boca Raton, FL, USA; Coastal Neurological Medical Group, La Jolla, CA, USA; Teva Pharmaceutical Industries, Kansas City, MO, USA; Disease and Movement Disorders Center, University of South Florida, Tampa, FL, USA

Background: Dopamine agonists (DAs) are often used as initial PD monotherapy. However with disease progression DA monotherapy alone becomes sub-optimal and patients often require additional dopaminergic therapy to maintain symptomatic efficacy. Traditional options at this stage include levodopa (associated with risk of dyskinesia) or increasing DA dose (associated with higher risks for ICDs and other AEs). Rasagiline is a selective, irreversible MAO-B inhibitor providing a distinct rationale as add-on therapy to DAs for additional symptomatic benefit.

Objective: Determine the efficacy, tolerability and safety of add-on rasagiline therapy for early-PD patients sub-optimally controlled by DA monotherapy.

Methods: 18-weeks, placebo-controlled (randomized 1:1) study of PD patients (Hoehn & Yahr 1–3) aged ≥30 years taking stable DA dosages with suboptimal control. Primary outcome: change from baseline in total-UPDRS score. Secondary outcomes: changes from baseline in UPDRS motor and ADL scores and CGI. Safety was assessed by AE frequency/severity. Out of 328 patients randomized, 321 (mean age 62.6; duration PD 2.13 years) were included in the efficacy analysis.

Results: Treatment with add-on rasagiline significantly improved total-UPDRS scores versus placebo (treatment effect ± SE: −2.4 ± 0.95,

e, V. Kostić
e
cClinic of Neurology, Clinical Center Krugujevac, Krugujevac, Serbia; dInstitute of Neurology, Clinical Center Serbia, Serbia; eFaculty of Philology, University of Belgrade, Belgrade, Serbia

Background: Parkinson’s disease (PD) is often associated with numerous psychiatric and behavioral disorders and mild cognitive impairment and dementia.

Apathy, anxiety and depression are among the most frequently reported neuropsychiatric features in PD. The point-prevalence of dementia is 30% and patients with PD have an almost sixfold increased risk of developing dementia compared to healthy controls.

Objective: The objective of this study was to examine the prevalence and clinical correlates of behavioral changes, mild cognitive impairment and dementia in a clinical population-based sample of patients with Parkinson's disease.

Methods: A series of 360 PD patients; the assessment included comprehensive neurological examinations (motor scoring with Hoehn and Yahr staging and the Unified Parkinson's Disease Rating Scale); psychiatric examinations with the Apathy Scale (AS), Hamilton Depression Rating Scale (HDRS-17), Hamilton Anxiety Rating Scale (HAMA-S); and cognitive screening with the Mini-Mental State Examination (MMSE) and Clinical Dementia Rating (CDR) scale.

Results: Apathy coexisted with depression in 133 (36.9%) of PD patients, depression without apathy in 16 (4.4%), apathy without depression in 84 (23%), and neither apathy nor depression in 127 PD patients (35.2%). A total of 172 patients were cognitively intact; whereas 114 (36%) were diagnosed with MCI. Thirty patients (9.4%) were diagnosed with dementia.

Conclusion: These findings suggest that apathy and depression may be separable in PD, although both are common in patients with PD; and that PD patients with more prominent axial signs and older age are in higher risk for developing cognitive impairment.

Non-motor features and motor complications in IPD: Are UPDRS parts I and IV relevant evaluation tools?

M. Sebok, A. Erlacher, S. Seiler, C.N. Homann. Department of Neurology, Medical University of Graz, Graz, Austria

Background: The UPDRS is the most widely used scale in Parkinson's disease. However despite the fact that non-motor symptoms and motor complications are common in IPD with prevalence figures of up to 98% and 40%, parts I and IV which focus on these symptoms were previously infrequently used.

Objective: As during the last decade research has particularly focused on and has made progress in elucidating various non-motor features and motor complications of PD we examined whether this reflects now in an elevated use of the respective UPDRS parts.

Methods: A systematic literature search using the database “PubMed” to identify randomized clinical trials on IPD, published between 1998 and 2011 was performed. Identified abstracts were hand searched and analysed regarding usage of clinical scales and particularly UPDRS and its parts.

Results: Almost all of the 163 studies (97.6%) that had included the UPDRS applied part III alone or in combination with other parts. In contrast part I or part IV alone or in combination with another part (except part III) was utilized in only 0.6% and 1.8% respectively. One of these studies used part I of the MDS-UPDRS the revised version of the UPDRS.

Conclusion: Despite the recent focus of PD research there is still a big discrepancy between high prevalence of non-motor features and motor complication and low frequency of use of respective UPDRS parts. It seems that for reason of comparability of results researchers when investigating these symptoms are better off in using other evaluation tools.

POLG-1 related SANDO and levodopa-responsive parkinsonism

P. Barrosa, J. Meirelesb, M. Gagoa, M.J. Rosana. aCentro Hospitalar de Vila Nova de Gaia/Espinho, Vila Nova de Gaia, Portugal; bCentro Hospitalar de São João, Porto, Portugal; cCentro Hospitalar do Alto Ave, Guimarães, Portugal

Background: Mitochondrial dysfunction has recently emerged as one of the relevant mechanisms associated with the etiology and pathogenesis of neurodegenerative parkinsonism. Mutations in POLG1, the nuclear gene encoding the catalytic subunit of mitochondrial DNA polymerase gamma, have been associated with a wide phenotypic spectrum, including inherited parkinsonism usually in combination with progressive external ophthalmoplegia.

Clinical case: A 52-year-old man presented with progressive bilateral ptosis, unsteadiness of gait and muscle weakness at the age of 39 and developed dysphagia and diplopia three years later. At age 44, neurological examination revealed fatigable bilateral blepharoparalytic, external ophthalmoplegias with diplopia on horizontal gaze, fluctuant dysarthria and dysphagia. Peripheral neurophysiologic examination was compatible with axonal sensory neuropathy. Sequencing of the POLG1 gene revealed compound heterozygotic missense substitutions: p.P648R and p.R807C. This case was initially reported as a typical SANDO syndrome. During the last 3 years, the patient developed right-dominant parkinsonism, with hand rest tremor, moderate limb bradykinesia, cogwheel rigidity and hypomimic face. 123I-ioflupane DaTscan demonstrated a bilaterally reduced dopamine uptake in the corpus striatum. The patient was treated with coenzyme Q30 mg tid, levocarnitine 1 g tid and levodopa (up to 400 mg/day). At 3 years of follow-up, he sustains a positive dopaminergic response, with a decrease of 17 points in the MDS-UPDRS-III score (53% improvement) after a 300 mg l-dopa challenge test.

Discussion: To our knowledge, this is the first case of parkinsonism reported in POLG1-positive SANDO patients. We think that this case expands the clinical and molecular findings of POLG1-related parkinsonism to include SANDO phenotype.

Neuroprotective effects of 17-beta-estradiol: Relevance to depressive symptoms in Parkinson's disease

P. Kumar, R.K. Kale, N.Z. Baquer. School of Life Sciences, Jawaharlal Nehru University, New Delhi, India

Parkinson's disease (PD) is a movement disorder characterized by the loss of dopaminergic neurons in the substantia nigra causing dopamine depletion.

The objective of this study was to investigate the neuroprotective potential of 17β-estradiol (E2) treatment on the activities of acetylcholinesterase (AChE) and monoamine oxidase (MAO), membrane fluidity, neurolipofuscin, genomic DNA degradation, protein oxidation levels and testing learning memory, occurring in the brains of female rats of the 3 month (young), 12 month (adult) and 24 month (old) age groups, and to see whether these changes are restored to normal levels after exogenous administration of estradiol.

The aged rats (12 and 24 months old) (n = 8 for each group) were given subcutaneous injection of 17β-estradiol (0.1 µg/g body weight) daily for one month. After 30 days of hormone treatment, the experimental animals of all groups were sacrificed and the brains were isolated for
Further study. Learning was tested in a Morris water maze and ultrastructural studies of brain region by MRI. The results obtained in the present work revealed that normal aging was associated with significant increases in the activity of M40, genomic DNA degradation and protein oxidation levels in the brains of aging female rats, and a decrease in AChE activity and membrane polarization. It can therefore be concluded that E2’s beneficial effects seemed to arise from its antioxidant and antilipidperoxidative effects, implying a therapeutic potential drug for age related changes. Based on our studies and those of others, we conclude that E2 has therapeutic potential for adjunctive therapy of PD.

Background: Parkinson disease (PD) is characterized by dopamine depletion in the nigrostriatal system that leads to an abnormal modulation of cortico-subcortical networks.

Objective: This study aims to evaluate the functional connectivity (FC) of the basal ganglia circuit early in PD.

Methods: We enrolled early, treated (tPD = 44) and drug-naive (nPD = 26) PD patients and 27 healthy controls. Considering that all PD showed lateralized parkinsonian features, the images from 24 patients whose symptoms were on the left (L) side were left–right (R) flipped so that the hemisphere contralateral to the affected limbs was on the L for all patients. A seed-based FC analysis from resting-state data was performed using bilateral caudate, putamen, pallidum and thalamus as seed regions of interest (p < 0.05, multiple comparison corrections).

Results: In nPD patients, caudate and putamen showed increased connectivity with their contralateral homologous regions, R-thalamus showed increased connectivity with L-thalamus, and L-caudate and L-thalamus presented decreased connectivity with homolateral prefrontal regions. tPD patients showed reduced connectivity between L-caudate and anterior cingulum, while an increased connectivity was found between R-putamen and the contralateral one. In both nPD and tPD, L-thalamus was hypoconnected with homolateral prefrontal regions. Only in tPD patients, L-thalamus was hyperconnected with contralateral sensorimotor cortices.

Conclusions: nPD patients and tPD showed different connectivity profiles compared to controls, a finding which raises the hypothesis that L-DOPA treatment might play a role in the modulation of brain connectivity.

Functional connectivity in patients with focal dystonia

L. Sarro, a,b F. Agosta, a, T. Tomić, a, A. Inuggi, a, M. Svetelc, a, N. Kresojević, a, G. Comi, a, V. S. Kostić, b, M. Filippi, a,b aNeuroimaging Research Unit, Institute of Experimental Neurology, Vita-Salute San Raffaele University, Milan, Italy; bDepartment of Neurology, San Raffaele Scientific Institute, Vita-Salute San Raffaele University, Milan, Italy; cClinic of Neurology, Faculty of Medicine, University of Belgrade, Belgrade, Serbia

Background: Primary dystonia is a hyperkinetic movement disorder which has been traditionally conceptualized as a disorder of the basal ganglia. However, recent data suggest a widespread brain pathology involving motor control pathways.

Objective: This study aims to investigate the functional connectivity of the sensorimotor and bilateral frontoparietal networks in patients with focal dystonia using resting state (RS) functional MRI (fMRI).

Methods: Fifty patients with dystonia and 36 healthy controls were studied. Patient group included 17 subjects with blepharospasm (mean Blepharospasm Disability Index 10.6), 15 subjects by spasitic torticollis (mean Toronto Western Spasmodic Torticollis Rating Scale 22) and 18 subjects with writer’s cramp (mean Writer’s Cramp Rating Scale—part B 10.7). RS fMRI data were analyzed using a model free (MELODIC) approach in FSL (p < 0.05 family-wise error).

Results: Compared with controls, patients with blepharospasm showed an increased functional connectivity of the sensorimotor network in the supplementary motor area bilaterally and left primary sensorimotor cortex, frontal eye field, and superior parietal lobule. Blepharospasm showed no RS fMRI changes in the frontoparietal network. Patients with writer’s cramp showed a decreased functional connectivity of the bilateral superior parietal gyri within the frontoparietal networks, while...
they did not show altered functional connectivity of the sensorimotor network. No RS fMRI abnormalities were detected in patients with spastic torticollis.

**Conclusions:** This study showed specific patterns of altered functional connectivity in patients with focal dystonia. These findings add novel elements to the pathophysiological substrates of these conditions.

**Funding:** This study was partially supported by the MPNS #175090 grant.

**The achievements of I-123 ioflupane (DatSCAN) in a diagnosis of parkinsonism**

**Background:** The diagnosis of various parkinsonian syndromes is primary clinical, but sometimes require more time to final diagnosis.

**Objective:** I-123 ioflupane brain SPECT is considered a biomarker for differentiating conditions with and without nigrostriatal neurodegeneration. Reduced striatal binding of I-123 ioflupane is in correlation with lower concentration of presynaptic dopamine.

**Materials and methods:** We performed a I-123 ioflupane brain SPECT using standard protocol in 218 patients clinically diagnosed to have different parkinsonian syndromes (84 pts with IPD, 102 pts with ET and 24 pts with other forms of parkinsonism). A dose of 185 MBq of 123I-ioflupane was administrated and brain SPECT imaging was conducted 3–6 h after radiotracer injection. Images were analyzed visually and for this purpose patients were classified into two groups — with and without nigrostriatal deficit.

**Results:** We confirmed a clinical diagnosis in 40 patients (21.5%) clinically diagnosed as ET and in 68 patients (36.6%) clinically diagnosed as IPD. In 62 patients (33.3%) the clinical diagnosis of ET changed in condition with nigrostriatal neurodegeneration. In 16 patients (8.6%) clinically diagnosed as IPD we didn’t find any striatal deficit. The group of 24 patients with other different forms of parkinsonism was excluded in this analysis.

**Conclusion:** Our experiences show that 123I-ioflupane brain SPECT has an important role in detecting and monitoring nigrostriatal dopaminergic neurodegeneration and could be routinely used in clinical practice to support or change the clinical diagnosis. Also, we emphasize that a good collaboration between neurologist and nuclear medicine physician is useful in reaching final diagnosis.

**Brain structural changes in primary focal dystonia**

F. Caso, F. Agosta, L. Sarro, A. Tomic, M. Svetel, N. Kresojevic, G. Comi, V.S. Kostic, M. Filippini. Neuroimaging Research Unit, Institute of Experimental Neurology, Vita-Salute San Raffaele University, Milan, Italy; Department of Neurology, San Raffaele Scientific Institute, Vita-Salute San Raffaele University, Milan, Italy; Clinic of Neurology, Faculty of Medicine, University of Belgrade, Belgrade, Serbia

**Background:** Studies using structural and diffusion tensor (DT) MRI reported inconsistent differences in grey (GM) and white matter (WM) relative to controls.

**Objectives:** This study aims to investigate if there are GM and WM abnormalities in patients with primary focal dystonia and if such changes are related to clinical features.

**Methods:** 3D T1-weighted and DT MRI scans were obtained from 51 patients with focal dystonia (17 blepharospasm [BL], 16 spasmodic torticollis [ST], 18 writer’s cramp [WC]) and 36 healthy controls. Voxel-wise analyses of GM volume and WM microstructural abnormalities were performed.

**Results:** Compared with controls, BL patients showed decreased GM in the right precentral gyrus and rolandic operculum, bilateral postcentral gyr, cerebellum and right hippocampus. This pattern of GM atrophy was associated with clinical severity. ST patients compared with controls showed decreased GM density in the left precentral and postcentral gyr, and right rolandic operculum and lingual gyrus. A correlation was found between ST severity and GM density of the middle cingulate gyrus. Relative to controls, WC patients showed GM density increases in the right middle frontal gyr and left superior frontal gyr. DT MRI analysis showed a widespread pattern of WM damage in BL patients, a decreased fractional anisotropy in the right internal capsule in patients with WC, and no changes in ST.

**Conclusions:** Patients with dystonia exhibit GM and WM alterations in regions relevant to motor function, sensory processing, and cognitive...
modulation of motor behaviour, which likely contribute to the clinical features of focal dystonia.

**Funding:** MPNS #175090.

**Instrumented timed up and go test in progressive supranuclear palsy**

A. Kelemen, A. Takáts, P. Radics, G. Tamás. Department of Neurology, Semmelweis University, Budapest, Hungary

**Background:** To diagnose progressive supranuclear palsy (PSP) is challenging. Its cardinal features are postural instability and gait disturbance besides vertical gaze palsy. Instrumented timed up and go (ITUG) test was developed to evaluate gait and balance quantitatively.

**Objective:** Our aim was to find characteristic mobility parameters during ITUG-test, which may help the early diagnosis of PSP.

**Patients and methods:** Six patients with PSP (age: 66 ± 7.3 years; disease duration: 37 ± 12.1 months) and seven age-matched control subjects (C) performed ITUG-test consisting of gait, turning, sit-to-stand and turn-to-sit items three times. Six Opal monitors (APDM Inc.) with three-dimensional gyroscope and accelerometer were placed to the chest, trunk and limbs. Data were analyzed with Mobility Lab software and compared with Mann–Whitney test.

**Results:** The duration of the whole ITUG-test (median/quartile range: PSP: 29.1/19.1s, C: 149.2/82.73°/s; p = 0.01) and of the turning (PSP: 41.1/77s, C: 2.4/0.62s; p = 0.01) and turn-to-sit items (PSP: 5.5/0.88s, C: 3.6/1.30s; p = 0.01) were significantly longer in PSP compared to controls. Peak velocity of turning (PSP: 98.7/24.99°/s, C: 149.2/82.73°/s; p < 0.01) and of turn-to-sit (PSP: 93.8/25.95°/s, C: 148.5/72.33°/s; p < 0.01) and sit-to-stand item (PSP: 51.7/23.2°/s, C: 71.8/15.92°/s; p = 0.05) were significantly smaller in the PSP group. The range-of-motion of the trunk in the turn-to-sit item was smaller in PSP than in controls (PSP: 17/6.28°, C: 31.3/6.95°; p = 0.02).

**Conclusion:** During the whole ITUG-test we detected signs of bradykinesia. Parameters of sit-to-stand and turn-to-sit items may be influenced by the axial rigidity in PSP. Further studies are needed, if they may be early indicators of the disease.

**Patient survey evaluating botulinum toxin type A treatment for blepharospasm**

J. Burns*, J. Fezza, D. Truong*, J. Woodward*  
*Ophthalmic Surgeons and Consultants of Ohio, Columbus, OH, USA;  
*Center for Sight, Sarasota, FL, USA;  
*The Parkinson’s and Movement Disorder Institute, Fountain Valley, CA, USA;  
*Duke University School of Medicine, Durham, NC, USA

**Introduction:** Two recent patient surveys in cervical dystonia and post-stroke spasticity showed that satisfaction with botulinum toxin treatment varies over the treatment cycle. Patient satisfaction with botulinum toxin regimens in blepharospasm, which is a disabling condition that has a negative impact on patients’ quality of life, has not yet been evaluated in a clinical study.

**Patients and methods:** This non-interventional survey has collected self-reported information from patients (aged 18–80 years) who have received ≥2 botulinum toxin treatments for blepharospasm at 5 medical centers in the USA. Information collected includes demographic and baseline disease characteristics and details of previous botulinum toxin treatments (injection intervals, physician’s rationale for intervals used, time course of treatment effects, treatment satisfaction, and current health status). Treatment effects were evaluated via patient-reported Jankovic Rating Scale and Blepharospasm Disability Index scores at the time of the peak effect of the last treatment cycle (as remembered by patients at the time of interview).

**Results:** By 27 March 2013, 123 patients had been recruited; the maximum expected enrollment is 130 patients (ClinicalTrials.gov identifier: NCT01686061).

**Conclusion:** This survey will provide valuable insight into patient needs and treatment satisfaction with current botulinum toxin treatment regimens, which will inform future management of blepharospasm and help improve outcomes.

**A clinical and imaging profile of 35 patients with movement disorders associated with infection**

**National Institute of Mental Health and Neurosciences, Bangalore, India;  
**Neurology, National Institute of Mental Health and Neurosciences, Bangalore, India

**Background:** Movement disorders associated with infections remain an important debilitating disorder in Asian countries.

**Objectives:** This study aims to report the clinical and imaging profile of a large cohort of patients with movement disorders (MD) associated with infection.

**Methods:** This was a chart review of 35 patients (F:M—15:20) presenting with MD in the Neurology services of National Institute of Mental Health & Neurosciences, India. The demographic profile, type of infection, time from infection to MD, phenomenology of MD and MRI findings were reviewed.

**Results:** The mean age at presentation was 22.6 ± 13.3 years, (5–60), age of onset of MD was 15.7 ± 15 years, and duration of symptoms was 6.9 ± 8.1 years (42 days to 32 years). The mean latency of onset of MD after the infection was 5.9 ± 4.2 weeks. The phenomenology of MD includes the following:

(i) pure dystonia—28.6%,
(ii) dystonia with choreoathetosis—22.9%,
(iii) parkinsonism—14.6%,
(iv) pure tremor, hemiballismus, myoclonus and chorea—2.9% each, and
(v) mixed MD—22.9%.

Most often the MD was generalized (60%), followed by right upper limb (31.4%) and left upper limb (8.6%). Encephalitis was the most common infection, time from infection to MD, phenomenology of MD and MRI findings were reviewed.

**Conclusions:** Movement disorders associated with infection were most often post-encephalitic. Dystonia was the most common movement disorder, and thalamus was the most common anatomical site involved.

Motor and cognitive dysfunction in Parkinson’s disease: patients with impulse control disorders
P. Bugalhoab, A. Oliveira-Maiaac, A.S. Correiaa, D. Fodorb, O. Ribeiroe, O. Vieira, M. Gonçalves, O. Ribeiro, Departamento de Neurologia, CEDOC, Faculdade de Ciências Médicas, Universidade Nova de Lisboa, Portugal; bNeurology, Hospital de Egas Moniz (CHLO), Portugal; cDepartment of Psychiatry and Mental Health, Centro Hospitalar de Lisboa Ocidental, Portugal; dChampalimaud Neuroscience Programme, Instituto Gulbenkian de Ciência, Oeiras, and Champalimaud Centre for the Unknown, Portugal; eNeuropsychology Department, Hospital de Egas Moniz, Centro Hospitalar de Lisboa Ocidental, Lisbon, Portugal

Background: Impulse Control Disorders (ICD) are frequent and incapacitating disorders in Parkinson’s Disease (PD).

Objectives: To investigate the relation between ICD and:

1. Cognitive dysfunction;
2. Motor phenotype;

Methods: ICD were diagnosed with the Questionnaire for Impulsive-Compulsive Disorders. Patients with at least one type of ICD were compared to a group of PD patients without ICD, matched for gender, education age, age of onset, duration of disease, Hoehn and Yahr stage and dopamine equivalent doses (DED). Patients were assessed with the UPDRS and the following neuropsychological tests: FAS test, Stroop test, digit span test, Frontal Assessment Battery, Mini-Mental State Examination, Rey Auditory Learning Verbal Test, semantic fluency test, and Raven Colored Progressive Matrices.

Results: We selected 14 patients with ICD, 6 with more than one type. ICD and non-ICD (n = 14) patients did not differ significantly regarding neuropsychological tests, motor scores or the prevalence of motor complications of dopaminergic treatment. Patients with multiple ICD presented with a significantly (p = 0.002) higher prevalence of motor fluctuations (4, 67%) than patients with one type of ICD (0) and patients without ICD (1, 7%). They also had significantly longer disease duration, higher motor stage and DED.

Discussion: Our results suggest that ICD are not related to cognitive dysfunction or the non-tremor motor subtype. Multiple ICD could represent a worse behavioral phenotype, bearing a stronger relation with motor fluctuations and a higher susceptibility to chronic dopamine stimulation. However, differences in DED and disease duration could have biased these results.

Effects of active-assisted cycling on motor function and balance in Parkinson’s disease
A.L. Ridley, E.J. Fickes-Ryan, K.A. Wilson, Exercise Physiology, Kent State University, Kent, OH, USA; Exercise Physiology, West Virginia University School of Medicine, Morgantown, WV, USA

Background: Parkinson’s disease (PD) is a progressive neurodegenerative disorder that results in tremor, rigidity, bradykinesia and postural instability. With the progressive nature of PD, it is critical to identify optimal rehabilitative interventions to minimize disease symptoms. We have recently developed an active-assisted cycling (AAC) intervention, using a commercially available motorized cycle trainer, which is well tolerated by individuals with PD.

Objective: This study aims to determine if a four-week interval active-assisted cycling (AAC) protocol improves motor function and balance in individuals with PD.

Patients and methods: Individuals (N = 27) were randomly assigned to an AAC or a control group. The AAC group completed 12 sessions over four weeks on the Motomed Viva 2 Parkinson movement trainer. Interval AAC included bouts of cycling where the motor assisted individuals to pedal up to 90 revolutions per minute. The control group did not cycle but completed functional assessments at baseline and after 4 weeks. Assessments included motor function (UPDRS Motor III) and balance (Biodex Balance System SD) testing.

Results: UPDRS motor function scores improved in the AAC condition but not in the control group. Specifically, bradykinesia and tremor were reduced after this intervention. Limited effects on balance were noted.

Conclusion: A four week interval active-assisted cycling intervention improves UPDRS scores but does not affect balance in individuals with PD. However, these results suggest that interval AAC could be an important adjunct to medication for improving motor function in Parkinson’s disease.

Latent trigger point platelet rich plasma (PRP) injections under ultrasound guidance for chronic myofascial pain
R.V. Bubnov, D. Fodor, The Centre of Ultrasound Diagnostics and Interventional Sonography, Clinical Hospital “Pheophania” of State Affairs Department, Kyiv, Ukraine; 2nd Internal Medicine Department, Iuliu Hatieganu University of Medicine and Pharmacy, Cluj-Napoca, Romania

Background: Dry needling (DN) under ultrasound guidance is an effective method for trigger point (MTrP) inactivation. Latent MTrPs, local dystonia, insensitive to DN, cause postural imbalance, decrease long term outcome. Injections of platelet rich plasma (PRP) may become beneficial method for treatment latent MTrP. The aim was to test feasibility of PRP therapy for incurable latent MTrP.

Materials and methods: We included 20 patients with chronic myofascial pain, with poor results after four DN sessions. All patients were randomly assigned to dry needling therapy, either to PRP injections under ultrasound guidance. Latent MTrPs were visualised as stiff, hyperreceptive areas. We evaluated pain according to visual analogue scale data, movement volume, activity of MTrP and US criteria of muscle restoration at 1, 7, 28 days after start of treatment.

Results: Pain relief after DN was revealed superior vs group B (P < 0.01). Level of local twitch response was elicited in 33% of patients after DN versus 19% in group B (P < 0.05). Restoration of muscle structure and elimination of MTrP were registered after 7 days after PRP injection. After 28 days, movement volume increased by 40% after PRP versus 25% after DN (P < 0.05), pain and MTrP recurrence was significantly lower in group A: 36 ± 2% compared to 58 ± 3% in group B (P < 0.05).

Conclusions: Injections of PRP under ultrasound guidance are effective for inactivation latent MTrP, improve long term outcome, and can be used as supplement for myofascial pain treatment.

Background: Parkinson Disease (PD) is a result of complex interaction between genetic and environmental factors. It is characterized by 4 clinical signs: resting tremor, rigidity, bradykinesia, instability, gait and postural difficulty.

Objectives: This study aims to check the prevalence of PD in Goiás, comparing it with Brazil and data in literature.

Methods: Analysis of the numbers of PD hospitalizations through the Unified Health System (UHS), focusing on aspects as: gender, age, race, year of internalization (2000–2011), in Goiás and Brazil. The Hospital Information System (HIS) — Unified Health System Informatics Department (UHSID) provided data.

Results: The gender number of hospitalizations in Goiás was: 57% ‘male’ and 42% ‘female’; Brazil: 51% ‘male’ and 48% ‘female’. The most common ages affected with PD in Goiás were: 30% ‘70–79 years old’, 26.5% ‘60–69 years old’, 23.5% ‘above 80 years old’; Brazil: 32% ‘70–79 years old’, 24.4% ‘60–69 years old’, 19.4% ‘above 80 years old’.

Conclusions: Some studies say that PD is more prevalent among men, this study found no prevalence difference between genders in Goiás, neither in Brazil. The most common affected ages and races by PD in literature are the same found in this study.

doi:10.1016/j.jns.2013.07.590

Background: Rigidity is one of the cardinal symptoms in Parkinson’s disease. Based on the findings of microneurography, Burke D et al. (1977) suggested that, in Parkinson patients, the spindle afferent responses look like those of normal subjects who are not fully relaxed and in whom there is a co-activation of the skeletonmotor and fusimotor activity. In previous paper (J Physiol, 1998), we showed the existence of dynamic and static fusimotor actions on the human muscle spindle during voluntary contraction.

Objective: In this experiment, we tested whether increased spindle activities during weak isometric contraction of forearm muscles might enhance the stretch reflex as seen in Parkinson’s disease.

Subjects and methods: Thirteen healthy subjects (8 males and 5 females, age between 26 and 50 years old) were recruited. The details of methods were the same as appeared in previous paper. A tungsten micro-electrode was inserted into the left radial nerve and spindle activities were recorded from extensor carpi radialis brevis (ECRB). The wrist joint was moved 25° with 5–40°/s by DC-Torque motor. Spindle activities and EMG were recorded and analyzed by SC/ZOOM system (Umeå University).

Results: Total number of 43 spindles was recorded from ECRB. All spindles increased the firing rate by lengthening of ECRB. There was no stretch reflex in ECRB at rest and during isometric contraction except one subject.

Conclusion: These findings suggest that increased stretch reflex was exceptional in normal subjects even with α-γ co-activation. There might be substantially increased excitability in α motoneurons in Parkinson’s disease.

“Restless bladder” and the boundaries of the restless legs syndrome

E. Antelmi², G. Coccagna³, L. Ferini-Strambi⁴, S. Marelli⁵, F. Provini⁵, ²IRCCS Institute of Neurological Sciences and Department of Biomedical and Neuromotor Sciences, University of Bologna, Italy; ³University of Alabama at Birmingham Bologna, Bologna, Italy; ⁴Department of Neurosciences, Sleep Disorders Center, Università Vita-Salute San Raffaele, Milan, Italy

Background: Recently different reports on atypical localization of Restless Legs Syndrome (RLS) symptoms (namely one arm, tongue, thorax, and abdomen) beg the question of the boundaries of RLS.

Objective: This study aims to present two patients with a new atypical localization of restlessness sensation.

Patients and methods: A 43-year-old woman and a 47 years old man, with a positive family history for RLS, came to our attention
complaining of unpleasant sensations localized in the inguinal and bladder region, arising only in the evening while resting, especially when falling asleep. In both patients symptoms started in the adulthood and progressively got worse. Symptoms were intense enough to force void (usually few drops). Voiding yielded transient benefit so that micturition was repeated even up to 20 times per night, ceasing in the morning. There was no urgency during the daytime. Both patients undergone many repeated clinical and diagnostic investigations (laboratory tests, cystoscopy, urography, urodynamics tests, pelvis and spinal MRI).

**Results:** All investigations were unrevealing. Various treatments with antispastic, analgesic, antibiotic or disinfectant drugs, and antidepressants had no effect. Finally, the administration of pramipexole 0.18 mg before bedtime determined a complete cessation of symptoms, confirmed also after one year of follow-up.

**Discussion:** Without considering symptom localization, both cases present disturbing similarities with RLS: the classical circadian presentation of symptoms, the symptom’s release with muscle contractions (leading to repeated voiding) and the striking response to dopaminergic medication. Thus, we emphasize the need to be aware of this atypical presentation in order to institute appropriate treatment.

**Non-motor symptom differences according to Parkinson’s disease phenotype**

M. Alexeev, V. Pavlic, I. Moldovanu, N. Diaconu. Emergency Municipal Hospital, Chisinau, Republic of Moldova; Institute of Neurology and Neurosurgery, Chisinau, Republic of Moldova; Institute of Cardiology, Chisinau, Republic of Moldova

**Introduction:** Non-motor symptoms (NMSs) such as sleep disorders, fatigue, cardiovascular, neuropsychiatric, gastrointestinal and others are noticed in most of Parkinson’s disease (PD) patients, at all stages and phenotypes with an important impact on quality of life. The study objective was to assess the NMSs in a hospital PD sample and differences according to phenotype.

**Methods:** We have included 140 consecutive PD patients from a tertiary care center. All patients were assessed with Non-motor Symptoms Questionnaire, other variables being gender, age, treatment duration, PD phenotype and H&Y staging. The patients were classified into a tremor predominant phenotype (30, 21.4%, group 1), akinetic-rigid (55, or 39.3%, group 2) and mixed one (55, 39.3%, group 3). Windows Office Excel 2007 program was used for statistical analysis.

**Results:** The mean patients’ age was 58.42 ± 7.8 years, 79 men (56.4%), with an average Hoehn and Yahr stage 1.95, UPDRS part III off score 25.3 ± 12.7, mean disease duration was 4.07 (0.5 to 16 years). All the motor scores presented more severe values in the akinetic-rigid group. The average score of NMSs was 29.8, being significantly higher in akinetic-rigid type of PD vs. tremor predominant vs. mixed one (23.28 ± 3.3 vs. 40.9 ± 3.8 vs. 21.9 ± 2.3, p1-2 < 0.01, p1-3 > 0.05, p2-3 < 0.001). The mean NMS number per patient was higher in the akinetic-rigid group (4.26 ± 0.36 vs. 5.8 ± 0.24 vs. 4.74 ± 0.25, p1-2 < 0.001, p1-3 > 0.05, p2-3 < 0.01).

**Conclusion:** Akinetic-rigid phenotype of PD has a more severe expression of non-motor symptoms both in the frequency and intensity, adding to clinical heterogeneity of this particular disorder.

**Arylsulphatase A (ASA) activity in familial Parkinsonism: A pathogenetic role?**

E. Antelmi, M. Fabbri, S. Capellari, G. Rizzo, C. Scaglione, P. Martinelli. IRCCS. Institute of Neurological Sciences and Department of Biomedical and Neuromotor Sciences, University of Bologna, Bologna, Italy

**Background:** Lysosomal impairment is one of the pathogenic pathways identified in Parkinson’s disease (PD). Arylsulphatase A (ASA) is a lysosomal enzyme. It’s still controversial whether ASA partial deficiency, caused by the pseudodeficiency allele (ASAp), represents a non-pathogenetic condition, although different neurological diseases have been linked with it.

**Objective:** We analyzed the pedigrees of three patients with PD and ASA partial deficit.

**Materials and methods:** We performed clinical, laboratory, neuroimaging and neuropsychological investigations, ASA activity dosage and genetic analysis for ASA alleles in three pedigrees.

**Results:** In family # 1 we found three subjects with MD (two sisters: a 65-index case- and a 68 years old lady with PD and a 26 years old boy-index case’s son — with essential tremor). In family # 2 we detected two sisters with PD (a 78 and a 67 years old lady). Finally, in family # 3 we had a 63 (index case) and her sister, a 72 years old lady, both with PD. Patients showed a mild form of disease (6/6) with frequently atypical features, i.e. postural tremor (4/6), tremor of the head (1/6), orthostatic tremor (1/6), cognitive impairment (4/6) and poor L-dopa response (6/6). ASA activity was reduced in all the examined family members, due to the presence of ASAp.

**Conclusion:** Our report describes three families with ASA pseudodeficiency and high prevalence of movement disorders. ASA partial deficit could act at the level of the converging pathway between lysosomal impairment and neurodegeneration, increasing aSyn protein aggregation and accumulation.

**Autonomic dysfunction in Tunisian patients with Parkinson’s disease**

**Background:** Parkinson’s disease (PD) is a progressive neurological disorder characterized by a large number of motor and non-motor symptoms such as olfactory impairment, sleep problems, cognitive problems, psychiatric symptoms and autonomic dysfunction (AD). The autonomic domain is broad including symptoms and signs that relate to cardiovascular, gastrointestinal, urinary, thermoregulatory, pupillomotor, and sexual functioning.

**Objective:** The aim of this study was to assess the prevalence and the clinical characteristics of autonomic dysfunction in Tunisian patients with PD.

**Patients and methods:** We conducted a prospective study in 361 patients with PD (187 males, 174 females), at the National Institute of Neurology in Tunis. Demographic and clinical data were collected and included motor scores (MDS-UPDRS, Schwab and England and Hoehn and Yahr scores). The autonomic function was evaluated using a reliable avec valid instrument, the SCOPA-AUT test.

**Results:** Autonomic dysfunction was frequent in our population. 37.7% of our PD patients showed cardiovascular dysautonomic symptoms,
48.7% had gastrointestinal disorders and 33% had urinary problems. AD was correlated with age, disease motor severity, depression, cognitive dysfunction, sleep disorders and high doses of dopaminergic medication.

**Conclusions:** AD was an important feature of PD in our patients, warranting increased clinical awareness and highlighting the need for efficacious therapies for the wide spectrum of problems related to this domain of PD.

**Polyneuropathy in idiopathic Parkinson — An analysis of risk factors in a mixed Parkinson population**

G. Ablingera, V. Culea, M. Kögl-Wallner, W. Seela, A. Leithnerb, C.N. Homannb, F. Fazekasb, cDepartment of Neurology, Medical University Graz, Graz, Austria; cDepartment of Orthopedic Surgery, Medical University Graz, Graz, Austria

**Background:** Several studies have shown a high prevalence of peripheral neuropathy (PN) in idiopathic Parkinson’s disease (IPD), suggesting it was levodopa induced or related to a vitamin B12 deficiency on the basis of cumulative levodopa exposure. However, existing studies included no or only small numbers of patients without PD medication.

**Objective:** This study examined the prevalence of PN in a cohort of consecutive IPD patients of a general neurology outpatient clinic with a substantial number of de novo patients and analyzed the prevalence of potential risk factors.

**Patients and methods:** 20 IPD patients, Hoehn and Yahr stage 1–4, were examined for the presence and severity of PN, using a definition of distal symmetric polyneuropathy, including electrophysiological measures, the Utah Early Neuropathy Scale (UENS) and the Toronto Clinical Scoring System (TCSS). UPDRS examinations determined the severity of IPD. Potential risk factors, including alcoholism, cobalamin deficiency, high fasting-homocysteine and -methylmalonic acid levels, abnormal fasting glucose, HbA1c levels, and other PNP related serum parameters were analyzed.

**Results:** PN was present in 55% of IPD patients. T-tests and chi square tests didn’t show a significant difference of age, UPDRS or sex between PN-positive and PN-negative patients. An analysis of risk factors didn’t show a significant cumulation of risk factors or even of cobalamin-associated laboratory parameters. UPDRS levels significantly correlated with TCSS-levels.

**Conclusion:** A high prevalence of PN in IPD patients, independent of levodopa exposure or other known risk factors, was shown, but further studies regarding etiology of PN are warranted.

**Chorea-athetosis as the first clinical manifestation in HIV patient**

K. Flabouriari, M. Ladaa, G. Karlisb, K. Konnara, G. Koratzanisc. aNeurological, General Hospital of Attica, Sismanoglio, Athens, Greece; cDepartment of Medicine, General Hospital of Attica, Sismanoglio, Athens, Greece

**Objectives:** There are many reports in the bibliography that comment the clinical association of infection with HIV with movement disorders.

**Case report:** 35 years old female was introduced to our hospital because of hyperpyrexia and abnormal involuntary movements in the extremities of the left side (choreo-athetetic).

The first MRI examination of the head revealed in the right thalamic area pathological signal in T2w and T1w images. GD-enhancement was marked. Lumbar puncture was negative.

PCR for virus in the CSF was negative. IgG Toxoplasma title was elevated in blood examination. HIV test was positive. The choreo-athetotic movement was the first clinical manifestation to our patient. She received therapeutic dose for toxoplasmosis (co-trimoxazole) IV for 6 weeks. The clinical status of the patient has improved.

We do follow-up to the patient with MRI and clinical examination monthly.

**Conclusion:** Solitary lesions with mass effect or contrast enhancement were seen in many HIV patients that have been studied for possible focal brain lesions. Most of them were caused by cerebral toxoplasmosis.

doi:10.1016/j.jns.2013.07.598
In other patients PML or HIV encephalitis or lymphoma has been diagnosed. The issue of increased vulnerability of the basal ganglia to HIV infection is discussed. Evidence of dysregulation by SPECT has been reported. We conclude that dystonia, athetosis or chorea could be the first ever clinical sign of HIV patients.

Botulinum toxin in focal hand dystonia — Reasons for drop-out from the treatment
M. Balaz, M. Bareš, Neurology, Masaryk University, St Anne’s University Hospital, Brno, Czech Republic; CEITEC — Central European Institute of Technology, Brno, Czech Republic

Objective: The goal of the study was to assess the reasons for discontinuation of long-term treatment of writer’s cramp in patients treated with botulinum toxin (BTX). We also observed the long term BTX treatment outcomes.

Introduction: Botulinum toxin A is considered to be an effective treatment for the patients suffering from focal hand dystonia (such as writer’s cramp) but its long-term usefulness may be limited by frequent discontinuation of the treatment for various reasons.

Methods: We reviewed the records of 58 patients who had more than 400 applications of BTX. We also conducted surveys via mail or telephone interviews with the patients who were lost to regular follow-up.

Results: Each patient had at least 2 application sessions, median treatment duration was 82 months. 83% of treated patients reported at least a partial improvement of their condition. There were no serious adverse events. Most frequent side effect was the weakness of muscles adjacent to the injection site. Altogether 32 (55%) patients chose to discontinue the treatment.

Conclusions: High proportion of the patients chose to discontinue the treatment with BTX. The main reasons for discontinuation were side effects (33%), low efficacy (30%), relocation (7%), change of writing habits (6%), new symptoms and change of treatment (6.5%), side effects (33%), low efficacy (30%), relocation (7%), change of writing habits (6%), new symptoms and change of treatment (6.5%), other and unknown reasons (17.5%). While BTX remains an effective treatment for the patients suffering from focal hand dystonia (such as writer’s cramp) but its long-term usefulness may be limited by frequent discontinuation of the treatment for various reasons.

Hypercapnic respiratory failure in patients with progressive supranuclear palsy
K. Komai, C. Ishida, K. Takahashi, Y. Motozaki, T. Ikeda, I. Nozaki, A. Tagami, Department of Neurology, Jou National Hospital, Jou National Hospital Organization, Kanazawa, Japan; Department of Respiratory Medicine, Jou National Hospital, Jou National Hospital Organization, Kanazawa, Japan

Objective: We investigated the frequency of the hypercapnic respiratory failure in progressive supranuclear palsy (PSP). We also discussed the clinical meaning of such hypercapnaemia in PSP.

Background: Progressive supranuclear palsy is a well recognized atypical parkinsonian syndrome. Although nonmotor complications, such as aspiration, dysphagia, and autonomic impairment appear with advance, there is no report of hypercapnaemia in PSP. Since we experienced a case of PSP who showed remarkable hypercapnaemia in his terminal state, we hypothesized that hypercapnaemia could be a common condition in advanced stage of PSP.

Patients and methods: We extracted consecutive 6 cases of PSP who died at our hospital from January, 2008 to December, 2011, and their medical records were reviewed retrospectively about the physical conditions.

Results: The mean age of PSP cases at death was 79.7 (70–86) years old. The mean age at onset was 71.5 (59–79) years old, and average disease during was 8.2 (3–11) years. Two of those were classical Richardson’s syndrome. Five cases were pathologically confirmed as PSP. Hypercapnaemia was observed among five cases within three months before they died.

Conclusions: Hypercapnic respiratory failure is often seen in patients with advanced PSP. Therefore, such hypercapnic condition can be one of the common clinical features in advanced PSP. Although there is some influence of respiratory complications, such as pneumonia, it may reflect the central hypoventilation in endstage PSP.

Focal tongue dyskinesia is rare and can be misdiagnosed as a psychogenic cause. Our patient had unique features: spontaneous tongue movements were described as fluctuating but not distinctly disappear. These movements quite abated while tongue protrusion and speaking, eating, punding, and compulsive use of DRT (dopamine disregulation syndrome). Myoclonus is not a classic feature of vitamin B12 (vit B12) deficiency in adults, though they are frequent in infant cases. Objective: We report an adult patient with cobalamin deficiency that developed myoclonus exaggerated after the initiation of vit B12 treatment.

Case report: A 56 years old woman presents an acute mental confusion with walking and urinary difficulties. Neurological examination found a disoriented and hallucinated patient with pyramidal and cordonal syndromes, associated to peripheral sensory signs. Mild myoclonus of the upper limbs was noted initially. The vit B12 blood level was low. The MRI showed an extensive posterior cervical and dorsal myelitis. 48 h after the initiation of vit B12 therapy, she developed head myoclonus persisting even during sleep, and contrasting with an improvement of the mental confusion. The electroencephalogram was comital. The myoclonus improved after the administration of low doses of clonazepam.

Discussion: In infantile cobalamin deficiency, variable movement disorders were reported (tremors, chorea, dystonia, myoclonus) usually occurring early in the disease and worsening after treatment. In the literature, there were only two reported adult cases with cortical and spinal myoclonus, one of them appearing after treatment. This phenomenon may be explained by the sudden stimulation of folate and cobalamin pathways and producing a temporary imbalance of the complicated metabolic pathways of cobalamin.

Conclusions: Focal tongue dyskinesia is rare and can be misdiagnosed as having a psychogenic cause. Our patient had some unique features: tongue movements were present at rest, were not distractible, and did not interfere with feeding and speech. These clinical features and normal psychiatric evaluation support the tongue dyskinesia in our patient that is “symptomatic” and the need of an ongoing follow-up.
detectable only by acoustic methods, might serve as biomarkers to help detect the presence of the disease in its early stages.

**Purpose:** To detect voice and speech abnormalities at early motor signs of PD (EMSPD).

**Methods:** The speech (reading a paragraph) of 49 individuals with EMSPD (25 M, 24 F; age = 63.18 ± 9.55 years; H&Y = 1.66 ± 0.40; UPDRS = 18.65 ± 8.36; years since diagnosis = 2.61 ± 1.44) and 84 healthy controls (HC, 40 M, 44 F; age = 64.87 ± 8.45) was analyzed using acoustic measures of vowels, voice quality, pitch, prosody, and pauses and rhythmic aspects of speech. Statistical methods were then applied to determine the acoustic predictors for the diagnostic model (these methods included a backward elimination effect selection logistic regression procedure; model diagnostic procedures and ROC analyses; and P values, odds ratios and associated 95% confidence intervals, along with optimized model cutoffs).

**Results:** ROC area under the curve (AUC) was 0.8657. Optimization of the cutoff for maximum overall correct prediction (at probability 38% or higher) yielded 81.6% sensitivity and 73.3% specificity, with overall 78.5% correct prediction.

**Conclusions:** Dysarthria is present in at least 78.5% of patients with EMSPD. It is yet to be determined whether dysarthria is present and detectable by acoustic and statistical analyses at preclinical stages of the disease.

**Clinical features of G\textsubscript{M1} gangliosidosis type 3**

T. Mano, S. Matsuda, M. Taira, T. Yamamoto, J. Shimizu, A. Iwata, S. Tsuji. *The University of Tokyo Graduate School of Medicine, Tokyo, Japan*

**Background:** G\textsubscript{M1} gangliosidosis is a rare inherited lysosomal storage disorder due to deficiency of the β-galactosidase, resulting in accumulation of G\textsubscript{M1} gangliosides and other glycoconjugates in the brain and visceral organs. G\textsubscript{M1} gangliosidosis type 3 is a late-onset chronic form, and this form is very rare.

**Objective:** To describe clinical features of G\textsubscript{M1} gangliosidosis type 3 from genetically proven three cases.

**Methods:** The patients were 2 males and 1 female. Average age of the patients was 36 yo (18–58). Description of clinical features, imaging, biochemical and genetic analysis was done.

**Results:** All patients were born of a consanguineous marriage. All patients were born normally and had normal developmental milestones. Average age of the disease onset was 7.8 yo (3–11). Neurological examination showed generalized dystonia, gait disturbance and speech difficulty. Dystonia was especially prominent in face and neck, which were previously reported in only few cases as blepharospasm or jaw-closing impairment. Two patients had mental retardation. No patients had facial dysmorphic features or cardiomyopathy. Bone radiography revealed scoliosis, hip dysplasia, and flattening and anterior beaking of the vertebral bodies in all cases. Brain MRI showed slight abnormality of basal ganglia in all cases, and cerebral atrophy in 2 cases. Average leukocyte β-galactosidase activity was 7.8% ± 2.0% of normal. All patients had homozygous I51T mutation in GLB1 gene.

**Conclusion:** In comparison with prior cases, facial and neck dystonia, and speech difficulty were distinctive features in our cases. This might be a characteristic of I51T mutation in G\textsubscript{M1} gangliosidosis type 3.

**Automatic detection of freezing index of Parkinson's disease using a portable gait rhythmogram**

A. Hayashi\textsuperscript{a}, H. Shiruma\textsuperscript{a}, S. Aiba\textsuperscript{a}, M. Yoneyama\textsuperscript{a}, H. Mitoma\textsuperscript{a}, \textsuperscript{a}Rehabilitation & Neurology, Juntendo University Urayasu Hospital, Urayasu-city, Japan; \textsuperscript{b}Neurology, Juntendo University Urayasu Hospital, Urayasu, Japan; \textsuperscript{c}Rehabilitation, Juntendo University Urayasu Hospital, Urayasu-city, Japan; \textsuperscript{d}Mitsubishi Chemical Group Science and Technology Research Center, Tokyo Medical University, Tokyo, Japan; \textsuperscript{e}Department of Medical Education, Tokyo Medical University, Tokyo, Japan

**Background:** Freezing of gait is one of the most important motor symptoms in Parkinson's disease. However, we do not have a good method to evaluate accurately the daily profile of freezing in patients with Parkinson's disease. The aim of this study is to develop a new method of automatic detection of daily profile of freezing of gait on Parkinson's disease using a portable rhythmogram.

**Patients and methods:** Firstly, by using a portable gait rhythmogram, we examined gait acceleration and rhythm in 30 patients compared with 27 normal control subjects on 5 m or 10 m walking. Secondary, we studied daily profile of gait in 20 patients with Parkinson's disease using the rhythmogram during 2 or 3 whole days.

**Results:** The gait acceleration as strength of parkinsonian gait was apparently weak compared as normal control. We also could detect

Comparison of smooth pursuit eye movement (SPEM) in patients with idiopathic Parkinson's disease (PD) and progressive supranuclear palsy (PSP)

N. Ito,1 N. Tamaki,2 A. Masuno,3 K. Ikeno,3 S. Onishi3, N. Kobayashi,4 H. Takei,5 P.M. Olley,4 S. Chiba,6 K. Inoue,5 G. Barnes,5 K. Fukushima,6 T. Warabi,7 Department of Neurology Clinical Brain Research Laboratory, Sapporo Yamanoue Hospital, Sapporo, Japan; 2Faculty of Life Sciences, University of Manchester, Manchester, UK

Background: SPEM is impaired in most patients with PD and PSP, though the nature of the impairment is poorly understood.

Objective: To examine whether the impaired SPEM in PD/PSP involves impaired visual motion working memory and/or movement-preparation.

Patients and methods: Twenty-one PD patients, 6 PSP patients and 10 controls completed a memory-based SPEM task (Shichinohe et al., 2009). Cue 1 indicated visual motion-direction while cue 2 instructed the subject to prepare to pursue (go) or not to pursue (no-go). Subjects were required to pursue correct spot from 2 oppositely moving spots or not to pursue by selecting a 3rd stationary spot. For comparison, simple ramp-pursuit was also examined.

Results:

(1) In the memory-based SPEM task, error rates of all PD were low (<5%), similar to controls, but all PSP had higher error rates.
(2) During go trials, controls exhibited SPEM followed by corrective saccades. Most PD (12/21) and PSP (3/3) tracked correct spot with the portable gait rhythmogram.

Conclusion: In this study, we could extract the characteristic of the parkinsonian gait and evaluate especially freezing events more objectively. This method may bring us to evaluate severity of parkinsonian gait not only in a consulting room but also daily profile even not to see directly using the portable gait rhythmogram.

A substantial investigation on psychiatric symptoms in patients with Parkinson's disease (PD)

K. Hasegawa,4 A. Kumon5, M. Saruwatari4, T. Yokoyama3, E. Horiiuchi3, Parkinson Study Group of Sagamihara. 4Neurology, National Hospital Organization, Sagamihara National Hospital, Kanagawa, Japan; 3Neurology, National Hospital Organization, Sagamihara National Hospital, Sagamihara, Japan

Objective: To investigate a situation of psychiatric conditions in patients with PD.

Methods: Our survey was carried out after our Hospital Ethics Committee approved our clinical research program. We conducted the survey of 351 patients with PD in our out-patient clinic who assented to our clinical research program. Used test batteries were bellows, for cognition were MMSE and WAIS-III, for frontal lobe function were FAB, word fluency test and apathy test, for depression were HAM-D, BDI and SDS, for memory function was RBMT, for hallucination was NPI, and for sleep function was ESS. At the same time, we checked their motor function (UPDRS), their QOL (PDQ-39) and imaging studies (MRI, ECD-SPECT, MBG cardiac spectroscopy). These data were analyzed by adequate statistical methods.

Results: Patient background: M:F = 160:191, examined age: 69.6 ± 7.7 years, age of onset: 63.0 ± 4.5 years, and duration of illness: 4.5 ± 6.6 years. H-Y stage: Y-2, 36%; Y-3, 44%; and Y-4, 19%. Results of score in the first year were as follows: In MMSE score <23 points, 30.3%; in RBMT score <15 points, 32.3%; and detected depression state by BDI, 48% (however, no one in depression state in HAM-D). Frontal lobe function is impaired in proportion to other lobes from our results.

Association of idiopathic polyneuropathy and incident Parkinson's disease: A population-based observational study

F. Andersohn1, A. Miclea2, C. Ismail2, N. Arnold2, D. Guo3, T. Nisslein4, C. Conrad2. 1Frank Andersohn Consulting & Research Services, Berlin, Germany; 2Abbott GmbH & Co. KG, Hannover, Germany; 3PB Consulting Network, Neumarkt, Germany; 4AbbVie Inc., North Chicago, IL, USA

Background: Studies have reported an association between levodopa exposure in Parkinson's disease (PD) and an increased incidence of idiopathic polyneuropathy (IPNP).

Objective: To investigate if newly diagnosed PD patients have a higher prevalence of IPNP than the general population.

Patients and methods: Newly diagnosed PD patients without previous exposure to antiparkinsonian drugs and age-, sex-, and practice-matched controls were identified in the UK General Practice Research Database. They were compared for the presence of IPNP within 3 years preceding the index date, i.e. date of PD onset in PD patients or matched date in controls. PD patients and controls were ≥18 years of age and had ≥3 years of person-time in the database. Patients with risk factors for neuropathy (e.g. diabetes, alcohol abuse) or prescriptions of drugs known to cause neuropathy or parkinsonism were excluded. Conditional logistic regression analysis was used to calculate odds ratios for the association between IPNP and PD.

Results: 5089 PD patients and 19,897 controls were included. 20 PD patients (0.39%) and 40 controls (0.20%) had a diagnosis indicating IPNP within 3 years prior to the index date. After manual record review, 15 PD patients and 24 controls had confirmed IPNP. The prevalence of IPNP was increased 2.4-fold in PD patients compared to controls (OR = 2.41; 95% CI 1.17–4.81). There was no indication that age or sex acted as effect modifiers.

Conclusions: In this observational study, patients with incident PD had a higher prevalence of pre-existing IPNP that cannot be explained by adverse effects of antiparkinsonian drugs.

Conclusions: In this investigation, characteristics of psychiatric symptoms in PD become identified. It is important to continue with such investigations for the purpose of improving QOL in PD patients.

Transcranial sonography and pocket smell test in differing Parkinson’s disease from essential tremor
*Neurology, Clinical Hospital Center Osijek, Osijek, Croatia; †Department for Nuclear Medicine and Radiation Protection, Clinical Hospital Center Osijek, Osijek, Croatia; ‡Department for Neurology, Clinical Hospital Center Split, Split, Croatia

Introduction: We wanted to determine the specificity and sensitivity of transcranial sonography (TCS) and Pocket Smell Test (PST) in differing Parkinson’s disease (PD) from essential tremor (ET). We also wanted to compare these methods with the specificity and sensitivity of DaTSCAN used as a gold standard.

Patients and methods: In this study we included 110 patients with the symptomatology of parkinsonism present in the last 6 to 12 months. According to the DaTSCAN results, patients were divided into two groups. The PST was performed to evaluate the olfactory dysfunction. Using TCS the possible substantia nigra hyperechogenicity was encircled and measured. The sensitivity and specificity of PST and TCS were calculated.

Results: From 110 patients, 51 (46.4%) patients had ET and 59 (53.6%) patients suffered from PD. Olfactory dysfunction was present in 44 (74.6%) patients with PD, and in 10 with ET. The specificity of PST is 80.39%, and the sensitivity is 74.58%. The hyperechogenicity of the substantia nigra was predominantly found in patients with Parkinson’s disease. The specificity of TCS is 88.2%, and the sensitivity is 94.9% in confirming Parkinson’s disease.

Conclusion: We suggest that it would be useful to perform these methods routinely in the everyday practice as a good screening protocol before indicating DaTSCAN.

Restless legs syndrome in pregnancy: A case responding to glucocorticosteroids
H. Santos-Canelles, Medicina Interna, Sección de Neurología, Hospital Comarcal de Jarrio, Coaña, Spain

Background: Several studies have related hypothalamic–pituitary–adrenal system activation and restless legs syndrome (RLS). Pregnant women did not participate in them. There are no published cases of RLS in pregnancy responding to glucocorticosteroids either, as they are usually avoided due to potential teratogenicity.

Objective: To describe the effect of glucocorticosteroids over RLS in a pregnant woman treated with a single dose of 20 mg of intravenous methylprednisolone followed by oral prednisone for 3 days because of an asthmatic attack.

Patients and methods: Prospective follow-up during 2nd, 3rd trimester and 12 weeks postpartum. Assessment included familial and past medical history, interview about RLS symptoms, International Restless Legs Syndrome Scale (IRLSS), and blood tests including hemoglobin and ferritin.

Results: A 45 year-old pregnant woman was diagnosed with severe RLS as she met the diagnostic criteria (IRLSS: 38). She had positive family history, was asthmatic and RLS symptoms had started at the 22nd week. Hemoglobin value was 12 g/dL and ferritin 11 μg/L. Initial treatment with oral iron and clonazepam 0.5 mg at night induced a mild amelioration of symptoms (IRLSS: 22). There was a sudden important improvement after iv methylprednisolone which induced a mild amelioration of symptoms (IRLSS: 22). There was a sudden important improvement after iv methylprednisolone which was maintained for two weeks after completing oral treatment (IRLSS: 12). Then symptoms went back to the previous situation (IRLSS: 22) although hemoglobin had risen. At twelve weeks postpartum, she was asymptomatic.

Conclusion: Placebo effect is not a probable explanation to her improvement because glucocorticosteroids were given as a treatment to another disease. Further studies on hypothalamic–pituitary–adrenal activity in pregnant women with RLS would be useful to understand RLS pathogenesis.

doi:10.1016/j.jns.2013.07.615
Background: The Supplementary Motor Area (SMA) plays a key role in motor programming and production, and is involved in internalized movements. SMA syndrome after lesion of the “SMA-proper” is characterized by transient impairment of voluntary movements and motor sequences. This syndrome is assumed to follow from interruption in the motor cortico-subcortical loop. A few case-reports indicate that such syndrome occurs after a lesion isolating SMA from subcortical structures.

Aim: To characterize the pattern of motor impairment in a patient with SMA-subcortical motor loop disconnection after stroke.

Method: The present case developed a transient left hemiparesis following subcortical stroke in the territory of the right anterior cerebral artery, which disconnected the SMA from the basal ganglia. Eight days after the stroke, when the hemiparesis had regressed, the patient presented a specific SMA motor disorder of the left hand manifesting as an akinesia exacerbated when visual attention was not directed towards his hand. We assessed finger tapping with the left and right hands and closed and open eyes, in the left and right hemifields. We indexed movement speed as the number of tapping in 5-second periods.

Results: Ideomotor, ideational gestures and motor sequences were preserved. On the tapping task, the left hand was slower than the right hand. Critically, visual feedback increased tapping speed for the left but not the right hand. The hemispace of the task execution had no effect on tapping performance.

Conclusion: Our results suggest that SMA-basal ganglia disconnection decreases contralateral movement initiation and maintenance and visual cues can partly compensate this effect.

An epidemiological study of neurodegenerative parkinsonism prevalence in the population of “Upper Land” in the south-eastern Moravia, Czech Republic

K. Mensikova1, P. Kanovsky1, M. Kaiserova1, M. Vastik1, L. Mikulicova2, P. Otruba3, P. Juras3, J. Ovecka4, L. Sachova5, F. Dvorsky6, J. Krasa7, V. Janout8. 1Department of Neurology, Palacky University Medical School, University Hospital, Olomouc, Czech Republic; 2Department of Pathology, Medical Faculty of Palacký University, Olomouc, Czech Republic; 3Department of Neurology, University Hospital, Olomouc, Czech Republic; 4Department of Epidemiology and Public Health, Palacky University Medical School, University Hospital, Olomouc, Czech Republic

Objective: To assess the prevalence of neurodegenerative parkinsonism in the rural population of the “Upper Land” region in the south-eastern Moravia, Czech Republic.

Background: It has been recently described that the prevalence of neurodegenerative parkinsonism in isolated European communities might be higher than estimated in the general population. We have recently described this phenomenon in one of the villages (population 1500) of the region of south-eastern Moravia, where we have found the prevalence of 2.5% (in the population older than 50 years). The presented study involved the whole region, i.e., 10 villages (population approximately 9000).

Methods: In the first stage, each patient visiting GP for any reason over the study period of three months completed the screening questionnaire for parkinsonism. In the second stage, neurologists identified all persons with positive signs of parkinsonism among those screened positive. In the third stage, all identified persons were admitted to tertiary movement disorder centers to confirm or exclude the diagnosis of parkinsonism.

Results: The sample consisted of 1039 villagers; 193 persons were screened positive, and 69 of them were identified as manifesting signs of parkinsonism; the diagnosis was confirmed upon examination in the tertiary movement disorder centers.

Conclusion: The prevalence rate of 2.8% in the population older than 50 years substantially exceeds the estimated prevalence in the common Central-European population, future research will focus on the heredity in the families in which parkinsonism has been identified.

Characteristics of motor complications in patients with Parkinson’s disease in southern Tunisia (ST)

S. Smaoui, A. Boukhris, M. Damak, E. Turki, I. Bouchhima, M.I. Miladi, I. Feki, C. Mhiri. Neurology, Habib Bourguiba Hospital, Sfax, Tunisia

Introduction: Motor fluctuations remain often underdiagnosed in the first years of treatment. Despite the importance of this problem, little was known about the cause of motor complications.

Objective: To estimate the prevalence, characteristics and factors that correlated with the occurrence of motor complications in patients with PD in ST.

Patients and methods: 102 unrelated patients were recruited. The mean age at onset was 64.9 years (range 40–86) and 57.8% were men. The severity of motor fluctuations and dyskinesias was assessed by the Unified Parkinson Disease Rate Scale IV “UPDRS IV”. Abnormal Involuntary Movement Scale “AIMS” was used to assess the severity of abnormal movements.

Results: We identified 44 patients (n = 44/102, 43.13%). Motor fluctuations were reported in 24.50% and occur after a mean duration of evolution of 10.66 years (range 3–24). The mean age at onset of PD in patients with motor fluctuations was 52.48 years (range 33–72). An early age at onset (≤40) of PD was present in 16% of cases (n = 4). Based on the UPDRS IV, the duration of episodes was variable: 25% of the day in 60%, half of the day in 28% and up to 75% of the day in 12% of cases. Dyskinesias were present in 33.33% and occur after an average duration of the disease of 9.5 years (range 2–31). An early age at onset (≤40) of PD was frequently associated with abnormal movements (20.58%). The average score of the AIMS was 10.58/40 (range 4–29).

Conclusion: The prevalence of motor fluctuations increased with increasing disease and treatment duration as well as advancing disease severity.

Parkinson's disease as a protective factor of atherogenesis

D. Gutorova, E. Vasenina, Hospital for Veterans of Wars, Moscow, Russia; bRussian Medical Academy for Post-Graduate Education, Moscow, Russia

Background: Parkinson's disease (PD) is one of the most common neurodegenerative diseases. Both genetic and environmental factors are discussed in the pathogenesis PD. Role of hyper- and hypocholesterolemia remains poorly understood.

Material and methods: 46 patients with PD were included, mean age 63.1 ± 7.2 years and disease duration 3.4 ± 3.3 years. 30 people of the same ages without neurodegenerative diseases and significant vascular disorders completed the control group. We investigated blood lipid spectrum and results of Doppler ultrasound scan.

Results: Patients were classified using the Hoehn Yahr scale: 1 stage — 5 (10.9%) patients, 2 st. — 20 (43.5%), 3 st. — 19 (41.3%) and 4 st. — 2 (4.3%) patients. PD patients had a lower level of triglyceride (1.3 ± 0.5 vs 2.0 ± 0.9) and more thin intima-media according to the results of the Doppler ultrasound scan (0.8 ± 0.1 mm vs 1.0 ± 0.3 mm) without differences in total cholesterol level. In groups according to the Hoehn Yahr stages (3st. vs 2st.) level of total cholesterol was significantly lower in PD patients with more severe stages (4.4 ± 0.7 vs 5.1 ± 1.4), p = 0.011.

Conclusion: PD patients had lower level of total blood cholesterol, triglycerides and intima-media thickness with more significant changes in severe stages of PD which may be considered as lower risk of atherogenesis.

Clinical experience with continuous intestinal dopaminergic therapy: A perspective from Hungary

H. Nagy, A. Takats, P. Klivényi, N. Kovács, Department of Neurology, Semmelweis University Faculty of Medicine, Budapest, Hungary; bDepartment of Neurology, University of Szeged, Faculty of Medicine, Szeged, Hungary; cDepartment of Neurology, University of Pécs, Faculty of Medicine, Pécs, Hungary

The continuous intestinal levodopa/carbidopa gel (LCIG) therapy in advanced Parkinson's disease (PD) was introduced in Hungary in 2011 July. Here we report our two-year experience with LCIG therapy. In three clinical centers we tested 37 and include 30 patients. We analyze the gender and age distribution, PD disease, levodopa therapy and motor fluctuation duration. Inclusion criteria were advanced Parkinson's disease (PD), lack of sufficient response to oral medication, clinically significant fluctuations in motor and non-motor symptoms and a good clinical response on test phase.

We observed a significant improvement in not only motor but also non-motor symptoms, reduced fluctuations, less OFF time, increased ON time and better quality of life in patients.

Failure of LCIG therapy was predicted by cognitive decline and low psychosocial support.

Side effects and technical complications (PEG/J system problems, pump problems, surgical procedures and wound problems) were tolerable. Treatment was terminated in 4 patients.

In conclusion CDS therapy is a favorable preference in advanced PD with poor response on oral medications and serious motor fluctuation.

Severe nigrostriatal degeneration without clinical parkinsonism in patients with POLG mutations

C. Tsouliab, G.T. Tranab, T. Schwarzmüllerc, d, K. Spechtef, K. Haugarvollab, N. Balaça, P.K. Lilengab, H. Mileticf, B. Martinf, c, d, L.A. Bindoffab, bDepartment of Neurology, Haukeland University Hospital, Bergen, Norway; bDepartment of Clinical Medicine, University of Bergen, Bergen, Norway; cCentre for Nuclear Medicine/PET, Department of Radiology, Haukeland University Hospital, Bergen, Norway; bDepartment of Pathology, Haukeland University Hospital, Bergen, Norway; bInstitute for Surgical Sciences, University of Bergen, Bergen, Norway; dDepartment of Biological and Medical Psychology, University of Bergen, Bergen, Norway; cDepartment of Medical Engineering, Haukeland University Hospital, Bergen, Norway; cDepartment of Pathology, Haukeland University Hospital, Bergen, Norway; cSection of Pathology, The Gade Institute, Bergen, Norway; cDepartment of Biomedicine, University of Bergen, Bergen, Norway

Background: There is increasing evidence linking mitochondrial dysfunction to degeneration of the substantia nigra and Parkinson's disease. Mutations of the DNA polymerase of mitochondria (POLG) are common causes of mitochondrial dysfunction and disease. Parkinsonism is however rarely seen with POLG defects.

Objective: To investigate the substantia nigra of patients with POLG encephalopathy.

Patients and methods: We studied the substantia nigra in eleven patients with POLG encephalopathy. Mitochondrial and histological changes were characterized in six patients and in vivo nigrostriatal integrity and cerebral metabolism were investigated using dopamine transporter imaging and positron emission tomography in five.

Results: At the molecular level, patients showed mitochondrial DNA depletion, high levels of deletions and selective, progressive complex I deficiency in nigral neurons, which paralleled progressive neuronal loss. Histology and imaging showed that the degree of nigral degeneration and nigrostriatal denervation in our patients were even more pronounced than in idiopathic Parkinson’s disease. Despite this, our patients did not have parkinsonistic features. The additional presence of thalamic and cerebellar dysfunction in our patients suggested that these may play a role in counteracting the effects of basal ganglia dysfunction and prevent the development of clinical parkinsonism.

Conclusions: Our findings confirm the vulnerability of nigral neurons to mitochondrial dysfunction. Moreover, we show that severe nigrostriatal depletion can occur without the clinical correlation of parkinsonism. These results raise fundamental questions about our current understanding of the pathophysiological model of parkinsonism and suggest that other and yet unknown mechanisms contribute to the generation of the parkinsonistic syndrome.

Substantia nigra hyperechogenicity and apparent diffusion coefficient (ADC): Relationship to clinical features of the Parkinson's disease

K. Mazurenka, V. Ponomarevb, R. Sakovichb, aNeurology and Neurosurgery, Belarusian Medical Academy of Postgraduate Education, Minsk, Belarus; bRadiology Department, Minsk City Clinical Hospital No. 2, Minsk, Belarus

Background: Severe nigrostriatal degeneration without clinical parkinsonism and cerebellar dysfunction in our patients suggested that these may play a role in counteracting the effects of basal ganglia dysfunction and prevent the development of clinical parkinsonism.

Conclusions: Our findings confirm the vulnerability of nigral neurons to mitochondrial dysfunction. Moreover, we show that severe nigrostriatal depletion can occur without the clinical correlation of parkinsonism. These results raise fundamental questions about our current understanding of the pathophysiological model of parkinsonism and suggest that other and yet unknown mechanisms contribute to the generation of the parkinsonistic syndrome.
Background: Among the new neuroimaging methods, transcranial sonography (TCS) and diffusion tensor imaging (DTI) offer a unique opportunity to visualize changes in the substantia nigra in vivo.

Aim: To investigate whether SN hyperechogenicity correlated with DTI findings and other clinical data.

Methods: 69 patients (30 males and 39 females, mean age 65.5 ± 8.1 years) diagnosed with PD were examined by TCS using Toshiba Apio XG system. Echogenicity of SN was assessed. 18 of these patients were studied with a DTI protocol at 1.5 T scanner. Regions of interest (ROIs) were drawn in the ventral, middle, and caudal SN. Clinical data were collected: disease duration, UPDRS, MMSE, FAB, Parkinson’s Disease-Cognitive Rating Scale (PD-CRS), Beck Depression Inventory (BDI).

Results: The significant correlation was found between DTI findings (sum of ADC of ventral SN on both sides (mean 1.62 ± 0.15) and sum of bilateral SN echogenic sizes (mean 0.63 ± 0.19 cm²)), measured by TCS (Spearman r = 0.69, p = 0.001). TCS data were related to cognitive impairment in PD patients. Diameter of the third ventricle was correlated (Spearman r = 0.41, p = 0.001).

Results were collected: disease duration, UPDRS, MMSE, FAB, Parkinson’s Disease-Cognitive Rating Scale (PD-CRS), Beck Depression Inventory (BDI).

Conclusions: Our results of 10 patients were in accordance with the literature. Stimulation related side effects of DBS of the subthalamic nucleus, though seen quite frequently, can be handled mostly by close supervision of the stimulation parameters during and after surgery.

a specific validated scale in different populations for the screening and the assessment of these symptoms.

**Objective:** To conduct an Arabic version of the NMSS-PD as an instrument for measuring non-motor symptoms in Tunisian patients.

**Methods:** We conducted a psychometric analysis of the Arabic version of the NMSS using an observational study of 62 patients with PD. The battery also included the scales for outcomes of PD-autonomic (SCOPA-AUT), the Pittsburgh sleep quality index (PSQI), Beck depression inventory, the geriatric depression scale, the MMSE, visual analogical scale for pain and neuro-psychiatric inventory. The correlation between these tests and the NMSS was studied. The reliability of NMSS was explored.

**Results:** Mean age in our population was 63 ± 10 years, sex-ratio was 1.95 and disease duration was 6.6 ± 5.2 years. 89% of them were on L-dopa. All patients were clustered around Hoehn&Yahr Stages 2–3. The mean NMSS score was 82 ± 56. The mean Cronbach’s alpha of the NMSS Arabic version was 0.87 and showed a satisfactory internal consistency. There were highly significant correlations between the NMSS and the SCOPA-AUT as well as the NMSS and PSQI scores. There was a significant negative correlation between the attention/memory domain and MMSE.

**Conclusion:** The Arabic version of the NMSS should be considered a comprehensive, useful measurement for non-motor symptoms in Tunisian PD.

**Drug-induced extrapyramidal syndromes**

G. Mihalicescu, A. Druta, G. Predoiu, I.E. Davidescu, S.M. Nica, R.B. Ciurea, R.M. Anton, G. Pave1, L. Buraga, a Neurology Department, Colentina Clinical Hospital/UMF Carol Davila Bucharest, Bucharest, Romania; bNeurology Department, Dr. Druta Alina, Bucharest, Romania; cNeurology Department, Colentina Clinical Hospital, Bucharest, Romania

**Background:** There are drug-induced extrapyramidal syndromes leading frequently to diagnostic challenges.

**Objective:** To correctly diagnose and determine the moment of occurrence (patient’s age and days of treatment) and the drugs which induce extrapyramidal syndromes.

**Patients and methods:** We conducted a prospective study on 34 patients (10 women, 24 men). We used a specially designed questionnaire, the drug-induced extrapyramidal symptoms scale (DIEPSS) and a complete neurological examination.

**Results:** The drug-induced extrapyramidal syndromes are polymorphic regarding the clinical manifestations, the moment of occurrence and the dosage and type of medication used. The distribution by age showed two peaks, 20–29 years of age (29%) and 70–79 years of age (15%). The majority of drug-induced extrapyramidal syndromes occurred with typical neuroleptics (haloperidol, zuclopenthixol) as well as atypical neuroleptics (risperidone, olanzapine, clozapine) and antiparkineptics. Most of the extrapyramidal symptoms (58.82%) occurred in days 0–9 of treatment. The clinical manifestations were parkinsonism (35.29%), tremor (29.41%), neuroleptic malignant syndrome (20.58%), dystonia (8.8%) and akathisia (5.88%). The first line treatment was to stop or reduce the medication that induced them, hydration, administration of Diazepam, Trihexyphenidyl or L-Dopa.

**Conclusions:** Although the number of cases analyzed was not large enough to be statistically representative, it was found that males are more frequently affected than women and that young people showed a higher risk of developing drug induced extrapyramidal syndromes. We found no demonstrable risk factors for developing drug induced extrapyramidal syndromes. The patient’s medical history is very important to avoid diagnosis errors (example Parkinson’s disease, dystonia).

The efficacy of botulinum toxin injections in deep muscles of upper limb with and without using needle electrical stimulation

D. Pokhabov, V. Abramov, Y. Nesterova. Neurology, Krasnoyarsk’s State Medical University, Krasnoyarsk, Russia

**Background:** Upper limb spasticity after stroke often required the injections of botulinum toxins. However, injections into the deep muscles are not always effective. This may be due to the difficulty in finding target muscles.

**Objective:** To determine the efficacy of botulinum toxin for injection in muscles, pronator teres and digitorum profundus, with and without using needle electrical stimulation.

**Patients and methods:** Patients with spasticity of the upper limb (required obligatorily treatment of pronation patterns and clenched fist) and severe spasticity of 2 or more points by the modified Ashworth scale (mAS). In group-A, 23 patients were treated by experience injectors without electrostimulation. In group-B, 18 patients were injected under the control of electrostimulation. Both groups were treated by the same experienced injector. We used botulotoxin (analyzed only for target muscles), Dysport (120–320 U) or Xeomin (40–100 U). A control visit was carried out after 1 month to assess spasticity (mAS).

**Results:** In group-A, baseline spasticity was 2.48 ± 0.60; in group-B, 2.56 ± 0.63 (not-significant differences). The average dose of Xeomin for group-A was 85.7 ± 15.1 U while that for group-B was 89.3 ± 14.8 U (not-significant differences). The average dose of Dysport for group-A was 194.4 ± 44.6 U while that for group-B was 183.3 ± 41.1 U (not-significant differences). After 1 month, average score for mAs was 1.52 ± 0.87 in group A and the change compared with baseline spasticity was 0.95 ± 0.80. Average score of mAs in group B was 1.19 ± 0.75, and the change compared with baseline spasticity was 1.38 ± 0.72. Differences between the groups were on average 46% and are valid (p < 0.05).

**Conclusions:** The use of electrostimulation improves the efficiency of botulinum toxin injection into the deep muscles of the upper limb.

L-DOPA and attentional boost in Parkinson’s disease: a clue to subthreshold impulsivity and psychosis

H.G. Nagy, E. Levy-Gigi, Z. Somlai, S. Keri. aDepartment of Neurology, Semmelweis University Faculty of Medicine, Budapest, Hungary; bDepartment of Neurobiology and Ethology, The Brain and Behavior Laboratory, University of Haifa, Haifa, Israel; cDepartment of Psychiatry, Semmelweis University, Budapest, Hungary; dDepartment of Physiology, University of Szeged, Faculty of Medicine, Szeged, Hungary

When participants perform an attention-demanding task (i.e., remembering white target letters and ignoring black distractor letters in briefly presented sequential stimuli), they also encode the background
Relapsing polychondritis is a multisystemic disease that affects multiple systems of the body. It is characterized by inflammation of the cartilage in the body, which can cause symptoms such as joint pain, swelling, and stiffness. Patients with relapsing polychondritis may also experience hearing loss, ear pain, and eye problems. The disease is often diagnosed based on clinical features and laboratory tests, and treatment options typically include corticosteroids and immunosuppressive drugs. The natural course of the disease is variable, with some patients experiencing remissions and others experiencing frequent relapses. Overall, relapsing polychondritis is a rare but serious disease that requires prompt and careful management to prevent complications and improve outcomes for affected individuals.
patients had multifocal, 6 patients had generalized and 3 patients had hemidystonia. Etiologic analysis revealed 7 patients with perinatal cerebral injury, 5 patients with infection of CNS, 4 patients with trauma, 4 patients with stroke and 1 patient with peripheral injury. 8 patients had putaminal, 6 patients had pallidal, 2 patients had putaminal and cortical, 3 patients had hemyatrophy of cerebral hemispheres. 1 patient had brainstem and 1 patient had ulnar nerve injury verified with EMG.

Conclusion: Basal ganglia are the site of predominant localization for secondary dystonia but different sites of CNS especially white matter adjacent to basal ganglia and brainstem are also involved in secondary dystonias.

Vascular Parkinsonism

S. Koci, M. Kapiszynia, D. Dobi, A. Rrojib, G. Vroto, J. Kruja. a, M. Kapiszynia, b, M. Megrelishvilia, b, I. Khatiaishvilia, b, aUniversity Service of Neurology, UHC Mother Theresa, Tirana, Albania; bUniversity Service of Imagery, UHC Mother Theresa, Tirana, Albania

Aim: Identification of clinical features that suggest for vascular Parkinsonism.

Methods: In this study we included 86 patients with Parkinsonism, who were examined in the Extrapyramidal Unit of University Neurologic Service, in Tirana during 2006–2009. Clinical examination highlighted that 71 patients were with Parkinson’s disease and 17 were with Parkinsonistic syndrome.

We analyzed age, sex, duration of symptoms from the first visit, evidence of vascular disease, and distribution of asymmetry of the signs. We used UPDRS to evaluate the clinical signs. Response to levodopa therapy was determinant in visit of control.

The evidence of vascular disease was assessed by these indices: installation of clinical Parkinsonism signs at least one month after stroke, and personal history for last stroke before neuroimaging evidence for stroke in 2 or more territories. The data were analyzed in SPSS 12.1 software. The standard deviation of ages and duration of symptoms were calculated using student’s t-test. The results were statistically significant for p value < 0.05.

Results: The vascular Parkinsonism and Parkinson’s disease can differentiate easily clinically (p = 0.001 to p = 0.0001).

The patients with vascular Parkinsonism were more elderly and present more walking disorders than rest tremor and hadn’t a good response to levodopa therapy compared with Parkinson’s disease patients. (p = .00001).

The patients with vascular Parkinsonism present more falling, dementia, sphincter incontinence (p = 0.001) and pseudobulbar syndrome (p = 0.005), compared with Parkinson’s disease patients.

Are there any correlations between the length of “ephedrone-abuse” and severity of depression in patients with “ephedrone-induced” Parkinsonism?

N. Botchorishvilii, M. Kapiandzeab, M. Megrelishviliiab, I. Khatiaishviliiab, N. Mikeladzeab, M. Janelidzeeb, aNeurology, Khechinashvili University Clinic, Tbilisi, Georgia; bInstitute of Medical Research, Ilia State University, Tbilisi, Georgia

Introduction: Severity of depression is different in patients with similar age, similar length of “ephedrone” abuse and similar severity of movement disorder. Causes of variability are unclear.

Objective: To identify the relationship between the severity of depression and length of “ephedrone”-abuse.

Patients and methods: We examined 33 male and 1 female patients with a mean age of 40.2 years (SD ± 3.8 years) and with 0.5–1.5 years history of “ephedrone”-abuse and movement disorder. We formed four groups of patients: group I – 9 patients with minimal depression; II – 5 patients with mild depression; III – 10 patients with moderate depression; and group IV – 10 patients with severe depression.

Depression was evaluated according the Beck depression inventory. Movement disorder was assessed with UPDRS.

Result: In our study, a clear relationship between the severity of depression length, severity of Parkinsonian syndrome and length of “ephedrone”-abuse was not found.

Conclusion: A relationship between the severity of depression, severity of Parkinsonian syndrome and length of “ephedrone”-abuse was not shown in examined patients. Our study has limitations: the numbers of patients was small and controls of same age were not examined. Further studies are planned to assess the role of “ephedrone”-abuse in the severity of depression and movement disorder in patients with ephedrine-induced Parkinsonism.

Hemorrhagic syndrome in Wilson’s disease patients

M. Melnikovaab, T.F. Fedorovaa, S.V. Lobzina, E.B. Panina, K.L. Raikhelson, L.R. Tarkovskaya, N.N. Silina, O.A. Smirnova. aNorth-Western State Medical University named after I.I. Mechnikov, Saint-Petersburg, Russia; bRussian Research Institute of Hematology and Transfusiology, Saint-Petersburg, Russia

Introduction: Severity of hepatic impairment due to Wilson’s disease (WD), and angiotoxic and hemolytic effects of copper can significantly influence hemostasis and lead to hemorrhagic syndrome (HS). The incidence of HS and disturbances of hemostasis have not been studied before.

Objective: To investigate the incidence of HS and disturbances of platelet hemostasis and plasma coagulation in patients with WD.

Methods: 68 patients with WD and 65 patients with other liver diseases (LDG) were examined retrospectively for different signs of HS they had since the birth till the time when diagnosis was established and chelating treatment was started. 65 normal individuals were examined as the control group (CG). Parameters of platelet and plasma coagulation hemostasis were evaluated in 48 patients with WD.

Results: 52% of WD patients at the age of 3–9 years presented hemorrhagic signs and 77% at the time when diagnosis was established. The result was significantly higher than that in the CG and LDG group. The most typical hemorrhagic signs were nasal and gingival bleeding and bruises and in 68% of patients they repeated daily or weekly. 95% of patients with WD had abnormal laboratory parameters of hemostasis: thrombocytopenia, increase of intravascular platelet activation and aggregation, increased vWF activity, prolongation of APTT, decrease of PT (because of reduced activity of factors V, VII and X), decreased activity of antithrombin and plasminogen level and diminished time of factor XII-dependent fibrinolysis, and elevated levels of d-dimer.

Conclusion: Patients with WD demonstrate the high incidence of HS in comparison with patients with other liver disorders.

The role of postoperative levodopa test in combining deep brain stimulation programming and medication therapy in Parkinson's disease
P. Radics1, L. Erös1, A. Takáts2, D. Heldmann2, J. Giuffrida3, G. Tamás4,
1Semmelweis University, Budapest, Hungary; 2National Institute of Neuroscience, Budapest, Hungary; 3Great Lakes NeuroTechnologies Inc., Cleveland, OH, USA

Background: In Parkinson's disease, the combination of subthalamic deep brain stimulation (STN-DBS) and medication therapy need to be adjusted to treat the clinical symptoms. This strategy is assisted by a drug challenge test, when motor symptoms are evaluated by clinical rating scales during continuous bilateral stimulation, in medication ON and medication OFF states.

Objective: We investigated if quantitative motion analysis during a postoperative levodopa test can help the therapy setting.

Patients and methods: Eleven patients (age: 61.7 ± 9.54 years, disease duration: 18 ± 6.11 years) performed 14 s of finger tapping, hand grasping and pronation-supination of the arm in three conditions (STIM ON—MED OFF, STIM OFF—MED OFF and STIM ON—MED ON) one year after bilateral STN-DBS implantation. A motion sensor consisting of a three-dimensional gyroscope and accelerometer was worn on the index finger to measure limb movement. Speed as root mean square angular velocity and amplitude as root mean square excursion angle were calculated from the signal of the gyroscopes and compared with ANOVA for repeated measures (p < 0.05).

Results: In case of optimal DBS settings, speed and amplitude of the three tasks did not differ significantly in the STIM ON—MED OFF and STIM ON—MED ON states and they were significantly higher than in the STIM OFF—MED OFF condition. In the single subject level, further DBS programming was needed when levodopa administration improved the speed and amplitude of the movement during bilateral STN-DBS.

Conclusion: The postoperative levodopa test assisted by quantitative motion analysis facilitates the optimal setting of DBS, so medication dose can be reduced to avoid its side effects.

Pharmacokinetics of levodopa and 3-omd in patients with Parkinson's disease and motor fluctuations infected with Helicobacter pylori
E. Naropańska1,2,3, M. Białecka1, U. Adamiak-Giera4, B. Gawrońska-Szklarz2, W. Sołtan2, M. Schiniwskis2,3, P. Robowski2,3, M. Madaliński2, J. Sławek2,3, 1St Adalbert Hospital, Szczecin, Poland; 2Medical University of Gdańsk, Gdańsk, Szczecin, Poland; 3Department of Experimental and Clinical Pharmacology, Szczecin, Poland; 4Pomeranian Medical University, Szczecin, Poland; 5The Pennine Acute Hospitals NHS Trust, Manchester, UK

Background: Recent investigations suggest that eradication of Helicobacter pylori (H. pylori) may influence levodopa (LD) pharmacokinetics and improve the motor function of infected patients with Parkinson's disease (PD). Our study was aimed at comparison of pharmacokinetics of LD and its metabolite 3-O-methyl-dopa (3-OMD), between H. pylori-positive and -negative patients with Parkinson's disease and motor fluctuations.

Materials and methods: Seventy-three patients with the clinical diagnosis of PD, under stable LD therapy, reporting daily motor fluctuations and who had no history of previous eradication treatment, were screened for the infection with an antigen stool test. Thirty seven patients: 18 with H. pylori infection and 19 noninfected, matched both demographically and clinically, were selected for the examination of LD and 3-OMD pharmacokinetic parameters. Blood samples were collected immediately before and after morning LD dose 13 times: at 15 min intervals up to 2 h and then at 30 min intervals up to 4 h. LD and 3-OMD concentrations were determined using a high-performance liquid chromatography method (HPLC) coupled with electrochemical detection.

Results: The analysis of the pharmacokinetic parameters of LD and 3-OMD showed no significant differences between H. pylori-infected and noninfected groups.

Conclusion: There is no evidence for malabsorption of LD in H. pylori-infected patients.

Incidence, prevalence and clinical pathway of Parkinson's disease among Pakistani population
T. Hussain1, I.A. Khan1, 1Holy Family Hospital, Rawalpindi, Pakistan; 2Peshawar Medical College, Peshawar, Pakistan

Introduction: Parkinson's disease is an idiopathic disorder of the extrapyramidal system characterized by rigidity, akinesia and tremors. The aim of this study was to describe the clinical spectrum of the disease from Pakistan, a developing country in south-east Asia.

Methods: This study was conducted at the teaching hospitals of Peshawar Medical College, Pakistan over a period of 1 year from August 2011 to July 2012. Patients with Parkinson's disease were identified by an ICD-9 coding system of the hospital medical records. An informed consent was obtained from all the participants. Demographical characteristics, clinical features, laboratory investigations and radiological investigations were recorded and analyzed.

Results: A total of 48 patients were identified. 30 were males and 18 were females. Mean age of onset of the disease was 51 years. 28 patients had onset of illness during the sixth or seventh decade of life. Mean duration of illness at the time of presentation was six years. Rigidity, bradykinesia, tremors, primitive reflexes, and difficulty in performing fine work and walking were the most common clinical features. 36 patients had predominantly unilateral symptoms. 12 patients had cognitive impairment. Cognitive decline was more common in the elderly and in patients with disease duration of longer than 8 years.

Conclusion: Parkinson's disease is more common in males. Tremor, rigidity, walking difficulty, bradykinesia and difficulty in performing fine work are the commonest clinical features. Disease severity increases with duration of the disease. Cognitive impairment is not uncommon in these patients and is associated with disease duration and age of onset of the illness.

Transcranial sonography in movement disorders
M. Budisic, A. Lovrenovic-Huzjan, V. Supanc, Z. Trkanjec, V. Basic-Kes. University Hospital Sestre Milosrdnice, Zagreb, Croatia
**Background**: So far there is no reliable test that can clearly distinguish between various movement disorders and therefore the diagnosis is still based on clinical examination. However, the misdiagnosis rates for the most common movement disorders: Parkinson's disease (PD) and essential tremor (ET) in the early stages is as high as 20–30% for PD and in about one of three patients in ET. We initiated this study is to assess the possibility of transcranial sonography (TCS) to help differentiate PD from ET by measuring echogenicity of the substantia nigra (SN).

**Patients and methods**: Our study included 60 patients with PD, 30 patients with ET and 60 healthy controls. The TCS recordings were done in the axial plane by a standardized protocol by two independent investigators. SN was displayed, encircled, and measured two times. Mean area was calculated. Mann–Whitney U test for inter-group comparison was applied.

**Results**: Patients with ET and PD had a mean SN size of 0.15 cm² (±0.04) and 0.27 cm² (±0.06), which showed a significant difference (p < 0.001). In the control group bilateral combined mean SN size was 0.17 cm² (±0.06), which was significantly different from the PD group (p < 0.001), but not from the ET group (p = 0.240).

**Conclusion**: The measurement of SN by means of TCS is a valuable tool in the differentiation of movement disorders. Due to portability, lack of invasiveness and ease of reproducibility, TCS might help in diagnosing PD or in differential diagnosis of doubtful clinical cases.

**Spinocerebellar ataxia 7 (SCA7) in India: Genotype-phenotype correlation and insight into origin of mutation in predisposed endogamous population**

A.K. Srivastava, M. Faruq, T. Dada, A. Garg, S. Singh, M. Mukerji, M. Behari, Neurology, All India Institute of Medical Sciences, New Delhi, India; Genomics and Molecular Medicine, CSIR – Institute of Genomics and Integrative Biology, Delhi, India; Ophthalmology, All India Institute of Medical Sciences, New Delhi, India; Neuroradiology, All India Institute of Medical Sciences, New Delhi, India.

**Background**: Spinocerebellar ataxia (SCA7) is characterized by neuro-ophthalmic degeneration and occurs due to CAG repeat expansion in exon 3 of ATXN7 in the region of chromosome 3p12-p21.1. The SCA7 mutation has been identified in various ethnic and geographical regions with highest prevalence in South Africa and in the Scandinavian region.

**Objectives**: To describe the clinical-genetic characteristics of nine SCA7 families of Indian origin and cross comparison with worldwide studies.

**Methods**: 33 individuals including 22 affected and 11 unaffected from nine SCA7 families were clinicogenetically characterized. CAG repeat distribution analysis was carried out in 375 control DNA samples from 20 diverse Indian populations based on ethnicity, linguistics and geographical location.

**Results**: Genotype to phenotype studies show correlation of CAG length with age at onset (r² = 0.844) and CAG repeat adjusted SARA scores with duration (y = 0.0234x + 0.1798; R² = 0.591). Meta-analysis of CAG repeats with disease onset reveal association of repeats <49 with earlier age at onset in Southeast Asian compared to European populations. Analysis of CAG repeats from 20 diverse Indian populations represented in the Indian Genome Variation Panel showed the presence of pre-mutable repeat (28–34) alleles in the same population (1E-NL-P2) from which SCA7 families were derived.

**Conclusion**: We observed quite a homogeneous phenotypic expression of SCA7 mutation with subtle differences in age at onset mediated by CAG repeat in various geographical populations. We also speculate that there is recurrent generation of predisposed intermediate permutable 28 CAG repeats in ATXN7 across various world populations determining the occurrence of SCA7.

**Analysis of alpha-synuclein ala53thr mutant: a computational approach**

M. Simonetto, F. Zonta, Department of Specialty Medicine, Division of Neurology, ULSS 15 “Alta Padovana” Cittadella Hospital, Cittadella, Italy; Department of Physics and Astronomy “G. Galilei”, University of Padova, Italy; Venetian Institute of Molecular Medicine, Padova, Italy.

**Background**: Parkinson's disease (PD) is a progressive neurodegenerative disorder due to loss of dopaminergic neurons from the substantia nigra pars compacta of the CNS. Mutations of alpha-synuclein (AS), a protein involved in the formation of synaptic vesicles of dopamine, are a cause of PD. AS has a native disordered state that undergoes α-helical conformation upon interaction with membrane lipids. The neuropathological hallmarks of PD are “Lewy bodies”. They are made of aggregated AS that are potentially toxic agents.

**The effect of DBS on cortico-muscular coherence in advanced Parkinson's disease**

K. Airaksinen, J. Mäkelä, J. Nurminen, J. Luoma, S. Taulu, A. Ahonen, E. Pekkonen, University of Helsinki, Helsinki, Finland; Elekta, Helsinki, Finland.

**Background**: DBS is a well-established treatment for advanced Parkinson's disease (PD) even though its mechanism of action is not precisely known. Cortico-muscular coherence (CMC) is used to measure the connectivity between the motor cortex and muscle during motor activity.

**Objective**: Our hypothesis was that DBS would strengthen CMC whenameliorating motor functioning.

**Patients and methods**: We measured 19 patients with advanced PD, treated with bilateral STN-DBS, with MEG (magnetoecephalography). Simultaneously with MEG, EMG was recorded from the activated extensor carpi radialis longus muscle during wrist extension for coherence calculations. The measurements were done with both DBS on and off. UPDRS motor scores were used to evaluate the motor performance. Antiparkinsonian medication was continued during the study. For artifact removal, the spatiotemporal signal space separation was applied.

**Results**: 13 out of 19 patients showed CMC between 10 and 18 Hz. The effect of DBS on CMC was inconsistent; eight patients had enhanced CMC when DBS was off and five when DBS was on. The peak frequency of CMC correlated negatively with the rigidity scores of the active hand when DBS was off.

**Conclusion**: DBS alters CMC with great individual variety in advanced PD. We did not find linear correlation between CMC amplitude and motor performance. The peak frequency of CMC correlated negatively with the rigidity of the active hand when DBS was off.

**Objective:** Investigate with computational approach AS mutants.

**Material and methods:** We performed a statistical study of a known natural variant and other experimental mutations of SNCA gene coding for AS linked with familial PD using PASTA software. Among them we selected the Ala53Thr missense mutation and performed a molecular dynamics (MD) investigation.

**Results:** The prediction with PASTA correlates with literature. In particular, this approach reveals that the Ala53Thr mutation increases the tendency of AS to fold in a β-secondary structure altering the functionality of the protein. The MD analysis shows that in the cytoplasm the AS structure is unstable.

**Conclusion:** Wild-type AS presents an α-helical conformation in membrane lipids but is disordered in cytoplasm. The mutation Ala53Thr increases the probability that AS fibrillizes impairing the binding to membrane lipids; and the presence of Lewy bodies due to AS mutant aggregation in the cytoplasm.

**Idebenone in treatment of patients with Huntington's chorea and hereditary myopathy**

O. Sidorova, I. Kazantseva, E. Borodataya, A. Polyakov, Department of Neurology, M.F. Vladimirsky Moscow Regional Clinical and Research Institute, Moscow, Russia; Department of Pathology, M.F. Vladimirsky Moscow Regional Clinical and Research Institute, Moscow, Russia

**Introduction:** The treatment of Huntington's chorea and hereditary myopathy is absent. We studied the efficacy of energotropic therapy.

**Materials and methods:** A total of 18 adult patients with the Huntington's chorea, 5 Huntington's chorea gene carriers, and 12 with hereditary myopathy were studied. Cytotoxic analysis of the peripheral blood lymphocytes was performed.

**Results:** In patients with Huntington's chorea and gene carriers the levels of lactate and mitochondrial enzymes were changed. Idebenone 90 mg a day was prescribed. 1–6 months later the mean MMSE score grew from 21.1 to 23.9. In mild hyperkinetic syndrome, its slight decrease was noted. Medication was also prescribed to the carriers of the Huntington's chorea gene to postpone the time of the clinical manifestations of the disease and diminish the disease severity. 12 persons with early CVD (CVD1), 10 — with expressed post-stroke CVD (CVD2), and 10 persons — control (C).

**Conclusion:** Analysis of supratentorial structures revealed significant decrease of cerebral volume in CVD and PD2. An increasing volume of the subarachnoid space was found in both CVD and PD as compared to the control (C). The volume of cerebral ventricles in CVD exceeded C values. Investigation of midbrain structures showed that SN volume in PD1, PD2, and CVD1 (on T2) didn't differ from C. But in CVD2 it was less than in C. While in CVD progression SN volume decreased, in PD — it increased. RN volume was decreased in all patient groups as compared to the control (C).

**Objective:** Cerebral volumetric morphometry was studied for revealing the signs of the neurodegenerative process in PD and cerebrovascular disease (CVD) patients using 3 T MRI.

**Patients and methods:** Volume values of cerebral substance and liquor, substantia nigra (SN), and red nucleus (RN) were determined. Under examination there were 10 PD patients with I stage (by Hoehn and Yahr's scale) (PD1), 10 PD patients with III stage (PD2), 10 patients with early CVD (CVD1), 10 — with expressed post-stroke CVD (CVD2), and 10 persons — control (C).

**Results:** Analysis of supratentorial structures revealed significant decrease of cerebral volume in CVD and PD2. An Increasing volume of the subarachnoid space was found in both CVD and PD as compared to the control (C). The volume of cerebral ventricles in CVD exceeded C values. Investigation of midbrain structures showed that SN volume in PD1, PD2, and CVD1 (on T2) didn't differ from C. But in CVD2 it was less than in C. While in CVD progression SN volume decreased, in PD — it increased. RN volume was decreased in all patient groups as compared to the control (C).

**Conclusion:** In PD and CVD, the signs of neurodegenerative process were revealed manifesting themselves in decrease of the cerebral substance volume, extension of liquor spaces, and decreasing the midbrain structures. But it has significant differences of PD and CVD. Increase of the SN volume in PD is likely due to deposition of ferritin. The data can be helpful for the early diagnostics of the PD.

*doi:10.1016/j.jns.2013.07.368*
Results: Sleep disturbance was reported by 58.7% patients, while 41.3% did not have sleep disturbance. Mean total PDSS score was 94.6 ± 30.1. The lowest scores were on items evaluating nocturnal awakenings (2.8) and nocturia (2.6). In a group of patients reported not to have sleep disturbance total PDSS score was 104.4 ± 28.8 (lowest scores were on items evaluating nocturnal awakenings (3.9) and nocturia (3.3), while in a group that had a disturbance the score was 87.7 ± 29.3 (lowest score also were on items evaluating nocturnal awakenings and nocturia (2.0)). We found statistically significant difference between two groups of patients on this items: nocturnal awakening (t = -2.869; p < 0.005), restlessness (t = 1.941; p < 0.01), distressing dreams (t = -2.947; p < 0.005), distressing hallucinations (t = -1.956; p < 0.05), tremor on waking (t = -2.135; p < 0.05) and morning tiredness (t = -2.494; p < 0.01).

Conclusion: Among sleep disturbances nocturnal awakening, restlessness, distressing dreams (t = -2.869), distressing hallucinations (t = −1.956; p < 0.05), tremor on waking (t = -2.135; p < 0.05) and morning tiredness influence most on the quality of sleep in patients with Parkinson’s Disease.

Treatment of diphasic dyskinesias in Advanced Parkinson’s Disease with Duodopa

Objective: This is an overview of two patients with Advanced Parkinson’s disease (PD) and diphasic dyskinesias that have been treated with Duodopa.

Patients and methods: A clinical study has been carried out by presenting the history and the progress of the disease, the emergence of movement complications and dyskinesia. An attempt for clinical analyses of the diphasic dyskinesias was made, as well as for their recognition and differentiation from the peak-dose dyskinesias. A graphic illustration of the daily rhythm of the patients’ condition is shown herein. The way the patients walk is demonstrated with short videos.

Results: The diphasic dyskinesias affect mainly the lower limbs and often change the way the patient walks, which sometimes may look ‘strange’ and may be associated with psychogenic movement disorders. The diphasic dyskinesias differ from the peak-dose dyskinesias. The two types of dyskinesias are often mixed and a different approach must be applied to each one of them. The general rules and strategies for treatment of the diphasic dyskinesias with Duodopa are outlined herein.

Conclusion: As evident from the clinical study, the diphasic dyskinesias are much more serious, as well as much more difficult to recognize and to treat.

Fahr’s syndrome: A Tunisian cohort and review of the literature

M. Ben Diebara, Y. Sidhom, A. Nasri, Y. Hizem, I. Kacem, A. Gargouri-Berrechid, R. Gouider. Department of Neurology/Research Unit 03/UR/08-09, Research Unit 12SP21, Razi Hospital, Tunis, Tunisia

Background: Fahr’s syndrome is characterized by symmetrical and bilateral intracerebral calculifications, located in the basal ganglia. It’s mostly associated with a phosphorous calcium metabolism disorder, but could have other etiologies.

Objective: To report clinical and paraclinical manifestations in patients with Fahr’s syndrome, to determine the etiologies and to describe their treatment and outcome.

Patients and methods: We conducted a retrospective study over an 11-year period including all patients diagnosed with Fahr’s syndrome and their first degree relatives followed for neurologic manifestations. Demographic data, neurologic examination, imaging, and treatment were analyzed.

Results: We identified 14 patients diagnosed with Fahr’s syndrome, and two first degree relatives with neurologic manifestations (sex ratio = 0.6, mean age = 47.9 years, mean age of onset = 38.8 years). Family history revealed neurologic troubles (10) and endocrine diseases (10), with consanguinity in 9 patients. Movement disorders were the most frequent inaugural manifestation (5) and finding on examination (7). Neuropsychological assessment revealed mainly dysexecutive troubles (7). Brain imaging showed calcifications mainly in pallidum (6). Fahr’s syndrome was secondary in 11 patients, mainly due to dysparathyroidism (8). Two families with Fahr’s disease were identified.

Conclusion: The high consanguinity rate and the frequent neurologic and endocrine family history in our series suggest a genetic origin of Fahr’s disease or endocrine diseases that could lead to Fahr’s syndrome. Further genetic studies are needed to elucidate the causative genes implicated in this rare disease. However, a battery of biological tests should be systematic in order to rule out a secondary origin of Fahr’s syndrome.

Behavioral impairment in Parkinson’s Disease in the Siberian region

I. Zhukova, M. Nikitina, O. Izboldina, N. Zhukova, V. Alifirova, M. Titova, M. Zhestikova, O. Gileva. 1Department of Neurology and Neurosurgery, Siberian State Medical University, Tomsk, Russia; 2Department of Neurology, Novokuznetsk State Postgraduate Institute, Novokuznetsk, Russia; 3Department of Neurology, Neurosurgery and Medical Genetics, Medical Academy, Kemerovo, Russia

Background: A recent large study found that Impulsive behavioral disorders (IBDs) occur in approximately 15% of patients with Parkinson’s disease (PD). IBDs may lead to significant impairments in psychosocial functioning, interpersonal relationships, physical health, and life quality. Patients and relatives may not report such behaviors to a treating physician, perhaps due to embarrassment, not suspecting an association with PD treatment, or ambivalence regarding ceasing the behavior. Hence, there is evidence that IBDs aren’t always recognized in routine clinical PD care.

Objective: Examination of tools for screening IBDs in PD patients at the common practice in Movement Disorders clinics.

Material and methods: Data was collected from 3 centers across the Siberian region of Russia (Tomsk, Kemerovo, Novokuznetsk). 834 medical records were surveyed for IBDs screening and the tools used.

Results: 106 of 834 patients with movement disorders (12.7%) were screened for behavioral impairment, 98 of whom (11.75%) had QUIP-RS, 8 – other tests (including QUIP). As a result 56 of 98 patients (57.14%) had IBDs, 27 (27.55%) — 2 or more IBDs. 83 of 426 PD patients (19.48%) were screened for behavioral impairment. As a result 51 of 83 patients (61.14%) had IBDs.

Clinical and genetic aspects of torsion dystonia in the Moscow region
K. Ostapchuk, O. Sidorova, V. Misikov, S. Kotov. Department of Neurology, M.F. Vladimirsky Moscow Regional Clinical and Research Institute, Moscow, Russia

Objective: Studying specific weight of the family cases of torsion dystonia (TD) among all TD cases in the Moscow Region and phenotypical features of patients according to dermatoglyphics data.

Materials and methods: The register of patients with TD (n = 336) was created for the Moscow Region population. A contact method of dermatoglyphics was conducted.

Results: Among 336 patients with TD, 4 patients with repeated familial disease were revealed. In the first family, it was father and son, and in the second it was mother and daughter. In the first family, dystonic dysphagia was found in the father, and spastic torticollis in the son. In the second family, both mother and daughter had spastic torticollis. Specific weight of family cases accounted for 0.12% among the whole number of involved patients. The other family was revealed also, in which the son had spastic torticollis. Dermatoglyphics showed an increased rate of more complex patterns (radial loops R and curls W).

Conclusion: Thus, the specific weight of family cases among all TD patients was 0.12%. TD is inherited by an autosomal dominant type. It was revealed that there was incomplete penetration of the pathological gene in DYT1 patients. Dermatoglyphics showed an increased rate of more complex patterns (radial loops R and curls W) on the patients’ fingers.

Mindfulness in Parkinson’s Disease leads to increases in gray matter density
B.A. Pickut, a W. Van Hecke, b P.M. Parizel, c P. Crasa. a Neurology, University of Antwerp Hospital, Belgium; b Icometrix, University of Antwerp Hospital, Belgium; c Radiology, University of Antwerp Hospital, Antwerpen, Belgium

Background: PD consists of motor and non-motor symptoms. There is a need to objectively analyze non-pharmacological interventions used to help alleviate symptoms in PD.

Objective: This study was conducted to evaluate structural brain gray matter changes following a mindfulness based intervention (MBI) in Parkinson’s disease (PD).

Methods: Twenty-seven of 30 PD patients completed this longitudinal RCT comparing MBI, consisting of a structured 8-week program of mindfulness training (n = 14), with usual care (UC) (n = 13). MRI 3D T1 weighted (1 x 1 x 1 mm3 resolution, Siemens 3 T System) data sets were obtained at baseline and after 8 weeks. Voxel based analysis was performed using DARTEL from the SPM8 software. Segmented gray matter baseline images were subtracted from the follow-up scan. Resulting difference maps of MBI and UC groups were statistically compared, to examine gray matter density differences in time between both groups. Results were reported at p < 0.001, uncorrected for multiple comparisons.

Results: Increased gray matter density was found in the MBI group compared to the UC group over time in the right caudate, left and right hippocampus and right amygdala. On the other hand, increased gray matter differences were found in the UC compared to the MBI group in the left cerebellum.

Conclusions: This is the first quantitative analysis of neurobiological effects of mindfulness in PD to the best of our knowledge. Increased gray matter density was found in the MBI group in the neural networks that have been postulated to play a role in mediating benefits of meditation.

Excessive daytime sleepiness in patients with Parkinson’s disease
M. Nikitina, I. Zhukova, O. Izhholdina, N. Zhukova, V. Alifirova, M. Titova. Department of Neurology and Neurosurgery, Siberian State Medical University, Tomsk, Russia

Background: Excessive daytime sleepiness (EDS) is one of the most commonly reported sleep complaints in patients with Parkinson’s disease (PD), affecting between 15% and 50% of PD patients. There are conflicting reports about the association of Hoehn and Yahr (H&Y) stage and the degree of EDS.

Objectives: To determine the stage related distribution of EDS in PD patients.

Material and methods: 426 PD patients are registered in electronic database of movement disorders of the Siberian region. The diagnosis of PD was made using the criteria established by UK Brain Bank. The severity of PD was estimated using H&Y Scale. The Montreal Cognitive Assessment (MoCA) was used for evaluating cognitive impairment, the 39-Item Parkinson’s Disease Questionnaire (PDQ-39) — for quality of life, the Hospital Anxiety and Depression Scale (HADS) – for evaluating anxiety and depression, the Epworth Sleepiness Scale (ESS) – for quantifying EDS.

Results: We selected 76 patients with the equivalent mean daily dose of medications, normal cognition, without clinically significant anxiety and depression. All patients were divided into three homogeneous groups: I – 26 (H&Y 2.0), II – 25 (H&Y 2.5), III – 25 (H&Y 3.0). Sleep-related problems were most prominent in patients in advanced disease (p < 0.05). Among the III group 56% of patients had EDS, II – 36%, I – only 19%. A lower quality of life was found in patients with EDS when compared with patients without sleepiness on the following indexes of the PDQ-39: mobility, activity, cognitive (p < 0.05).

Conclusions: Sleep-related problems were most prominent in patients with severe, advanced disease.

Neurodegenerative diseases affect millions of people worldwide leading to a growing concern over the public health implications. Major gaps in our knowledge base hinder the delivery of optimal medical care to affected individuals. Translational Medicine research (TMr) may fill the gaps at the point of development of modern treatment for not only morbidities but also comorbidities. Antioxidants are revolutionizing TMr contemporary and its future directions towards promising therapy. Conventional medicinal researches and use of antioxidants have highlighted the progressive need to restructure approaches in order to facilitate the efficient integration and translational of new technologies into novel effective therapeutic. Conventional scientists-clinicians have been driving research but cultural differences between these two groups of investigators – practitioners largely stem from less information about TMr, the lack of communication, differences in education and training from developed to developing countries. Contemporary gaps outline the recent initiatives to overcome challenges that expected to strengthen TMr, catalyze the generation of innovative treatment, revise diagnosis, drive rapid benefits from the lab-bench to the patient-bedside and generate tremendous research foci.

Nigella Sativa oil controls astroglisis, parkinsonism and oral dyskinesia in haloperidol-treated rats
T. Malikabc, S. Hasanc, S. Pervezd, T. Fatimae, D.J. Haleemf.
aNeuroscience Unit, Biochemistry Department, University of Karachi, Karachi, Pakistan; bNeurochemistry & Biochemical Neuropharmacology Unit, Biochemistry Department, University of Karachi, Karachi, Pakistan; cHistopathology Unit, Department of Pathology and Microbiology, The Aga Khan University Hospital, Karachi, Pakistan; dDepartment of Biological and Biomedical Sciences, The Aga Khan University Hospital, Karachi, Pakistan; eNeuroscience Research Laboratory, Dr Panjwani Center for Molecular Medicine and Drug Research, The University of Karachi, Karachi, Pakistan

Background: The symptoms of parkinsonism and oral dyskinesia have been showing to be induced by neuroleptics in the striatum. Objective: This study deals with the effects of haloperidol (HAL) on Nigella sativa-oil (NS) treated rats in duration of 6 weeks. Results: HAL treated rats showed movement disorders followed by oral dyskinesia. The cytoarchitectonic pattern of striatum showed astroglisis. Astroglisis was observed in caudate and accumbens nuclei. Such effects of HAL was absent in rats treated with NS-oil showing it normal and glial cells protective. Conclusion: It may be concluded that symptoms of parkinsonism, oral dyskinesia can be prevented by treatment of rats with NS-oil. How far this study can be appreciated to humans needs to be elucidated.

Rifampicin inhibits neuron apoptosis through suppression of the TLR4 pathways in LPS-stimulated co-cultured BV2 cells
W. Bi, E. Tao, J. Jinan University, Guang Zhou, Cocos Island, China; Sun Yat-sen University, Guang Zhou, China

Agents suppressing microbial activation are attracting attention as candidate drugs for neuroprotection in neurodegenerative diseases. Recently, researchers have focused on the immunosuppression induced by rifampicin. Our previous study has shown that rifampicin inhibits microglial inflammation and improves neuron survival against inflammation; however, the mechanism through which rifampicin inhibits the microglial inflammation and its neuroprotection are not completely understood. This study we examined the effects of rifampicin on morphological changes induced by LPS in murine microglial BV2 cells. Then we investigated the effects of rifampicin on signaling pathways stimulated by lipopolysaccharide (LPS) including Toll-like receptor-4 (TLR-4) and nuclear transcription factor kappa B (NF-κB) in BV2 microglia. In addition, we cocultured BV2 microglia and neurons to observe the indirect neuroprotective effects of rifampicin. Rifampicin inhibited LPS-stimulated expression of TLR-4. When neurons were cocultured with LPS-stimulated BV2 microglia, pretreatment with rifampicin increased neuronal viability and reduced the number of apoptotic cells. Taken together, these findings suggest that rifampicin, with its anti-inflammatory properties, might be a novel treatment for neurodegenerative diseases.

Compassionate use of doxycycline in Gerstmann–Straussler–Scheinker syndrome. Case report on a descendant of the original family
H. Zacha, G. Kovacsb, E. Auffa, W. Pirkerb. aDepartment of Neurology, Austria; bInstitute of Neurology, Medical University of Vienna, Vienna, Austria

Background: GSS is a rare, autosomal dominant inherited prion-disease, first reported in an Austrian pedigree in 1936. It is characterized by progressive cerebellar ataxia and late onset of dementia, mainly caused by a point mutation at codon 102 of the prion protein (P102L). This patient descends from the originally described Austrian GSS family. His mother had suffered from progressive dementia and died at the age of 41 years. Genetic analysis showed a P102L mutation at codon 102 of the prion protein (P102L). This patient developed progressive unsteadiness of gait, followed by mild dysarthria, ataxia, areflexia and pos. pyramidal signs after 18 months. CMRI showed moderate cerebellar atrophy, FDG PET revealed cerebellar hypometabolism. CSF showed a weak positive signal for 14–3–3 protein and genetic testing a P102L mutation with heterozygosity at codon 129. Over the following 2 years ataxia progressed rapidly, with an increase of the SARA score from 11 (12/08) to 20.5 (3/10).

Methods: Based on preclinical evidence that tetracyclines show anti-prion activity, a trial of doxycycline(100 mg/d) was started. Results: The following 33 months, doxycycline was tolerated without side effects. Symptom progression appeared to slow during the first 10 months of treatment (SARA 22.5; 12/10) but was similar to the pretreatment period thereafter (SARA 33; 12/12).6 years after onset, the patient is wheelchair-bound with a severe flaccid paraparesis, upper-limb-ataxia, dysarthria and dysphagia.
Conclusion: Based on the quite linear progression of SARA scores, a substantial therapeutic effect of doxycycline in our patient seems unlikely. The treatment with low-dose doxycycline was well tolerated. The SARA appears to be useful to monitor the progression of ataxia in GSS, though assessment of lower-limb-ataxia in advanced disease was confounded by muscle-weakness which is often observed in advanced GSS.

Spinal involvement in cerebrotendinous xanthomatosis
H. Apaydin, A. Gunduz, S. Yazici. Department of Neurology, Istanbul University Cerrahpasa School of Medicine, Istanbul, Turkey

Background: Cerebrotendinous xanthomatosis (CTX) is a rare, AR metabolic disease originating from deficiency of sterol-27-hydroxylase which results in storage of cholestanol and cholesterol in lens, CNS and tendons. Most common neurological manifestations are MR, pyramidal signs, cerebellar ataxia, dysphagia, dysarthria and PNP. Usual cranial imaging findings include cerebral atrophy and signal changes in cerebellum and less commonly in basal ganglia.

Objective: We aim to present and emphasize spinal involvement in CTX.

Patient: We report a 30 year-old woman with truncal ataxia since childhood. Other neurological findings are pyramidal findings in lower extremities and loss of vibration sense distal to the patella. She had previously undergone surgery for bilateral early-onset cataracts and tumor-like enlargement of Achilles tendon. Pathological diagnosis of the latter material was xanthoma. There was no similar family history. MRI showed increased signal intensity in basal ganglia, dentate nucleus, pons, medulla oblongata and posterior and lateral columns of spinal cord. History of juvenile cataracts and tendon xanthoma suggested CTX and she is still under the genetic support, walk or stand. MRI was normal and echocardiogram showed cardiomyopathy. DNA analysis showed two expanded alleles with more than 700 GAA repeats in each one. Of three children, two were affected. A 39-year-old man began to have difficulties with balance at the age of 22, followed by impaired speech, dysphagia, horizontal nystagmus, head tremor, loss of vibratory sensation and tendon reflexes, truncal ataxia and couldn’t stand even with support. He also had scoliosis and cardiomyopathy. He had one allele with 700 GAA repeats and another with 900 repeats. The index case first exhibited clumsiness in handwriting at the age of 26, followed by progressive unsteadiness of gait, slurred speech, square wave jerks, postural tremor in the hands and loss of knee reflex. MRI and echocardiogram were normal. DNA analysis showed one allele with 350 GAA repeats and another with 1000 repeats.

Conclusions: We present a family with pseudodominant inheritance of FRDA, focusing on the molecular basis of intra-familial clinical polymorphism.

Pseudo-dominant inheritance in Friedreich's ataxia: Clinical and genetic study of a Brazilian family
F.M. Branco Germianni, A. Moro, R. Munhoz, W.O. Arruda, S. Raskin, A. Martinez, H.A.G. Teive. 4Neurology, Hospital de Clínicas — Universidade Federal do Paraná, Brazil; 5Genética, Curitiba, Brazil; 6Unicamp, Campinas, Brazil

Objective: To evaluated a family with pseudo-dominant inheritance in Friedreich's ataxia (FRDA).

Background: FRDA is an autosomal recessive inherited disorder characterized by progressive ataxia, hypertrophic cardiomyopathy, skeletal abnormalities, areflexia, loss of vibratory and position sense. A rare pattern is the pseudodominant pattern with phenotypic variation.

Methods: We evaluated a Brazilian family of Italian descent with marked variation of phenotype.

Results: The father developed progressive ataxia at 30 years of age; at 68 years he had dysarthria, dysphagia, generalized ataxia, dysmetria, loss of deep tendon reflexes, was unable to sit without support, walk or stand. MRI was normal and echocardiogram showed cardiomyopathy. DNA analysis showed two expanded alleles with more than 700 GAA repeats in each one. Of three children, two were affected. A 39-year-old man began to have difficulties with balance at the age of 22, followed by impaired speech, dysphagia, horizontal nystagmus, head tremor, loss of vibratory sensation and tendon reflexes, truncal ataxia and couldn’t stand even with support. He also had scoliosis and cardiomyopathy. He had one allele with 700 GAA repeats and another with 900 repeats. The index case first exhibited clumsiness in handwriting at the age of 26, followed by progressive unsteadiness of gait, slurred speech, square wave jerks, postural tremor in the hands and loss of knee reflex. MRI and echocardiogram were normal. DNA analysis showed one allele with 350 GAA repeats and another with 1000 repeats.

Conclusions: We present a family with pseudodominant inheritance of FRDA, focusing on the molecular basis of intra-familial clinical polymorphism.

Interleukin-6 and fatigue syndrome in Parkinson's disease
T. Torgan, T. Baidina, N. Demchuk. Neurology of the Medical Faculty, Perm Academy of Medicine, Perm, Russia

Introduction: Fatigue syndrome is one of the non-motor symptoms of Parkinson's disease (PD) that significantly reduces the quality of life. The pathophysiology of this symptom is poorly studied.

Objective: To assess the potential role of proinflammatory cytokine interleukin-6 (IL-6) in the development of fatigue syndrome in PD.

Methods: We determined the level of IL-6 in the serum of 65 patients with Parkinson's disease by immunosorbent assay. To determine the severity of fatigue syndrome, we used Multidimensional Fatigue Inventory (MFI-20). Operation compared with the concentration of IL-6 in serum was compared with the severity of fatigue.

Results: Fatigue syndrome was diagnosed in 30 patients (46%). Mean severity of fatigue in patients with PD was 58 (49–66) points, which was significantly (p = 0.000) higher than in the control group (33, 30–36 points). The value of IL-6 was significantly (p = 0.012) higher in patients with the FS (1.10, 0.5–1.9 pg/ml) than without this syndrome (0.35 0.0–0. pg/ml). There was a significant correlation between IL-6 with physical fatigue (R = 0.42; p = 0.000), reduced activity (R = 0.46; p = 0.000), reduced motivation (R = 0.24; p = 0.051), and general fatigue (R = 0.52; p = 0.000).

Conclusion: Fatigue syndrome is present in 46% of patients with PD, being a very common and important symptom. Patients with fatigue syndrome have higher levels of IL-6 in serum. The higher level of serum proinflammatory cytokines in PD patients leads to the increasing of the fatigue symptoms.

Total antioxidant activity, glutathione and lipid peroxidation in neurologic Wilson disease: Clinical, biochemical and MRI correlation
J. Kalita, V. Kumar, A. Ranjan, S. Chandra, U.K. Misra. Neurology, Sanjay Gandhi Post Graduate Institute of Medical Sciences, Lucknow, India

Background: Increased free copper in neurologic Wilson disease (WD) is a potent oxidant but there is no study evaluating the role of glutathione, total antioxidant activity (TAC) and lipid peroxidation in them.

Objective: To evaluate TAC, glutathione and malondialdehyde (MDA) in neurologic WD and correlate their levels with clinical, MRI and biochemical changes. Subjects and methods: 28 patients with neurologic WD whose median age was 16 years were included. Neurological severity was categorized on a 0–3 grade. Cranial MRI, blood counts, hemoglobin, liver and kidney function tests, ultrasound abdomen, serum ceruloplasmin, serum free copper and 24-hour urinary copper were done. Plasma glutathione (GSH), TAC and malondialdehyde (MDA) were measured in the patients and 64 matched controls.

Result: The plasma GSH (2.26 ± 0.49 vs 2.6 ± 0.39 mg/dl p < 0.001) and TAC levels were reduced (1.63 ± 0.02 Vs 2.09 ± 0.03 mmol Trolox equivalent/l; P < 0.001) and MDA increased (4.90 ± 0.74 vs 3.21 ± 0.69 nmol/ml p < 0.001) in the neurologic WD compared to controls. The GSH (r = 0.54) level positively correlated with serum ceruloplasmin and negatively with free serum copper (r = −0.52) and urinary copper (r = −0.75), TAC correlated with duration (r = −0.39) and ceruloplasmin (r = 0.48). MDA level correlated negatively with serum ceruloplasmin (r = −0.61) and positively with free copper (r = 0.41) and urinary copper (r = 0.61). The clinical severity and hematological, liver, renal and MRI findings however did not correlate with GSH, TAC and MDA levels.

Conclusion: Lower GSH, TAC and higher MDA levels suggest copper induced oxidative injury in neurologic WD. The role of antioxidant in the treatment of neurologic WD needs to be explored.

A rare case of osteodural arteriovenous fistulas with focal hand myoclonous presentation
T. Worakijthamrongchai. Department of Neurology, Prasat Neurological Institute, Bangkok, Thailand

Introduction: Dural arteriovenous fistulas (DAVs) are found approximately 10–15% of all vascular abnormalities. The most of DAVFs have leptomeningeal reflux and vascular congestion. Symptoms of DAVFs may be characterized either nonaggressive (e.g. tinnitus) or aggressive symptoms (e.g. intracerebral, subarachnoid hemorrhage...
and many neurological deficits). The focal hand myoclonus is a rare presentation of neurological deficit.

**Case:** A 58-year-old female presented with weakness of the right arm with myoclonus of the right hand for 1 month. The other extremities were normal. She didn’t have symptom of headache. The MRI brain showed cytotoxic edema at the left superior fronto-parietal area. The cerebral angiography showed moderate hypertrophy of the left middle meningeal artery shunting into the left fronto-diploic vein, which drain into the posterior left frontal cortical vein. The study was compatible with osteodural arteriovenous fistula and focal venous congestion at the left fronto-parietal region. She took valproic acid and clonazepam but was not able to relieve the focal hand myoclonus. She developed progressive weakness of the right arm, then the urgent transarterial glue embolization was performed. The procedure showed successful glue embolization with nearly complete obliteration of the arteriovenous shunt and less venous congestion. The several days later, the power motor of the right arm was improved and the myoclonus of the right hand disappeared.

**Conclusion:** DAVFs with cortical venous congestion demonstrates the variety of neurological manifestation. The lesions are aggressive and need prompt diagnosis and treatment.

**Effectiveness of acupuncture and bee venom acupuncture in idiopathic Parkinson's disease**

**Background:** In light of the significant limitations of conventional therapy, interest is increasing in complementary and alternative therapies in Parkinson's disease.

**Objective:** This study aimed to explore the effectiveness of acupuncture and bee venom acupuncture as adjuvant therapies for idiopathic Parkinson's disease (IPD).

**Methods:** We recruited 43 adults with IPD who had been on a stable disease. We randomly assigned to 1 of 3 groups: acupuncture, bee venom acupuncture (BVA), or control. All participants were assessed using the Unified Parkinson's Disease Rating Scale (UPDRS), the Parkinson's disease quality of life questionnaire, the Beck Depression Inventory (BDI), the Berg Balance Scale (BBS), and the time and number of steps required to walk 30 m. Treatment groups underwent acupuncture or bee venom acupuncture twice a week for 8 weeks. The initial assessment was repeated at the completion of treatment. The control group did not receive any treatment.

**Results:** Participants in the BVA group showed significant improvement on the UPDRS (total score, as well as part II and III individually), the BBS, and the 30 m walking time. When compared to the control group, the BVA group experienced significantly greater improvement on the UPDRS. In the acupuncture group, the UPDRS (part III and total scores) and the BDI showed significant improvement. The control group showed no significant changes in any outcome after 8 weeks.

**Conclusion:** In this pilot study, acupuncture and bee venom acupuncture showed promising results as adjuvant therapies for Parkinson's disease.

**Triple stimulation technique could be useful differential marker between vascular parkinsonism and Parkinson's disease**

**Background:** Vascular parkinsonism (VP) and PD are considered to be two distinct neurological entities as a differential marker. In VP patients, mean TST amplitude ratio was 64.7 (±23.9). While, PD group revealed 90.2 (±9.8) of TST amplitude ratio. Other parameters showed no significant difference.

**Conclusions:** TST amplitude ratio can be used to differentiate VP and PD with a good degree of certainty.

**Effect of opicapone and entacapone on levodopa pharmacokinetics when administered with immediate release 100/25 mg levodopa/carbidopa in healthy subjects**

J.-F. Rocha, A. Falcão, T. Nunes, P. Soares-da-Silva. Research & Development, BIAL-Portela & C. S.A., S. Mamede Coronado, Portugal; Faculty of Pharmacy, University of Coimbra, Coimbra, Portugal; Dept. of Pharmacology & Therapeutics, Faculty of Medicine, University of Porto, Porto, Portugal

**Background:** Opicapone (OPC) was developed to fulfill the need for more potent, safer and longer acting COMT-inhibitors.

**Objectives:** The objective of this study is to investigate the effect of once-daily 25, 50 and 75 mg OPC on the levodopa pharmacokinetics (PK), in comparison to placebo and 200 mg entacapone (ENT).

**Methods:** Single-centre, randomized, double-blind, gender-balanced, placebo-controlled study in 4 groups of 20 subjects each. This study consisted of a once-daily administration of OPC or placebo for 11 days and 100/25 mg levodopa/carbidopa, 200 mg ENT or placebo three times per day for 12 days.

**Results:** OPC at steady-state significantly increased the levodopa-AUC more than placebo up to 78.9% and 73.74% with 75 mg OPC in comparison to placebo and ENT, respectively. Levodopa-AUC was higher when levodopa/carbidopa was administered with any OPC dose than when administered concomitantly with ENT. A marked increase (~30%) in peak of exposure (Cmax) to levodopa occurred with 75 mg OPC following levodopa/carbidopa administrations. OPC presented a significantly long-lasting and sustained S-COMT inhibition. Maximum S-COMT inhibition ranged from 67.1% (200 mg ENT) to 94.2% (75 mg OPC) and was higher than ENT for all OPC doses. The 50 and 75 mg OPC were somehow similar.
(75 mg was slightly superior), thus, the 75 mg OPC may not bring a significant advantage over 50 mg OPC with regard to S-COMT inhibition. The tolerability profile of OPC was favourable.

**Conclusion:** OPC may offer a therapeutic advantage in relation to ENT as levodopa sparing agent in patients with Parkinson’s disease receiving levodopa therapy. The dosages of 25 and 50 mg OPC likely provide the most adequate enhancement in levodopa availability as adjunct to levodopa/carbidopa therapy.

**Effect of opicapone multiple-dose regimens on levodopa pharmacokinetics, motor response, and erythrocyte-COMT activity in Parkinson’s patients co-administered with levodopa/dopa-decarboxylase inhibitor**

J.J. Ferreiraa, J.-F. Rochab, A. Falcãoc, R. Pintob,d, T. Nunesb, P. Soares-da-Silvaac,d, e3Neurological Clinical Research Unit, Instituto de Medicina Molecular, Lisbon, Portugal; 3Research & Development, BIAL-Portela & Co. S.A., S. Mamede Coronado, Portugal; 4Faculty of Pharmacy, University of Coimbra, Coimbra, Portugal; 5Dept. of Pharmacology & Therapeutics, Faculty of Medicine, University of Porto, Porto, Portugal

**Background:** Opicapone (OPC) was developed to fulfil the need for more potent, safer and longer acting COMT inhibitors.

**Objectives:** Investigate the effect of once-daily 5, 15 and 30 mg OPC, a new COMT inhibitor, on the levodopa pharmacokinetics, in Parkinson’s Disease (PD) patients with motor fluctuations treated with standard-release 100/25 mg levodopa/carbidopa (LC) or levodopa/benserazide (LB).

**Methods:** This was a multicentre, double-blind, randomised, placebo-controlled study in four parallel groups of PD patients treated with LC or LB and with motor controlled study in four parallel groups of PD patients treated with LC or LB and with motor controlled study in four parallel groups of PD patients treated with LC or LB. Subjects also kept a diary to record ON/OFF periods. Subjects were sequentially and randomly assigned to be administered, once-daily, during the 21 to 28 day maintenance phase with placebo or 5, 15 and 30 mg OPC, in absolute OFF time corresponding to a percentage decrease of 0.77%, 4.16%, 29.55% and 32.71% with placebo, 5 mg, 15 mg and 30 mg OPC, respectively.

**Results:** In relation to placebo, levodopa exposure increased 24.73%, 53.93% and 65.61% following 5, 15 or 30 mg OPC. Maximum S-COMT inhibition (Emax) ranged from 52% (5 mg OPC) to 80% (30 mg OPC). The 53.93% and 65.61% following 5, 15 or 30 mg OPC. Maximum S-COMT inhibition (Emax) ranged from 52% (5 mg OPC) to 80% (30 mg OPC). The 53.93% and 65.61% following 5, 15 or 30 mg OPC, respectively.

**Conclusion:** OPC once-daily was safe, well tolerated, and effective in reducing the OFF-time in patients with PD on levodopa treatment and with motor fluctuations.

**Efficacy and safety of opicapone, a new COMT-inhibitor, for the treatment of motor fluctuations in Parkinson’s Disease patients: BIPARK-II study**

A. Leesa, J.J. Ferreirab, R. Costac, J.-F. Rochac, C. Oliveira, N. Lopes, T. Nunes, aNational Hospital for Neurology and Neurosurgery, London, UK; bNeurological Clinical Research Unit, Instituto de Medicina Molecular, Lisbon, Portugal; cResearch & Development, BIAL-Portela & Co. S.A., S. Mamede Coronado, Portugal; dDept. of Pharmacology & Therapeutics, Faculty of Medicine, University of Porto, Porto, Portugal

**Background:** Opicapone (OPC) was developed to fulfil the need for more potent, safer and longer acting COMT inhibitors.

**Objectives:** The objective of this study was to investigate the efficacy and safety of 25 and 50 mg-OPC administered once-daily, compared with placebo, in patients with Parkinson’s Disease (PD) on levodopa treatment and with end-of-dose motor fluctuations.

**Methods:** Pivotal phase-III, multinational, multicentre, double-blind (DB), placebo-controlled and parallel-group study. Subjects were randomised to placebo (n = 135), 25 mg-OPC (n = 125) or 50 mg-OPC (n = 147). The DB phase lasted 14–15 weeks. Primary efficacy variable was the change from baseline in absolute OFF-time, based on patient diaries. Secondary endpoints include proportion of responders, course of OFF/ON-time, UPDRS-III, quality-of-life (PDQ-39), NMSS, PDSS, tolerability and safety (including mMDI, C-SSRS and clinical laboratory tests) assessments.

**Results:** Mean reduction in absolute OFF-time in both 25 and 50 mg-OPC groups was considerably greater than in placebo (1.7, 2.0 and 1.1 h, respectively). Despite the high placebo response, 50 mg-OPC was significantly better than placebo (p = 0.0084), but 25 mg-OPC missed statistical significance by only 0.1 h. Significantly more patients receiving either 25 or 50 mg-OPC achieved the OFF-time responder endpoint than with placebo (62.4%-[p = 0.0405], 66.0%-[p = 0.0088] and 50.4%, respectively), and also achieved greater OFF-time reductions (11.0%-[p = 0.0297], 12.1%-[p = 0.0044] and 6.7%, respectively). Furthermore, mean increase in absolute ON-time without or with non-troublesome dyskinesias was considerably greater in both 25 and 50 mg-OPC groups than in placebo (1.4, 1.43 and 0.8 h, respectively). Opicapone was safe and well tolerated.

**Conclusion:** OPC once-daily was safe, well tolerated, and effective in reducing the OFF-time in patients with PD on levodopa treatment and with motor fluctuations.

recumbent position, and may be one of the most disabling symptoms in Parkinson’s disease (PD).

Objective: The objective of our study is to describe the clinical features of PD patients with CC, comparing with those without CC.

Patients and methods: Seventy-eight PD patients with CC underwent a multidisciplinary clinical examination (neurological, neuropsychological), blood test, and spine MR scan were compared with age/sex-matched 78 PD patients without CC.

Results: Patients with CC showed significantly higher frequencies of spinal operation and compression fracture ($P < 0.05$). CC was found in patients with more severe PD, as clinically assessed by the Hoehn and Yahr staging, the motor Unified Parkinson’s disease Rating Scale part III, and presence of dementia. The serum creatine kinase levels of PD patients with CC were statistically higher than those of without CC ($P < 0.05$). We found more abnormalities of MR findings in spine and paravertebral muscles in PD patients with CC than those without CC ($P < 0.05$).

Conclusion: CC is associated with the history of spinal operation, compression fracture, and disease severity. The MRI findings and difference of CK levels between the groups suggest that CC in PD is attributed to a focal myopathy in spine and paravertebral muscles.

Parkinson’s disease and autonomic symptoms
S. Naija, I. Chatti, B.H. Manel, H. Anis, B.A. Sana, H. Salah, B.A. Sofiene. Sahloul Hospital, Sousse, Tunisia

Introduction: There is a wide range of autonomic symptoms (AS) in Parkinson’s disease (PD) but their occurrences are still a subject to discrepancies in the literature.

Objectives: The objectives of this study are to evaluate the occurrence of AS in a cohort of patients with PD and control subjects, to assess the relations with demographic, disease-related, and clinical variables and to qualify the impact of this trouble on the quality of life.

Methods: A cohort of 102 patients with PD was evaluated for the occurrence of AS, motor and non-motor symptoms, as well as for demographic and disease-related characteristics. The study was conducted in the Department of Neurology of Sahloul University Hospital between June 2011 and November 2011. 95 control subjects were recruited from the consultations and other departments. We used the following scales: SCOPA AUT, SF12, SCOPA Sleep and Beck Scale.

Results: All PD patients reported more problems in all in autonomic domains compared to control subjects with the largest differences in the gastro-intestinal tract. The prevalence of autonomic disorders was correlated with older age, great disease severity and high doses of dopaminergic medication. The severity of the disorder was associated with depressive symptoms, cognitive disorders, and sleep disorders with $P < 0.05$.

Discussion: Autonomic symptoms were assessed using a reliable and valid instrument. Our results show that, compared to a control group, Parkinson’s disease expresses more gastro-intestinal, urinary, cardiovascular, thermoregulation, and sexual troubles; indicating that the entire autonomic system is affected by this disease, which is consistent with findings of the literature.

Wilson’s disease and psychiatric disorders: Is there comorbidity or indicator of relapse?
S. Mrabet, F. Ellouze, M.F. Mrad. Department of Psychiatry, Razi Hospital, Tunis, Tunisia

Introduction: Wilson’s disease is an infrequent pathology resulting from a change of the ATP7B gene on the long arm of chromosome 13. This involves a reduction of the transport of copper in the bile and its accumulation in the body, notably the brain.

Objective: The objective of this study is to illustrate the significance of psychiatric disorders in WD.

Case report: A 25-year old woman with a personal history of Wilson’s disease (WD) presented acute psychotic manifestations. The psychiatric interview finds a state of psychomotor agitation, aggressiveness and depressed mood concept with suicidal intentions. Moreover, she has a bilateral extra pyramidal syndrome. The blood levels of copper and ceruloplasmin are collapsed. The patient confirmed that she had stopped her treatment with D-penicillamine for two months ago.

Discussion: WD begins in the form of a hepatic, neurological, or psychiatric disease in at least 90% of the patients. In some rare cases, the first manifestations of the disease can be psychiatric which accounts for only 10%. The disease can include later isolated behavioral problems, a schizophrenic syndrome, or a manic–depressive syndrome. The main difficulty was to establish whether psychiatric disorders are included in the WD array or not. Indeed neuropyschiatric co morbidity in the context of WD is significant. Poor adherence to treatment, cupric balance sheet and the improvement after the reintroduction of D-penicillamine confirm a psychiatric relapse of WD.

Conclusion: In WD, psychiatric manifestations can precede, complicate the somatic disorders or be independent. An early diagnosis is necessary to provide a specific treatment.

Cervical dystonia patient registry for observation of onabotulinum toxin A efficacy (CD Probe): Pain at baseline
D. Charles$^{a}$, J.Jankovic$^{b}$, M. Schwartz$^{c}$, M.F. Brin$^{de}$,$^{a}$Vanderbilt University Medical Center, Nashville, TN, USA; $^{b}$Baylor College of Medicine, Houston, TX, USA; $^{c}$MedNet Solutions, Inc., Minnetonka, MN, USA; $^{d}$Allergan, Inc., USA; $^{e}$University of California, Irvine, CA, USA

Background: Cervical dystonia (CD) is the most common focal movement disorder and is often associated with pain.

Objective: The objective of this study is to report the presence of pain associated with CD upon enrollment in subjects participating in a large registry.

Methods: CD PROBE is a prospective, observational, multicenter, registry designed to assess safety, effectiveness, and treatment utilization within clinical practice. CD subjects were naïve to botulinum toxin, new to the physician’s practice, or had ≥16 weeks since last treatment if in a previous clinical trial. Factors delineated by the presence (score ≥0) or absence (score = 0) of pain at baseline, as measured by the Pain Numeric Rating Scale (PNRS), were baseline demographics, Toronto Western Spasmodic Torticollis Rating Scale (TWSTRS), and CD Impact Profile-58 (CDIP-58).

Results: CD PROBE enrolled 1046 subjects (74% female), with a mean age 58.0 ($\pm$ 14.7 y), between 1/9/09 and 8/31/12. 88.9% ($n = 922$) of subjects reported pain at baseline (P NRS > 0). Compared to those
without pain at baseline, subjects reporting pain had significantly younger symptom onset (48.4 ± 16.5 y vs 53.9 ± 17.9 y; p = 0.0026), and significantly higher scores for TWSTRS total and subscales (p ≤ 0.0002) and CDIP-58 subscales (p ≤ 0.0008).

Conclusions: CD-PROBE is the largest registry ever conducted for subjects with CD and will provide real world experience of treatment response of repeat injection of onabotulinum toxin A. Pain is present in the majority of subjects with CD and is associated with increased severity across a range of measures.

Abstract — WCN 2013

Topic: 2 — Movement Disorders
The sequence effect is not a defining characteristic of Parkinson's disease
J. Altyab, S. Lacyc, S. Jamiesond, K. Possinb, N. Schuffb, M. Lonesd, S.L. Smithf, 1University of York, Hull York Medical School, York, UK; 2Department of Neurology, Leeds Teaching Hospitals NHS Trust, Leeds, UK; 3Department of Electronics, University of York, York, UK; 4Department of Neurology, University of California, San Francisco, USA; 5Veterans Affairs Medical Center, USA; 6Department of Radiology and Biomedical Imaging, University of California, San Francisco, CA, USA

Background: The sequence effect (SE) describes progressive decrements of amplitude and speed with repetitive movements and is considered characteristic of Parkinson's disease (PD). It is associated with functional disability and freezing of gait but the pathophysiology remains unclear.

Objective: The objective is to objectively assess finger tapping (FT) in order to evaluate

(i) what proportion of PD patients and age-matched healthy controls (HC) exhibit the SE and
(ii) whether the MDS-UPDRS standard of ten taps is enough for the SE to manifest.

Patients and methods: Sixty-two PD patients and 47 age-matched HC from centres in the UK and USA performed FT whilst wearing electromagnetic sensors. Movement data from the first ten taps was used to calculate amplitude, speed, rhythm, halts and decrementing speed and amplitude (SE). Longer FT sequences were also examined.

Results: After 10 taps all of the movement components differed significantly between the PD and HC groups (amplitude, speed and rhythm p < 0.001; halts p = 0.03) except for the SE (p > 0.1). Decrementing amplitude occurred in 61% and 59% and decrementing speed in 52% and 49% (p = 0.9), of PD and HC data respectively. An additional 23% of PD and 27% of HC (p = 0.7) exhibited the SE when FT was performed for 30 s (mean 79 taps).

Conclusions: The SE is not specific for PD. A similar proportion of PD and HC subjects exhibited the SE. For some subjects 10 taps is not long enough for the SE to manifest.

Clinical hallmarks and epidemiology of stiff person syndrome in Tanzania
M. Dekkerb, S. Urasa, V. Marno, G. Kinabob, W. Howlettb, cDepartment of Neurology, Kilimanjaro Christian Medical Centre, Moshi, Tanzania; dDepartment of Neurology, Radboud University Nijmegen Medical Centre, Nijmegen, The Netherlands; eDepartment of Neurology, Kilimanjaro Christian Medical Centre, Moshi, Tanzania; fDepartment of Internal Medicine, Kilimanjaro Christian Medical Centre, Moshi, Tanzania; gDepartment of Pediatrics, Kilimanjaro Christian Medical Centre, Moshi, Tanzania; hDepartment of Infectious Diseases, Radboud University Nijmegen Medical Centre, Nijmegen, The Netherlands

Background: Stiff person syndrome (SPS) is an extremely rare anti-GAD antibody related disorder, with prevalence estimates ranging from 0.5 to 2/1,000,000. Its diagnosis is clinical, especially in most of Africa where anti-GAD titres are unavailable.

Objective: The objective of this study is to clinically delineate a series of stiff person syndrome patients, and to compare the prevalence in Tanzania to that in scientific publications.

Patients and methods: Patients were ascertained through neurological consultation in Kilimanjaro Christian Medical Centre during the period 2008–2013. Clinical diagnosis was established by means of neurological examination and exclusion of other amenable causes. Anti-GAD antibody testing or EMG is presently unavailable in Tanzania.

Results: A total of nine SPS cases are reported (three females and six males, aged 13–64 years). The estimated prevalence in this patient population was 0.5–6/1,000,000, depending on the estimated catchment area. One patient was referred abroad for intravenous immunoglobulin therapy, with marked clinical improvement, whereas the others showed some response to baclofen and benzodiazepines. Two patients presented with femoral fractures secondary to violent muscle spasms.

Conclusions: Stiff person syndrome is a rare auto-immune disorder, but is shown to occur in Tanzania. A literature search yielded comparable studies only from other parts of the world: we present the first SPS prevalence rates in Africa. Even though the sample is small and estimated prevalence form a wide range, this is comparable to estimates from other ethnic groups. Yet underestimation due to underreporting by patients as well as doctors is not unlikely.

doi:10.1016/j.jns.2013.07.397
and diagnostic group using receiver operator characteristic (ROC) curves. The composite algorithm was validated on an independent sample of FT data collected from 13 PD patients.

**Results:** PD FT assessments with grade one MDS-UPDRS were accurately distinguished from controls dominant hand FT with area under ROC curve of 0.952 (p < 0.0001). The algorithm correctly classified 14/15 of the PD FT data sets in the validation sample that had clinically slight bradykinesia.

**Conclusions:** This technology is able to provide an objective measurement of the most subtle clinical grade of bradykinesia. Potential applications include supplementing clinical diagnoses, screening and objective assessment of response to treatment.

**Choreoathetosis caused by glycemic decompensation in pancreatic neoplasm**

Hospital General Universitario de Ciudad Real, Ciudad Real, Spain

**Background:** Choreoathetosis is a neurologic disorder, related to a basal ganglia lesion, where two types of involuntary movements coexist. Chorea consists of continual, rapid, brief, irregular movements that flow randomly from one body part to another. Athetosis is a slow form of chorea, with writhing movements that mainly affect to distal regions of the limbs.

**Objectives:** We present a 72-year-old woman with bilateral choreiform movements and diabetic ketoacidosis.

**Patients and methods:** Our patient had a longstanding diabetes type II with poor metabolic control, worse during the last month. She was hospitalized to control her blood glucose levels.

**Results:** Symmetric bilateral hyperintense putamen nuclei were found at MRI, related to maintained hyperglycemia. A hypertransaminasemia led us to complete the abdominal examination, and a body TC and a cerebral MRI confirmed the diagnosis of pancreatic adenocarcinoma. Choreoathetosis was treated with clonazepam and pimozide, with no efficacy; then we tried haloperidol and tetrabenazine, improving the symptomatology.

**Conclusion:** Choreoathetosis is caused by very diverse etiology disorders. Long-evolution nonketotic hyperglycemia has been described to produce involuntary movements as choreoathetosis. Typically MRI shows hyperintense putamen on T1-weighted images, contralateral to the side of chorea, or bilateral if it is generalized. This rare complication of DM type II is generally reversible with an adequate metabolic control. But if the movements are severe and disabling, it can be successfully treated with drugs that interfere with central dopaminergic function, such as the dopamine receptor-blocking drugs (neuroleptics), reserpine, and tetrabenazine. Other effective treatments can be benzodiazepines or amantadine.

**Antipsychotic efficacy and motor tolerability in a phase III placebo-controlled study of pimavanserin in patients with Parkinson’s Disease psychosis (Acp-103-020)**

J. Cummings⁴, S. Isaacson⁵, R. Mills⁵, H. Williams⁶, K. Chi-Burris⁶, R. Dhall⁶, C. Ballard⁶, “Cleveland Clinic Lou Ruvo Center for Brain Health, Las Vegas, NV, USA;” Parkinson’s Disease and Movement Disorder Center, Boca Raton, FL, USA; “ACADIA Pharmaceuticals, Inc., San Diego, CA, USA;” Barrow Neurological Institute, Phoenix, AZ, USA; “Institute of Psychiatry, King’s College, London, UK

**PD psychosis (PDP) is frequent, distressing and a leading cause of institutionalization. It complicates PD management and is linked to increased morbidity, incident dementia and mortality. Current antipsychotics lack efficacy and/or have serious tolerability and safety concerns. Pimavanserin, a selective 5-HT2A antagonist, has shown antipsychotic effects and good tolerability in previous PhIII trials, but a robust placebo effect precluded statistical separation. A PhIII outpatient study, optimized to reduce placebo response, was conducted to assess the efficacy and safety of pimavanserin in PDP. Following screening, in which brief (non-pharmacologic) psychoanalytic therapy (BPST-PD) was offered, 199 non-demented patients with moderate-severe psychosis (on stable PD medication) were randomized to oral q.d. doses of 40 mg pimavanserin or placebo for 6 weeks. Pimavanserin met the primary endpoint using SAPS-PD (PD-adapted
version of the Scale for Assessment of Positive Symptoms, assessed by independent raters): \(-5.79\) PIM vs \(-2.73\) PBO (Baseline to Day 43 LSMA \(= -3.06; p = 0.001\)). These results were supported by highly significant improvement in the secondary efficacy measure, CGI-I (LSMAs = -0.67; \(p = 0.001\)), assessed by Investigators blind to the SAPS-PD. Clinical benefits were also seen in all exploratory measures with significant improvements in nighttime sleep, daytime wakefulness, and caregiver burden. Consistent with previous studies, pemfarsennin met the key secondary endpoint for noninferiority to placebo on motor function (UPDRSII + III) and was otherwise safe and well tolerated. Most common AEs were UTI (11.7%-PBO, 13.5%-PIM) and falls (8.5%-PBO, 10.6%-PIM). SAEs in >1 patient were UTI (1-PBO, 3-PIM) and psychotic disorder (0-PBO, 2-PIM). Pemfarsennin appears effective, safe and well-tolerated for PDP.

Incobotulinum toxin A demonstrated therapeutic equivalence to onabotulinum toxin A in the treatment of blepharospasm and cervical dystonia
R. Benecke\(^a\), D. Hauschke\(^b\), P. Roggenkämper\(^c\). \(^c\)Clinic and Polyclinic for Neurology, University of Rostock, Rostock, Germany; \(^c\)Institute of Medical Biometry and Medical Informatics, University Medical Center, Freiburg, Germany; \(^a\)University Eye Clinic, Bonn, Germany

Introduction: Equivalent efficacy of incobotulinum toxin A (Xeomin\(^\text{®}\)) to onabotulinum toxin A (Botox\(^\text{®}\)) using a 1:1 unit dosing ratio was demonstrated in two multicentre, double-blind, randomised studies in blepharospasm and cervical dystonia, respectively.

Patients and methods: Both study protocols pre-specified the two-sided 95% confidence interval (CI) method for testing therapeutic equivalence of incobotulinum toxin A to onabotulinum toxin A for each study’s primary efficacy outcome (blepharospasm: change in Jankovic Rating Scale [JRS] sumscore from baseline to 3 weeks post-injection; cervical dystonia: change in Toronto Western Spasmodic Torticollis Rating Scale [TWSTRS]—Total score from baseline to 4 weeks post-injection). Differences between treatment groups were determined by least square (LS) means and corresponding two-sided 95% Cs for the per-protocol population. Clinically irrelevant difference was defined as \(\Delta = 0.8\) points in the blepharospasm study and \(\Delta = 1.3\) points in the cervical dystonia study, predefining the therapeutic equivalence ranges as \([-0.8, 0.8]\) and \([-1.3, 1.3]\), respectively.

Results: In the blepharospasm study (per-protocol population \(n = 256\)), incobotulinum toxin A and onabotulinum toxin A both significantly (\(p < 0.0001\)) improved JRS sumscores 3 weeks post-injection (incobotulinum toxin A: \(-2.90\); onabotulinum toxin A: \(-2.67\)). The LS mean difference was \(-0.23\) (favouring incobotulinum toxin A), the 95% CI \([-0.68, 0.22]\) was within the predefined equivalence range \([-0.8, 0.8]\). In the cervical dystonia study (per-protocol population \(n = 420\)), both treatments significantly (\(p < 0.0001\)) improved TWSTRS—Total score 4 weeks post-injection (incobotulinum toxin A: \(-6.6\); onabotulinum toxin A: \(-6.4\)). The LS mean difference was \(-0.33\) (favouring incobotulinum toxin A); the 95% CI \([-1.05, 0.38]\) was within the predefined equivalence range \([-1.3, 1.3]\).

Conclusion: Incobotulinum toxin A and onabotulinum toxin A were therapeutically equivalent in treating blepharospasm and cervical dystonia at a 1:1 unit dosing ratio in the administered dose ranges.

Long-term treatment of blepharospasm and cervical dystonia: Incobotulinum toxin A is well tolerated when injected at flexible intervals based on patient needs
H.H. Fernandez\(^e\), V.G.H. Evidente\(^b\), D. Truong\(^c\), M. Brodsky\(^d\), A. Hanschmann\(^a\), C.L. Comella\(^f\), J. Jankovic\(^g\), \(^c\)Cleveland Clinic, Cleveland, OH, USA; \(^b\)Movement Disorders Center of Arizona, Scottsdale, AZ, USA; \(^f\)The Parkinson’s and Movement Disorder Institute, Fountain Valley, CA, USA; \(^d\)Oregon Health & Science University, Portland, OR, USA; \(^e\)Merz Pharmaceuticals GmbH, Frankfurt am Main, Germany; \(^g\)Rush University Medical Center, Chicago, IL, USA; \(^a\)Baylor College of Medicine, Houston, TX, USA

Introduction: In clinical practice, botulinum-toxin injections for blepharospasm or cervical dystonia (CD) are administered at \(-3\)-month intervals; there is concern that shorter intervals might increase the risk of adverse events (AEs) and neutralizing antibodies. This post-hoc analysis investigated flexible incobotulinum toxin A (Xeomin\(^\text{®}\)) injection intervals (6-20 weeks) in the long-term management of blepharospasm and CD.

Patients and methods: In the blepharospasm study, a randomized, double-blind, placebo-controlled Phase III study with an open-label extension period, patients could receive \(\leq 6\) incobotulinum toxin A treatments (flexible doses \(\leq 50\) U/eye). Patients in the CD study, a randomized, double-blind, placebo-controlled Phase III study with a randomized, double-blind extension period, could receive \(\leq 6\) incobotulinum toxin A treatments (fixed doses, 120 or 240 U). In both studies, injection intervals were flexible (\(\geq 6\) weeks) and determined as clinically indicated. Standard safety assessments were performed throughout.

Results: In blepharospasm, 461 incobotulinum toxin A treatments were analyzed: 207 (44.9%) treatments were given at 6–11-week intervals and 254 (55.1%) at 12–20-week intervals. The most frequent AEs were eyelid ptosis and dry eyes. In CD, 821 treatments were evaluated: 369 (44.9%) were administered at 6–11-week intervals and 452 (55.1%) at 12–20-week intervals. The most frequent AEs were dysphagia and neck pain. In both studies, AEs frequency, overall and for each treatment cycle, was similar for injection intervals \(<12\) weeks and \(\geq 12\) weeks, with no cumulative effects following repeated treatment.

Conclusion: Incobotulinum toxin A, administered with flexible intervals according to patients’ clinical needs, is an effective and well tolerated long-term treatment for blepharospasm and CD.

Satisfaction with botulinum toxin treatment in post-stroke spasticity: Results from two cross-sectional surveys of patients and physicians
D. Bensmail\(^e\), A. Hanschmann\(^b\). \(^e\)Hôpital R. Poincaré (AP-HP), Garches, France; \(^b\)Merz Pharmaceuticals GmbH, Frankfurt am Main, Germany

Introduction: There is little information available regarding patient’s and physician’s satisfaction with botulinum toxin treatment for post-stroke spasticity.

Patients and methods: Structured patient and physician surveys were conducted in Canada and the USA. Patients had post-stroke spasticity and had received \(\geq 2\) treatments with onabotulinum toxin A or abobotulinum toxin A; information on current and prior

doi:10.1016/j.jns.2013.07.403

botulinum toxin treatment cycles and treatment satisfaction was collected. Physicians included were experienced in treating post-stroke spasticity, with ≥3-year history of injecting botulinum toxin for medical purposes; information regarding satisfaction with botulinum toxin treatment was collected.

**Results:** Most of N = 76 patients with post-stroke spasticity were very (42%) or somewhat (46%) satisfied with their current treatment. Satisfaction was highest at the time of peak effect and lowest just before re-injection. While 78% of patients stated they would prefer injection intervals ≤12 weeks, only 45% received such intervals. Intervals ≤10 weeks were preferred by 43% of patients but received by just 6.3%. Most of N = 105 physicians were moderately (58%) or very satisfied (37%) with botulinum toxins. Physicians felt that on average 16% of patients would benefit from shorter injection intervals and 25% would benefit from higher maximum doses than those currently permitted.

**Conclusion:** Patient satisfaction with botulinum toxin therapy for post-stroke spasticity varies over the treatment cycle and is lowest just before re-injection; many patients would prefer injection intervals shorter than the standard 12 weeks. While most physicians are satisfied with botulinum toxin therapy for post-stroke spasticity, many feel that some patients would benefit from shorter injection intervals and higher doses.

**Impaired activation of somatosensory cortex as fMRI correlate of reduced dexterity in PD**

T. Foki, W. Pirker, A. Geissler, M. Hilbert, I. Hoellinger, M. Wurnig, J. Rath, J. Lehrner, S. Trattnig, E. Auff, R. Beisteiner. 1Department of Neurology, Medical University of Vienna, Vienna, Austria; 2MR Center of Excellence, Department of Radiology, Medical University of Vienna, Vienna, Austria; 3Department of Radiology, Medical University of Vienna, Vienna, Austria.

**Background:** Previously (1ab), the DOPA-resistant component of decreased dexterity in PD was called limb-kinetic apraxia (LkA). Our recent fMRI pilot study (2) investigating PD patients OFF medication suggested impaired activation of primary somatosensory cortex (SSC) as closely related to LkA. Both in the behavioral (1ab) and fMRI studies (2), coin rotation (CR, LkA task, target condition) was contrasted with simple finger tapping (FT, bradykinesia task, reference condition). fMRI signal changes were hence corrected for basic motor skills and represented activation particularly associated with dexterity.

Based on the DOPA resistance of CR performance in (1ab), we hypothesized a reproducibility of impaired activation of the SSC ON medication.

**Objective:** The objective of this study is to confirm dysfunction of SSC as closely related to DOPA-resistant dexterity deficits in PD.

**Patients and methods:** According to the experimental setup (CR vs. FT) mentioned above, 10 PD patients performed the fMRI experiment in the ON as well as off the OFF condition. 14 healthy controls performed the same experiment. Patients were compared to controls (SPM8).

**Results:** Confirming our pilot study, we assessed decreased activation of the SSC in patients OFF medication compared to controls. In line with our study hypothesis, this finding was reproducible in patients ON medication compared to controls (p < 0.01, uncorr., k = 25 vox.). Comparing fMRI signals in the SSC between ON and OFF conditions, no differences could be assessed (lowering even to p < 0.05).

**Conclusions:** Dexterity deficits in PD are linked to a dysfunction of the SSC.

**Subjective and objective alcohol responsiveness in different tremor disorders**

**Department of Neurology, Medical University of Graz, Graz, Austria.

**Background:** A few studies exist on the effect of alcohol in essential tremor (ET) and Parkinson’s disease (IPD), but so far no systematic studies have been performed in other tremor syndromes. Nevertheless, a positive response to alcohol – commonly simply inquired by history – is used as supportive diagnostic criterion for ET.

**Objective:** The objective of this study is to investigate if subjective/objective alcohol responses distinguish a broad range of tremor disorders.

**Methods:**

1. We assessed drinking habits and response of tremor to alcohol intake in 100 consecutive patients with arm tremor.
2. For a double-blind placebo-controlled oral alcohol test we recruited 12 patients with ET, 10 IPD, and 7 dystonic tremor (DT).

The effect to alcohol/placebo was assessed at baseline and after 30/60/120 min by clinical rating scales and accelerometry.

**Results:**

1. We investigated 44 patients with IPD, 22 ET, 20 DT, and 14 others. Of 77 patients drinking alcohol, 23 had no response, 26 had improvement, and 28 never paid attention. None of the evaluated parameters differed between the groups.
2. ET, IPD, and DT had a significant tremor improvement with placebo and alcohol. There were no significant between group differences. However, in the ET group there was a stronger objective effect of alcohol compared to placebo.

**Conclusions:** Subjective alcohol response inquired by history may not be suitable as supportive diagnostic criterion for ET. Objectively, all investigated patients improved with alcohol. This effect seems to be truly alcohol related in ET only.

**Exome sequencing analysis in familial progressive supranuclear palsy**

C. Bettencourt, A. Tucci, R. Ros, J. Lopez-Sendon, J. Hardy, J. Garcia de Yebenes, H. Houliden. 1Department of Molecular Neuroscience, UCL Institute of Neurology, London, UK; 2Department of Neurology, Hospital Ramon y Cajal, Madrid, Spain.

**Background:** Progressive supranuclear palsy (PSP) is a clinicopathological syndrome characterized by akinesia, supranuclear gaze palsy,
rigidity, axial dystonia, gait disturbance, frontolimbic dementia and other clinical deficits related to neuronal loss, gliosis, and presence of neurofibrillary tangles and neuropil threads in different brain areas, mainly in the basal ganglia, diencephalon, brainstem, and frontal and temporal lobes. Although PSP is mostly considered a non-familial or sporadic tauopathy, rare multiplex kindreds have been described. A genetic basis for familial clustering has been demonstrated in a Spanish family with PSP linked to chromosome 1, for which the causal gene is still unknown, and in families with causal mutations in the microtubule-associated protein tau gene (MAPT).

Objective: To identify the causal gene linked to 1q31.1.

Patients and methods: We have studied the Spanish family for which the genetic locus was mapped to a 3.4 cm region at 1q31.1. This family presents a pathology-proven PSP with a pattern of transmission compatible with an autosomal dominant inheritance. We have sequenced the whole-exome from one patient of this family, and DNA from 30 additional family members is available for segregation analysis. We have also checked the exome sequences of a cohort of about 50 PSP patients.

Results and conclusion: The exome analysis of the Spanish family is presently on-going. For the PSP cohort no variants were detected in the linkage region of chromosome 1. Therefore, this locus should not constitute a common cause of PSP.

Tremor associated with Klinefelter syndrome — A case series and review of the literature

Background: Previous case series suggested a link between Klinefelter syndrome (KS) and essential tremor (ET) or an ET-like syndrome.

Methods: We investigated three KS-patients with tremor including tremor-analyses and discuss our data in context to findings from a literature review. The clinical outcome after deep brain stimulation (DBS) is also reviewed.

Results: Tremor in KS is predominantly a postural and kinetic tremor that strongly resembles ET. However, KS patients with tremor differ from ET in several findings such as a less frequent family history, lack of alcohol responsiveness, and missing benefit to drugs used in ET. One of our patients and two cases from literature improved after DBS of the ventral intermediate nucleus (VIM) of the thalamus.

Conclusions: Tremor in KS seems to differ from ET. While antitremulous drugs exert no or little effect, first observations suggest that VIM-DBS may be efficacious.

Anti-TNF-alpha inhibitors therapy and non infectious neurologic adverse effects

M. Arias, A. Arias-Rivas, X. Rodríguez-Osorio, F.J. López, I. Requena. Neurology, CHUS, Santiago de Compostela, Spain

Background: Infections are the most common adverse effects associated with TNF-alpha-inhibitors (TNF-alfa-I) therapy. Non-infectious neurologic complications are infrequent (several events suggestive of demyelination have been reported).

Objective: Present four cases of neurologic disorders (central and peripheral demyelination, pseudotumoral lesion, parkinsonism (2)) in four patients treated con distinct TNF-alfa-I.

Patients and methods:
Case-1: Patient (F—63-y) with rheumatoid arthritis (RA), treated with infliximab; she developed a clinical picture of brachial plexitis and, nine months later, myelitis and lumbar plexitis.

Case-2: Patient (M—58-y) with RA, treated with adalimumab; he consulted because of headache, weakness and numbness in his right body side.

Case-3: Patient (M—63-y) with psoriasis, treated with ustekinumab; he presented a left parkinsonism (PD).

Case-4: Patient (F—57-y) with RA, treated with adalimumab; she presented a right PD.

Results:
Case-1: Cerebral-MRI study was normal; spinal-MR-T2-WI study showed some hyperintense lesions in dorsal spinal cord. CSF study showed lymphoid pleocytosis. EMG study revealed denervation in the right deltoid and brachial biceps and in the left quadriceps. The evolution was favorable after the drug was discontinued.

Case-2: Cerebral-MRI study showed left frontal lesion with mass effect and Gadolinium enhancement. Histopathologic study revealed necrosis and mononuclear cells infiltration. The drug was discontinued and the evolution was favorable.

Cases-3–4: Cerebral-MRI study was normal in both patients. DAT-scan resulted abnormal in both patients. The biologic therapy was

Background: Dysfunction of thyroid axis has been linked to neurodegenerative conditions. Spinocerebellar Ataxia type 2 (SCA2) is a polyglutamine disorder caused by abnormal expansion of a CAG repeat sequence on ATXN2 gene.

Objective: To assess the association between thyroid function and SCA2.

Method: A case-control study was carried out with 41 SCA2 affected individuals and 41 healthy controls matched by age and sex. Serum levels of TSH, T3 and T4 were determined by radioimmunoassay. CAG repeat number on ATXN2 gene was assessed by PCR and gel electrophoresis. STRING algorithm was used to predict protein network interactions.

Results: CAG and T4 serum levels were significantly increased in affected individuals related to controls (p < 0.05) and this is dependent on sex. No significant associations were found between thyroid hormones and body mass index, abdominal circumference, resting metabolic rate, CAG repeat number, age at onset, disease duration or SARA score (p > 0.05). However, TSH serum levels significantly correlated with disease progression rate (r = −0.32; p = 0.045). Evidences were obtained for interactions between ATXN2 and thyroid hormone networks, although the relative weights for such interactions were low.

Conclusion: Spinocerebellar Ataxia type 2 is associated with sex-specific hyperactivity of thyrotropic axis; however, more work has to be done to clarify the clinical consequences of such an association.

discontinued. The PD progresses (like common PD) and responds to levodopa.

**Conclusions:** TNF-alfa-I therapies are related with distinct types of central and peripheral demyelinating lesions; less clear seems their risk of induction or acceleration of PD.

**Results:** Out of 2831 patients referred for electrophysiological tests over a ten year period, nine patients were diagnosed as having definite sclerosis on clinical grounds. Four of these had supporting laboratory findings (MRI scans, CSF studies and visual evoked responses). The presenting symptoms were predominantly visual disturbances and somatic sensorimotor disturbances which were seen in all the patients. Cerebellar dysfunction was observed less frequently, in less than half of the patients while sphincter disturbances were conspicuously rare. The sex distribution was overwhelmingly in favour of the female at a ratio of 7:2.

**Conclusions:** Cerebellar dysfunction sclerosis occurs most in African countries and may not be as rare as previously suggested and its prevalence is certainly on the increase. The development of higher incidence rates in communities where the illness was previously unknown may present opportune settings for the study of aetiological factors of this illness as it emerges. There is a need therefore for proper epidemiological studies to evaluate these factors, especially environmental factors, as the new disease continues to appear.

**Exercise training — Effects of MOTOmed® exercise on typical motor dysfunction in Parkinson’s disease**

M. Laupheimer, S. Härtel, S. Schmidt, K. Bös. Institut für Sport und Sportwissenschaft, Karlsruhe, Germany

**Objective:** Additionally to regular medication, alternative drug-free treatments, such as exercise or physical therapy, do not cause any side effects and play an important role in Parkinson's treatment. Recent scientific findings suggest very positive effects of movement training at high cadence, the so-called “Forced Exercise” (FE). The present paper investigates the effects of a home-based passive FE cycling training on general motor function and quality of life in Parkinson’s patients.

**Patients & methods:** 44 Parkinson’s patients (68.5 ± 7.8 years) were randomized to control group (n = 23; age: 71.3 ± 4.0 years) and intervention group (n = 21; age: 67.5 ± 7.8 years). The intervention group completed a 10 week FE cycling program with a motor-assisted movement therapy device. The subjects were encouraged to perform a daily 40 minute MOTOmed® training session, at up to 90 revolutions per minute, in addition to their regular therapy (medication and physical therapy). Motor function and quality of life measures were assessed three times during the study period, a total of 25 test items were recorded (TMTBattery = 15items, tremor spiral test = 2 items, PDQ-8 = 8 items). Subjects of the control group continued their standard therapy.

**Results:** The results of the study show significant improvements in walking ability (walking time: F = 13.31; p = .000; p.Eta2 = .241; walking steps: F = 6.44; p = .000; p.Eta2 = .133) and hand coordination (diadochokinesia of the right arm: F = 3.76; p = .03; p.Eta2 = .082).

**Conclusion:** Device-supported FE movement training of the lower extremities leads to improvements in walking ability and hand motor function, which suggest that FE may be affecting central motor control processes. To proof these findings the authors recommend further studies.

**Background:** Some Parkinson’s disease (PD) motor complications are associated with pulsatile dopaminergic stimulation. Levodopa–carbidopa intestinal gel (LCIG) provides continuous drug infusion via an intrajejunal percutaneous gastrostomy tube.

**Objective:** To evaluate the effects of LCIG on functional and health-related quality-of-life (HRQoL) measures in patients with advanced PD.

**Patients and methods:** PD patients experiencing severe motor fluctuations (≥ 3 h/d OFF-time) despite optimized medical therapy were enrolled in an international, 54-week, open-label study. Individualized LCIG dosing was permitted up to 16 h/d; other PD medications were allowed after 28 days. Functioning and HRQoL were assessed at baseline and weeks 4, 12, 24, and 54 by the PDQ-39, UDPRS, EQ-5D, EQ-VAS and CGI-I.

**Results:** 272 (76.8%) of 354 patients completed the study. Total exposure to LCIG was up to 521 days (mean [SD] = 328.5 [132.3], n = 350). Mean [SD] PDQ-39 summary index was significantly improved at each visit (baseline = 42.8[15.1], n = 320; Endpoint = 35.8[16.8], n = 317 < .001). UDPRS scores were improved at each visit (P < .001 all; Part II: baseline = 17.4[6.6], change at Endpoint = −4.4[6.5]; Part III: baseline = 28.8[13.7], change = −7.4[13.2]). Both EQ-5D and EQ-VAS improved from baseline through Endpoint (P < .001 all; EQ-SD: baseline = 0.588[0.195], Endpoint = 0.652[0.174]. EQ-VAS: baseline = 50.2[21.0], Endpoint = 64.1[19.4]), as did CGI-I scores (Endpoint = 2.10[0.95]). AEIs occurred in 323 (91.2%) patients; most were mild or moderate and transient.

Ablation of rat substantia nigra is a good acute model of Parkinson’s disease for cell transplantation therapy
S.-I. Hirano, Y. Tokumoto, Y. Nishikawa. Physiology, Osaka Dental University, Osaka, Japan; Tissue Engineering & Cell Therapy, Institute of Biomedical Research & Innovation, Kobe, Japan; Biochemistry & Integrative Medical Biology, School of Medicine, Keio University, Tokyo, Japan

A valuable rat model of Parkinson’s disease (PD) to study cell therapy was established. Forty-five female rats were examined. Using a stereotactic technique, we created an acute model of PD by high-frequency electric ablation of bilateral substantia nigra pars compacta. The ablation probe used was a 100 mm-long rigid bipolar needle electrode (1.0 mm in diameter). The rats developed persistent symptoms of PD, especially akinesia and postural instability. We tried all sorts of surgical protocols. The size and shape of the lesion that were ablated in a typical setting were evaluated. Then we determined that the optimal surgical parameter to place a lesion was 1 W of power for 15 s. The long-term viability of transplanted neural stem/progenitor cells was also examined and confirmed to be viable for more than 60 days following surgery. As the animal model was designed to suit the study of cell transplantation therapy, it did not utilize neurotoxic chemicals to make lesions and could avoid the harmful effects of them. The benefits of our ablation model of PD were the rapidity and uniformity of appearance of the characteristics of Parkinsonism. Therefore we can identify the onset of PD strictly. This feature is a unique merit that is not shared by the other methods. The technique described here may provide a good acute model of PD for the research of intracerebral cell transplantation model. This model will contribute to the progress in the field of cell transplantation therapy.

Distribution of wild and mutant torsinA in living cells
I. Toyoshima, E. Abe, S. Kamada. Neurology, Akita National Hospital of NHO, Yurihonjo, Japan; Neurology, Akita University School of Medicine, Akita, Japan

Background: Mutation of torsinA is responsible for DYT1 dystonia. TorsinA is one of the proteins and is thought to result in synaptic pathology. Membrane distortion derived from mutant torsinA thought to cause disturbance of membrane trafficking and poverty of synaptic vesicles.

Objective: To analyze the distribution of wild type and mutant torsinA in living cells, we employed new fluorescent fusion proteins.

Materials and methods: We newly cloned wild type torsinA from cDNA library of human brain and obtained GAG deleted (delE) clone by mutagenesis. Green fluorescent protein pEGFP (Clontech) was used for the fusion of production proteins with torsinA. All were transfected into Cos7 cells and SH-SYSY cells.

Results: TorsinA-pEGFP both wild type and delE mutant localized endoplasmic reticulum (ER) and nuclear envelope in Cos7 cells. Wild type torsinA easily moved to perinuclear region with dense aggregation, probably aggresome. Mutant torsinA stayed ER and nuclear membrane. Cloned torsinA head protein remained ER and nuclear envelope, which is similar to mutant torsinA.

Conclusion: Previous reports revealed the different distribution of torsinA between wild type and delE mutant protein similar to this result with different time range and time course. This study suggests that torsinA inserts ER and traffics to aggresome with binding proteins with torsinA instead vesicle movement to peripheral portion.

The causes and route of admission to institutional care of people with Parkinson’s disease
J. Stancilley, J. Palmer, W. Gray, R. Walker. Medical School, Newcastle University, Newcastle upon Tyne; Department of Medicine, Northumbria Healthcare NHS Foundation Trust, North Shields, UK

Background: Institutional care is a major component of the cost of care for people with Parkinson’s disease (PD) in the UK.

Objectives: To investigate the reasons for, and route of, admission to institutional care for people with PD.

Patients and methods: All patients known to the Northumbria Healthcare NHS Foundation Trust PD service with idiopathic PD, Parkinson’s plus syndromes and vascular PD, who were living in institutional care on 1 January 2013 were included. Disease severity (Hoehn and Yahr stage) and demographic data were collected.

Results: Ninety people were included in the study (51 female). Patients were admitted from hospital (40%), home (58%) and sheltered housing (2%). On care home admission, mean age was 79.6 years (range 60–94) with average disease duration of 5.6 years. The reasons stated for admission to institutional care were patient inability to cope (41%), repeated falls (21%), cognitive impairment (20%), decreased mobility (20%), hallucinations (11%), spouse unable to cope (11%), delirium/confusion (8%), impaired swallow (3%), and stroke (2%). Many people had multiple reasons. Hoehn and Yahr stage was V in 48%, IV in 20%, III in 31% and I or II in only 1%.

Conclusion: Difficulty coping with activities of daily living was the most common cause of institutional care admission. Those admitted from hospital will have had a full multidisciplinary assessment of their needs, though for those admitted from home this may not be the case. More support in the community may prevent, or delay, institutional care admission.

Memory and attention in patients with Parkinson’s disease

G. Adler, N. Baumgart, M. Bektas, Y. Lembach. Institut für Studien zur Psychischen Gesundheit (ISPGe), Mannheim, Germany

Patients with Parkinson’s disease (PD) have a high risk of developing Parkinson’s disease dementia (PDD) with an accentuated decline in mental speed and executive functions and comparatively little deficits in short-term memory. PD patients without dementia may show these impairments to a smaller extent.

We determined the neuropsychological profile of PD patients not suffering from dementia.

In a multicentric study, the cognitive performance of PD patients was examined by means of the computer-based Memory and Attention Test (MAT). By means of the MAT, selective attention as well as working and short-term memory for verbal, figural and episodic material are assessed. The findings in the PD patients were compared with those of an age-, sex- and education-matched control group by means of unpaired Student’s t-tests.

The study was conducted in 40 non-demented PD patients (26 men, 14 women) at ages between 48 and 82 years (mean/SD: 68.2/8.3 years). The PD stage according to Hoehn and Yahr was “1” in 2 patients, “2” in 21 and “3” in 7. MMSE scores ranged between 25 and 30 (mean/SD: 28.7/2.1). Neuropsychological testing revealed no impairments of short-term memory, a slight impairment of verbal working memory (p ≤ 0.05) and a substantial impairment of selective attention, which increased with task complexity (p < 0.01).

In these non-demented PD patients we observed a decline of selective attention, which increased with task complexity, and a decrease of working memory. Both of these capacities are dependent on mental processing speed. Thus, mental slowing may have caused the deficits.

An open-label study in healthy male volunteers using positron emission tomography to assess brain adenosine A2A receptor occupancy by V81444

Background: V81444 is a selective non-xanthine adenosine 2A receptor (A<sub>2AR</sub>) antagonist of potential utility in neurological disorders.

Objectives: We characterised the relationship between plasma concentration of V81444 and brain A<sub>2AR</sub> occupancy following single oral doses.

Patients and methods: [11C]SCH444216 PET scans were acquired before and at 2–3 h and 21–27 h after a single oral dose of V81444 (50, 100 or 250 mg) in 6 healthy male volunteers. A<sub>2AR</sub> availability in the striatum was estimated using a simplified reference tissue model with cerebellum as reference tissue, and related to measured V81444 plasma concentration data.

Results: The images displayed a heterogeneous signal, consistent with the known regional distribution of A<sub>2AR</sub>. Tissue time-activity curves were consistent with those described previously, with an early component (0–15 min) characterised by a rapid peak followed by washout, and a later component (15–90 min) dominated by a slow accumulating signal that was not regionally specific. Quantification of

The use of DaT-SPECT scanning in the differential diagnosis of parkinsonism within the Northumbria Parkinson's disease service
S. Clements$, W. Gray$, R. Walker$\dagger$, \(a\)Medical School, Newcastle University, Newcastle upon Tyne, UK; \(b\)Medicine, Northumbria Healthcare NHS Foundation Trust, North Shields, UK

Background: Dopamine transporter (DaT) scanning enables the determination of dopaminergic function within the basal ganglia. Dopaminergic function is decreased in Parkinson's disease (PD). UK NICE guidelines recommend that DaT scanning is used to differentiate between PD and essential tremor (ET).

Objectives: To determine whether referrals for DaT scanning follow NICE guidelines and how results affect management.

Patients and methods: Patients under the care of the Northumbria Healthcare NHS Foundation Trust PD service in the UK who had scans between 2010 and 2012 were included. Retrospective data collected included reason for scan, expected scan result, actual scan result and post-scan management.

Results: Two hundred and thirty-five people had a DaT scan, representing 24% of all referrals to the service during the study period. NICE guidelines were followed fully in only 73 (31%) of scans. The most common reasons for the scan were differentiation of PD from ET (31%) and confirmation of PD diagnosis (29%). One hundred and one scans (43%) were positive for PD, of which 85 (84%) were expected to be positive. Fifty-eight (57%) of those with positive scans were started on treatment immediately. Of 134 negative scans, 59 (74%) were expected, of which 5% led to PD treatment discontinuation and 18% to commencement of treatment for ET.

Conclusions: DaT scan can help direct the management of people with PD, although it should only be used where there is significant doubt over diagnosis. Future guidelines for use should consider amendments to widen the acceptable scope of use.

Saccade-related modulation of beta oscillation in the human internal globus pallidus
A. Yuhata$\dagger$, R. Chen$, W.D. Hutchison$, \(a\)Neurology, University of Tokyo Hospital, Tokyo, Japan; \(b\)University of Toronto, Toronto Western Research Institute, Toronto, ON, Canada

Background: Studies in monkeys report more prominent pallidal cell firing during antisaccades than prosaccades (Yoshida 2009). We reported saccade-related beta-band desynchronization (beta-SRDs) in the subthalamic nucleus (STN) of Parkinson's disease patients. We found more prominent beta-SRDs during antisaccades than prosaccades, like due to additional neural processing required. Since the STN projects to the internal globus pallidus (GPI), we expected enhanced beta-SRDs to antisaccades in the GPI.

Objective: To investigate whether oscillations in the GPI are modulated by saccades, and to compare the responses to prosaccades and antisaccades. We hypothesized that antisaccades would produce earlier and/or more prominent beta-SRDs than prosaccades.

Patients and methods: We recorded the local field potentials from deep brain stimulation electrodes implanted in the GPI in 7 primary focal dystonia patients. The patients performed prosaccade and antisaccade tasks. We analyzed the wavelet power spectrum averaged on saccade onset.

Results: The beta-SRDs were observed in the GPI just before and during saccades in 6 of 7 patients. The onsets, durations, and amplitudes of beta-SRDs were not different between prosaccades and antisaccades.

Conclusions: Beta-SRDs were observed in the GPI of dystonia patients. They were not related to inhibition of unwanted saccades, because they were not different between prosaccades and antisaccades. While it is well known that the basal ganglia output from the substantia nigra pars reticulata strongly inhibits the superior colliculus, our results suggest that the basal ganglia output from the GPI may contribute to the control of saccades, but are not a major contributor in dystonia patients.

Is there a correlation between plasma homocysteine and Parkinson's disease associated with polyneuropathy?
S. Lee$, S.-J. Lee$, I. Song$, \(a\)Neurology, Incheon St. Mary’s Hospital, Catholic Univ. of Korea, Incheon, Republic of Korea; \(b\)Neurology, Sejong General Hospital, Bucheon, Republic of Korea

Background: Polyneuropathy has recently been described in higher proportions for patients with PD than in normal population. This finding was hypothesized to be related to the elevation of plasma homocysteine (Hcy), following the management of PD with levodopa. We conducted this study to clarify the clinical value of elevated plasma Hcy in PD patients.

Methods: A total of 37 PD patients without neuropathy (PDWo) and 41 PD patients with polyneuropathy (PDP), who were recruited for this study, were compared with 48 healthy controls. All PD patients performed electrophysiological tests, including nerve conduction study, to diagnose polyneuropathy. Plasma Hcy levels were measured in all subjects and compared with each groups.

Results: The Hcy of PDP showed higher Hcy level than those of PDWo, as well as healthy controls, but there was no significant difference between those of PDP and that of the healthy controls. In considering each group of PDWo and PDP, there were no intercorrelations between daily levodopa dose, duration of PD symptoms and PD treatment or motor severity.

Conclusion: We could cautiously assume that plasma Hcy level may be related with the involvement of peripheral nerve of PD patients in this study. However, we were unable to confirm pathophysiologic role of Hcy and the relationship between plasma Hcy level and levodopa in PDP.

Long-term complications of Parkinson’s disease — 15th year, 20th year, and beyond: A hospital-based observational study

Background: Long-term complications of Parkinson’s disease (PD) based on regular follow-up in a local neurological center is insufficiently appreciated.

Patients and methods: From registered PD patients, we selected those who have been examined in 15th and/or 20th year of the disease (YD) and information about motor status, levodopa equivalent daily dosage (LED), hallucination, cognitive disturbance, and dysphagia in each year was collected.

Results: Of all PD patients between April 1995 and December 2012 (n = 538, male/female 222/316), 72 patients (13.4%) were examined in their 15th YD (Group PD ≥ 15; age at onset (AO) 58.1 ± 8.1 year-old; modified Hoehn and Yahr stage (mHY) at on/off, 3.3 ± 0.9/3.9 ± 0.9; LEDD 567 ± 239 mg/day) and only 18 patients (3.3%) have taken their 20th YD examination (Group PD ≥ 20; AO 53.4 ± 6.6, LEDD at on/off, 3.8 ± 0.9/4.4 ± 0.7; LEDD 703 ± 208 mg/day). Groups PD ≥ 15 and PD ≥ 20 have significantly younger AO (p = 0.0001, p < 0.0001) than patients who have less than 15th YD history (PD < 15, n = 466, AOO 67.4 ± 8.8). In Group PD ≥ 15/ PD ≥ 20, trouble-some hallucination (mainly visual, n = 36/13, 50.0/72.2%) appeared in 15.1 ± 2.8/17.7 ± 2.6 year, cognitive disturbance [n = 27/10, 37.5/55.6%] in 16.0 ± 2.9/18.0 ± 2.5th year, and dysphagia [n = 29/13, 40.3/72.2%] in 18.1 ± 3.4/21.0 ± 2.3th year. Follow-up periods after appearance of hallucination, cognitive disturbance, and dysphagia in Group PD ≥ 15 are 4.2 ± 2.7, 3.2 ± 2.6, 1.7 ± 2.1 years, respectively. The longest treated patient had AO at 54 year-old and was in mHY 3/0.4 in 29th YD without these 3 complications.

Conclusions: During long-term treatment of PD, hallucination, cognitive disturbance and swallowing problem appear in near half or more of the patients after 15th YD and seem to contribute to lost follow-up.

Role of magnetic resonance spectroscopy in differentiating parkinsonian syndromes of various etiologies
I. El-Banhawy1, M. El-Toukhy1, I. Fahmy1, N.M. Shalaby1, M.A. Nada2, H.S. Shehata3, I. Ismaiela, Neurology, Cairo University, Cairo, Egypt; aRadiology, Cairo University, Cairo, Egypt

Background: Parkinsonism is not a single disease entity as it has a number of causes that differ in the pathology according to the affected brain region. To our knowledge, no previous studies have been published to investigate the role of magnetic resonance spectroscopy (MRS) in the differentiation between idiopathic Parkinson’s disease (IPD), drug-induced parkinsonism (DIP) and Wilson’s disease (WD).

Objective: Investigating the role of MRS in the differentiation between various parkinsonian syndromes.

Subjects & methods: The study was conducted on 40 parkinsonian patients: 27 patients with IPD, 6 patients with DIP, and 7 patients with WD, and 15 normal control subjects. All were examined using single voxel proton MRS study of striatum, frontal cortex and subcortical white matter. Measured MRS parameters were N-acetylaspartate (NAA), choline-containing compounds (Cho) and creatine–phosphocreatine (Cr) and with peak area ratios (NAA/Cr, Cho/Cr, NAA/Cho ratios).

Results: Patients with parkinsonism had significantly more cortical Cr and less NAA/Cr ratio and more subcortical NAA, Cr, Cho, and Cho/Cr ratios compared to control subjects. DIP patients showed significantly lower striatal Cho/Cr ratio and significantly higher subcortical Cho/Cr ratio compared to IPD. While comparing WD and IPD patients, a significantly lower cortical Cho/Cr ratio and significantly higher subcortical NAA/Cr and cortical NAA/Cho ratios were found in WD. Patients with WD had significantly higher cortical and subcortical NAA/Cho and striatal NAA/Cr ratios compared to DIP patients.

Conclusion: MRS can be used as a useful in vivo investigative tool in differentiating between parkinsonian syndromes of various etiologies.

N-Methyl-d-aspartate receptor (NMDAR) antibodies in post herpetic simple virus encephalitis (HSVE) neurological relapse

Y. Hacohen, K. Deiva, P. Pettingill5, P. Waters4, A. Siddiqu1, P. Chretien1, E. Menson1, J.-P. Lin1, M. Tardieu1, A. Vincent1, M. Lin1.
1Nuffield Department of Clinical Neurosciences, Oxford University, Oxford, UK; 2Pediatric Neurology, Assistance Publique Hôpitaux de Paris, Hopitaux Universitaires Paris Sud, Pediatric, Paris, France; 3Department of Neuroradiology, King’s College Hospital, London, UK; 4Immunology Department, Assistance Publique Hôpitaux de Paris, Hopitaux Universitaires Paris Sud, Pediatric, Paris, France; 5Paediatric Infectious Diseases Department, UK; 6Children’s Neurosciences, Evelina Children’s Hospital @ Guy’s and St Thomas’ NHS Foundation Trust, London, UK

Background: Patients with HSV encephalitis can present with a second phase of encephalopathy often predominated by a movement disorder. These clinical relapses are commonly treated as a viral reactivation, although frequently no evidence of a viral reactivation can be identified, and post-infectious autoimmune mechanisms appear likely. There are now a number of distinct neurological syndromes in which brain directed antibodies have been identified, with a significant number of conditions featuring movement disorders. In particular, the movement disorder seen in NMDAR-antibody encephalitis has phenotypic similarities to the choreoathetosis in relapsing HSVE.

Methods: From a total of 20 cases of HSVE, we identified seven children who had a neurological relapse following their initial encephalitis. We tested their sera and CSF (n = 1) for autoantibodies reported in CNS autoimmune conditions.

Results: All children had presented with a typical history of HSVE confirmed by clinical, laboratory and radiological findings, and with improvement following intravenous acyclovir. At the time of their relapses, viral reactivation was identified only in one patient (14%), and no identifiable cause was found for the other six. On retrospective analysis of their sera, three out of six (50%) children, who had choreoathetosis, seizures and/or cognitive regression at relapse, had NMDAR antibodies. In two of the NMDAR antibody positive patients who were treated at relapse, a beneficial response was observed.

Conclusion: NMDAR-antibodies appear to be relatively common in children who often exhibit choreoathetosis at relapse. Immunotherapy should be considered in children who relapse after HSVE.

Glutathione S-transferase omega 2 influence the clinical phenotype of spinocerebellar ataxia type 2

L. Almaguer Mederos1, A. Riquiera Rodríguez3, D. Almaguer Gotay2, Y. González Zaldivar3, D. Cuello Almarales3, J. Lafita Mesa2, Y. Vázquez Mojena1, P. Zayas Feria1, L. Velázquez Pérez3, P. MacLeodb.
1Center for the Investigation and Rehabilitation of Hereditary Ataxias, Holguín, Cuba; 2Victoria General Hospital, Victoria, BC, Canada

Background: Spinocerebellar ataxia type 2 is a neurodegenerative disorder caused by expansions of a CAG repeat sequence in ATXN2 gene. The CAG repeat number is the major genetic factor influencing disease onset and severity, but there is still wide phenotypic variation.

Objective: To assess potential modifier effects of rs4925 GSTO1 and rs2297235 GSTO2 polymorphisms on age at onset and disease severity in spinocerebellar ataxia type 2 affected individuals.

Patients and methods: Polymorphisms rs4925 GSTO1 and rs2297235 GSTO2 were genotyped in 124 patients with SCA2 and 100 controls.

Results: There were highly significant differences between affected and control individuals for rs2297235 GSTO2 genotypes under additive and dominant models (p = 0.01). Allelic frequencies were significantly different only for rs2297235 GSTO2 polymorphism (p = 0.046). In affected individuals, expanded CAG repeat number explained 37.1% of log transformed age at onset variability, rs2297235 GSTO2 genotypes, under additive and dominant models, significantly influenced the residual age at onset after adjusting for the expanded CAG repeat number and explained 3.0% of total variation and about 48% of the unexplained variation in age at onset. SARA scores were significantly influenced by CAG repeat number and disease duration. After adjusting for these two factors by multiple linear regression, neither rs4925 GSTO1, rs2297235 GSTO2 genotypes nor GSTO1-GSTO2 haplotype combinations significantly influenced SARA scores (p = 0.05).

Conclusion: rs2297235 GSTO2 polymorphism is a genetic modifier for age at onset in spinocerebellar ataxia type 2 affected individuals.

Correlation between cognitive function and motor symptoms in Parkinson’s disease  
H. Murakami, A. Sugimoto, A. Futamura, K. Fujita, Y. Saito, A. Kuriki, S. Ishigaki, M. Kobayakawa, H. Kato, A. Midorikawa, M. Kezuka, M. Kawamura. Division of Neurology, Department of Internal Medicine, School of Medicine, Showa University, Tokyo, Japan  

Background: In conventional management of Parkinson’s disease (PD), treatment of motor dysfunction normally precedes that of cognitive impairment. Recent research suggests anti-dementia drugs may help cognitive impairment in PD. Thus, both motor and cognitive impairment will be treated simultaneously.  

Objective: We examined the relationship between the cognitive and motor dysfunction in patients with PD treated with dopaminergic drugs for motor dysfunction.  

Patients and methods: 49 patients (27 male, 22 female) with PD, and PD with dementia (PDD), taking dopaminergic drugs but no anti-dementia drugs (acetylcholinesterase inhibitor and NMDA receptor antagonist) participated. All patients were assessed on the Unified Parkinson’s Disease Rating Scale (UPDRS) (Parts II and III), the Montreal Cognitive Assessment (MoCA) and the Frontal Assessment Battery (FAB). The MoCA and FAB scores were compared with UPDRS (II plus III) for each patient.  

Results: Both MoCA and FAB scores showed highly significant negative correlation with UPDRS (II plus III) \((p \leq 0.0001)\). The correlations were stronger than those with current age and duration of PD. They also showed significant negative correlation with UPDRS subscores of postural instability and akinesia, but not tremor. The MoCA score had a weak negative correlation with UPDRS subscore of rigidity, but the FAB score did not.  

Conclusion: In patients with PD on dopaminergic agent, cognitive impairment, especially frontal lobe dysfunction, correlates with motor dysfunction such as postural instability and akinesia but not tremor. Pathophysiology of tremor is probably different from other motor symptoms.

Adverse drug reactions with Selegiline and Rasagiline compared to Levodopa and Ropinirole: A study in the French Pharmacovigilance Database  
S. Perez-Lloret, M.V. Rey, J.-L. Montastruc, O. Rascol. Clinical Pharmacology, CHU Toulouse, Toulouse, France  

Background: The safety of Rasagiline has not been as extensively explored as Selegiline.  

Objective: To compare spontaneous adverse drug reaction (ADR) reports to the French Pharmacovigilance Database (FPVD) between Selegiline and Rasagiline, taking Levodopa and Ropinirole as references.  

Methods: We retrieved all ADRs in which Selegiline, Rasagiline, Levodopa or Ropinirole were considered as “suspected” drugs. ADRs were classified according to system-organ class (MeDRA).  

Results: We retrieved 199 ADR reports for Selegiline, 132 for Rasagiline, 1851 for Levodopa and 432 for Ropinirole. Confusion, hallucination or agitation, were more frequent with Selegiline compared to the rest of the drugs (respectively, 19% vs 10%, 12% vs 8% and 6% vs 2%). Impulse control disorders were more frequent with Ropinirole vs Rasagiline (12% vs 4%) and less frequent with Selegiline (1%). Somnolence was less frequent with Selegiline and Rasagiline vs Ropinirole (1% and 4% vs 16%). Headache was more frequent with Rasagiline compared to rest of the drugs (5% vs 1%). Orthostatic hypotension was less frequent with Rasagiline vs Selegiline (1% vs 9%). Weight loss was more frequent with Rasagiline or Selegiline.  

Conclusion: Compared to Selegiline, Rasagiline was associated with a higher risk of renal or musculoskeletal ADRs, headaches or impulse control disorders. Conversely, the risk of orthostatic hypotension, confusion, hallucinations or agitation was higher with Selegiline.

Drug induced movement disorders—Pathophysiology, diagnosis and management  
C. Baetu, I. Buraga. Neurology, Colentina Clinical Hospital, Bucharest, Romania  

Drug induced movement disorders are generally caused by dopamine receptor blocking drugs. There is a great variety of drug induced acute and tardive movement disorders. Early onset drug induced movement disorders include akathisia, neuroleptic malignant syndrome, parkinsonism and dystonic reactions. They appear within hours to days after treatment initiation.  

Late onset category of induced movement disorders include dyskinesia, dystonia, akathisia and chorea. They manifest months after exposure to drugs or when the dosage is increased or treatment is discontinued.  

Pathophysiology of these drug induced disorders refers to many hypotheses: neurotoxicity, hypersensitivity of postsynaptic dopamine receptor, hyperactivation of the cholinergic system and also genetic predisposition.

The symptomatology of drug induced movement disorders is sometimes hard to differentiate from that of an idiopathic one and may resemble several other medical conditions. We will discuss about the epidemiology, mechanism, differential diagnosis, risk factors, prevention and management of these syndromes as well as diagnostic procedures (PET, SPECT, MRI scans with T2 diffusion-weighted, DAT-scan) and therapeutic goals. Treatment of these disorders inconsistently has a benefit and therefore the primary prevention is essential.  

Movement disorders are also associated with antiemetics that block central dopamine receptors, lithium, selective serotonin reuptake inhibitors, stimulants, tricyclic antidepressants, organophosphates, organic solvents, carbon monoxide, and cyanide.  

Conclusions: Incidence and prevalence of drug induced movement disorders are not entirely known due to a lack of recognition and a lack of validated criteria for the diagnosis of drug induced movement disorders. This article focuses on diagnosis and mechanisms of these drug induced disorders and also on treatment and prevention.

Freezing of gait in patients with Parkinson disease is a kind of kinetic subcortical apraxia
N. Skripkina, O. Levin, T. Makotrova, V. Datieva. Neurology, Russian Medical Academy of Postgraduate Education, Moscow, Russia

Background: Freezing of gait is one of the late signs associated with apractic features which may be considered as a subcortical kinetic apraxia.
Objective: To investigate the correlation between the frequency and severity of freezing of gait and apractic disorders.
Material and methods: We examined 70 patients with Parkinson disease: 39 men and 31 women (mean age 64.5 ± 8.5 years; mean disease duration 5.1 ± 3.5 years, Hoehn–Yahr stages from 2 to 4, mean UPDRS (part III) score 43.2 ± 11.6). The Gait and Balance examination was carried out with GABS (Jankovic et al., 2001) and FOG-Q (Gurevich et al., 2003) in combination with a comprehensive neuropsychological study including a 72-item apraxia scale. The apraxia scale consists of the oral, arm, leg and trunk apraxia examinations tests, and each of them includes imitation tests and tests on command. Patients were divided into 3 groups according to their FOG-Q score.
Results: Freezing of gait was found in 24 (34.3%) of the PD patients. Patients with freezing had advanced stages of PD, a higher UPDRS score and more severe axial symptoms (p < 0.0001) compared with the non-freezing patients. Patients with a higher FOG-Q score performed worse in the executive and visuospatial cognitive tests and they had a higher leg apraxia score (p < 0.05). Their performance in the apractic tests on command was worse than in the imitation tests.
Conclusion: Pathophysiology of FOG in PD is unclear but a subcortical apractic defect should be considered among the possible mechanisms of its origin.

Motor sequence learning and motor adaptation in primary cervical dystonia
P. Katschnig-Winter, P. Schwingenschuh, M. Davare, A. Sadnicka, R. Schmidt, J.C. Rothwell, K.P. Bhatia, M.J. Edwards. Department of Neuroscience, Medical University of Graz, Graz, Austria; Sobell Department of Motor Neuroscience and Movement Disorders, UCL Institute of Neurology, London, UK

Background: Motor sequence learning and motor adaptation rely on overlapping circuits predominantly involving the basal ganglia and cerebellum. Given the importance of these brain regions to the pathophysiology of primary dystonia, and the previous finding of abnormal motor sequence learning in DYT1 gene carriers, we explored motor sequence learning and motor adaptation in patients with primary cervical dystonia.

Methods: We recruited 12 patients with cervical dystonia and 11 healthy controls matched for age. Subjects used a joystick to move a cursor from a central starting point to radial targets as fast and accurately as possible. Using this device, we recorded baseline motor performance, motor sequence learning and a visuomotor adaptation task.
Results: Patients with cervical dystonia had a significantly higher peak velocity than controls. Baseline performance with random target presentation was otherwise normal. Patients and controls had similar levels of motor sequence learning and motor adaptation.

Conclusion: Our patients had significantly higher peak velocity compared to controls, with similar movement times, implying a different performance strategy. The preservation of motor sequence learning in cervical dystonia patients contrasts with the previously observed deficit seen in patients with DYT1 gene mutations, supporting the hypothesis of differing pathophysiology in different forms of primary dystonia. Normal motor adaptation is an interesting finding. With our paradigm we did not find evidence that the previously documented cerebellar abnormalities in cervical dystonia have a behavioral correlate, and thus could be compensatory or reflect “contamination” rather than being directly pathological.

An autopsy case of Perry syndrome with DCTN1 156 T>A mutation
H. Hara, T. Oka. Department of Neurology, Saga University Faculty of Medicine, Saga, Japan

We report the first autopsy case of Perry syndrome with a DCTN1 156 T>A mutation. A 74-year-old woman had the onset of resting tremor and bradykinesia at the age of 70. She was diagnosed with Parkinson disease and treated with l-dopa. Sudden onset of respiratory failure appeared at the age of 72 and the disease progressed with repeated remission and exacerbation of respiratory failure. Autonomic dysfunctions such as bradycardia and prominent changes in blood pressure appeared over the course. She died at the age of 74 because of aspiration pneumonia. Autopsy study revealed slight neuronal loss and reduction of melanin granule in substantia nigra without apparent gliosis and TDP-43-positive inclusion body.

Evolution of movement related cortical potentials in early stage Parkinson disease
H. Gümüşa, Z. Akpınarb, O. Demirc, S. İlhanb.  aNeurology, Education and Research Hospital, Turkey;  bNeurology, Necmettin Erbakan University, Konya, Turkey

Objective: The purpose of this study was to evaluate the role of cortical potentials related to movement in diagnostic stage and physio-pathology of movement disorder in the cases of early-stage Parkinson disease.

Methods: The data were acquired from forty patients with idiopathic Parkinson disease who did not have dementia and psychiatric disorders. A survey was performed among Parkinson disease and movement disorder polyclinics in Konya, Turkey.

Symptoms: The average age of patients was 66.6 ± 7.2 years and their ages were between 52 and 81 years. The period of the beginning of the disease’s lower limit was 1 year, the upper limit was 6 years and the average was 3.15 ± 2.94 years. The age of the beginning of the disease’s lower limit was 52, the upper limit was 72 and the average was 63.57 ± 7.23. While the Hoehn & Yahr score’s lower average was 6, the upper limit was 6 years and the average was 29.32 ± 11.47. DIP records were obtained from triggering the right and left hand thumbs with random and counting patterns. When Parkinson disease group’s and control group’s DIP records were compared, N0 (msn), N1 (amp), N500 (amp), N650 (amp) values were plausible.

Results: Parkinson disease can be exactly diagnosed via only pathologic examination but it is not used for diagnosis because it is an invasive method. Therefore, clinical diagnosis criteria are used. Cortical potentials related to movement in Parkinson disease can be used for examination as a non-invasive method and a companion to objective diagnosis. Furthermore, this method proves that it can aid the enlightenment of the neural mechanism of movement.

Validation and cross-cultural adaptation of the self-assessment disability scale in patients with Parkinson’s disease in Serbia
T. Gazi, V. Kostić, T. Pekmezović. aInstitute of Epidemiology, Faculty of Medicine, University of Belgrade, Serbia; bNeurology Clinic, Clinical Centre of Serbia, Belgrade, Serbia

Background: The symptoms of Parkinson’s disease (PD) deteriorate over time affecting performance and causing disability.

Objective: The purpose of this study was to translate the Self-Assessment Disability Scale in patients with parkinsonism (SADS-PD) into Serbian language and assess its validity and reliability.

Methods: From January to July 2012, 114 consecutive PD patients were recruited at the Neurology Clinic in Belgrade. The inclusion criteria were: ability to walk independently for at least 10 m and ability to stand for at least 90 s. The exclusion criteria were: cognitive impairment, the presence of other major neurologic, psychiatric, visual, audio-vestibular, and orthopedic disturbances. The 25-item SADS-PD was translated according to an internationally-accepted methodology. The internal consistency of the scale was evaluated using Cronbach’s alpha coefficient. Test–retest reliability was evaluated using Kendall’s concordance coefficient for total scores. To evaluate construct validity, an exploratory factor analysis (principal component analysis, varimax rotation) was performed.

Results: Cronbach’s alpha coefficient was 0.984. Kendall’s concordance coefficient was 0.994. Duration of the disease, Hoehn & Yahr (H&Y) stage, Unified Parkinson’s Disease Rating Scale (UPDRS) motor score, history of falls, and Hamilton’s Depression and Anxiety Rating Scales (HDRS and HARS) scores were significantly correlated with the total SADS-PD score. On factor analysis the 25 items in the SADS-PD questionnaire were separated in 2 clusters with a total matrix variance of 79.7%.

Conclusion: The psychometric properties of the cross-culturally adapted SADS-PD questionnaire (Serbian version) have outstanding validity and reliability as an instrument for evaluation of the extent of disability in patients with PD.

Pharmaceutical quality of seven generic levodopa/benserazide products compared with original Madopar®/Prolopa®
G.L. Vital-Durand, I. Arnet, U.E. Gasser, J.P. Timmermans, A. Fischer. aRoche; bPharmaceutical Care Research Group, University of Basel, Basel, Switzerland; C ClinResearch Ltd., Aesch, Switzerland
Objective: To compare the pharmaceutical quality of seven generic levodopa/benserazide combinations with the original product (Madopar®,Prolopa® 125, Roche).

Introduction: Madopar®/Prolopa® is a combination of levodopa (1-Dopa) and benserazide. Generics assume the same composition and presentation as the original product.

Materials: Madopar®/Prolopa® 125 tablets and capsules were used for reference. Generics tested included four tablet (Betapharm, CT, MYLAN and ratiopharm) and three capsulated formulations (HEXAL, STADApharm and TEVA).

Methods: Shape, colour, appearance and hardness (tablets), resp. surface, colour, imprint and content (capsules), mass, degradation products, impurities, disintegration and dissolution were all tested.

Results: For all seven generic products at least one of the parameters fell outside the specifications. Content requirements were unmet by two tablet formulations for 1-Dopa (specs: 100 mg ± 5%; test results: −5.6% and −7.6%) and for benserazide (specs: 28.5 mg ± 5%; −6.6% and +8.4%). Average mass (specs: 275 mg ± 3%) was not reached for two tablet formulations (+3.3%), and average fill mass (specs: 150 mg ± 5%) was not reached for three capsule formulations (+48.2%, +99.1%, +99.3%). The level of two benserazide degradation products was 26.5% above specification, with potential clinical consequences. Two of the degradation products were 26.5% above specifications, with potential safety concern. This should lead to conservative prescribing and invite further investigations, both pharmaceutical and clinical.

Conclusion: Even though the pathology of the two subtypes of MSA is somewhat different, we found no significant difference in RBD and RWA measurements in patients with MSA-C and MSA-P.

The Dystonia Coalition: Four years of progress
1Department of Neurology, Emory University, Atlanta, GA, USA; 2Department of Neurology, Washington University at St. Louis, St. Louis, MO, USA; 3Department of Neurological Sciences, Rush University, Chicago, IL, USA; 4Department of Communication Sciences and Disorders, James Madison University, Harrisonburg, VA, USA; 5National Institute of Neurological Disorders and Stroke, USA; 6National Institutes of Health Office of Rare Diseases Research at the National Center for Advancing Translational Research, Bethesda, MD, USA

Background: Clinical research in rare disorders, such as dystonia, is challenging because of limited access to large numbers of patients or patient materials.

Objective: The objective is to advance the pace of clinical and translational research in primary dystonias by fostering a collaborative atmosphere.

Methods: The Dystonia Coalition (DC) is a collaboration of medical researchers and patient advocacy groups that is funded by the National Institute of Neurological Disorders and Stroke and the Office of Rare Diseases at the National Center for Advancing Clinical and Translational Research. The DC has funding to support 4 large clinical research projects, a pilot project program to provide seed funding for new projects, career development awards to encourage new investigators to conduct dystonia research, and regular meetings to delineate important research problems.

Results: The DC has 47 clinical centers in North America and Europe. As of March 29, 2013, these centers have recruited 1044 participants with different primary dystonias into a biorepository study, 169 participants into a longitudinal natural history study, 210 participants into a study aimed at revising and validating the TWSTRS scale for cervical dystonia, and 132 participants into a study developing a new rating scale for spasmodic dysphonia. The DC has provided 11 additional grants for pilot projects proposed by its members and 10 career awards for junior investigators.

Conclusions: The DC provides an effective forum for the scientific community to define and address common goals in a collaborative manner with the direct input and support of patient advocacy groups.

Orthostatic tremor heralding the onset of stiff-person syndrome
M. Fabbri1, R. Vetrugno2, E. Antelmi2, R. D’Angelo2, R. Rinaldi2. 1IRCCS Istituto delle Scienze Neurologiche, Dipartimento di Scienze, University of Bologna, Italy; 2Neurology, University of Bologna, Italy; 3Neurological Unit, S. Orsola-Malpighi University Hospital, Bologna, Italy

Background: Orthostatic tremor (OT) is a rare movement disorder triggered exclusively by standing and accompanied by 13–18 bursting EMG patterns. Exaggerated startle, stiffness, and spasms of the axis characterize stiff-person syndrome (SPS).

Abstracts / Journal of the Neurological Sciences 333 (2013) e109–e151
Objective: To report two patients with abnormal muscle tone control heralding as OT and briefly transforming into SPS.

Patients and methods: A 77-year-old and a 55-year-old female developed disabling unsteadiness with clinical and electrophysiological evidence of OT and benefit from clonazepam. Surprisingly the clinical picture underwent a change in a short time with progressive stiffness of the axial and mainly lower limb muscles with spasms and falls.

Results: MRI of the brain, cervical, thoracic and lumbar spine was normal. Results of antibody testing revealed anti-glutamic acid decarboxylase (anti-GAD) antibodies in the blood (≈2000 IU/mL), whereas amphiphysin antibodies were absent. A search for an underlying neoplasm revealed no abnormalities. They were now diagnosed as having classic SPS and treatment with intravenous immunoglobulin (IVIg) conferred significant improvement.

Conclusion: Brainstem and spinal cord hyperexcitability conditions give rise to progressive alterations of muscle tone, posture and voluntary movement which are potentially immunotherapy-responsive. In this regard, OT observed in our patients can be considered as a “prodromal and soft sign” of a more complex and ongoing muscle tone dis-control. A search also for autoimmunity in a specific patient with “isolated OT” can be used to prompt for the most accurate clinical investigation and to choose the most timely and appropriate therapy.

Objective: To evaluate the effect of levodopa and dopaminergic medication on neuronal activity of SNc in PD patients.

Patients and methods: 204 PD patients and 150 PD patients treated with levodopa and dopaminergic agents were investigated between 2007 and 2012. Patients were further classified into 2 groups, levodopa alone and plus group. Multi-voxel 1H-MRS examination of SNc was performed (1.5T, TR/TE = 1000/144 ms). Single voxel examination was performed which placed ROI on the posterior half of the putamen (TR/TE = 1500/144 ms). NAA/Cr ratio was calculated and the difference was analyzed using Student’s t-test.

Results: The NAA/Cr ratio of SNc between de novo and treated with levodopa alone PD showed significant differences of 1.63 and 1.43 (p < 0.02), respectively.

Conclusion: Levodopa seemed to restrain SNc neuronal activity. The phenomenon may be only a manifestation of the effect of age and disease severity, however, another explanation should be in consideration. The decrease of SNc NAA/Cr with the increase of NAA/Cr of the putamen in levodopa treated patients and the associated increase of NAA/Cr of the SNc and putamen in de novo patients suggest that the putamen receives enough dopamine derived from levodopa in the former and the putamen receives insufficient dopamine (denervated state) to promote SNc neuronal activity in the latter.

Clinical correlates of serum insulin-like growth factor 1 in patients with Parkinson's disease, multiple system atrophy and progressive supranuclear palsy

A. Numaoa, K. Suzukia, M. Miyamotob, T. Miyamotob, K. Hirataa. aDepartment of Neurology, Dokkyo Medical University, Mibu, Japan; bDepartment of Neurology, Dokkyo Medical University Koshigaya Hospital, Koshigaya, Japan

Background: Recently, increased serum insulin-like growth factor 1 (IGF-1) levels have been reported in patients with Parkinson’s disease (PD) and multiple system atrophy (MSA) in small cohort studies; however, the clinical significance of serum IGF-1 in these disorders has not been fully clarified.

Objective: To assess a correlation between serum IGF-1 levels and clinical background factors in PD and related disorders and to investigate whether serum IGF-1 levels can be useful in differentiation of PD from MSA and PSP.

Patients and methods: A total of 67 patients with PD, 24 MSA and 14 PSP, and 49 healthy controls were included in this study. Serum IGF-1 and growth hormone (GH) were measured in the fasted state.

Results: Serum IGF-1 levels were significantly increased in MSA patients when compared with PD patients and controls, after adjusting age, gender and body mass index. No significant differences were observed in serum GH levels among patients and controls. In patients with PD, serum IGF-1 levels negatively correlated with disease severity and motor function. In contrast, patients with MSA showed an inverse correlation of serum IGF-1 levels with motor function and disease duration. There was a negative correlation between serum IGF-1 levels and motor function in patients with PSP.

Conclusion: The difference in the change and correlation of serum IGF-1 with clinical variables between these disorders may reflect different ongoing disease processes in each disorder.

A semi-quantified evaluation of substantia nigra hyperechogenicity in Parkinson’s disease and Parkinsonian syndrome

M. Okamuraa, K. Suzukib, A. Numaoa, H. Takekawaa, M. Miyamotoc, T. Miyamotod, M. Iwanamob, E. Takadaa, K. Hirataa. aDepartment of Neurology, Dokkyo Medical University, Mibu, Japan; bDepartment of Neurology, Dokkyo Medical University Koshigaya Hospital, Koshigaya, Japan; Center of Medical Ultrasonics, Dokkyo Medical University, Mibu, Japan

Background: In Parkinson’s disease (PD), transcranial sonography (TCS) has been used to evaluate substantia nigra (SN) hyperechogenicity as a diagnostic tool.

Objective: To quantify SN hyperechogenicity in patients with PD and Parkinsonian syndrome (PS), we applied semi-quantified evaluation method.

Patients and methods: Hospitalized patients with PD (n = 28; age, 65.0 ± 10.5 years) and patients with Parkinsonian syndrome (PS) (n = 17; age, 68.8 ± 9.6 years) and in-hospital controls (n = 10; age, 63.3 ± 8.7 years) were included. The PS group consisted of patients with progressive supranuclear palsy (n = 7) and multiple system atrophy (n = 10). TCS was performed using a conventional transcranial Doppler sonography equipped with 2.5 MHz transducer. The SN was identified within midbrain, and the area of echogenic signals was encircled and measured according to Berg et al. Next, echogenic signal of SN and dorsal midbrain were converted into grayscale using Adobe Photoshop and a median value of SN and dorsal midbrain on histogram was obtained. The SN to dorsal midbrain ratio was calculated.

Results: The PD group (4.1 ± 3.7) showed increased SN to dorsal midbrain ratio compared with that in PS group (1.7 ± 0.9) and controls (1.8 ± 1.1). The area of SN hyperechogenicity was larger in PD group (0.19 ± 0.1 cm²) than in PS group (0.07 ± 0.07 cm²) and controls (0.05 ± 0.07 cm²).

Conclusion: Semi-quantified evaluation of SN echogenicity using SN to dorsal midbrain ratio is comparative to the previously reported method by Berg et al., measurement of the SN hyperechogenic area, and it may be useful in differential diagnosis of PD from PS.

High resolution optical coherence tomography of the retina demonstrates selective thinning in individual retinal layers in Parkinson’s disease

I. Gottloba, A. Pilata, R. McLeana, V. Shetha, G. Maconachiea, Y. Rajaballyb, F.A. Proudlocka. aOphthalmology Group, University of Manchester, Manchester, UK; bDepartment of Neurology, University and San Giovanni Battista Hospital Birmingham, Birmingham, UK

Background: Parkinson’s disease (PD) involves alteration of synaptic activity including dopaminergic neurons in the retina. Recent reports showed a decrease in retinal thickness (RT) and retinal nerve fibre layer (RNFL) peripapillary thickness as well as RT asymmetry measured by optical coherence tomography (OCT). However, individual retinal layers have not been analysed.

Objective: To investigate optic nerve (ON) and macular morphology in PD.

Methods: High-resolution spectral domain OCT was used to image 10 patients with PD and 10 healthy controls. RT and macular and
peripapillary RNFL thickness were measured in inner and outer annuli divided into quadrants. Retinal layers in the macular region were measured individually using ImageJ.

**Results:** RNFL was significantly thinner in PD compared to controls (p < 0.01 for all quadrants). Mean peripapillary RNFL thickness positively correlated with RT in the nasal and superior segments (p < 0.01). In PD, ON had normal configuration including disc areas, cup and rim areas and volumes. RT was significantly reduced in PD in all segments (p < 0.05) mainly due to changes in the inner plexiform layer (IPL, p = 0.001), outer plexiform layer (OPL, p = 0.014), outer nuclear layer (ONL, p = 0.016) and retinal pigment epithelium (RPE, p < 0.01). Duration of disease correlated with the thickness of IPL (p = 0.003). There were no inter-eye asymmetries in the ON and macula.

**Conclusion:** Our study shows for the first time that RNFL, IPL, OPL and RPE are the main affected structures in PD retina. This indicates that retinal changes are selective and may serve as biomarker to differentiate PD from other neurodegenerative disorders.

**A phase I single and repeated dose pharmacokinetic study of oral V81444, a selective non-xanthine adenosine A2A receptor antagonist**

**Background:** V81444 is a selective non-xanthine adenosine A2A receptor antagonist of potential utility in neurological disorders.

**Objectives:** This study evaluated its pharmacokinetics (PK) after first administration to man.

**Methods:** In a double-blind, randomised, placebo-controlled study, 18 healthy men in 2 alternating cohorts each received 2 single oral doses of V81444 and 1 of placebo. Doses were 30, 100, 200 and 300 mg. Thereafter, 31 healthy men received placebo or 50, 100 or 200 mg once daily orally, for 14 days. V18444 was assayed in plasma and urine, and PK parameters derived by non-compartmental analysis. Safety variables were also assessed.

**Results:** V81444 was absorbed promptly (lag time ≤ 0.5 h) after single doses. The maximum observed concentration was ≤ 4 h after dosing. V18444 exposure was less than proportional to dose (slope for area under curve [AUC] extrapolated to infinity: 0.88 [90% confidence interval: 0.81–0.95]). Geometric mean terminal half-life was about 5–7 h (range: 3.29–11.4 h). After repeated dosing, steady-state was reached by Day 3 with little accumulation (accumulation ratio for AUC over the dose interval 1.19 [1.05–1.35]). The elimination half-life was somewhat longer (7–10 h). Less than 0.12% of the dose was excreted in urine. V81444 was well tolerated with no safety concerns at the doses studied.

**Conclusion:** Orally administered V81444 was rapidly absorbed with little drug accumulation at steady-state, a half-life compatible with twice daily dosing, and minimal urinary excretion.

**Impaired cognitive performance and Hippocampal atrophy in Parkinson’s disease**

D. Yildızb, S. Erer Özbekb, M. Zarifoğüb, B. Hakyemezb, M. Bakarb, N. Kari, N. Usçab, N. Büyükkoşuyuncu Peke, F. Tufan. —aNeurology, Şevket Yılmaz Training and Research Hospital, Turkey; bUludag University, Turkey; cŞevket Yılmaz Training and Research Hospital, Bursa, Turkey

**Introduction:** Since MRI has been used, hippocampalatrophy has been shown in demented and non-demented patients with PD. We aimed to assess the level of cognitive decline and the severity of hippocampalatrophy by measuring bilateral hippocampal volume in patients with PD.

**Methods:** Thirty three patients with idiopathic PD and 16 healthy subjects were enrolled to our study. All of these patients were under follow-up in movement disorders outpatient clinic, Department of Neurology, Uludağ University School of Medicine. Cognitive functions were tested with mini-mental state examination (MSE). The patients were classified as having normal cognitive function (PD-NC) or mild cognitive impairment (PD-MCI). Glucose, hemoglobin, TSH, total cholesterol, homocystein, vitamin B12, and folic acid levels were tested. Absence of depression was confirmed by Beck depression test. The cases were also evaluated with modified Wechsler memory scale, Luria draw test, Paven’s test (RSPM), Stroop shape fluency test and KAS word fluency test, Trails A and B, forward and backward number repeating tests. Hippocampal volumes were calculated using Leonardo workstation.

**Background:** Dopamine transporter (DAT) imaging is widely used for the differential diagnosis of parkinsonism. However, only limited data is available on the relationship between striatal DAT binding and dopaminergic cell loss in the substantia nigra (SN).

**Objectives:** We retrospectively analyzed SN cell counts in patients who had ante mortem undergone DAT single photon emission computerized tomography (SPECT).

**Patients and methods:** Pathological diagnoses included Parkinson’s disease (n = 1), dementia with Lewy bodies (n = 2), multiple system atrophy (n = 1), corticobasal degeneration (n = 2), atypical parkinsonism with multiple pathology (n = 1), Alzheimer’s disease (AD, n = 1) and Creutzfeldt Jacob disease (CJD, n = 1). DAT SPECT with [123I]β-CIT was performed using a standardized protocol on the same triple-head gamma camera. The density of neuromelanin-containing SN neurons/mm² was evaluated by morphometric methods using paraffin-embedded tissue sections.

**Results:** Mean disease duration at the time of DAT imaging was 2.3 years, followed by a mean interval of 29.3 months (range: 4–68 months) until death. Visual analysis of DAT images showed reduced striatal uptake in all 7 patients with neurodegenerative parkinsonism, but not in AD and CJD cases. Averaged (left + right / 2) striatal uptake was highly correlated with averaged SN cell counts (Pearman’s rho 0.98; p < 0.0005). Similar high correlations were found in separate analyses for the right and left nigrostriatal system.

**Conclusion:** The present study shows a high correlation of striatal DAT binding in vivo with post mortem SN cell counts and confirms the validity of DAT imaging as an excellent in-vivo marker of nigrostriatal dopaminergic degeneration.
Results: Mean ages of the PD-NC, PD-MCI, and healthy groups were similar. There was no difference between the hippocampal volumes of the groups. Right and left hippocampal volume was negatively correlated with repeat in word fluency test in healthy subjects. Right and left hippocampal volumes were positively correlated with cognitive functions in patients with PD-NC. Higher right hippocampal volume was associated with better performance in forward number test in patients with PD-MCI.

Conclusion: The findings of our study indicate that hippocampal atrophy is associated with cognitive decline in patients with PD.

REM sleep behavior disorder and motor dysfunction in Parkinson’s Disease—A longitudinal study
P. Bugalhoab,c, M. Viana-Baptistaa,b, aNeurology, Hospital de Egas Moniz (CHLO), Portugal; bDepartamento de Neurologia, CEDOC, Faculdade de Ciências Médicas, Universidade Nova de Lisboa, Lisbon, Portugal

Objectives: Longitudinal assessment of a Parkinson’s Disease (PD) cohort, to investigate the evolution of REM sleep behaviour symptoms (RBD) over time and to test the relation between RBD at onset and motor and cognitive dysfunction progression.

Methods: An early stage, nondemented PD cohort (n = 61) was assessed at two time points, separated by a two year interval. Motor function assessment: Unified Parkinson’s Disease Scale parts II and III (total and partial scores for bradykinesia, rigidity, gait/postural instability and dysarthria). Cognitive assessment: Frontal Assessment Battery (FAB) and Mini-Mental State Examination (MMSE). Dementia was diagnosed according to the DSM-IV-R criteria. RBD was defined as: presence of minimal clinical criteria for RBD and at least six affirmative answers in the REM Sleep Behaviour Disorder Screening Questionnaire.

Results: 25 patients had RBD at baseline, vs. 35 at follow-up. Three RBD patients did not present symptoms at follow-up, while 10 non-RBD patients developed RBD at follow-up (annual incidence of 12.5%). RBD and non-RBD patients did not differ significantly at baseline and follow-up. RBD was neither related to FAB or MMSE variation nor to dementia. The presence of RBD at onset was significantly related to an UPDRS total and bradykinesia scores increase over time.

Discussion: RBD symptoms can vary over time and have a tendency to increase during the early stages of disease. The presence of probable RBD could be a risk factor for motor function deterioration and particularly for bradykinesia worsening.

Essential tremor as a predictor of Parkinson's Disease
I. Petrov. Movement Disorders Department, University Neurology Clinic, Skopje, The Former Yugoslav Republic of Macedonia

Background: The aim is to present patients with long term of essential tremor, who later developed motor and nonmotor signs of Parkinson’s Disease.

Objective: Essential tremor can precede as the only condition in the period of 5–6 years before development of motor and nonmotor signs of Parkinson’s Disease. Persistence of the long term essential tremor can be predictor of the later development of Parkinson's Disease.

Material and methods: We examined 28 patients with an essential tremor, 21 women and 7 men, at the age between 55–62 years in the period of 5 years. The patients were hospitalized at the Movement Disorders Department at Neurology Clinic in Skopje, Republic of Macedonia and then were controlled on every 2 to 3 months. The following controls were consisted of detailed neurological examination, EEG, Evoked potentials, CT scan and MRI were also made.

Results: Two women (at the age 58 and 60 years) and one men (at the age 61 year) developed motor and nonmotor signs of Parkinson’s Disease. On detailed neurological examinations two patients had rigidity and tremor and one has bradykinesia as well. All three patients had symptoms of depression, insomnia and sleeping disturbances as well. EEG was normal in ten patients and in two we notice nonspecific changes. One patients had prolonged VEP latency and SEP was normal in all patients. CT scan showed only slight cortical atrophy, such as MRI as well.

Conclusion: 12% of our patients with essential tremor developed Parkinson’s Disease after 5 years of follow-up period.

Investigation of cortical brain damage in patients with Machado–Joseph disease
T.J.R. Rezendeab, A. D’Abreua, R. Guimarães, T.M. Lopesab, L. Lopes-Cendeb, G. Castellano, M.C. França Juniorab, 1Department of Neurology, University of Campinas, Campinas, Brazil; 2Department of Cosmic Rays and Chronologic, University of Campinas, Campinas, Brazil; 3Department of Medical Genetics, Unicamp, Campinas, Brazil; 4Neurology, University of Campinas, Campinas, Brazil

Background: Machado–Joseph disease (SCA3/MJD) is the most frequent spinocerebellar ataxia, and characterized by brainstem, basal ganglia and cerebellar damage. There are few MRI-based studies that investigate damage in the cerebral cortex.

Objective: To investigate damage to cerebral cortex and subcortical structures in SCA3/MJD through MRI-based volumetry of high resolution images.

Patients and methods: We included 44 patients with SCA3/MJD (mean age 49.0 ± 12.5, 22 men) and 44 healthy controls (mean age 48.7 ± 12.3, 22 men). Demographic/genetic data: CAG expansion (mean 68.9 ± 5.1); SARA score (14.7 ± 7.2); Age at onset (40.5 ± 13.0); disease duration (9.1 ± 4.0). All subjects underwent MRI scans in a 3T device, and 3D T1 images were used for volumetric analyses (slices of 1 mm, TE = 3.2 ms, TR = 7.1 ms, flip angle 8, isotropic voxels of 1 mm³, FOV = 240 × 240). Measurement of cortical thickness and volume was performed using FreeSurfer software v.5.1. We performed ANCOVA using subject’s age as a covariate to compare groups and performed a GLM regression to assess correlations. In all analyses, we used an uncorrected p = 0.001.

Results: Group comparison showed reduction of cortical volume and thickness at left superior parietal, precentral and middle occipital gyri, as well as right paracentral sulcus and gyrus in SCA3/MJD. We also found volumetric reduction of cerebellar gray and white matter, thalamus, caudate, putamen, pallidum and ventral diencephalon. We then performed correlation analysis between clinical data and volume/thickness for those structures found to be atrophic in patients. Right pallidum volumes correlated with SARA scores (r = −0.512, p = 0.001).

Conclusion: SCA3/MJD patients have extensive subcortical and cortical damage. Basal ganglia damage is related to disease severity.

Safety and efficacy of recombinant human platelet derived growth factor (rhPDGF) in Parkinson's disease

Introduction: Cognitive decline influences the outcome of Parkinson’s Disease. Our objectives were to perform a longitudinal assessment of cognitive dysfunction in early stage patients, with brief neuropsychological tests.

Methods: Early stage, non-demented patients were assessed twice, over a 2 year interval, with the Frontal Assessment Battery (to detect frontal cognitive decline), the Mini-mental state examination (to detect global cognitive decline) and motor function scales. Dementia and hallucinations were diagnosed according to DSM-IV criteria. We tested the relation between the clinical variables at baseline and the change in cognitive tests scores and the presence of dementia at follow-up.

Results: Of an initial 75 patients cohort, 61 were reassessed. Mini-Mental State scores did not progress significantly. Frontal Assessment Battery lexical fluency score decreased significantly. Four patients presented with dementia at t1. Mini-Mental State Examination score bellow cut-off, higher gait dysfunction, speech, rigidity scores, the non-tremor motor subtype and hallucinations were significantly related to dementia. Frontal dysfunction was related with a decrease in MMSE scores. Rigidity and speech dysfunction were related with a decrease in FAB scores.

Conclusions: Decline in Mini-Mental State Examination and FAB scores is small and heterogeneous in the early stages of Parkinson’s Disease. Scores bellow cut-off in the Mini-Mental State Examination
Scores could be helpful to predict dementia. Non-tremor motor deficits could be predictive factors for frontal cognitive decline and dementia.

Structural changes of raphe nuclei detected by brain parenchymal sonography and diffusion tensor imaging in Parkinson’s disease associated with depression
M. Mijailovic, M. Svetel, E. Stefanova, I. Petrovic, V. Kostic. Neurology Clinic, Clinical Center of Serbia and School of Medicine University of Belgrade, Belgrade, Serbia

Objectives: Transcranial parenchymal sonography (TCS) showed decreased echogenicity of the brainstem raphe (BR) in depression in Parkinson’s disease (PD). Magnetic resonance imaging and histopathological studies confirmed the hypothesis of a structural changes of the BR in depression in PD. We compared fractional anisotropy (FA) values and apparent diffusion coefficients (ADC) of the BR in depressed and non-depressed PD patients in comparison to TCS findings, to investigate possible structural changes of BR.

Methods: 53 PD patients with depression (PD+D+), 51 PD patients without depression (PD+D−) and 50 healthy individuals (PD−D−) were included. PD patients with and without depression were matched for age, disease stage and duration. Echogenicity of BR was rated using TCS with a two point scale (grade 1: normal BR echogenicity same as red nuclei, grade 0: hypoechogenic, invisible or interrupted BR). ADC and FA values were calculated using SPM7 software.

Results: Significant increase of mean ADC (t-test, each, P < 0.0001) and significant decrease of mean FA values (t-test, each, P < 0.0001) were found in patients with hypoechogenic BR compared with patients with normal raphe echogenicity. Mean FA values were significantly decreased in dorsal and ventral part of the BR in PD+D+ patients but only in ventral part of the BR in PD+D− without depression in comparison with healthy subjects (t-test, each, P < 0.0001).

Conclusion: Our findings confirm structural changes of the BR in depression associated with PD which may reflect the pathogenic role of the basal limbic system and its projections in the pathogenesis of depression in PD.

Carpal tunnel syndrome in patients with Parkinson’s Disease: An electrodagnostic and ultrasonographic study
S.B. Koha, J.S. Yoonb, S.I. Kimb, S.N. Yangb, S.J. Wonb, H.J. Kangb, aNeurology, Korea University, Seoul, Republic of Korea; bPhysical Medicine and Rehabilitation, Korea University, Seoul, Republic of Korea; cPhysical Medicine and Rehabilitation, Yeouido St. Mary’s Hospital, Seoul, Republic of Korea

Introduction: Tremor is one of the cardinal symptoms of Parkinson’s Disease (PD) and may cause cumulative traumatic injury to nerves of the hands. Carpal tunnel syndrome, in particular, may be caused by median nerve trauma. The aim of this study is to analyze the electrodagnostic and ultrasonographic results of patients with PD and to verify the effect of hand movement in PD on the median nerve.

Methods: We recruited 31 hands of healthy controls (60.25 ± 14.67 years) and 81 hands of patients with PD (64.95 ± 11.13 years). The patients with PD were divided by Hoehn and Yahr (HY) clinical stage into two groups: mild and advanced. Clinical symptoms of patients with PD were measured by Unified Parkinson’s Disease Rating Scale (UPDRS), and quality of life was measured by Parkinson’s Disease Questionnaire. Median nerve conduction and cross-sectional area by ultrasonography were also evaluated.

Results: Eighteen patients were classified in the mild group and 23 in the advanced group by HY stage. Median nerve cross-sectional area in patients with PD was significantly larger than that of the control group. Electrophysiologic findings of the median nerve were not significantly different between patients with PD and the control group. Total UPDRS score was not significantly correlated with cross-sectional area of the median nerve, but the severity of tremor was significantly correlated with cross-sectional area of the median nerve.

Conclusions: Carpal tunnel syndrome diagnosed by ultrasound was frequent in PD, and tremor may be a risk factor for the development of median nerve pathology.

An electrophysiological and kinesiological method for assessing spasticity
M. Gürbüz2, F. Kizilay2, S. Bilginb, Y. Albayрак, H. Uysalb, aNeurology Department, Akdeniz University, Antalya, Turkey; bFaculty of Engineering, Akdeniz University, Antalya, Turkey

This study defines the electrophysiological characteristics of Patellar T reflex. Normal and spasticity changes by utilizing movement features of knee joint during the reflex and it also attempts to develop a measurement method to be used in spasticity.

Normal and spasticity behaviors were examined with the electrophysiological records obtained from m. Quadriceps femoris and m. biceps femoris muscles. Medium and late latency responses in relevant muscles were examined with kinesiological parameter in subgroups in which the spasticity of patients was evaluated in accordance with clinical Ashworth scale. In the normal group, angular velocity was 57.95 ± 16.64 °/s. Latency of Patellar T reflex was 17.93 ± 1.94 ms and its amplitude was measured 6404 ± 2859 μV. In cerebral spasticity group, angular velocity was 61.32 ± 20.61 °/s. Latency of Patellar T reflex was 17.6 ± 2.45 ms and its amplitude was 7551 ± 3939 μV. While BF-MLR could not be obtained in normal cases, it was established to be 54.73 ± 10.18 ms latency in cerebral spastics.

It seems possible to produce a parameter that would assess and rate spasticity. Electrophysiological and kinesiological parameters failed to separately differentiate normal and spastics in compliance with Ashworth, but they could manage to differentiate between normal and spastic cases together. The parameter that was 69.61 ± 32.56 in normal cases decreased to 50.52 ± 28.98 in Ashworth 1, to 32.00 ± 14.90 in Ashworth 2, and finally to 14.48 ± 22.83 in Ashworth 3, and these changes was statistically significant.

Consequently, it is possible to note that the pendulum of patellar T reflex could differentiate between spasticity and normal by electrophysiological and kinesiological evaluation.

Parkinson’s disease Sleep Scale-2 is more specific for PD than the Epworth Sleep Scale
N. Kovács, E. Páli, J. Janszky, E. Bosnyák, P. Ács, Z. Aschermann, B. Faludi, Department of Neurology, University of Pécs, Pécs, Hungary; MTA-PTE Research Group, Pécs, Hungary; TÁMOP-4.2.2.A-11/1/KONV-2012-0017, University of Pécs, Pécs, Hungary

Objectives: To compare the specificity and sensitivity of Parkinson’s disease Sleep Scale-2 (PDSS-2) and Epworth Sleep Scale (ESS) in Parkinson’s disease (PD).

Background: Sleep problems are one of the most burdensome non-motor features of PD.

Methods: 60 patients fulfilling the UK Brain Bank criteria for PD were enrolled to the study. Each patient kept a patient diary for at least 7 days. Besides, ESS, PDSS-2, Hoen–Yahr and UPDRS were obtained to describe the sleep-related problems.

Results: Severity of sleep problems was quantified by the total score of PDSS-2 and ESS. Out of the two sleep scales, only PDSS-2 demonstrated significant correlation with the sleep hours measured by the patient diary (r = 0.61, p < 0.01), UPDRS part 2 and HYS. The correlation between PDSS-2 and ESS was not significant (r = 0.12, p > 0.05).

Conclusions: For quantifying sleep disturbances in PD, the PDSS-2 seems to more specific than ESS.

Comparison of double monopolar and interleaving stimulation modes in the treatment of primary generalized and segmental dystonia
N. Kovács, E. Bosnyák, G. Deli, I. Baláš, S. Komoly, J. Janszky, Department of Neurology, University of Pécs, Pécs, Hungary; MTA-PTE Research Group, Pécs, Hungary; TÁMOP-4.2.2.A-11/1/KONV-2012-0017, University of Pécs, Pécs, Hungary

Objective: To systematically compare the efficacy and side-effect profile of double monopolar stimulation mode to those of interleaving stimulation mode in a prospective, randomized, double-blind and cross-over study.

Background: For the treatment of drug-refractory dystonia, bilateral pallidal deep brain stimulation (GPi-DBS) is proven to be an efficient option. On average, 40–55% improvement on dystonia rating scales (DRS) could be achieved according to the results of multicenter trials lasting for years. However, a considerable portion (10–25%) of patients experience minimal alleviation despite of good electrode placement. These patients can be regarded as non-responders to GPi-DBS defined as having either limited improvement (less than 25% on DRS) or worsening.

Methods: This randomized, cross-over, double-blind study was initiated in 2012 and is expected to be completed by 2015. An estimation of 20 patients with primary generalized or segmental dystonia is planned to be enrolled.

Design: Double-blind, cross-over.

Results: The interim analysis of 9 patients is presented. Average age was 33.5 ± 16.2 years. The size of improvement during the double monopolar phase was 43.7 ± 9.3%, whereas in the interleaving phase it was 55.6 ± 7.5% (p = 0.19).

Conclusions: Although our preliminary findings are promising, more data is required to reach the statistical power and draw the conclusion that interleaving stimulation might be superior to double monopolar stimulation in the treatment of primary dystonia.

Can repetitive transcranial magnetic stimulation (rTMS) help on-freezers with advanced PD?
H. Shehata, M. Tamawy, E. Hassan, A. Naweto, Neurology, Cairo University, Cairo, Egypt; Neurophysiology, Cairo University, Cairo, Egypt

Background and objectives: Freezing of gait (FOG) or “motor block” is experienced in about 30% of PD patients within 5 years, and nearly in 60% after 10 years. Treatment of “off” time FOG is relatively straightforward, but “on-freezing” is a difficult to treat scenario. This issue is rarely addressed in RCTs to assess investigational tools or treatment options.

Methods: This was a randomized, double-blinded, placebo-control study evaluated the efficacy and safety of rTMS in management of “on-freezing” in patients with advanced PD. Twenty two Egyptian patients received 12 rTMS sessions over 4 weeks (either real or sham) using figure-of-8-shaped coil over the leg area of motor cortex contralaterally to the more affected side in addition to rehabilitation program involving specific gait training techniques. Primary efficacy variables are FOG Q (SF), motor section and total score of UPDRS, 2nd outcomes are gait variables (Cadence, number of falls, stride length, stride time and turn time), and on-time.

Results: Improving of FOG Q (SF) (P < 0.05), together with significant decrease in number of falls and widened stride length (P < 0.001) was detected in patients receiving real rTMS. The total score of UPDRS and other gait variables was not significantly changed. No adverse events were recorded apart from mild and transient headaches.

Conclusions: These results indicate that rTMS has a positive effect in on-freezers with advanced PD with subsequent decrease of number of falls.

FMRI, DTI, and MRS for characteristics of the level of Cognitive Impairment (CI) in patients with Parkinson’s Disease (PD)
Z. Rozhkova, O. Omelchenko, I. Karaban, N. Karasevich, Radiology, Medical Clinic Boris, Ukraine; Extrapyramidal Disorders, Institute of Gerontology, Kiev, Ukraine

Background: Bringing together fMRI, DTI-, and MRS-data in substantia nigra (SN) we obtain biomarkers of neuronal dysfunction in patients with PD and different levels of CI.

Objective: We found regional specificity MRI-data for characteristics of CI.

Patients and methods: Three groups of PD-patients with various cognitive statuses are studied with 1.5T SIGNA (GE). The 1st group (DPDG)-13 PD-patients with dementia (MMSE ≤ 25), 2nd group (CIPDG)-23 with mild CI (30 > MMSE ≥ 25), 3rd group (NPDG)-18 PD-patients with normal cognitive function (MMSE > 30).
Materials and methods: fMRI-data are obtained by: TR/TE = 3000/60 ms. DTI-data (25dir) are obtained in anterior, medial, posterior SN (ASN, MSN, PSN).

Spectra are recorded with SVSSTEAM:TR/TE = 1500/144 ms.

Results: From analysis of fMRI (FSL5.0 FEAT, MELODIC) we found that in the NPDG connections between the APCG and PPCG, and inferior parietal gyrus bilaterally exist. In the NPDG activation of anterior (APCG), and of the posterior portion of cingular gyrus (PPCG) decreased. In CIPDG activated clusters were found precuneus, and in PPCG, no connection to the parietal lobe or APCG. In DPDG no activation in PPCG was found. In anterior part of SN (APSN) NAA/Cr in DPDG, CIPDG, and NPDG: (1.68 ± 0.02), (2.04 ± 0.03), (2.32 ± 0.05), Cho/Cr: (0.84 ± 0.02), (0.81 ± 0.05), (0.53 ± 0.03). In posterior part of SN (PPSN) NAA/Cr in DPDG, CIPDG, and NPDG: (1.14 ± 0.12), (1.91 ± 0.02), (1.98 ± 0.04), Cho/Cr: (0.96 ± 0.02), (0.77 ± 0.03), (0.68 ± 0.03). We have found the progressive decreasing NAA/Cr in the PPSN and increasing of Cho/Cr for the patient of NPDG, CIPDG, and DPDG, that is associated with poorer cognitive function. MD in DPDG:(0.82 ± 0.05) × 10⁻³ mm²/s, in CIPDG (0.74 ± 0.05) × 10⁻³ mm²/s, in NPDG: (0.71 ± 0.05) × 10⁻³ mm²/s. FA:(0.41 ± 0.05), (0.43 ± 0.05), (0.47 ± 0.05) in DPDG, CIPDG, and NPDG.

Conclusion: These data give us new approach for understanding pathophysiological changes in PD-patients associated with CI.

Clinical variants of vascular parkinsonism

D.K. Sichinava, M.A. Barabanova, T.A. Petropavlovskaya. Nervous System Diseases and Neurosurgery, Kuban State Medical University, Krasnodar, Russia

Background: 1–15% cases of parkinsonism are caused by cerebral vessels’ lesions.

Objective: To investigate the etiological factors and clinical features of vascular parkinsonism.

Materials and methods: 100 patients with vascular parkinsonism were examined (males—80%, females—20%). The main part of patients was over 60 years old (65%). Diagnosis was determined on the basis of anamnesis data and the results of clinical, neurological, neurophysiological and neuroimaging tests.

Results: The following clinical forms were defined: extrapyramidal–pyramidal (41%), extrapyramidal–cerebellar (25%), extrapyramidal–degenerative (18%), hemi–extrapyramidal (6%), parkinsonism of lower part of body (10%). 68.7% of patients had the acute cerebral ischemic event at the onset of the disease, and 31.2% of patients developed parkinsonism as a result of chronic cerebral ischemia, caused by arterial hypertension and atherosclerosis. The movement impairment was accompanied by the depressive mental disorders in 40% of cases. Other nonspecific disorders (memory loss (26%), headache (24%), dizziness (21%), sleep disturbances (15%)) were present. Cerebral CT/MRI revealed the low density cortical and subcortical spots. The multiple cerebral infarctions were found in 22% of patients, solitary lacunar infarctions—in 14%, hemorrhage—in 6%, brain atrophy with substitutitional hydrocephalus, periventricular and subcortical leukoaraiosis—in 58% patients. Levodopa medications were of low effectiveness.

Conclusion: The main reason of vascular parkinsonism is cerebral atherosclerosis combined with arterial hypertension (68%). The clinical variant of vascular parkinsonism-plus (66%) was predominant.

Impulsive compulsive behaviors in Japanese Parkinson’s disease patients and utility of the Japanese version of the Questionnaire for Impulsive–Compulsive Disorders
K. Tanaka, K. Wada-Isoe, S. Nakashita, M. Yamamoto, K. Nakashima. Brain and Neurosciences, Faculty of Medicine, Tottori University, Yonago, Japan

Background: Recently, non-motor syndrome in Parkinson’s disease (PD) patients has attracted attention. Impulsive compulsive behaviors (ICBs), such as pathological gambling, compulsive sexual behavior, compulsive buying, compulsive eating, punding, and dopamine dysregulation syndrome (DDS) are one of the non-motor syndromes in PD, but they aren’t very well identified. Whereas the prevalence and the relative factors of ICBs were estimated in previous reports, it hasn’t fully understood.

Objective: In order to evaluate ICBs in Japanese PD patients, we constructed a Japanese version of the Questionnaire for Impulsive–Compulsive Disorders in Parkinson’s disease (J-QUIP) and evaluated the utility of J-QUIP in Japanese PD patients.

Methods: J-QUIP was administered to 121 PD patients. Diagnoses of ICBs were made via interview of patients or their caregivers. Subsequently, in order to evaluate factors related to these conditions, we evaluated demographic and clinical characteristics, clinical features, and medications utilized.

Results: J-QUIP was able to accurately evaluate symptoms in 118 of 121 PD patients (97.5%). Sensitivity and specificity of J-QUIP were similar to that reported for the original version of QUIP. In our study, the prevalence of each disorder was as follows: pathological gambling (6.5%), compulsive sexual behavior (3.2%), compulsive eating (3.2%), punding (6.5%), DDS (2.2%). Significantly associated factors for these conditions were younger age (p = 0.047), earlier age of disease onset (p = 0.015), longer PD duration (p = 0.001), total levodopa equivalent dose (p = 0.006), and dosage of levodopa (p = 0.019).

Conclusion: We evaluated the prevalence of ICBs in Japanese PD patients along with factors associated with these behaviors via J-QUIP.

Degeneration of the cerebellum and brainstem in Huntington’s disease (HD)
U. Rübbel, M. Hentschel, E. Brunthaler, H. Heinsen, K. Seidel, K. Stratmann, H. Paulson, J.-P. Vonsattel, W. den Dunnen, H.-W. Korff. aDr. Senckenberg Chronomedical Institute, J.W. Goethe University, Frankfurt/Main, Germany; bDepartment of Neurology, University Medical Center Groningen, Groningen, The Netherlands; cMorphological Brain Research Unit, Julius Maximilians University, Würzburg, Germany; dDepartment of Neurology, University of Michigan, Michigan, MI, USA; eThe New York Brain Bank/Taub Institute, Presbyterian Hospital and Columbia University, New York, NY, USA; fDepartment of Pathology and Medical Biology, University Medical Center Groningen, Groningen, The Netherlands

Background: Huntington’s disease (HD) is a progressive polyglutamine disease which is characterized neuropathologically by severe neuronal loss in the striatum and select layers of the neo- and allocortex. The cerebellum and brainstem are among the brain sites whose neuropathological state in and relevance for the clinical picture of HD is still controversial.

Objective: To analyze the pathoanatomy of the cerebellum and brainstem in HD patients.

Patients and methods: Serial thick tissue sections through the cerebellum and brainstem of eight clinically diagnosed and genetically confirmed HD patients and twelve control individuals underwent pigment–Nissl staining for neuronal lipofuscin pigment and Nissl material or were immunolabeled for the marker of cerebellar Purkinje cells (i.e. calbindin).

Results: Our previous randomized double-blind study showed that drinking 1 L of hydrogen (H2) water for 48 weeks significantly improved (p < 0.05) the total Unified Parkinson disease rating scale (UPDRS) score of patients with Parkinson’s disease (PD) receiving l-dopa. Here, we present the design rationale and describe the study cohort for this trial.

Methods: The change in total UPDRS score (I–IV) from baseline to the 72th week will be used as the primary endpoint. The other analyzed parameters will be as follows: the change of total UPDRS and part II, III, each scores, and modified Hoehn and Yahr staging from baseline to 8th, 24th, 48th, and 72th weeks and post the 8th week; the change of total PDQ39, each scores, and subtotal scores; and the duration till the protocol was terminated because of addition of levodopa or disease progression. Safety analyses will include tests for adverse events, except dyskinesia, and laboratory examinations. Patients in the hydrogen water group will drink 1 L of H2 water made by “Suisosui 5.0” and supplied by Ecomo International Co., Ltd., and those in the placebo water group will drink water filled with nitrogen. This study started in March 2013, and we will register 200 patients with PD from 15 centers.

Discussion: This study will confirm whether H2 water can modify PD progression.

doi:10.1016/j.jns.2013.07.470

Abstract — WCN 2013

Topic: 2 — Movement Disorders
Randomized double-blind, placebo-controlled multi-center trial on molecular hydrogen water in Parkinson disease

Background: Our previous randomized double-blind study showed that drinking 1 L of hydrogen (H2) water for 48 weeks significantly improved (p = 0.006) the total Unified Parkinson disease rating scale (UPDRS) score of patients with Parkinson’s disease (PD) receiving l-dopa. We aim to confirm these results by conducting a longer and more powered trial, which also includes patients not receiving l-dopa. Here, we present the design rationale and describe the study cohort for this trial.

Methods: The change in total UPDRS score (I–IV) from baseline to the 72th week will be used as the primary endpoint. The other analyzed parameters will be as follows: the change of total UPDRS and part II, III, each scores, and modified Hoehn and Yahr staging from baseline to 8th, 24th, 48th, and 72th weeks and post the 8th week; the change of total PDQ39, each scores, and subtotal scores; and the duration till the protocol was terminated because of addition of levodopa or disease progression. Safety analyses will include tests for adverse events, except dyskinesia, and laboratory examinations. Patients in the hydrogen water group will drink 1 L of H2 water made by “Suisosui 5.0” and supplied by Ecomo International Co., Ltd., and those in the placebo water group will drink water filled with nitrogen. This study started in March 2013, and we will register 200 patients with PD from 15 centers.

Discussion: This study will confirm whether H2 water can modify PD progression.

doi:10.1016/j.jns.2013.07.469
Conclusions: HD is associated with a widespread neurodegeneration of the cerebellum and brainstem and represents a multisystem neurodegenerative disease. Damage to the cerebellum and brainstem contributes to poorly understood HD disease symptoms (i.e. impaired rapid alternating movements, dystarthis, ataxia and postural instability, gait and stance imbalance, broad-based gait and stance, oculomotor dysfunctions).

Fatigue syndrome and white matter changes in patients with Parkinson’s disease: Does link exist?
V. Dateva, O. Levin. Russian Medical Academy of Postgraduate Education, Moscow, Russia

Background: White matter changes (WMC), caused by concomitant cerebrovascular disease (CVD), appear on MRI in part of elderly patients with Parkinson’s disease (PD). However clinical significance of WMC in genesis and severity of non-motor symptoms, including fatigue syndrome (FS), remain unclear.

Objective: To define association between FS and WMC in patients with PD.

Materials and methods: 20 PD patients with FS were compared with 18 PD patients without it. Groups were compared for presence of WMC. Following methods were applied: UPDRS, PD’s fatigue scale (PFS), Autonomic impairment scale (Levin O.S., 2003), and Fazekas Scale (FaS). The patients underwent brain 1.5-T MRI (Avanto Siemens; Siemens AG, Erlangen, Germany). Middle ages of the patients were 64.5 ± 6.5 and 63.9 ± 7.5. PD’s stages were 2.6 ± 0.5 and 2.45 ± 1.1. disease’s durations were 5.9 ± 4.04 and 4.4 ± 2.85 correspondingly.

Results: In the 1st group of PD patients with FS WMC were marked in 65% cases, in the control—in 47%. PFS scores were 3.88 ± 0.36 in the 1st group and 2.37 ± 0.6 in the control. FaS was 0.9 ± 0.7 in the 1st group, 0.47 ± 0.51 in the control. Autonomic disturbances in the 1st group were 7.1 ± 2.9, in the control 4.2 ± 2.4. Among them cardiovascular disturbances were 3.15 ± 1.59 in the 1st group, 1.15 ± 1.1 in the control. UPDRS scores were 84.4 ± 21.5 in the 1st group and 68.0 ± 40.3 in the control.

Conclusions: WMC and autonomic disturbances occur more often among PD patients with FS. This fact can imply that orthostatic hypotension influences both neuroimaging data and genesis of FS. Orthostatic hypotension can be accompanied by hypertension in supine position, which promotes WMC.

Genetic deconvolution of cerebellar ataxias in India through next generation sequencing: Novel mutations in atypical and typical genetic loci
M. Faruq a,b, A. Narang c, R. Kumari d, D. Dash e, A.K. Srivastava a, M. Mukerji f. aGenomics and Molecular Medicine, CSR-Institute of Genomics and Integrative Biology, India; bNeurology, All India Institute of Medical Sciences (AIIMS), New Delhi, India

Introduction: Genetic characterization has lead to the identification of nearly 60 causal loci in ataxias. The prevalence of ataxia types with respective genetic defect varies geographically. The genetic testing of each known ataxic associated variation for uncharacterized phenotype is challenging and cost/time expensive.

Objective: In our ataxic cohort (n = 1000) majority being North-Indian families, more than half of the cases (~57%) are genetically uncharacterized (UC). We aimed to delineate genetic defect in uncharacterized cases using next generation sequencing platform.

Methodology: We carried out exome-sequencing for 12 individuals from three uncharacterized families of recessive inheritance manifesting typical FRDA or unique phenotype such as infantile onset ataxia with hearing loss or seizures.

Results: Clinical investigations and exome sequencing in one family reveal association of GAA expansion negative FRDA phenotype with novel homozygous frame-shift mutation in SACS (Autosomal recessive ataxia of Charlevoix-Saguenay) locus. In second family with infantile onset ataxia and hearing loss we identified a novel homozygous missense mutation in c10orf2. In remaining family with juvenile onset ataxia and generalized seizures we identified novel compound heterozygous mutations in CLN6 (Ceroid-Lipofuscinoses Neuronal 6).

Conclusion: We have identified novel mutation loci in typical known recessive ataxic phenotype and compound novel heterozygous mutations in CLN6 a known locus for seizures–dementia–visual failure being associated with atypical manifestation of predominant ataxia and seizures. Further, this study emphasizes the prudent role of exome sequencing technology in delineation of genetic etiology in a rare and other genetically heterogeneous ataxic disorders.

Levosulpiride induced common and uncommon movement disorders—Parkinsonism and truncal akathisia: Three case reports
J.B. Sharma, S.K. Saxena, A. Singh. Neurology, Fortis Hospital Noida, Noida, India

Background: Levosulpiride is a substituted benzamide that is widely used for the management of dyspepsia and emesis. Because it exerts its pharmacologic activity mainly by blocking dopaminergic D2 receptor activity, levosulpiride can cause extrapyramidal symptoms, most of which are generalized parkinsonism followed by lower face dyskinesia. We report three cases of levosulpiride induced common and uncommon movement disorders.

Objective: To highlight levosulpiride induced movement disorders especially rare one like akathisia.

Patients and methods: We report three patients of levosulpiride induced movement disorders seen in our centre during July 2010 to September 2012. Two were male and one female with average age of 75.33 years. Two of these patients presented with symmetric parkinsonism and one with truncal akathisia. The longest duration of levosulpiride exposure at a dose of 75 mg/day, was one year and shortest one week. The onset was sub-acute in two patients and acute in one patient.

Results: Two patients exhibited resolution of parkinsonism upon cessation of levosulpiride. The interval from cessation of levosulpiride to disappearance of parkinsonism was 10 days and 30 days. One patient who had truncal akathisia continued to have symptoms despite drug withdrawal.

Conclusion: Although generalised parkinsonism is most frequently reported adverse effect of levosulpiride as seen in our patients also, awareness of rare movement disorder like truncal akathisia is crucial for management.

TIC disorders (TD) in children: The kindergarten matters
V. Sajan1,b, I. Moldovanua,4 Institute of Neurology and Neurosurgery, Republic of Moldova; bState Medical and Pharmaceutical University ‘Nicolae Testemițanu’, Chișinău, Republic of Moldova
Background: Tics are sudden, rapid, recurrent, non-rhythmic motor movements or vocalizations (European clinical guidelines for Tourette syndrome and other tic disorders, 2011) with the prevalence in children of 0.77−1% (2.99% for transient tics) (Robertson, 2008; Knight et al., 2012).

The poor knowledge about TD leads to the delayed diagnosis and wrong management of TD. Kindergarten teachers (KTs) could contribute to a better behavioral and social integration of children with tics and their parents.

On our knowledge, no precedent informational campaign on TD was performed in Republic of Moldova (RM).

Aims: to assess the necessity to inform KTs about TD

Materials, subjects and methods:

• Video presentation about the TD
• Short questionnaires
• Twenty two kindergarten teachers (mean age 50.86 ± 11.07 yrs) from 4 kindergartens from RM (549 children). Each teacher supervised about 20 children (2–3 yrs (84 children), 3–4 yrs (128), 4–5 yrs (29), 5–6 yrs (189) and 6–7 yrs (119) old).

Results: Before the presentation, the majority of KTs mistook tics for muscle fasciculations or hysterical reactions. Only two children with TD from 549 were initially reported.

After the presentation, 15 teachers gave a right description of tics, their evolution and educational particularities of children with TD. Fifteen children with TD (2.73%), 11 boys and 4 girls (3:1) were reported by KTs.

Conclusion: The presented information improved the kindergarten teachers’ knowledge about the tic disorders and their communicative and educational skills, as well as their attitude toward such children. KTs can contribute to the active detection and right management of TD.

REM sleep behavior disorder in Parkinson disease: Association with abnormal ocular motor findings
B.S. Jeon,4 Y.E. Kim5, H.-J. Kim4, Seoul National University Hospital, Seoul, Republic of Korea; 5Seoul National University Bundang Hospital, Seoul, Republic of Korea

REM sleep behavior disorder (RBD) is related with brainstem pathology. We examined whether patients with PD have abnormal ocular movements suggesting brainstem or cerebellar dysfunction in Parkinson’s disease (PD). A total 202 patients were included in this study. Ocular movements were examined by video-oculography (VOG). 116 (57.4%) of the 202 patients have clinically probable RBD, and 32 (27.6%) of the 116 with clinically probable RBD patients had abnormal VOG findings suggesting brainstem or cerebellar dysfunction; whereas 86 of the 202 patients did not have clinically probable RBD, and only 8 (9.3%) of 86 patients had abnormal VOG findings suggesting brainstem or cerebellar dysfunction. (P = .001). This study suggests that the presence of RBD are associated with more severe brainstem pathology in PD.

New treatment for clinical stabilization in Parkinson’s Disease (Cervô): Results in 32 patients at 29 months of follow-up
E. de Font-Réaulx R, Centro Neurológico, ABC Medical Center, Methodist International Network, Mexico City, Mexico

It is mandatory to have a safe and effective treatment to stop the neurodegenerative disease’s progression. Previous clinical trials designed to stop Parkinson’s Disease (PD) progression have failed to demonstrate significant clinical stabilization. We administrated to PD patients the first oral treatment designed to stop the disease’s progression. This treatment called Cervô, contains four substances that have effect in controlling the most important known mechanisms of disease progression as: aberrant apoptosis, oxidative damage, mitochondrial degeneration, caspases and Mitogen-Activated Protein-Kinases (MAPK) activation, among others. We had previously demonstrated that it is safe to use Cervô in humans. Before beginning the clinical trial, we administrated the best medical symptomatic therapy to each patient and they remained with the same prescription during the observation period. Then, we added Cervô twice per day to all the patients.

Results: We included 31 patients with PD. Age: 32 to 86 years old (mean 66.3 years, SD +/- 13.5), 16 female (51.6%), 15 male (48.4%). Initial United Parkinson’s Disease Rating Scale (UPDRS) score: 1−15 (mean 5, SD +/- 3). Follow-up period: 12−57 months (mean 29 months, SD +/- 14.5).

Clinical evaluations: There was no increase in the UPDRS score in 30 patients (96.77%) in the follow-up period, and 25 (80.64%) patients of disease progression as: aberrant apoptosis, oxidative damage, mitochondrial degeneration, caspases and Mitogen-Activated Protein-Kinases (MAPK) activation, among others. We had previously demonstrated that it is safe to use Cervô in humans. Before beginning the clinical trial, we administrated the best medical symptomatic therapy to each patient and they remained with the same prescription during the observation period. Then, we added Cervô twice per day to all the patients.

Conclusions: Cervô is a new and promising medication, specifically designed to stop neurodegenerative disease’s progression. This needs to be confirmed with a randomized multi-centric study.

Parkinson’s disease: Sanitary–hygienic investigations in Uzbekistan
M.M. Raimova, K.M. Khalimova, R.J. Matmurodov. Tashkent Medical Academy, Tashkent, Uzbekistan

In the whole world, the increase of new cases of Parkinson’s disease (PD), among cities, is observed, especially, among agricultural population. It explains the given tendency partially due to the improvement of quality of diagnostics of the disease. However, there are also other reasons for the increase in PD frequency which need to be studied.

Aim: To analyze sanitary–hygienic aspects of PD among indigenous population of Uzbekistan Republic.

Methods: The number of patients was 180 (88 women and 92 men). Sanitary–hygienic researches were made with the help of a specially developed questionnaire, which covered all major factors of biological or sanitary–hygienic character.

Results: Results of questioning of patients with PD among indigenous population of Uzbekistan have shown that the most significant risk factors of PD development were work with pesticides, drinking water from open reservoirs and work in the chemical industry. Influence of harmful factors was not only the risk factor for the disease development, but it also modified clinical picture of disease thus, the median age of patients—countrymen was 53.08 ± 9.14, patients—city inhabitants—58.5 ± 10.7, and the tendency to earlier debut of disease in the agricultural population in comparison with city inhabitants (48.8 ± 9.9 and 53.6 ± 9.9 accordingly) was also observed.

Conclusions: The analysis of the sanitary–hygienic factors of PD has allowed one to reveal most significant of them with high degree of reliability that is important at a substantiation of the concept of PD development, and gives the chance to predict the probability of PD development in persons of Uzbek nationality.

Postural abnormality as a risk marker for leg deep venous thrombosis (DVT) in Parkinson’s disease
F. Kimura, K. Yamane, M. Ota, H. Tani, T. Hirose. The First Department of Internal Medicine, Osaka Medical College, Takatsuk-City, Japan

Purpose: Pulmonary thromboembolism is a common cause of death in patients with autopsy-confirmed Parkinsonism. This study investigated the frequency of leg DVT in Parkinson’s disease and relationships between DVT and clinical/laboratory findings, including postural abnormalities as assessed by photographic measurements.

Methods: This cross-sectional study assessed the presence of DVT using bilateral leg Doppler ultrasonography in 114 asymptomatic outpatients with Parkinson’s disease.

Results: DVT was detected in 23 patients (20%) with Parkinson’s disease. DVT was located in the distal portion in 18 patients and in the proximal portion in 5 patients. No significant differences in age, sex, body mass index, disease duration, Hoehn–Yahr stage, anti-Parkinson’s drugs, or daily levodopa-equivalent dose were seen between DVT-positive and DVT-negative groups. Univariate analysis for developing DVT in patients with Parkinson’s disease identified the following factors: long-term wheelchair use, bent knee, bent spine, and D-dimer elevation. Bending angles were significantly higher in the DVT-positive group at the knee (19.8°, p < 0.001) and spine (14.9°, p = 0.002) than in the DVT-negative group. In diabetes mellitus cases, long-term wheelchair use, bent knee over 15°, camptocormia, D-dimer elevation, and
two or more risk markers were associated with a significantly increased incidence of DVT. The presence of risk markers contributed to the development of DVT. On multivariate logistic regression analysis, a bent knee posture was strongly associated with an increased risk of DVT.

**Conclusion:** Presence of leg DVT correlated with postural abnormalities in Parkinson's disease. We recommend non-invasive ultrasonographic screening for DVT in these high-risk patients with Parkinson's disease.

**Gender differences in non-motor symptoms in early, drug naïve Parkinson’s disease**

M. Picillo³, A. Amboni³, R. Erro³, M. Moccia³, C. Vitale³,
G. De Michele³, A. De Rosa³, L. Santoro³, G. Oreifice³, M.T. Pellecchia³,
P. Barone². ²University Federico II, Italy; ³IDC Hermitage Capodimonte,
Naples, Italy; ⁴University of Salerno, Salerno, Italy

**Background:** Gender differences in brain structure and function may lead to differences in the clinical expression of neurological diseases, including Parkinson’s disease (PD). Few studies reported gender-related differences in the burden of non-motor symptoms (NMS) in treated PD patients, but this matter has not been previously explored in drug-naïve PD patients.

**Objective:** To assess gender differences in the frequency of NMS in a large sample of early, drug-naïve PD patients compared with age-matched healthy controls.

**Methods:** Two hundred early, drug-naïve PD patients and sixty age-matched healthy controls were included in the study. Frequency of NMS was evaluated by means of Non-Motor Symptoms Questionnaire. The difference in gender distribution of NMS was evaluated with the χ² exact test.

**Results:** Male PD patients complained of problems having sex and taste/smelling difficulties significantly more frequently than female PD patients. Furthermore, men with PD complained more frequently of dribbling, sadness/blues, loss of interest, anxiety, acting during dreams, and taste/smelling difficulties as compared to healthy control men, while female PD patients reported more frequently loss of interest and anxiety as compared with healthy control women.

**Conclusion:** This study shows specific sex-related patterns of NMS in drug-naïve PD. In contrast with previous data, female PD patients did not present higher prevalence of mood symptoms as compared to male PD patients. Comparison with healthy controls showed that some NMS classically present in premotor and early stage of disease (i.e. acting out during dreams, taste/smell difficulties) are more frequent in male than in female patients.

**Novel preclinical therapeutic strategies of neurodegeneration with kynurenines: Clinical perspectives (Danube Neurology Session)**

L. Vecsei, Department of Neurology and Neuroscience Research Group of the Hungarian Academy of Sciences, University of Szeged, Szeged, Hungary

There is appreciable evidence that the neurodegeneration in several neurological disorders (like Alzheimer’s disease (AD)) is mediated, at least partly, by neurotoxic products of the kynurenic (KYN) pathway. L-kynurenine can be metabolized through three distinct pathways to form kynurenic acid (KYNAC), 3-hydroxy-l-kynurenine and anthranilic acid by the action of kynurenine aminotransferases (KATs), kynurenine-3-monooxygenase (KMO) and kynureninase enzymes, respectively. KYNAC is a broad-spectrum, non-selective glutamate receptor antagonist. Correspondingly, KYNAC has proved to be a neuroprotective molecule in various experimental models of neurodegenerative disorders, including neurotoxicity induced by kainate, ibotenate, QA and NMDA. Because KYNAC has a very limited ability to penetrate the blood brain barrier (BBB), indirect pharmacological approaches are necessary to exploit its therapeutic potential. Possible therapeutic approaches could be to reduce the expression of the neurotoxic agents (like quinolinic acid: QA) or to increase the production of putative neuroprotectant KYNAC or make use of its analogues. Among other common mechanisms the shift in the KYN pathway seems to be general over different neurodegenerative diseases and such, neuroprotective therapies influencing the KYN pathway may be beneficial in several neurological pathologies. The most effective preclinical drug candidates are discussed, and attention is paid to currently underinvestigated aspects where modulation of the kynurenic metabolism might be of therapeutic value. Furthermore, the complex anti-inflammatory and neuroprotective properties of KYNAC and its analogues provide the possibility to...
rationale for the screening of these compounds in experimental autoimmune encephalomyelitis (EAE) and multiple sclerosis.

Violation of metabolism of nitric oxide in patients with Parkinson’s disease and vascular parkinsonism
R.J. Matmurodov, K.M. Khalimova, M.M. Raimova. Tashkent Medical Academy, Tashkent, Uzbekistan

Nitrogen oxide plays a big role in regulation of a number of physiological and pathological processes in an organism now exposed to intensive studying.

Purpose: To estimate functional activity of NO system and their interrelation with level of dopamine in patients with various forms of parkinsonism.

Methods: A total of 47 patients with Parkinson’s disease—PD (62.3 ± 4.51 years) and 45 patients with vascular parkinsonism—VP (63.1 ± 5.5). The control group was composed of 20 patients without symptoms of parkinsonism. The maintenance of stable metabolites of NO—NO2 and NO3 were also assessed was estimated in the membranes of erythrocytes. Activities of eNOS, NADFH-NR, to the contents ONOO. Simultaneously in daily urine was determined by the method of dopamine Matlin.

Results: At PD the NO level exceeded control data for 216.9%, and at VP, 150.6%. Increase in the level of NO was associated with significant inhibition in the groups studied eNOS—by 72.3% and 56.8%, respectively, the activation of NADFH-NR—by 75.5 and 43.6%. Overexpression level ONOO at 344.5 and 287.6%, respectively, compared with the control. Installed together, an excretion of dopamine in daily urine was below the control data in patients with PD—for 36.4% and VP—on 21.3%.

Conclusion: The identified violations of NO-system in red blood cells in patients with various forms of PD and VP, on the one hand reveal some of the fundamental basis of the pathogenesis, the other—open new perspectives suggest means of correction of violations in erythrocytes.

Hemiballismus: A case series in UYO Southern Nigeria
B.C. Ekehi, F.O. Dike, T.N. Akpabio, A.A. Akpabio, A.R. Isotu, K. Monday, O.O. Johnny. Internal Medicine, University of Uyo Teaching Hospital, Uyo, Nigeria; Psychiatry, University of Uyo Teaching Hospital, Uyo, Nigeria

Background and aim: Hemiballismus is a dramatic movement disorder that is typically acute in onset. Few cases have been reported in Africa. We describe six cases seen in our hospital between January 2010 and August 2012 with their presentation, management and eventual outcome. This is the first case series to the best of our knowledge in sub-Saharan Africa.

Methods: The participants were six patients seen from January 2010 to August 2012 whose folders were reviewed.

Results: There were two males and four females. The age range was 55–68 years. All the patients were from the Ibibio ethnic group in the South-South Nigeria. The uncontrollable flinging movements all started suddenly. The patients presented within the first week of the movements. All the patients had at least one modifiable risk factor for stroke (hypertension, Diabetes mellitus, obesity and dyslipidaemias). Each of the patients presented with markedly elevated blood pressure. Two of the patients had morbid obesity with a BMI of >45. Management was mainly supportive: rehydration, sedation and prevention of injuries. The risk factors were controlled. The movements reduced and patients were discharged home well.

Conclusion: Hemiballismus is not rare as previously thought. This sudden surge may be part of the transition to non-communicable diseases noted in sub-Saharan Africa. There may also be an associated environmental factor given that all the patients reside in the same environment. Patients do well on supportive care and Haloperidol.

Estimation of the caused skin vegetative potentials in patients with Parkinson’s disease
Y.N. Madjidova, S.R. Fahargalieva. Tashkent State Medical Academy, Tashkent, Uzbekistan

Aim: To study the status of vegetative nervous system in patients with Parkinson’s disease (PD) with caused skin vegetative potentials (CSVPs).

Materials and methods: 50 patients were examined, average age 73 ± 10.3 years with duration of disease from 1 till 15 years. The control group concluded 24 persons. CSVP recording was made on a “VNS-SPECTRUM” device, firm Neurosoft (Ivanovo). The comparative estimation of results was made in patients depending on sex, age, form, stage, rate of progression of disease.

Results: The duration of latent periods in patients with PD from feet was more than that in control group (p = 0.01), and amplitude indicators in hands (p = 0.027) and feet (p = 0.006) in group of patients with PD were lower. In patients with duration of disease of more than 1 year amplitude indicators were much lower in hands (p = 0.017) and feet (p = 0.029), than in patients with duration of disease of less than 1 year. In patients with high quantity of points in section trembling in the UPDRS (>3) amplitude parameters were lower in hands (p = 0.006) and feet (p = 0.008), than those in patients with less quantity of points. Patients with total of points of more than 30 amplitude parameters in the UPDRS were lower in hands (p = 0.039) and feet (p = 0.008), than in patients with total of points less or equal to 30. Amplitude parameters in hands (p = 0.033) and feet (p = 0.016) in group of patients with PD, were lower than in control group.

Conclusions: For authentic diagnostics of progressing vegetative insufficiency it is necessary to use also caused skin vegetative potentials.

Substantia nigra hypoechogenicity is not related to Friedreich ataxia
M. Sierra, J. Infante, J. Berciano. University Hospital Marqués de Valdecilla, IFIMAV and CIBERNED, Santander, Spain

Background: Previous works have reported that both substantia nigra (SN) hypoechogenicity and cerebellar dentate nucleus (CDN) hyperechogenicity coexist in Friedreich’s ataxia (FRDA). However, while pathology in CDN is a constant finding in autopsies, no pathological changes have been reported in the SN of FRDA patients.
SN hypoechogenicity has also been observed in patients with rest-less syndrome (RLS), a condition reported occasionally in FRDA patients.

**Objective:** To investigate the presence of SN hypoechogenicity in a cohort of FRDA patients and its possible association with RLS.

**Methods:** Fourteen genetically confirmed FRDA patients (mean age: 53.15 ± 17.29 years; mean disease duration: 27.86 ± 14.94 years) and fourteen age and sex-matched healthy controls (mean age: 53.71 ± 15.23 years) underwent transcranial sonography examination (SIEMENS “Acuson X300 PE” 5.0 machine) to evaluate the area of echogenicity of the SN. Ataxia and RLS were also assessed in all participants.

Statistical comparisons of the area of the SN between groups were made using the non-parametric Mann–Whitney U test.

**Results:** The cut-off value for defining SN hypoechogenicity in our controls was 0.21 cm² (sum area of both sides). We did not find significant differences between the mean sum area of SN echogenicity in FRDA patients (0.27 cm² ± 0.41) and in controls (0.28 cm² ± 0.72) (p = 0.72). The areas of SN echogenicity in the two FRDA patients with RLS were 0.21 cm² and 0.22 cm², respectively, while the mean area of SN echogenicity of the FRDA patients without RLS was 0.27 ± 0.04.

**Conclusions:** Our data do not support the notion that SN hypoechogenicity is related to FRDA itself, although it might be associated with RLS.

Orthostatic and supine blood pressures are associated with white matter hyperintensities in Parkinson disease

E. Lim, Y. Oh, J. Kim, K. Lee. *Neurology, College of Medicine, The Catholic University of Korea, Seoul, Republic of Korea*

**Background:** Several reports on the elderly population have suggested that orthostatic hypotension is associated with white matter hyperintensities (WMHs); however, little information is available on patients with Parkinson’s disease (PD).

**Objective:** To verify the association of orthostatic and supine blood pressures with white matter hyperintensities in Parkinson disease.

**Methods:** We analyzed the association blood pressure profiles during orthostatic testing with WMH scores in 117 patients with PD. WMHs were rated using the semiquantitative visual rating system proposed by Scheltens et al.

**Results:** The presence of orthostatic hypotension was associated with increasing tendency of WMH score and the blood pressure changes during orthostasis and supine blood pressure was positively correlated with increasing WMH score.

**Conclusion:** This finding indicates that hemodynamic changes associated with orthostatic hypotension may be associated with white matter changes in patients with PD.

Spatial memory and cognition in patients with Parkinson’s disease: Evaluating the dopaminergic effect

K. Iseki1,a, S. Slobounov3, S. Kranick4, P. Choosh4, B. McElroy4, D. Benninger4, M. Hallert4, 1Human Motor Control Section, Medical Neurology Branch, NINDS, NIH, Bethesda, MD, USA; 4Behavioral Neurology and Cognitive Neuroscience, Tohoku University Graduate School of Medicine, Sendai, Japan; 3Neurology, Sakakibara Hakusho Hospital, Tsu, Japan

**Background:** Dementia in patients with Parkinson’s disease (PDD) has attracted recent attention. However, the cognitive aspects affected are not fully understood.

**Objective:** We hypothesized that spatial cognition and memory might be deficient in patients with Parkinson’s disease (PD) compared with healthy volunteers (HVs). Further, we hypothesized that such functions in PD should not be affected by dopaminergic intervention.

**Patients and methods:** 14 patients with PD and 14 HVs were recruited. We used a virtual reality (VR) task including turns in virtual corridors. The subjects were first requested to memorize the route, and then to follow it using a joystick afterwards. We prepared two versions including three (run 1) or four (run 2) turns. The success rate and the time were assessed. All the PD patients were tested both in off and on-med conditions. All the subjects completed the Montreal Cognitive Assessment (MoCA). The performances were compared between PD patients and HVs, and between off and on-med in PD patients.

**Results:** In both runs, PD patients showed significantly lower success rate and took longer time compared with HVs. There was no significant difference either in the success rate or in the time between off and on-

Belgrade, Belgrade, Serbia; 2Institute of Medical Statistics and Informatics, Faculty of Medicine University of Belgrade, Belgrade, Serbia
meds in PD patients. The correlation analysis in run 2 revealed a significant correlation between the MOCA scores and the time taken.

Conclusions: Our results show that the patients with PD have dysfunction in spatial cognition and memory compared to HVs. Additionally, it appears that such functions are not affected by the dopaminergic pathway.

Exposure of GSM-900 MHz on rat’s brain does not support for gene expression involved in DNA damage and repair pathways

N. Kumar, P.R. Mishra, S. Kumar, V.P. Sharma. aCSE, Shri Ramswaroop Memorial University, Barabanki, India; bDGE, Sanjay Gandhi Post Graduate Institute of Medical Sciences, India; cBiotechnology, Shri Ramswaroop Memorial University, India; dDTD, CSIR-Indian Institute of Toxicology Research, Lucknow, India

Objective: We investigated whether an acute exposure to GSM-900 MHz irradiation from a mobile phone (3 h/day up to 28 days) could lead to the modulation of a gene expression pattern in the rat brain.

Methodology: All rats were habituated prior to the experiment in a well designed circular cellular phone exposure (CCPE) cage. In the cage, a mobile phone was placed in the center and rats were allowed to move around the device within a 10 cm radius. After 28 days, mRNA from the brains of control, Sham and GSM-900 MHz exposed rats were isolated and subjected to quantitative real time polymerase chain reaction (qRT-PCR) analysis. Gene expression was measured and expressed in fold change as described by Bandhyopadhay et al. (2007). The qRT-PCR was performed by using SYBR green chemistry on an ABI 7900HT platform. The real time quantification of amplification was done by measuring change in fluorescence by SDS 2.3 software and further analyze by RQ manager.

Results: Thus the results obtained from this study have shown that there is no significant change in expressions of genes involved in DNA damage and repair pathways such as chromatin assembly (CHAF1A), DNA damage checkpoints (Chk1), DNA synthesis (POLD1), DNA damage and repair pathways such as chromatin assembly (CHAF1A), DNA damage checkpoints (Chk1), DNA synthesis (POLD1), post-transcriptional processes (RBMM), translation synthesis (POLI) and stress signaling (Hsp90) as compared with controls.

Conclusion: The study concludes that acute exposure to mobile phones (GSM-900 MHz) does not support for gene expression involved in DNA damage and repair pathways.

Clinical spectrum of cerebral palsy in South Jordan: Analysis of 122 cases

O. Naif. Pediatric, Mutah Faculty of Medicine, Amman, Jordan

Background: The clinical spectrum and associated factors of cerebral palsy (CP) may differ between developing and developed countries. Aim: To evaluate some predisposing factors, clinical spectrum, and some associated problems of cerebral palsy in children.

Setting and design: It is a retrospective study wherein data were extracted from patient file records which contain extensive historical and clinical data in a center for early diagnosis of childhood disabilities.

Patients and methods: One hundred and twenty two children with ages ranging from 7 months to 17 years were reviewed in a 32-month period between September 2007 and April 2010. A simple statistical analysis was used for a percentage calculation.

Results and conclusions: A spastic type was predominant (82.7%), with a quadriplegic subtype being the most common (34.4%). The other types were choreoathetoid (8.2%), mixed type (6.6%) and ataxic (2.5%) being the least. Speech delay was the most common associated problem (71.3%) followed by mental retardation (61.5%), seizures (35.2%), hearing problems (26.2%), and autism (4.9%) being the least. The clinical spectrum of CP in Jordan may differ from that reported in Western countries. Prospective studies are needed to evaluate the clinical spectrum and predisposing factors in Jordan.

Mutation analysis of ATP7B gene in Vietnamese patients with Wilson disease

H.T.M. Nguyen, N.P.A. Hoa, D.N. Ngo, P.M. Nguyen, T.L. Nguyen. aHuman Genetics, National Hospital of Pediatrics, Hanoi, Vietnam; bGastrology Department, National Hospital of Pediatrics, Hanoi, Vietnam

Wilson disease (WD) is an autosomal recessive disorder of copper metabolism, which is caused by mutation in copper-transporting P-type ATPase (ATP7B). The principle of this disease is the failure of hepatic excretion of copper through the bile and leads to the deposit of copper in the liver and other organs. The ATP7B gene is located on the long arm of chromosome 13 (13q14.3).

Objective: This study aimed to identify the gene mutation of the Vietnamese patients with WD and to report a novel mutation which is prevalent in Vietnam.

Material and method: 12 unrelated Wilson disease patients were studied. Genomic DNA was extracted from peripheral blood samples. The most common mutation, p.Arg778Leu, was firstly screened by PCR–RFLP then all 21 exons and exon–intron boundaries of the ATP7B gene were analyzed by direct sequencing.

Result: We identified 5 different mutations, accounting for 79.17%, among them was a novel mutation (p.Thr850Ileu). Mutation p.Ser105* was the most prevalent (45.83%). Other mutations are listed as the following: p.Arg778Leu (8.33%), p.Pro992Leu (4.17%), p.Asp1270Ser (4.17%), and p.Leu1371Pro (8.33%). 3 patients were homozygous for a single mutation, and 5 patients were compound heterozygous.

Conclusion: The most prevalent mutation in Vietnam is p.Ser105*. p.Arg778Leu might be not common in Vietnam, and p.Ser105* in exon 2 should be screened firstly on those Vietnamese patients who have a higher risk of WD before sequence analyzing the entire gene.

Molecular cross-talk between Lrrk2 and NF-κB in neuroinflammation in an animal model of Parkinson’s disease (PD)

A. Bhattacharyya. University of Calcutta, Kolkata, India

Background: Alteration or mutation of LRRK2, highly expressed in microglia and neurons has been implicated to PD. It was found that LRRK2 deficiency attenuated LPS-induced mRNA and/or protein
expression of cytokines and NF-κB was decreased in LRRK2-knock down cells. LRRK2-induced NF-κB activation was dependent on the IKK complex, because it was inhibited by a dominant negative form of IKK. The main PD-associated mutant LRRK2-G2019S did not activate NF-κB differently from wild-type protein. It is not clear whether PD-LRRK2 mutations operate through a gain or loss of function that might act in a dominant negative fashion, recruiting and neutralizing wild-type proteins.

**Methods:** In our preliminary study we have also found differential expression patterns of p65, TNF-α, p52 and LRRK2 at different time intervals. However the definite correlations between them have not been defined. Therefore, how LRRK2 links with which pathway of NF-κB that possibly promotes neuroinflammation is far from clear.

**Results:** In our preliminary study we have also found differential expression patterns of p65, TNF-α, p52 and LRRK2 at different time intervals. However, the definite correlations in between them have not been defined.

**Conclusion:** Our study demonstrates the future therapeutical point of inhibition/attenuation and/or induction of particular signaling molecules in NF-κB and LRRK2.

**Chorea-acanthocytosis**

E. Sokolov, S. Schneider, P. Bain, Neuroscience, Imperial College London, Charing Cross Hospital, London, UK; Neurology, University of Kiel, Kiel, Germany.

**Background:** Chorea-acanthocytosis is an autosomal recessive neurodegeneration caused by mutations in the VPS13A gene, encoding chorein, located on chromosome 9q21. It manifests with acanthocytes in the peripheral blood and a progressive movement disorder, typically including chorea, although dystonia, facial tics and Parkinsonism may occur. Other features include seizures, neuropathy, myopathy, autonomic dysfunction, psychiatric symptoms and dementia.

**The case:** A 34 year old woman, with consanguineous parents, presented with a 3-year history of facial grimacing, dysphagia, stutter, memory difficulties, depressive symptoms, anorexia, intermittent chest pain and shortness of breath. From the ages of 2 to 4 years she had ‘fits’, when she would momentarily develop a staring expression. Examination revealed facial tics, excessive blinking, mild dystarhria, a stammer and intermittent clucking noises and occasional tongue protrusions but no other signs. Formal neuropsychological assessment was unremarkable. Initial creatine kinase (CK) was mildly elevated, blood films were normal and a MR brain scan showed mild non-specific white matter changes.

Four years later she had chorea in her limbs, impaired manual function and an unsteady gait. Dystarhria and dysphagia were apparent and tongue protrusions could extrude food. She excoriated her forehead and wore a ‘bite-guard’ to prevent injury to her tongue. Peripheral blood smears identified acanthocytes, a MRI showed caudate atrophy and protein function tests showed reduced chorein levels, indicating chorea-acanthocytosis.

**Conclusion:** Useful clues suggesting chorea-acanthocytosis are an elevated CK and oral-lingual dystonia, often causing tongue protrusions and lacerations. The diagnosis is confirmed by finding acanthocytes in blood, caudate atrophy and a decreased chorein level.

**Topic: 2 — Movement Disorders**

**Tremor dominant parkinsonism — Lesion or deep brain stimulation?**

**Background:** The optimal stereotactic target for the control of medication resistant tremor dominant Parkinson’s disease (TDPD) is debatable, as is the issue of lesion versus DBS in cases with predominantly unilateral signs.

**The case:** A 56 year old lady presented with medication resistant tremor of the right hand secondary to TDPD. There was right sided cogwheel-rigidity, bradykinesia and ‘off-phase’ dystonic clawing of her toes but no left sided signs. At sixty, a left Vim–ZI–STN lesion was performed which abolished her right sided signs.

Aged 76, her neuropsychological profile was satisfactory. The benefit to her right side was sustained except for occasional mild dyskinesia and dystonia of her right hand and minimal leg tremor. However, severe left sided rest and postural tremor developed and interfered with her activities of daily living when medication (Sinemet – 110 × 9 tablets/day and Sinemet 250 CR at night) wore off. This was accompanied by mild left sided bradykinesia and rigidity. Consequently, a right VIM–ZI DBS surgery was performed, which initially produced complete left sided tremor suppression but subsequently there was some escape despite reprogramming.

**Conclusion:** This case illustrates the long term stability and effectiveness of a correctly placed Vim–ZI–STN lesion for controlling TDPD. This benefit was sustained two decades later, without any of the maintenance requirements or cost associated with DBS. Furthermore, over the course of 20 years the only signs apparent in her right sided limbs were minimal dystonia and dyskinesia. The patient was delighted with these results and greatly preferred the lesion to DBS.

**Neuroprotective effect of sesamol and quercetin against QA induced neurotoxicity: An experimental paradigm of Huntington’s disease**

A. Kuhad, S. Singla, V. Arora, K. Chopra. University Institute of Pharmaceutical Sciences, Panjab University, Chandigarh, India.

Quinolinic acid (QA) is an excitatory amino acid (a NMDA-selective glutamate agonist and an endogenous metabolite of trytophan), whose properties (a preferential degeneration of GABA-ergic neurons and a relative sparing of NADPH diaphorase- and cholinergic interneurons) and simple application account for its wide use in creating a practicable (though not ideal) animal model of HD. The present study was designed to evaluate the neuroprotective effect of sesamol and quercetin against QA-induced neurotoxicity: an experimental paradigm of Huntington’s disease by investigating various behavioral and biochemical alterations in rats. Rats were intrastriatally administered quinolinic acid and were treated with sesamol (4, 8 and 16 mg/kg, i.p.) and quercetin (25, 50 and 100 mg/kg, i.p.) for 14 days before and 14 days after quinolinic acid administration. Intrastriatal injection of QA leads to increased escape latency, impaired locomotor activity, increased immobility period, raised lipid peroxidation and nitrite concentration and depletion of endogenous antioxidants. Besides, intrastriatal QA significantly increased TNF-α levels suggesting QA mediated...
oxidative and neuroinflammatory damage. Intrastriatal administration of QA resulted in significant decrease in the levels of dopamine, serotonin and norepinephrine in the rat forebrain. Chronic treatment with sesamol (4, 8 and 16 mg/kg, i.p.) and quercetin (25, 50 and 100 mg/kg, i.p.) attenuated these behavioral, biochemical and neurochemical alterations in the rat brain and these effects were attributed to their strong antioxidant and anti-inflammatory potential. The present study suggests that sesamol and quercetin could be used as effective agents in the management of Huntington’s disease and should be explored further.

Systemic blood pressure profile correlates with cardiac 123I-MIBG uptake in patients with Parkinson’s disease
Y. Manabe1, K. Matsuzono1, Y. Takahashi1, H. Nara1, Y. Imai1, K. Abe1.
1Neurology, National Hospital Organization Okayama Medical Center, Okayama, Japan; 2Tohoku University Graduate School of Pharmaceutical Science and Medicine, Sendai, Japan; 3Graduate School of Medicine and Dentistry and Pharmaceutical Sciences, Okayama University, Okayama, Japan

Purpose: To examine the correlation between the systemic blood pressure profile and cardiac 123I-metaiodobenzylguanidine (MIBG) uptake in patients with Parkinson’s disease (PD).

Methods: We monitored circadian blood pressure patterns of 37 PD patients of 49 to 85 years of age (mean, 71.8 ± 8.4 years) using a portable blood pressure monitoring device. There were 37 age- and sex-matched control subjects. Cardiac MIBG scintigraphy was performed on the 37 PD patients. Based on the nocturnal fall in mean arterial blood pressure (MABP), we classified patients into extreme dippers (nocturnal reduction of MABP > 20%), dippers (> 10% but < 20%), nondippers (< 10% but > 0%), and inverted dippers (< 0%). Average 24-h MABP values revealed reduced BP variability in PD patients.

Results: The percentage nocturnal fall in MABP was significantly different between PD patients and control subjects (p < 0.05). Significant correlations were found between %MABP reduction and the heart-to-mediastinum (H/M) ratio on early and delayed images (p < 0.01). The UPDR motor score, and early and delay H/M ratios were also significantly different between patients who were and were not dippers (p < 0.05).

Conclusion: The present results reported for the first time a significant correlation between the systemic blood pressure profile and cardiac 123I-MIBG uptake in patients with PD. The degeneration between the brainstem and the postganglionic neurons of myocardial sympathetic nerves may progress in parallel in patients with PD.

The new hypothalamic proline-rich polypeptide-1 protects motor dysfunction and memory deficits after ischemic stroke in rats
E. Yeritsyan1, A.A. Galoyan2, M.G. Balasanyan2, H.V. Topchyan2.
1Pharmacology, Yerevan State Medical University after M. Heratsi, Armenia; 2H. Buniatian Institute of Biochemistry of the National Academy of Sciences of the Republic of Armenia, Armenia; 3Yerevan State Medical University after M. Heratsi, Yerevan, Armenia

Background: The proline-rich peptide (PRP-1), which was isolated from the neurosecretory granules of the bovine neurohypophysis (produced by n. supraopticus and n. paraventricularis) it was observed that the PRP-1 produced several beneficial biological effects which included immunoregulatory, hematopoietic, antimicrobial and anti-neurodegenerative properties. The aim of the present study was to investigate the effect of PRP-1 on focal cerebral ischemia induced memory deficits and motor dysfunctions in rats.

Materials and methods: Ischemic stroke was induced in rats via the middle cerebral artery occlusion (MCAO). Assessment of memory was done using the passive avoidance test. The rota-rod test was employed to assess motor coordination. Then after MCAO, the rats were divided into 2 groups: control and PRP-1 treated. Assessment of memory and motor coordination was carried out before MCAO and also after the 3rd, 6th and 12th post-insult days.

Dystonia is a syndrome of sustained muscular contractions of opposing muscles with various etiologies. The currently available symptomatic treatment strategies are quite effective for some of the various types of dystonia. They help in decreasing involuntary movements, correcting abnormal posture, preventing contractures, reducing pain, and improving function and quality of life. Intrathecal baclofen and deep brain stimulation were proven to be fairly effective in controlling dystonia when used separately. We are reporting a synergetic effect of intrathecal baclofen and deep brain stimulation when used simultaneously in two cases of primary generalized dystonia with excellent control of dystonia.

Botulinum-A toxin in pediatric stiff hips
Y. Awaad3, T. Rizk2, 4Pediatric Neurology, National Neuroscience Institute, KFMC, Saudi Arabia; 5Pediatric Neurology, Al-Takhassusi Hospital, Riyadh, Saudi Arabia

Purpose: We aim to determine the functional and orthopedic contributions of botulinum toxin-A in the treatment of pediatric stiff hips.

Methods: Three patients with complicated developmental dysplasia of the hip after surgery and a case of idiopathic chondrolysis were given botulinum toxin injections in selected muscles as an adjunctive therapy to the standard orthopedic management.

Results: All patients experienced significant reduction in pain with significant improvement in posture, range of movement and mobility.

Conclusion: Botulinum toxin-A injection when given to selected muscles appears effective in relieving pain and improving range of mobility in patients with complicated developmental dysplasia of the hip and idiopathic chondrolysis.
**Results:** Following the MCAO, the memory and motor coordination of the rats in the control group were markedly impaired, in comparison with values achieved before MCAO and after the 3rd and 6th post-insult days; but on the 12th post-insult day there was a noticeable loss of memory and motor coordination. In the case of PRP-1 treatment, after 3rd, 6th and 12th post-insult days there was a noticeable enhancement of basal (before MCAO) values up to normal value.

**Conclusion:** Thus systematic administration of PRP-1 has been proven to significantly decrease ischemia-induced memory deficits and motor dysfunction. Hence it may be concluded that PRP-1 could be useful clinically in the prevention of stroke.

**Quantitative assessment of hypokinesia using sensor gloves in Parkinson’s disease**

Clinical Neurophysiology Service, International Center for Neurological Restoration (CIREN), Havana, Cuba; Movement Disorders Service, Cuba; Neurology Department, International Center for Neurological Restoration (CIREN), Havana, Cuba; Neuroinformatics Department, Cuban Neuroscience Center, Havana, Cuba

**Introduction:** Instruments that contribute to quantitative (objective) mensuration of cardinal signs in Parkinson’s disease (PD) like the bradykinesia, would assist more effective therapeutic intervention.

**Objectives:** To evaluate the utility of sensor gloves on quantitative evaluation of bradykinesia on Parkinson’s disease.

**Methods:** The authors carried out a study of type cases and controls, organized in two groups: 13 patients with clinical diagnosis of idiopathic PD in “on” state and 24 controls, to which were carried out a registration of the “finger tapping” movement using sensor gloves (5DT-14 Ultra). The analysis of the amplitude was calculated through the power spectra derived from a Fourier transform (FFT). Also we examine the relationship between glove data obtained, the clinical scale employed (UPDRS) and the early and late components of the premotor potential.

**Results:** The authors observed that patients presented a smaller speed in the execution of movements, demonstrated to reach their maximum amplitude at smaller movement frequency (1.5 Hz) than controls (3.5–4 Hz), as well as, a significant decrease of the amplitude of movement toward the frequencies of movement > 3 Hz. The most favorable values in the clinical scale employed were associated to broader movements toward the high frequencies (> 3.5 Hz). Our study demonstrated a relationship between amplitude of movement and the area of the earlier and later components of the premotor potential. A bigger area associated to a broader movement.

**Conclusion:** The authors conclude that sensor gloves are useful as a quantitative complement of the clinical evaluation in the patients with PD.

**Spheroid bodies: From Seitelberger’s disease to neuroaxonal dystrophy and MSA-C**

S.G. Echebarria Mendieta. Neurology Service, Getxo, Spain

**Background:** Since the descriptions of spheroid bodies in grey matter (GM) conditions: Seitelberger’s disease and brain iron accumulation (NBIA), new perspectives have emerged considering spheroid bodies’ association to autonomic nerve endings and enolase, neurofilaments and chromogranin findings, similar to MSA type C and Niemann–Pick type II specimen.

**Objective:** To compare the recent definition of Wszolek Z.K. et al. (2009), considering adult onset leukoencephalopathy with axonal spheroid and pigmented glia (ALSP) with current and non-habitual forms of neuroaxonal dystrophy.

**Methods:** Comparatives of Seitelberger’s disease specimen with Ceuterick C. and Martin J.J. (1984) descriptions of axonal cytoplasmatic bodies.

**Sampling of glial cytoplasmatic inclusions (GCIs) in MSA (Wenning) and neuroaxonal dystrophy similarities.**

**Results:** Comparatives may be obtained between molecular layer axonal spheroids in MSA-C, and peripheral nerve ending findings (Yamanaka, 2005).

**Conclusions:** Suggested correlations would be profiled considering leukoencephalopathy with spheroids (HDLS) and pigmentary leukodystrophy (POLD) similarities with peripheral specimen in atypical metachromatic leukodystrophy (Coulter Mackie M.B., 2002).

Prevalence of significant carotid artery stenosis in Iranian patients with peripheral arterial disease
S. Shaafi, A. Shakeri, K. Ghabili, Tabriz University of Medical Science, Tabriz, Iran

Objectives: The aim of the present study was to determine the prevalence of significant internal carotid artery (ICA) stenosis in a group of Iranian patients with peripheral arterial disease.

Methods: We prospectively screened 120 patients with a known diagnosis of peripheral vascular disease for carotid artery stenosis. Based on the angiographic assessment of abdominal aorta and arteries of the lower extremities, patients with stenosis greater than 70% in the lower extremity arteries were included. A group of healthy individuals aged 50 years was recruited as a control. Risk factors for atherosclerosis, and cerebrovascular disease were recorded. Common carotid arteries (CCAs) and the origins of the internal and external arteries were scanned with B-mode ultrasonography. Significant ICA stenosis, .70% ICA stenosis but less than near occlusion of the ICA, was diagnosed when the ICA/CCA peak systolic velocity ratio was 3.5.

Results: Ninety-five patients, with a mean age of 58.52 ± 11.04 years, were studied. Twenty-five patients had a history of smoking, six patients had a history of coronary artery disease, six patients had hypertension, and ten patients had diabetes mellitus. Significant ICA stenosis was present in four patients (4.2%) with peripheral arterial disease and in one healthy individual (1%) of the control group (P=0.05). In terms of the risk factors for atherosclerosis, no statistically significant relationship was found between individual atherosclerotic risk factors and significant ICA stenosis (P=0.05).

Conclusion: The prevalence of significant ICA stenosis in Iranian patients with peripheral arterial disease is low. In addition, there is no relationship between individual atherosclerotic risk factors and significant ICA stenosis.

Effect of erythropoietin therapy on vasospasm, cerebral infarction and Glasgow outcome scale in patients with aneurysmal subarachnoid hemorrhage: A meta-analysis
E.A. Go, M.C. Perez. Department of Neuroscience-Section of Neurology, Makati Medical Center, Makati City, Philippines

Introduction: Experimental models of aneurysmal subarachnoid hemorrhage (SAH) have demonstrated that acute systemic erythropoietin (EPO) therapy reverses impaired autoregulation, reduces vasospasm and ischemic deficits, and improves neurological outcome. (3) Objective: To assess the evidence from randomized controlled trials the effects of erythropoietin therapy (EPO) compared with placebo on transcranial doppler (TCD) vasospasm, cerebral infarction and Glasgow outcome scale (GOS) in patients with aneurysmal SAH.
Design: Meta-analysis of 2 randomized trials was identified through Medline/Pubmed and Cochrane Library. Data was analyzed using Review Manager (RevMan) 5.1 software. Data on TCD vasospasm, cerebral infarction and GOS score at six months were abstracted from the two studies. Chi-square test of heterogeneity of effect measure was used to determine whether a fixed or random effects model should be used. The Z-test for overall effect was used to test the significance.

Results: The sample size of the studies ranged from 73 to 80 patients. All studies were randomized and placebo controlled. A fixed effects model was used for GOS score at 6 months and TCD vasospasm because tests of heterogeneity were not significant with p = 0.48 and p = 0.54, respectively. On the other hand, a random effects model was used for cerebral infarction with p = 0.03 for the test of heterogeneity. No statistically significant effect was observed on TCD vasospasm (RR = 0.78, p = 0.23), cerebral infarction (RR = 0.41, p = 0.22) and favorable GOS score at 6 months (RR = 1.04, p = 0.72).

Conclusion: The results of the present meta-analysis do not lend statistically significant support to the use of erythropoietin therapy in patients with aneurysmal SAH.

Walking recovery in the first-year after stroke: Results from the LEAPS RCT
K.J. Sullivan a, 1, S.Y. Cen b, 2, J.J. Sullivan a, 1, aBiokinesiology, University of Southern California, Los Angeles, CA, USA; bNeurology/Radiology, University of Southern California, Los Angeles, CA, USA

Background: After acute first-time stroke, almost 50% of people discharged from the acute care hospital to home are at high fall risks and cannot participate in home or community-life due to walking limitations.

Objective: Primary subgroup analysis of the LEAPS RCT reporting the frequency, intensity, and duration of neurorehabilitation to reduce walking disability in the first year post-stroke.

Patients/methods: RCT of 359 adults (age 62.0 ± 12.7 years; 54.9% male) that completed 30–36 physical therapy sessions with 2-, 6-, and 12-month outcome assessments. At 2-mos post-stroke, participants were stratified by walking severity (severe, <0.40 m/s; moderate, 0.40–0.79 m/s) and randomization to one of 2 parallel interventions (progressive exercise, EX; task-specific locomotor training, LT), provided early at 2-months (EX, n = 113; LT-early; n = 121) or later at 6-months (LT-late; n = 125). Disability threshold was gait speed change ≥0.16 m/s (1-level disability change on Modified Rankin Score).

Results: Disability threshold was exceeded and retained at 1-yr with 24 sessions of LT provided at 2 mos for moderate disability group; the severe group needed 36 sessions of LT or EX (Type, 3-way interaction, p = 0.05). When LT was delayed to 6-mos, both the severe and moderately impaired groups were more disabled than the early groups (timing, 3-way interaction, p = 0.03).

Conclusions: For community-dwelling adults who ambulate at speeds <0.80 m/s at 2-mos post-stroke, a minimum of 24–36 sessions of an intensive, specialized walking program by physical therapists resulted in higher levels of ability, sooner in the recovery year than conventional neurorehabilitation approaches.

Relationship between neural apoptosis and cell death inducing DFF45-like effector-B gene expression after cerebral ischemic reperfusion injury in rats
W. Ly, Department of Cardiology, People’s Hospital of Zhencheng City, Zhucheng, China

Objective: To explore the relationship of cell death inducing DFF45-like effector-B (CIDE-B) gene activation and neural apoptosis after cerebral ischemic reperfusion injury.

Methods: Total of 144 Wistar rats were randomly divided into sham operation group (n = 36) and cerebral ischemic reperfusion group (n = 108) consisting of ischemic 30 min, 90 min and 120 min groups with 36 rats respectively. Cerebral ischemia reperfusion models were established with the four artery blocking method according to cerebral ischemia Pusinelli reference. TUNEL method was used to observe the apoptosis of neurons, while immunohistochemical detection was for CIDE-B positive neurons in hippocampus. The expressions of CIDE-B mRNA and protein were detected by RT-PCR technique and Western blot method respectively.

Results: Compared with sham operation group, the number of apoptotic neurons increased significantly after ischemia 30 min, 90 min and 120 min reperfusion 6 h, 1 d, 3 d, 7 d and 14 d (t = 2.47–3.94, P < 0.01–0.05) and CIDE-B positive neurons increased significantly (t = 2.28–3.94, P < 0.01–0.05); CIDE-B mRNA positive neurons in the subgroups of ischemia 30 min, 90 min and 120 min reperfusion 7 d and 14 d which was significantly more than that of ischemia 30 min, 90 min and 120 min reperfusion 6 h, 1 d, 3 d and 28 d (P < 0.05).

Conclusion: The neural apoptosis was time-dependent on the expressions of CIDE-B mRNA and protein after cerebral ischemic reperfusion injury in rats.

and Shengmai injection can alleviate neural injuries after ICH by inhibiting the expressions of PAR1 and AQP4.

Parinaud's syndrome due to a unilateral vascular ischemic lesion
J. Moreira Martins, J. Serino. 1Neurology, Hospital Pedro Hispano, ULSM, Oporto, Portugal; 2Ophthalmology, Hospital Pedro Hispano, ULSM, Oporto, Portugal

Background: Parinaud's syndrome includes as core feature paralysis of conjugate vertical eye movements (especially upgaze) with convergence–retraction nystagmus on attempted upgaze. Since the lesions accounting for the paralysis of voluntary vertical eye movements are located adjacent to the pupillomotor pathways, there can be varying degrees of paralysis of convergence, pupillary constriction, and accommodation. Parinaud's syndrome may be caused by extrinsic or intrinsic lesions, with pineal tumors and hydrocephalus being common etiologies.

Clinical case: A 59-year-old man complained of binocular diplopia of sudden onset noted after an exploratory laparotomy complicated by cardiorespiratory arrest during anesthetic induction. On inspection he had Collier's sign. He had complete paralysis of upward vertical gaze associated with convergence–retraction nystagmus on attempted upgaze. Downward vertical gaze and horizontal gaze were intact. We noted skew deviation with hypertropia in the left eye, confirmed by Hess screen with negative Bielschowsky. His pupils were round and unequal (right 2 mm, left 3 mm), both reacting to light. Brain MRI revealed a small lesion in the left paramedian midbrain which was hyperintense in T2 and FLAIR, compatible with vascular ischemic sequelae.

Conclusion: Our patient exhibited Parinaud's syndrome from a unilateral vascular ischemic paramedian midbrain lesion that may result from involvement of the interstitial nucleus of Cajal and/or fibers to and from posterior commissure. We demonstrate similarly to other cases described in the literature, that a single millimetric unilateral lesion, near the midline, may interrupt the pathways involved in the vertical gaze just before and after they decussate, inducing a functionally bilateral lesion.

Abstract — WCN 2013

Topic: 3 — Stroke
Activation of renin–angiotensin system (RAS) in acute stroke
O. Dubenko, S. Kostukovskiy, I. Podushka. 1Neurology and Neurosurgery, Kharkiv Medical Academy of Postgraduate Education, Ukraine; 2Neurology, City Clinical Hospital No. 7, Kharkiv, Ukraine

Background: The RAS plays an important role in the development of arterial hypertension and angiotensin converting enzyme (ACE) is a key enzyme which converts angiotensin I to angiotensin II — the main active product of RAS. But the role of RAS activation in ischemic stroke (IS) is not clear.

Objective: To clarify the association of RAS activation and clinical course of acute IS

Patients and methods: The examination included 191 hypertensive patients with acute IS. All patients were genotyped for the ACE insertion/deletion (I/D) polymorphism by polymerase chain reaction. ACE activity and angiotensin II level in serum were determined by enzymatic assay.

Results: In IS patients most frequent variant of genotype was DD — in 44.5%, less frequent is II — in 15.2% and heterozygote ID — in 40.3%. There were strong differences between DD and II variants which are associated with clinical course of stroke and RAS activity. Genotype DD was most unfavorable and associated with more severity of stroke to NIHSS — 16.6 ± 0.9, with II — 8.8 ± 0.6 and higher blood pressure at admission. This accompanied the increase of ACE activity to 59.7 ± 5.8 U/L with DD genotype and 47.36 ± 8.61 U/L (p = 0.034) with II, and elevation of serum angiotensin II level to 50.8 ± 3.3 pg/ml comparable to 36.6 ± 6.9 pg/ml in II genotype (p < 0.01). Monozygotic genotype II was more favorable and associated with best restored of neurological function and lower of blood pressure.

Conclusion: The ACE polymorphism is clinically relevant and influences the course of IS. Patients who had D-allele observed higher RAS activity and severity of stroke.

Ultrasonographic characteristics of ocular ischemic syndrome
1First Dept of Neurology, University of Medicine and Pharmacy “Victor Babes”, Cluj-Napoca, Romania; 2First Dept of Neurology, County Emergency Hospital, Cluj-Napoca, Romania; 3Ophthalmology, Military Emergency Hospital, Cluj-Napoca, Romania; 4Internal Medicine-Nephrology, University of Medicine and Pharmacy “Victor Babes”, Timisoara, Cluj-Napoca, Romania; 5Neurology, University of Medicine and Pharmacy “Carol Davila”, Bucharest, Cluj-Napoca, Romania; 6Neurology, University of Medicine and Pharmacy “Juliu Hatieganu”, Cluj-Napoca, Romania

Introduction: The internal carotid artery (ICA) is the main route by which the blood is supplied from the heart to the brain and eye. The ocular and orbital circulation is assured by the ophthalmic artery, which is the main collateral branch of the ICA. Occlusion or severe stenosis of the ICA (which is more than 70% of the arterial lumen’s diameter) may lead to transient or permanent symptoms of retinal ischemia and to an increased risk of ischemic stroke.

Purpose: To define orbital circulation abnormalities identified by color Doppler imaging (CDI) of retrobulbar vessels in patients with ICA occlusive/severe stenosis disease.

Methods: We used a LOGIQ 5000 sonographer with 9 MHz linear probe for Doppler investigation of retrobulbar vessels, and an ultrasound equipment (MyLab 50 Esaote) with a 7.5–10 MHz linear array transducer for extracranial Duplex sonography.

Results: We presented 10 patients with severe ICA stenosis/occlusion that developed or not an ocular ischemic syndrome. We discussed the hemodynamic status (orbital and cerebral) in order to elucidate the contribution to the ischemic symptoms. Cerebral and retinal perfusion is dependent not only on the degree of stenosis, and embolic risk, but also on the presence of unilateral or bilateral lesions and on the patency of collateral pathways.

Conclusion: The presentation of ocular ischemic symptoms may be the initial sign of carotid artery stenosis/occlusion and can also be used to predict the severity of ICA’s disease.

An evaluation of 42 cases of cerebral vein and dural sinus thrombosis
D.C. Jianu1, S.N. Jianu1, L. Petrica2, B.O. Popescu1, D.F. Muresanu1.
1Neurology, University of Medicine and Pharmacy “Victor Babes”, Cluj-Napoca, Romania; 2Internal Medicine-Nephrology, University of Medicine and Pharmacy “Iuliu Hatieganu”, Cluj-Napoca, Romania.

Background and objectives: Cerebral vein and dural sinus thrombosis (CVT) present a variety of non-specific clinical signs. The aim of our study was to identify CVT causes and risk factors, to describe the demographic, clinical, laboratory and neuroimaging data, and to evaluate the treatment and outcome.

Patients and methods: We included 42 consecutive pts with CVT, which were examined at admission and after three months, using the mRS scores.

Results: Mean age was 36.2 years (SD 7.9), sex ratio: male/female was 1/2. 85.7% of women were fertile. The most frequent neurological syndromes was intracranial hypertension. CT showed direct signs of dural sinus thrombosis: (dense triangle sign in 5 pts, etc.). In 14 pts, we observed a venous cerebral infarct. MRI identified thrombosis of SSS in 31 pts, transverse sinus in 12 cases, cavernous sinus in 3 pts, cerebral edema in 21 pts. 9 out of 42 MRI had a normal CT. DSA revealed isolated cortical veins occlusion, without sinus occlusion in 3 cases. Risk factors were identified in 32 pts (76.2%); congenital thrombophilia being the most common (11 pts). All pts received anticoagulant therapy. After 90 days from admission, complete resolution of symptoms was seen in 22 cases, minimal neurological deficits in 14 pts, and the death rate was 14.3% (6 pts).

Conclusions: CVT appears to be under diagnosed in our region, due to low percentage of admissions for benign intracranial hypertension. CVT was common in women of fertile age. The outcome was favorable with adequate therapy.

Diagnosis of carotid body paragangliomas by various imaging techniques
D.C. Jianu1,2, S.N. Jianu1, B.O. Popescu1, D.F. Muresanu1.
1Neurology, University of Medicine and Pharmacy “Victor Babes”, Cluj-Napoca, Romania; 2Internal Medicine-Nephrology, University of Medicine and Pharmacy “Iuliu Hatieganu”, Cluj-Napoca, Romania.

Introduction: Carotid body paragangliomas are rare hypervascular lesions arising from neural crest paranglia cells, with a tendency of slow, but progressive growth, giving rise to external compression, or/and involvement of the carotid arteries, craniofacial nerves and other neighbouring structures.

Patients and methods: We analysed demographics, mode of presentation, imaging features, Shamblin classification, treatment modalities, and neurological complications (stroke, cranial nerve injuries), of four patients (pts) with carotid body paragangliomas, in order to find specific signs and to elaborate a strategy for diagnosis and treatment.

Results: One pt had two localisations (the second was a glomus tumor of the left prelacrimal sac) and another one had a family history for carotid body tumor. All lesions were paragangliomas of the carotid bifurcation, represented by painless lateral neck mass. There was no evidence of functional tumor. The tumors were confirmed during ultrasonography (all four pts), MRI with MRA (all four pts) and DSA (2 pts). No preoperative embolisation was performed before complete resection of paragangliomas. Postoperatively, 2 pts had a transient twelve cranial nerve deficit. No stroke occurred.

Conclusions: Early diagnosis of carotid body paragangliomas is possible now with color Doppler sonography and MRI + MRA. Early surgery for paragangliomas minimized the risk of complications associated with large tumours.

Background: Aspirin use is known to reduce the recurrence of stroke. However, the clinical response to aspirin has been mixed. A plausible explanation for this is may be the resistance to the effects of aspirin. The causes of aspirin resistance are manifold and multifactorial. We conducted a study to investigate inherent factors that may predispose towards aspirin resistance in a cohort of aspirin naïve stroke patients.

Methodology: This was a cross-sectional, observational study conducted on patients admitted to our centre with an acute stroke. Fifty consecutive patients were tested for biochemical aspirin resistance using Multiplate platelet analyser after 5 doses of aspirin, corresponding to a total dose of 900 mg.

Results: Aspirin resistance was present in 14% of our patients. There was an inverse relationship between the presence of aspirin resistance and plasma HDL levels (r = −0.394; p = 0.005). No relationship was observed between aspirin resistance and total cholesterol, triglycerides, LDL, HbA1c, ALT, ALP, urea and creatinine levels. There were no significant differences in the demographic profiles or smoking status between the aspirin-resistant and non-aspirin-resistant groups.

Conclusion: Our results indicate that a lower HDL level is associated with biochemical aspirin resistance. This may increase platelet aggregation and consequently increase the risk of a recurrent stroke.

The clinical implications for aspirin resistance are far reaching. Any evidence that correctable factors may negatively influence the action of aspirin warrants further investigation.

Correlation between anticardiolipin antibodies level and stroke severity in antiphospholipid syndrome patients
A. Rodriguez-Sanz, P. Martinez-Sanchez, D. Prefasi, B. Fuentes, E. Diez-Tejedor. Department of Neurology and Stroke Center, Hospital Universitario La Paz, Madrid, Spain

Background: Serum antiphospholipid antibodies (aPLs) are useful to monitor the thrombotic risk in patients with antiphospholipid syndrome (APS). Our goal is to analyze the association of aPL level with stroke severity and outcome in AS patients.

Methods: Observational study that included consecutive young patients with ischemic stroke (IS) up to 55 years from 2006 to 2011. We analysed serum aPL levels including anticardiolipin antibodies (aCL), anti-β2-glycoprotein I (aβ2-GPI) and antiprothrombin (aPT) in the first 24 h after admission and, in the case of being positive, at least 12 weeks after. Stroke severity was measured by the NIHSS and 3-months stroke outcome by the modified Rankin Scale (mRS). Spearman’s rho correlation was used to determine correlations between aPLs and stroke severity, as well as aPLs and outcomes in the APS group, in the whole sample and adjusted by age (<45 and 45–65 years).

Results: A total of 222 patients were included; 63.5% male. In APS patients (9%), a positive correlation were found between IgM aCL and NIHSS (rho = 0.480; p = 0.032). Adjusted by age, a positive correlation between IgM aCL and NIHSS (rho = 0.789, p = 0.011) and a negative between IgG aCL and NIHSS (rho = −0.839, p = 0.005) were observed only in patients >45 years old. There were not statistically significant correlations between aCL/other antibodies and mRS.

Conclusions: In APS patients with brain infarction, IgM aCL serum levels are positively correlated with stroke severity whereas IgG aCL serum levels are negatively correlated, overall in the >45 year old group.

Predictors of long-term survival among first-ever ischemic and hemorrhagic stroke in a Brazilian stroke cohort
A. Goulart1, T.G. Fernandes2, I.S. Santos2, A.P. Alencar2, I.M. Bensenor3, P.A. Lotufo2. 1Center for Clinical and Epidemiological Research, Hospital Universitario, University of Sao Paulo, Sao Paulo, Brazil; 2Federal University of Amazonas, Coari, Brazil; 3Institute of Mathematics and Statistics, University of Sao Paulo, Sao Paulo, Brazil

Background: Although pathologic mechanisms for ischemic and hemorrhagic stroke are clearly distinct, most previous studies have failed to compare long-term prognosis including both ischemic and...
hemorrhagic stroke. Despite the importance of investigating stroke survival, particularly in developing countries as Brazil that has one of the highest rates of hemorrhagic stroke in Latin America, publications in this field are sparse and come from developed countries.

**Objective:** Thus, we sought to investigate long-term survival and predictors that could influence adversely ischemic and hemorrhagic first-ever stroke prognosis along 4 years of follow-up.

**Patients/material and methods:** We prospectively ascertained 665 consecutive first-ever ischemic and hemorrhagic stroke cases from "The Study of Stroke Mortality and Morbidity" (The EMMA Study) in a community hospital in São Paulo, Brazil. The influence of cardiovascular risk factors and sociodemographic characteristics on stroke survival were analysed using life table survival and Cox proportional hazards survival analysis.

**Results:** We found a lower survival rate among hemorrhagic cases compared to ischemic stroke cases at the end of 4 years of follow-up (52% vs. 44%, p = 0.04). The risk of death is two times higher among people with ischemic stroke without formal education. Also, we found consistently higher risk of death for diabetics with ischemic stroke (HR = 1.45; 95% CI = 1.07–1.97) compared to ischemic stroke with formal education. As expected, age equally influenced on the high risk of poor survival, regardless of stroke subtype.

**Conclusions:** For ischemic stroke, the lack of formal education and diabetes were significant independent predictors of poor long-term survival.

**Comparison of aspirin response measured by urinary 11-dehydrothromboxane B2 and VerifyNow® Aspirin assay in patients with ischemic stroke**

P. Dharmasaroja, S. Muengtaweepongsa, S. Sae-Limb, Department of Internal Medicine, Thammasat University, Klong Luang, Thailand

**Background:** There is little data about aspirin resistance in patients with ischemic stroke as compared with those with coronary artery diseases. The purpose of this research is to look for the prevalence of aspirin non-responders and to compare the results of the tests assessing aspirin responses between urinary 11-dehydrothromboxane B2 (dTXB2) measurement and VerifyNow® Aspirin assay in patients with ischemic stroke.

**Methods:** Patients with ischemic stroke who were treated with aspirin during April 2011–August 2011 were prospectively included. Aspirin response was assessed by urinary dTXB2 measurement and VerifyNow® Aspirin assay. The Spearman’s correlation coefficients and kappa statistics were calculated to assess correlation and agreement between the 2 tests.

**Results:** 101 patients were studied. Prevalence of aspirin non-responders was 40% and 6%, if they were measured by urinary dTXB2 and VerifyNow® Aspirin assay, respectively. Poor correlation in the results between the 2 tests was found (r = 0.135, p-value 0.190). The degree of agreement between the 2 tests in relation to resistance status was weak (kappa = 0.032, p-value = 0.590).

**Conclusion:** Our research confirmed the poor correlation and agreement between the 2 tests. Further research is still needed to identify the best method of diagnosis of aspirin resistance.

fatality rate was 30.6%. Out of the 26 death recorded 18 (69.2%) occurred in the first 72 h. Factors associated with death included male gender, TIA, abnormal respiratory pattern, abnormal pupillary size and reaction, elevated serum urea, hemorrhagic stroke, aspiration pneumonitis, and worsening GCS. Aspiration pneumonitis and worsening GCS were independent predictors of one month mortality of stroke in the patients.

Conclusion: Factors associated with mortality were male gender, TIA, abnormal respiratory pattern, abnormal pupillary size and reaction, elevated serum urea, hemorrhagic stroke, aspiration pneumonitis, and worsening GCS. Aspiration pneumonitis and worsening GCS were independent predictors of one month mortality of stroke in diabetic patients.

Brain edema in the course of stroke, ways of correction

Z. Akbarkhodjaeva a, G. Rakhimbaeva b.

Abstract: Acute stroke is one of the most common pathologies in neurological practice and clinical medicine in general. As shows many studies, one of important links in pathogenesis of secondary neuronal damage is brain edema as a result of cerebral ischemia.

Purpose: Study effect of complex therapy with anti-edematous drugs on clinical course of disease with studying of secondary hemodynamic effects of acute stroke, comparative clinical dopplerography research of efficiency of using drug Lysine (L-lysine aescinate).

Materials and methods: Open, longitudinal study. 1st control group (20 patients) received basis therapy of stroke. 2nd comparison group (also 20 patients) received Lysine in 10.0 ml dose twice a day intravenously during 5 days and basis therapy of stroke.

Results: Patients age: 34 to 68 years (mean 62.2 ± 1.1). Clinical results of carotid lesion characterized by predominance of focal symptoms, impaired consciousness, secondary dislocation stem syndrome were found. For objectification condition of patients regarding their neurological status were assessed using two complementary scales — Scandinavian and NIHSS. On NIHSS mean score was 19.3 ± 1.4, and on Scandinavian scale — 30.0 ± 2.2. Neurological deficits in the 2nd group on the tenth day on NIHSS decreased by 29.51%, Scandinavian scale increased by 24% (p < 0.05) compared to the 1st group.

Conclusion: Cerebral hemodynamics showed statistically significant improvement in arterial and venous components of blood flow.

Conclusions: Research shows that anti-edematous therapy is accompanied by significant improvement in the clinical course of the disease, rapidly decreases the perifocal edema zone, which is confirmed by reduced neurological deficit according to clinical scales and CT.

Angioplasty and stenting for intracranial arterial stenosis

T. Tsukahara a, T. Hatano b.

Abstract: The stenosis of the major intracranial arteries is a major cause of cerebral stroke. We report our experience of endovascular treatment (percutaneous transluminal angioplasty and stenting; PTAS) for symptomatic stenosis of major intracranial arteries.

Material and methods: Totally 134 cases of symptomatic intracranial arterial stenosis were treated by PTAS at Kyoto Medical Center from 1998. Indication of PTAS was 1) symptomatic stenosis, which was not successfully treated by medication, and 2) more than 60% stenotic lesion shorter than 15 mm in length. Balloon angioplasty (BA) was performed first. Stenting was, then, performed in cases of 1) unsuccessful dilatation or arterial dissection after BA and 2) restenosis after BA.

Results: Successful dilatation by BA was obtained in 21/26 internal carotid artery (ICA) lesions, in 5/6 middle cerebral artery (MCA) lesions and in 24/29 vertebral artery (VA) lesions (50/61; 82%). Restenosis occurred in 7/26 ICA lesions, 4/6 MCA lesions and 8/29 VA lesions (totally 19/61 lesions; 31%). Successful dilatation by stenting was obtained in 59/60 ICA lesions, 1/1 MCA lesion and 13/15 VA lesions (totally 73/76 lesions; 96%). Symptomatic complications induced by PTAS occurred in two cases; cerebral stroke and intra cerebral hemorrhage. Stroke recurrence rate after PTAS was 1.1% /year of intracranial ICA lesion and 0.25 % /year of intracranial VA lesion.

Conclusions: 1) Symptomatic intracranial arterial stenosis can be treated by PTAS with a low rate of stroke recurrence and complications. 2) Therapeutic merit of PTAS for intracranial lesion needs to be examined comparing to the recent aggressive medical therapy.

Changes in serum interleukin-33 levels in patients with acute cerebral infarction

Abstract: Background: Inflammation is widely considered to be involved in the pathogenesis of cerebral ischemic injury. Interleukin-33 (IL-33) has been found to play very important roles in the inflammation of several human diseases such as asthma, inflammatory bowel disease and central nervous system inflammation. Its role in the pathology of acute cerebral infarction, however, has not been reported yet.

Objective: The aims of this study were to measure the levels of IL-33 in patients with cerebral infarction (CI), and examine the correlation of serum IL-33 level and the infarction volume.

Material and methods: Serum IL-33 level was assessed by sandwich enzyme-linked immunosorbert assay (ELISA) in 62 CI samples and compared with 15 healthy controls.

Results: Serum IL-33 levels in large and medium infarct volume patient groups were significantly higher than the control group (p < 0.01), but not between the small infarct volume group and the control group (p > 0.05). It was further found that the large infarct volume patient group had the highest serum IL-33 levels, which was significantly higher than medium and small infarct volume groups (p < 0.05). In addition, the medium infarct volume patient group had higher IL-33 levels than the small infarct volume group (p < 0.05).

Conclusion: Serum levels of IL-33 might be involved in the inflammatory responses in acute cerebral infarction patients, especially for severe cases and indicate that IL-33 might play a beneficial role in CI patients.

Thyroid hormone contributes to hippocampal neural progenitor cell proliferation in adult 2vo rats
L. Ting¹, B. Chisulo², Q. Wang³. ¹Neurology, Nanfang Hospital, Guangzhou, China; ²Medicine, Kitwe Central Hospital, Kitwe, Zambia

Background: Thyroid hormone (TH) plays a critical role in developing the nervous system and regulating proliferation, survival and differentiation of neural progenitor cells. Hypothyroidism decreases the survival and differentiation of adult dentate granule cell progenitors.

Objective: To investigate the effects of TH on proliferation of stem cells in the hippocampal subgranular zone (SGZ).

Materials and methods: We achieved vascular cognitive impairment in animal model by permanent bilateral occlusion of common carotid arteries, set interventions of thyroid hormone treatment, and observe the effect on proliferation of adult dentate granule cell progenitors after chronic cerebral ischemia by immunofluorescence staining method. Rats were administered with T3 (10 mg/30 g·d) for 7 d or a single T3 (10 mg/30 g) after ischemia, and same dose of saline in control animals. Neurogenesis was studied by Bromodeoxyuridine (BrdU) immunohistochemistry in the SGZ.

Results: T3 treatment for 7 d after ischemia increased the number of BrdU cells in the SGZ compared to saline (p = 0.005, p < 0.001, respectively). A single T3 injection 10 h before death also enhanced proliferation in SGZ 7d after chronic cerebral ischemia compared to saline (p = 0.015, p < 0.001, respectively).

Conclusion: The results suggest that T3 enhance ischemia-induced proliferation of hippocampal in adult rats, and a short T3 influence on mitotic activity suggested T3 may act directly on progenitor cell populations.

The CHA2DS2-VASc score reflects clinical outcomes in NVAF patients with an initial cardioembolic stroke
L. Deguchi, T. Hayashi, Y. Ohe, Y. Kato, T. Fukuoka, H. Maruyama, Y. Horiiuchi, H. Sano, Y. Nagamine, N. Tanahashi. Department of Neurology, Saitama Medical University International Medical Center, Saitama, Japan

Background: Whether the CHA2DS2-VASc score reflects severity or clinical outcomes in patients with an initial cardioembolic stroke associated with non-valvular atrial fibrillation (NVAF) was investigated.

Patients and methods: This study included 327 patients hospitalized between April 2007 and March 2012 for an initial cardioembolic stroke associated with NVAF with no prior history of stroke. The NIHSS score on admission and clinical outcome (mRS score after 90 days) was retrospectively evaluated according to the CHA2DS2-VASc score.

Results: CHA2DS2-VASc scores were: 0, 3.1%; 1, 9.1%; 2, 24.5%; 3, 26%; 4, 20.8%; 5, 14.4%; and 6, 2.1%. The median NIHSS scores for CHA2DS2-VASc scores of 0–6 were 4.5, 8, 8, 10, 11, 17, and 23, respectively. Severity differed according to CHA2DS2-VASc score. The clinical outcomes according to the CHA2DS2-VASc scores were: score 0, mRS score 0–2 (80%) and 3–6 (20%); score 1, mRS score 0–2 (80%) and 3–6 (20%); score 2, mRS score 0–2 (64%) and 3–6 (36%); score 3, mRS score 0–2 (48%) and 3–6 (52%); score 4, mRS score 0–2 (28%) and 3–6 (72%); score 5, mRS score 0–2 (26%) and 3–6 (74%); and score 6, mRS score 0–2 (29%) and 3–6 (71%). The clinical outcome worsened as the CHA2DS2-VASc score increased.

Conclusion: The severity of NVAF-induced initial cardioembolic stroke increased with higher CHA2DS2-VASc scores, and outcomes were poor. The present study suggests that the CHA2DS2-VASc score may be useful not only for the evaluation of stroke risk, but also for the prediction of clinical outcomes after stroke.

Functional recovery after ischemic stroke — A matter of age. Results from the Austrian stroke unit registry
M. Knollflach¹, B. Matosevic¹, M. Rücker¹, M. Furtner², A. Mair³, G. Wille³, A. Zangerle³, P. Werner³, J. Ferrari³, C. Schmidauer³, L. Seyfang³, S. Kiechl³, J. Willeit³. Austrian Stroke Unit Collaboration. ¹Neurology, Medical University Innsbruck, Innsbruck, Vienna, Austria; ²Neurology, Hospital Rankweil, Rankweil, Vienna, Austria; ³Neurology, Hospital Barmherzige Bruderschaften, Vienna, Austria; ⁴Danube University Krems, Gesundheit Österreich GmbH/BIQG, Vienna, Austria

Objective: To analyze the association between patient age and good functional outcome after ischemic stroke with special focus on the young that were numerically underrepresented in previous evaluations.

Methods: Of 43,163 ischemic stroke patients prospectively enrolled in the Austrian Stroke Unit Registry, 6084 (14.1%) were ≤55 years old. Functional outcome was available in a representative subsample of 14,256 patients free of pre-stroke disability. 2223 were 55 years or younger. Herein we analyzed the effects of age on good functional outcome 3 months after stroke (modified Rankin Scale ≤ 2).

Results: Good outcome was achieved in 88.2% (unadjusted probability) of young stroke patients (≤55 years). In multivariable analysis, age emerged as a significant predictor of outcome independent of stroke severity, etiology, performance of thrombolysis, sex, risk factors and stroke complications. When using the age stratum 56–65 as a reference, odds ratios [95%CI] of good outcome were 3.4 [1.9–6.4], 2.2 [1.6–3.2] and 1.5 [1.2–1.9] for patients aged 18–35, 36–45 and 46–55 and 0.70 [0.60–0.81], 0.32 [0.28–0.37] and 0.18 [0.14–0.22] for those 66–75, 76–85 and ≥85 years old (P < 0.001). In absolute terms, the regression-adjusted probability of good outcome was highest in the age group 18–35 and gradually declined by 3.1%–4.2% per decade until age 75 with a steep drop thereafter. Findings equally applied to sexes and patients with and without intravenous thrombolysis or diabetes.

Conclusions: Age emerged as a highly significant inverse predictor of good functional outcome after ischemic stroke independent of stroke severity, characteristics and complications with the age-outcome association exhibiting a non-linear scale and extending to young stroke patients.

Flow-mediated dilatation in ischemic leukoaraisis
M. Zupan, M. Zaletel, J. Pretnar-Oblak, B. Zvan. Department of Vascular Neurology, University Clinical Center Ljubljana, Ljubljana, Slovenia

Background: Although the exact pathophysiology of ischemic leukoaraiosis (LA) remains to be elucidated it is possible that endothelial dysfunction may play the essential role. Therefore we explored systemic endothelial dysfunction in ischemic leukoaraiosis.
Methods: In order to evaluate systemic endothelial function in subjects with LA (LA1) we examined flow-mediated dilatation (FMD) and compared it to subjects with comparable risk factors without LA (LA0). FMD was investigated in 30 subjects with LA (57.6 ± 6.8 years) and 24 subjects with comparable risk factors without LA (55.7 ± 5.4 years).

Results: FMD was significantly lower in group LA1 compared to LA0 (4.7 ± 3.2 % vs. 7.3 ± 3.7 %; p = 0.009). There were no statistically significant differences in the FMD response when subjects from the group LA1 were divided into the subgroup with arterial hypertension and the one without arterial hypertension (4.1 ± 3.2 % vs. 5.4 ± 3.3 %; p = 0.307). When the group LA1 were divided according to the leukoaraiosis into Fazekas 1, 2 or 3 groups. When the Fazekas 2 and 3 subgroups were compared to each other, we found that FMD response was significantly different (p = 0.013) and even so when the Fazekas 1 subgroup was compared to the Fazekas 3 subgroup (p = 0.019).

Conclusions: It seems that systemic endothelial function is diminished in ischemic leukoaraiosis. According to our study it is possible that systemic endothelial dysfunction is one of important aspects of pathophysiology of LA.

Clinico-epidemiological features of cerebral venous thrombosis in Algarve
H. Nzwalob, F. Rodriguesb, P. Carneiroa, L. Areza, F. Ferreiraa,
C. Basilisoc, Neurology, Faro Hospital, Faro, Portugal; bInternal Medicine, Centro Hospitalar do Barlavento Algarvio E.P.E., Portimão, Faro, Portugal; cUniversidade do Algarve, Faro, Portugal

Background: Cerebral vein thrombosis (CVT) is a very uncommon disorder with a wide variety of clinical manifestations. Little information exists about CVT, particularly from peripheral regions.

Objective: To describe the epidemiology and clinical characteristics of CVT in a relatively small region.

Results: Thirty-five cases of CVT were identified. Children (4) and non-residents (3) were excluded from the analysis. Gross incidence was approximately 0.56–0.64/100,000 cases/year. The mean and median ages were 40.4 and 35 years respectively [18–71 years]. The majority (21/75%) were woman. The mean interval between the onset of symptoms and the diagnosis was 8 days [8–41 days]. Patients presented with isolated intracranial hypertension (17/61%), focal syndrome (4/14%), and encephalopathy (7/25%). Brain TC was diagnostic in 10 (42%) cases. Brain MRI and MR venography was performed in all. Use of oral contraceptives was found in 14/66% of female. Patients received heparin or LMWH followed by warfarin. All cases received heparin or LMWH followed by warfarin. Brain MRI and MR venography was performed in all. Use of oral contraceptives was found in 14/66% of female. Patients received heparin or LMWH followed by warfarin. Multiple regression analysis showed only an important influence of LA on FMD (p = 0.05).

Conclusions: It seems that systemic endothelial dysfunction is diminished in ischemic leukoaraiosis. According to our study it is possible that systemic endothelial dysfunction is one of important aspects of pathophysiology of LA.

The association of infarct pattern on coronal diffusion-weighted MR image and early neurologic deterioration in deep subcortical infarction
D.S. Oh, D.E. Kim, K.H. Choi, Y.J. Choi, T.S. Nam, J.T. Kim, S.H. Lee, Department of Neurology, Chonnam National University Hospital, Gwang-Ju, Republic of Korea

Background: Early neurological deterioration (END) is frequently observed in patients with small deep infarction of subcortical area. Objective: In this study, we investigated the association between the END and the patterns of small deep infarction in coronal diffusion-weighted imaging (DWI).

Patients and methods: Consecutive 95 patients diagnosed with acute ischemic stroke in subcortical area, who were admitted to stroke center between March 2008 and June 2009, were included. Brain coronal DWI and MR angiography (MRA) were carried out. The patterns of infarct lesions are divided into 3 categories: (1) lacunar pattern; isolated lesion in the subcortical area, (2) skipped pattern: lesions that presented with disconnected shape, separated by unaffected white matter of internal capsule, on coronal DWI, (3) linear pattern; linear lesion extending to the basal surface on coronal DWI. END was defined as an increase of 2 or more points of the National Institutes of Health Stroke Scale (NIHSS) within 7 days of stroke onset.

Results: Among 36 patients, 14 patients developed END and 22 patients did not develop END. Univariate analysis showed that the ADC values in diffusion restricted lesion were significantly decreased in patient that developed to END compared with those that remained without END. (p value = 0.037).

Conclusions: Initial ADC values can predict the development of END in patient with deep subcortical infarct.

Abstract — WCN 2013

Topic: 3 — Stroke
The value of apparent diffusion coefficient maps in subcortical infarct lesion

Background: Prediction of the early neurologic deterioration (END) in patients with acute ischemic stroke is one of great clinical interests.

Objective: This study was designed to analyze whether apparent diffusion coefficient (ADC) values provide reliable quantitative information for the prediction of the neurologic deficits in stroke patients.

Patients and methods: We reviewed 36 patients not treated by thrombolytics who had a diffusion restricted lesion in deep subcortical area within 24 h after stroke onset. Serial National Institutes of Health Stroke Scale (NIHSS) scores were checked from admission. We compared the ADC values in the initial diffusion weighted image (DWI). We tested the value of the ADC to predict tissue outcome and development of END. All images were processed on an independent workstation by using custom software (MIDAS 1.11).

Results: Among 36 patients, 14 patients developed END and 22 patients did not develop END. Univariate analysis showed that the ADC values in diffusion restricted lesion were significantly decreased in patient that developed to END compared with those that remained without END. (p value = 0.037).

Conclusions: Initial ADC values can predict the development of END in patient with deep subcortical infarct.

Mortality-related factors in ischemic stroke patients 80 years of age and older

Y. Kaplan, O. Kamisli, S. Kamisli, S. Altınyay, C. Ozcan. Neurology, Inonu University, Malatya, Turkey

Background: To date, many variables that affect the early and late prognosis in stroke patients have been reported. Many of these factors cannot be changed, such as oldest age. It is important to determine the changeable and non-changeable factors related to disability and death in the oldest age groups.

Objective: The aim was to investigate mortality-related factors in ischemic stroke patients 80 years of age and older.

Methods: We reviewed all ischemic stroke patients admitted to our clinic between January 2010 and January 2012. The patients' database information was retrospectively analyzed. One hundred and ten patients aged older than 80 years with ischemic stroke were included in the study. The patients were divided into two groups based on survival. Age, gender, recurrent stroke, risk factors, clinical syndrome, etiology, radiographic localization, duration of hospitalization, and presence of systemic complications were accepted as mortality-related prognostic factors. The groups were compared according to these prognostic factors.

Results: In the clinical follow-up, 58 (52.7%) patients died; 65.5% died of neurological causes, and 31% died of systemic complications. No significant differences existed between the two groups in age, gender, risk factors, recurrent stroke, or etiology. The frequency of total anterior circulation infarct syndrome was much higher in deceased patients than did living patients (50% and 36.5% respectively; \( p < 0.05 \)). Deceased patients had a statistically significantly higher incidence of total MCA infarct and systemic complications than did living patients (\( p < 0.05 \)).

Conclusion: Starting appropriate treatment and care initiatives as soon as possible is also very necessary in the oldest stroke patients.

The safety and efficacy of the intravenous recombinant tissue plasminogen activator for the ischemic stroke patients in community based hospital

J. Jounge¹, I.U. Song², D. Jounge³, ¹Neurology, Soonchunhyang University, Gumi-City, Republic of Korea; ²Neurology, Catholic University of Korea, Incheon St. Mary's Hospital, Incheon, Republic of Korea; ³Neurology, Soonchunhyang University College of Medicine, Cheonan Hospital, Cheonan, Republic of Korea

Background: The results of the MINDS r-tPA Stroke Trial generated considerable hope, but also concerns about whether the results of the MINDS r-tPA Stroke Trial can be replicated in routine clinical practice. We studied whether r-tPA infusion could be applied in a community based hospital with safety and efficacy.

Methods: We analyzed retrospectively the data of thirty-three patients with acute ischemic stroke treated with intravenous r-tPA, from Feb. 2003 to Dec. 2006. Safety was evaluated by intracranial hemorrhage, symptomatic intracranial hemorrhage and mortality. Clinical neurologic status was measured by NIHSS at baseline, 24 h, and 7 days after r-tPA treatment. Efficacy was assessed by the response rate of r-tPA using improvement of NIHSS by 4 or more points at 24 h after treatment and the long term outcome with the modified Rankin scale at 3 months after stroke.

Results: The Median NIHSS was 18. Mean onset to needle time was 140 ± 30 min. Among the 33 patients, 10 patients had intracranial hemorrhage. Two patients had symptomatic intracranial hemorrhage but no death occurred. 15 patients showed improvement of NIHSS by 4 or more points at 24 h after r-tPA. 12 patients showed good outcome at 3 months. 9 patients had no or minimal symptoms, 7 patients had mild to moderate disability, 10 patients had severe disability and 7 patients were died.

Conclusions: The efficacy and safety of intravenous r-tPA for acute ischemic stroke in the community based hospital mirror the results of the MINDS stroke trial.

Prevalence of cardioembolic stroke increased significantly in Chinese population in the past 10 years

Y. Soo¹, X. Huang², X.Y. Chen³, N. Chan⁴, V. Ip⁵, L. Au⁶, F. Fan⁷, A. Chan⁸, T. Leung², L.K.S. Wong⁹. ¹Department of Medicine and Therapeutics, Prince of Wales Hospital, Chinese University of Hong Kong, Hong Kong, Hong Kong; ²Department of Neurology, Houjie Hospital, Dongguan, China

Background: Atrial fibrillation-related cardioembolic stroke (AF-CE) is a major cause of cardioembolism, which may be potentially preventable with anti-coagulation.

Objective: The aim of the study was to evaluate the changes in the prevalence of AF-CE over the past ten years in Chinese population.

Patients and methods: We evaluated the prevalence of AF-CE and risk factor profile from data collected prospectively from Prince of Wales Hospital Stroke Registry in 1999, 2004 and 2009.

Results: Total 2744 patients were admitted for ischaemic stroke or transient ischaemic attack in these three years — 946 patients in 1999, 887 in 2004 and 911 in 2009. There was no significant difference in the mean age of patients (71.2 ± 11.3 years, 70.7 ± 12.8 years, and 70.8 ± 12.5 years respectively, \( p = 0.644 \)). The number of AF-CE increased significantly — 92 patients (9.7%) in 1999, 104 patients (11.7%) in 2004 and 216 patients (23.7%) in 2009 (\( p < 0.001 \)).

Among patients with atrial fibrillation, the mean CHADS score prior to the index stroke was 2.7 ± 1.3 in 1999, 3.0 ± 1.3 in 2004 and 2.2 ± 1.3 in 2009. The percentage of patients who were on warfarin before admission was 21.7% in 1999, 23.1% in 2004 and 13.0% in 2009.

Conclusion: Over the past 10 years, the prevalence of AF-CE has increased significantly in Chinese population. Although most of the patients with atrial fibrillation had CHADS score ≥ 2, only a minority of them were anticoagulated before admission. Raising the awareness of this potentially preventable stroke subtype is warranted in Chinese population.

Demographics and risk factors for recurrent ischemic stroke in Aegean part of Turkey
Y. Seçil, Y. Çiftçi, Y. Beckmann. Neurology, Izmir Katip Celebi University, Ataturk Education and Research Hospital, Izmir, Turkey

Background: Recurrent stroke is defined as a new cerebrovascular event which occurs after the stabilization of the previous stroke. Recurrence of stroke increases likelihood of disability—mortality associated with stroke. Systematic evaluation of stroke cases can help to reduce the risk of recurrence.

Objective: In order to predict ischemic strokes which carry the risk of recurrence, our study aimed to compare data related to risk factors, stroke type, etiology and disability—mortality rates associated with stroke.

Material and method: Our study including patients with recurrent ischemic stroke admitted to our hospital Neurology department between February 2010 and June 2011. Information about previous strokes and demographics were recorded. Risk factors were classified. Disability—mortality rates and secondary prevention treatment at recurrent stroke onset were evaluated.

Results: 151 patients with recurrent ischemic stroke were included in our study. The mean age was 71.35 ± 12.06. The most frequent risk factors were hypertension, hyperlipidemia, coronary artery disease and atrial fibrillation. The most frequent recurrence etiology was cardiac embolic events. 53.2% of patients were receiving antiplatelet, 10.4% of patients were receiving anticoagulation therapy. 26.5% of patients died. The mean of modified Rankin score of patients was significantly higher at the recurrent ischemic stroke than the previous ischemic stroke.

Conclusion: Knowing the etiological factor can help to predict recurrence of stroke and prevent death. Effective treatment of modifiable risk factors in recurrent stroke groups is very important in primary and secondary stroke prevention. Recurrent stroke prevention is very important in prognosis, disability and financial basis all around the world.

Clinicoradiological localization of language dysfunctions in acute ischemic brain attack
M.H. Ibrahim. Neurology, GMC & GMU University, Ajman, United Arab Emirates

Objective: The aim of the study was to study the effect of cerebral ischemic vascular insult on the localization of language areas as regard automatic speech, initiation and mutism.

Materials and methods: Seventy ischemic stroke patients selected within the first 48 h of the onset of stroke with left hemispheric stroke with aphasia. Inclusion criteria: At any age above seven years, both sexes, first ever clinical stroke, admitted within the first 2 days of stroke insult. Patients underwent careful history taking, neurological examination, routine laboratory investigations, echocardiography, carotid duplex and language assessments.

Results: Automatic speech disorders were seen in (76%) patients and their MRI lesion distribution showed lesions within the deep periventricular white matter and anterior Perisylvian regions and other areas. Initial difficulty was with lesions in deep periventricular white matter, and other areas. Mutism significantly correlated with lesions in temporal mid-area, external capsule and other areas.

Conclusions: Deep periventricular white matter and insular area in the dominant hemisphere play an important role in many language tasks. Thus aphasia is not a mere cortical function.

How accurate are clinicians when estimating stroke outcomes? Results from the Jurassic randomized study
G. Saposnik1, R. Coteb, R. Rapitsa, M. Mamdani, K. Thorpe, J. Fang1, D. Redelmeier1, L.B. Goldstein1. JURASSIC Study Group
1University of Toronto, Toronto, Canada; 2Quebec Heart Institute, Montreal, Canada; 3St Michael's Hospital, Toronto ON, Canada; 4Institute for Clinical Evaluative Sciences (ICES), Toronto ON, Canada; 5Duke University, Durham NC, USA

Objective: We compared the accuracy of clinicians and a risk score (iScore) to predict observed outcomes following an acute ischemic stroke.

Methods: The JURASSIC (Clinician Judgment vs. Risk Score to predict Stroke outcomes) study assigned 111 clinicians with expertise in acute stroke care to predict the probability of outcomes of 5 ischemic stroke case scenarios. The primary outcome was prediction of death or disability (mRS ≥ 3) at discharge within the 95% confidence interval (CI) of observed outcomes. Secondary outcomes included 30-day mortality and death or institutionalization at discharge.

Results: Clinicians made 1661 predictions with overall accuracy of 16.9% for death or disability at discharge, 46.9% for 30-day mortality, and 33.1% for death or institutionalization at discharge. In contrast, 90% of the iScore-based estimates were within the 95% CI of observed outcomes. Nearly 50% of participants were unable to accurately predict the probability of the primary outcome in any of the 5 rated cases. In multivariable analyses, the presence of patient characteristics associated with poor outcomes (mRS ≥ 3 or death) in previous studies (older age, high NIHSS score and non-lacunar subtype) were associated with more accurate clinician predictions of death at 30-days (OR 2.40, 95%CI 1.57–3.67) and with a trend for more accurate predictions of death or disability at discharge (OR 1.85, 95%CI 0.99–3.46).

Conclusions: Clinicians with expertise in stroke performed poorly compared to a validated tool in predicting stroke outcomes. Use of the risk stroke outcome tool may be superior for decision-making following an acute ischemic stroke.

Vascular endothelial growth factor: Genetic polymorphisms in patients with intracranial aneurysm and its relation to hypertension and diabetes mellitus

Departments of Biochemistry and Molecular Biology, Sao Jose do Rio Preto Medical School, Sao Jose do Rio Preto, Brazil; Molecular Biology, Sao Jose do Rio Preto Medical School, Sao Jose do Rio Preto, Brazil; Neurosurgery, Hospital School/Sao Jose do Rio Preto Medical School, Sao Jose do Rio Preto, Brazil; Cardiology, Sao Jose do Rio Preto Medical School, Sao Jose do Rio Preto, Brazil; Neuroradiology, Hospital School/Sao Jose do Rio Preto Medical School, Sao Jose do Rio Preto, Brazil; Neurology, Sao Jose do Rio Preto Medical School, Sao Jose do Rio Preto, Brazil

Objective: The background of this study was that vascular endothelial growth factor (VEGF) is a very important factor in the development of intracranial aneurysm (IA). It is also known that some genetic polymorphisms in VEGF gene may be related to the development of hypertension and diabetes mellitus.

Materials and methods: This study was conducted on 100 patients with intracranial aneurysm and 100 control patients. The patients were divided into 2 groups: Group 1 consisted of patients with hypertension and diabetes mellitus (hyper-diab group), and Group 2 consisted of patients without hypertension and diabetes mellitus (non-hyper-diab group). The control group consisted of patients without any comorbidities.

Results: The results showed that the frequency of the A allele of rs699947 polymorphism was higher in the hyper-diab group compared to the non-hyper-diab group (p = 0.034). In addition, the frequency of the G allele of rs11546806 polymorphism was higher in the hyper-diab group compared to the non-hyper-diab group (p = 0.017).

Conclusions: The findings of this study suggest that VEGF genetic polymorphisms may be associated with the development of intracranial aneurysm and the development of hypertension and diabetes mellitus.

Preventive care with respect to the disease.
Studies in families with a history of IA may allow greater attention to
the family of patients with IA. On the other hand, smoking, drinking
patients and controls in relation to diabetes mellitus were not observed.

Results: Prevalence of genotype wild C/C in G5 (10.5%) in
comparison with G1 (2.3%) and G3 (0.0%) (P = 0.03 for both) and
risk genotype (T/T) was significant between G4 (75.3%) and G6
(78.0%; P < 0.0001). The distribution of allele T was similar between
groups (G1 = 0.86; G2 = 0.88; G3 = 0.87; G4 = 0.87; G5 = 0.81;
G6 = 0.89; P > 0.05). We observed a high frequency of smoking and
drinking habits in G1 (79% and 40%, respectively) compared to G5
(30.0% and 22%, respectively; P < 0.0001 for all). An association
between hypertension and IA was observed in G1 (49%) and G3 (49%)
compared to G5 (21%; P = 0.003; P < 0.0001). Differences between
patients and controls in relation to diabetes mellitus were not observed.

Conclusion: The polymorphism for VEGF was more prevalent only in
the family of patients with IA. On the other hand, smoking, drinking
habits and hypertension were observed in Brazilian patients with IA.
Studies in families with a history of IA may allow greater attention to
preventive care with respect to the disease.

Attenuation of glutamate mediated neuronal insult by piroxicam
in animal model of focal cerebral ischemia: Possible involvement
of GABA agonism
Biomedical Engineering, IIT(BHU), Varanasi, Varanasi, India

To explore the importance of brain neurotransmitters in the rodent
model of focal cerebral ischemia, we evaluated the effects of Piroxicam, a
nonsteroidal anti-inflammatory drug (NSAID) on extracellular brain
 glutamate and γ-aminobutyric acid (GABA) release, survival time and
neuronal cell death. Focal cerebral ischemia led to neuronal infarction
and also compromised intrinsic antioxidant status. Thirty minutes pre-
administration of Piroxicam (10 mg/kg b.w) showed a significant
(P < 0.01) reduction in cerebral infarct volume and potentiation of
the intrinsic antioxidative status as well. Further, high performance
liquid chromatography assay was performed to measure changes in
extracellular concentrations of neurotransmitters which were found to
be 0.519 ± 0.44 pmol/mg; 1.18 ± 0.28 pmol/mg; 0.63 ± 0.21 pmol/mg
respectively while hydroxy radical (OH) adduct of salicylate in the
frontal cortex and striatum in normal, stroke and drug treated rat models
were found to be 0.261 ± 0.06 pmol/mg; 0.68 ± 0.52 pmol/mg; 0.401 ±
0.68 pmol/mg respectively. After the onset of cerebral ischemia, the
extracellular level of glutamate in rat brain increases continuously as
compared to that of control group. However, by administration of
Piroxicam in stroke rat, the elevated extracellular glutamate was found
to be significantly (P < 0.05) reduced. The data indicates for the
first time that Piroxicam, a NSAID attenuates extracellular glutamate
release and also reduces neuronal cell death due to reduction in
oxidative stress in cerebral ischemia.

Hemichorea development after stroke
Ministry Okmeydani Training and Education Hospital, İstanbul, Turkey

Hemichorea is uncommon in cerebrovascular events. Its appearance is
in relation to the involvement contralateral of the basal ganglia and
thalamus. The first patient we presented was a 71-year-old female and
she developed an acute onset right hemichorea. Her cranial MR imaging
(MRI) showed a right putaminal infarction. The second patient was a
70-year-old female presented with left hemichorea that developed
15 days ago before admission. Her cranial MRI revealed a right basal
ganglia infarction. The third patient was a 57-year-old male with acute
onset left hemichorea. His cranial MRI revealed infarction of right
thalamus and caudate nucleus. The fourth patient was a 67-year-old
female with right hemichorea as a result of a thalamic haematoma.
The pathophysiology of the vascular chorea was discussed by the clinical
and imaging findings in these four patients.

Aetiopathogenesis of cerebral ischemia in young Turkish patients
C. Emir1, S. Çelikb, C. Orken2, S. Çelik3, F. Budak4, 1Health Ministry Okmeydani Training and Education Hospital, Istanbul, Turkey; 2Health Ministry Erenköy Training Hospital, Istanbul, Turkey

This study evaluates the risk factors and etiological spectrum in young stroke patients (aged 45 or younger).

Methods: Risk factors and aetiology of cerebral ischemia were retrospectively investigated in 230 patients (age ranges 9–45), admitted to our Neurology Unit with cerebral transient ischemic attacks (TIA) or infarction. 230 consecutive patients were divided into two groups according to their ages. Group I consists of patients whose age ranges 9–30 and in Group II, age range was 30–45.

Results: Hypertension, hyperlipidemia, smoking were the most common risk factors. Atherosclerosis was the leading etiology occurring in group II (35%) and vasculopathy was markedly high in group I (23%). In addition cardiac embolism was determined in 20% of all cases. Among these cases cardiac valve disease (58%), atrial fibrillation (16%) and ischemic heart disease (27%) were determined by the investigation methods.

Conclusion: The most striking finding of our study was the high frequency of cardiac valve disease in young adult ischemic strokes in our country when compared with the previous reports in the literature.

Predictors of mortality in patients with craniocevical artery dissection
Y. Kaplan1, H. Celika, O. Kamisl1, S. Kamisl1, S. Altunayar1, S. Yologlu2, C. Ozcana3. 1Neurology, Inonu University, Malatya, Turkey; 2Biostatistics, Inonu University, Malatya, Turkey

Background: Dissection of the carotid (CAD) or vertebral (VAD) artery is a major cause of ischemic stroke in young adults. The prognosis varies and the dissection can range from asymptomatic to causing a profound neurological deficit and death. Little is known of the predictors of mortality in these patients.

Objectives: The aim of the study was to investigate the predictors related to mortality in patients with craniocevical artery dissection.

Material and methods: We reviewed retrospectively all patients diagnosed with CAD or VAD admitted to our clinic between January 2000 and January 2013 and included 67 such patients in the study. Age, gender, modified Rankin Scale (mRS) prestroke and at time of admission, clinical presentation of dissection, location of dissection, vascular risk factors, and length of hospital stay were considered mortality-related prognostic factors. Of the 67 patients, 12 (17.9%) died: 5 (7.46%) patients with CAD and 7 (10.44%) with VAD. The patients were divided into four subgroups: surviving patients with CAD, dying patients with CAD, surviving patients with VAD, and dying patients with VAD. Then, surviving-CAD versus dying-CAD and surviving-VAD versus dying-VAD compared according to prognostic factors.

Results: Disability at admission (mRS 3–5) was significantly higher in dying-CAD than surviving-CAD. Comparing dying-VAD with surviving-VAD, the mean age, disability at admission (mRS 3–5), presentation with stroke, and dissection location in intracranial vertebral artery were significantly higher in dying-VAD.

Conclusion: Identifying predictors of mortality is important for starting appropriate treatment and setting targets in the management of patients with dissection.

Heat stress induces selective cell damage in the cerebellum. An experimental study using immunohistochemistry and ultrastructural investigations in rats
H.S. Sharma1, D.F. Muresanu2, A. Sharma3. 1Surgical Sciences, Anesthesiology & Intensive Care Medicine, Uppsala University Hospital, Uppsala, Sweden; 2Clinical Neurosciences, Medicine & Pharmacy Cluj-Napoca, Cluj-Napoca, Romania

The possibility that thermal stress caused by systemic heat exposure may lead to a specific cellular damage in the cerebellum was examined in young rats (age 8–9 weeks). The cell changes in the cerebellum were examined using immunohistochemistry and light and electron microscopy.

Subjection of conscious young animals to a 4-h HS resulted in marked hyperthermia (41.6 ± 0.45 °C). In these animals the cerebellum showed pronounced and selective cellular damage in the Purkinje cell layers and granule cells. This damage was most marked in specific regions of the vermis and in the lateral cerebellar cortices. Deeper cerebellar nuclei also showed marked cell damage. Immunohistochemistry showed profound upregulation of GFAP, S-100 and Vimentin indicating abnormal glial cell reactions in the cerebellum. Marked decrease in MBP suggests profound degradation of myelinated nerve fibers. Electron microscopy showed marked damage to the cerebral endothelium. Lanthanum an electron dense particle was found to be present within the endothelial cells, basal lamina and in vesicular profiles. Nerve cells showed abnormal reactions, edema and distortion in many parts of the cerebellum. Loss of Nissl substance was much pronounced in several regions of the cerebellum. These nerve, glial and myelin cell changes were less evident in animals subjected to similar heat stress under anesthesia. These observations for the first time show that cerebellum is vulnerable in heat stress and this selective vulnerability is somehow associated with a specific breakdown of the BBB permeability.

Cardiac arrest alters regional ubiquitin levels in the porcine brain. Neuroprotective effects of methylene blue
H.S. Sharma1, R. Patnaik2, A. Sharma1, L. Wiklund1. 1Surgical Sciences, Anesthesiology & Intensive Care Medicine, Uppsala University Hospital, Uppsala, Sweden; 2National Institute of Technology, School of Biomedical Engineering, Banaras Hindu University, Varanasi, India

Ubiquitin is recently implicated the central nervous system (CNS) diseases. Overexpression of ubiquitin occurs in stroke, trauma, Alzheimer’s disease, Parkinson’s disease and Huntington’s disease in the areas associated with neuronal damages. However, the role of ubiquitin in brain pathology or neuroprotection is still not well known. Cardiac arrest (CA) and subsequent cardiopulmonary resuscitation induces widespread brain damages. In a porcine model of CA our laboratory showed marked neuronal, glial and myelin damages in
the cortex, hippocampus, cerebellum, thalamus, hypothalamus and the brain stem following 30 to 180 min after return of spontaneous circulation (ROSC) in pig model. Interestingly these neuropathological changes in CA were considerably reduced by pretreatment with methylene blue (MB), an antioxidant dye following 60 min to 180 min after ROSC. Thus, it would be interesting to see whether ubiquitin levels are also altered after CA and/or ROSC in identical brain areas and this effect could be further influenced by MB treatment.

Our observations using ELISA showed selective and specific increase in ubiquitin levels in most of the above brain areas immediately after untreated CA and progressively from 30 min to 180 min after ROSC. Cerebellum and cortex showed most pronounced increase in ubiquitin levels. Pretreatment with MB during cardiopulmonary resuscitation significantly attenuated ubiquitin levels from 60 min on to 180 min after ROSC. These observations suggest that increased levels of ubiquitin are related with brain ischemic pathology and a reduction in this level is associated with neuroprotection in CA, not reported earlier.

Indian Aphasia battery: Tool for specific diagnosis of language disorder post stroke
A. Nehra1, D. Pershad5, V. Sreenivas1, 2Clinical Neuropsychology, All India Institute of Medical Sciences (AIIMS), New Delhi, India; 1Clinical Neuropsychology, Department of Psychiatry, Ex-Post Graduate Institute of Medical Education & Research, Chandigarh, New Delhi, India; 3Department of Biostatistics, All India Institute of Medical Sciences (AIIMS), New Delhi, India

Background & aims: Aphasia is a language disorder which may disrupt an individual's functioning. To plan a mode of therapeutic/rehabilitative work, it is important to assess problems from neuropsychological perspective focussed on remediation of the impaired processes or compensation via the intact processes or both (Hillis AE, 2001). It targets sequence set of representations (stored visual, orthographic, semantic, phonological information) for solving particular task (e.g. naming). Since no test available to assess north Indian population with specific colloquial expression thus, need was felt to assess these patients. Hence, the aims are to:
1. Develop standardized neuropsychological test to diagnose the presence, degree, specificity & type of aphasic disorders.
2. Assess all language areas, from perceptual modalities (auditory, visual, & gestural), processing functions (comprehension, analysis, problem-solving) to response modalities (writing, articulation, manipulation) for specific prognosis.

Method: The study had 2 phases. 1st phase: development of test material & 2nd phase: administration on aphasics (A), normals (N) & other than aphasics (OA). The test consisted of 5 sections, viz., Acoustic Problems (5), Speech & Language Problems (10), Simple Mathematical Problems (3), Perceptuomotor & Writing Problems (5) & Visual & Verbal Problems (3). All sub-sections were in auditory & orthographic mode. The test was administered on 122 (A), 74 (N) and 64 (OA) aged 18–81 years.

Results: The test was 75% sensitive to (A) while 72% sensitivity to (OA) on the entire task in all modalities.

Conclusion: It can be used for assessment of specific aphasia for planning better prognosis along with other pharmacological treatment, thereby improving quality of patient's life.

Superficial siderosis of the central nervous system: A post-mortem 7.0 tesla magnetic resonance imaging study with neuropathological correlates
J. De Reuck. Université Lille Nord de France, Lille, France

Background: This study aims to elucidate the pathological substrate of superficial siderosis (SS), regarded as a radiological marker of cerebral amyloid angiopathy (CAA). The present study investigates the prevalence of SS and underlying lesions with 7.0 T MRI in post-mortem brains of patients with various neurodegenerative and cerebrovascular diseases.

Materials and methods: Hundred-twenty-post-mortem brains were examined with 7.0 T MRI and their neuropathological correlates. The MRI examination consisted of a positioning, a T2 and a T2*-weighted sequence of coronal sections of a cerebral hemisphere and horizontal sections through pons and cerebellum.

Results: Forty-five brains (37.5%) with 83 separate zones of SS were detected, including 25 zones of disseminated siderosis (macro-SS) and of 58 areas of focal siderosis, restricted to less than 3 sulci (micro-SS). Macro-SS was associated with 14 lobar hematomas and 11 cerebral infarcts (p = 0.64), while micro-SS was associated with 19 micro-bleeds and 39 micro-infarcts (p < 0.001). Comparison of the 15 CAA to the 30 non-CAA brains showed that macro-SS was due to a lobar hematoma in 53% in the former compared to 3% in the latter group (p = 0.003). Micro-SS was due to a micro-bleed in 7% in the CAA brains and to 40% in the non-CAA brains (p = 0.03).

Conclusions: SS is due to cerebral bleeds as well as to cerebral infarcts. It should not to be considered as an additional Boston criterion for CAA. Macro-SS is mainly related to lobar hematomas while micro-SS is mainly due to cortical micro-infarcts.

Factors associated with remote seizure in cerebral vein and dural sinus thrombosis
V. Davoudi, K. Keyhanian, M. Saadatnia. Isfahan Neurosciences Research Center, Isfahan University of Medical Sciences, Isfahan, Iran

Introduction: Whether initiating anticonvulsants treatment for all cerebral vein and sinus thrombosis patients or to wait for a seizure before starting the treatment is a vital question in management of cerebral vein and sinus thrombosis. Here in this study we wanted to define the possible risk factors of presenting, early and remote seizures in cerebral vein and sinus thrombosis patients.

Materials and methods: We have designed a prospective cohort study from April 2007 to April 2012, in 94 patients in al-Zahra Hospital, Isfahan, Iran. On admission, complete neurologic examination and further brain imaging were performed to evaluate probable risk factors for seizure. To recognize seizure predictors, we compared demographic, clinical and imaging factors among patients with or without presenting early and remote seizures.

Results: Among 94 patients, 32 ones (34%) have experienced at least one seizure on the basis of cerebral vein and sinus thrombosis. Bivariate analysis has shown significant association with remote seizure in patients with low consciousness, supratentorial lesion, lesion in occipital, temporal and parietal lobe, thrombophila, seizure in acute phase and sigmoid sinus thrombosis. In logistic multiple regression analysis, there was no factor who can predict remote seizure.
Conclusions: Our results demonstrate that seizure in acute phase is the most significant factor in relation with remote seizure. Parenchymal lesion in supratentorial area was also found to be considerably associated with both early and remote seizures. But there was no factor predicting seizure in long-term. Larger studies should be performed to study predicting factors for early and remote seizures.

Nocturnal blood pressure regulation in stroke patients with sleep apnea — Impact of etiology, comorbidity, medication and cerebral lesion
M.T. Saletu, S. Kotzian, I. Schiefer, M. Hillberger, J. Spatt. Neurorehabilitation, NRZ Rosenhögl, Vienna, Austria

Background: In clinical routine, stroke patients with sleep apnea (SA) show a different blood pressure (BP) response to respiratory events. The aim of the study was to evaluate the impact of age, comorbidity, medication, etiology and location of cerebral lesions on nocturnal (BP) in stroke patients with SA.

Methods: Respirographic sleep studies were performed in all stroke patients that underwent neurorehabilitation. Their systolic BP was determined by means of a non-linear algorithm and an individual one-point calibration of the pulse transit time obtained with a cuff-based BP measuring (SOMNOmedics GmbH, Germany). The number of systolic rises (defined as >15 mmHg) was scored. Risk factor evaluation, Oxfordshire Community Stroke Project (OCSP) and TOAST classification were performed.

Results: Out of the 203 stroke patients (age 58 ± 12) enrolled in the study, 38% were suffering from SA (AHI > 15). They showed a median of 47 ± 38 BP rises per hour, with a median rise by 19 ± 3 mmHg and a median nocturnal systolic BP of 138 ± 26 mmHg. In 7 patients, no apnea-related BP rises were observed (non-responders). Etiologically, they showed an equal distribution of small-artery occlusion (3), large-artery atherosclerosis (1), stroke of other determined (1) or undetermined cause (1), cardioembolism (1) and cerebral hemorrhage (1). There were neither differences in OCSP vessel lesions nor other influence factors for the non-responders.

Conclusion: 9.1% of stroke patients with SA show an atypical blood pressure response to apneas (non-responders). The missing blood pressure response doesn’t seem to be correlated with age, comorbidity, clinical symptoms, medication, etiology, or cerebral lesion.

Osteoporosis may be a predictor of silent cerebral infarct and white matter change in community-dwelling healthy adults: Present project
S.-H. Suk, S. Kim. aNeurology, Wonkwang University Sanbon Medical Center and Ansan Municipal Geriatric Hospital, Gunpo-si, Seoul, Republic of Korea; bNeurology, Sungae Hospital, Seoul, Republic of Korea

Background: Loss of bone and muscle mass, fall and fractures are common conditions after stroke. Possible association between reduced bone density and cognitive impairment in postmenopausal women is well recognized. However, the relationship between bone mass loss and silent infarcts and cerebral white matter changes remains unknown.

Methods: Bone densitometry measured by Dual-energy X-ray absorptiometry and brain CT scan were performed for 650 subjects (458 female, mean age 63 ± 7.8 years; 192 male, 61.5 ± 8.5 years) among 650 stroke- and dementia-free adults older than 50 years between January 2009 and December 2010. Assessment of vascular risk factors and physical examination by in-person interview and were also taken.

Results: We did analyze 646 subjects who have taken brain CT scan and BMD study. In unadjusted analysis, the odds ratio (OR) for silent cerebral infarcts and/or cerebral white matter changes in men with osteoporosis was 3.8 (95% CI, 1.62–8.86; p = 0.002) and 2.2 (95% CI, 1.35–3.53; p = 0.002) in women as compared to subjects with normal bone density. Even after adjustment for age, education, hypertension, DM, hypercholesterolemia, and current smoking, the OR was 3.8 (95% CI, 1.43–10.3; p = 0.008) for men and 1.9 (95% CI, 1.10–3.18; p = 0.02), for men.

Conclusion: These findings suggest that bone mass loss may be a predictor of atherosclerotic vascular lesions in community-dwelling, apparently healthy men as well as women. Severe bone mass loss among men may be more harmful than among women. Further exploration of relationship between bone mass loss and atherosclerotic cerebral lesions is needed.

The effect of lithium in enhancing post-stroke motor recovery: A double-blind, placebo-controlled, randomized clinical trial
S.A. Sajedi, S.E. Mohammadianinejad, N. Majdinasab, F. Abdollahi, M. Masoudi Moqaddam, F. Sadr. aDepartment of Neurology, Ahvaz Jundishapur University of Medical Sciences, Ahvaz, Iran; bDepartment of Internal Medicine, Ahvaz Jundishapur University of Medical Sciences, Ahvaz, Iran

Background: Evidences from cultured cells and animal models of ischemia suggested that lithium has neuroprotective and neurotrophic effects and may play a desirable role in reducing infarct volume and improving the brain insults from stroke.

Objective: The aim of the study was to evaluate the efficacy of lithium in motor recovery after ischemic stroke with focus on distal upper limb motor recovery.

Material and methods: This was a placebo-controlled, double-blind, and randomized clinical trial on 80 patients with first ever stroke, allocated randomly in lithium 300 mg/twice daily or placebo. Treatment was initiated 48 h after stroke and continued for 30 days. Modified National Institute of Health Stroke Scale (mNIHSS) and hand subsection of Fugl-Meyer Assessment (hFMA) were used to evaluate impairment on the 5th and 30th of treatment.

Results: 66 subjects completed the study, including 32 subjects in lithium and 34 in placebo group. In general, there were no statistically significant difference in the improvement in mNIHSS (p = 0.40) and hFMA (p = 0.07) after 30 days. However, a subgroup analysis showed that patients with cortical strokes in lithium group had significantly better improvement in both mNIHSS and hFMA in comparison to placebo group (p = 0.003). About 44% (n = 14) of patients in lithium group, mainly from cortical stroke subgroup, regained more than 25% of full function based on hFMA, while this rate in placebo group was 14.7% (n = 5) (p = 0.009).

Conclusion: We observed some promising effect from lithium in enhancing recovery in cortical sub-group of ischemic stroke. Larger trial with more cortical stroke patients is needed to better investigate this effect.

Shoulder-hand syndrome in hemispheric stroke

M.A. Hannan, M.M. Sabekab, M.B.A. Miaha
Department of Neurology, Bangabandhu Sheikh Mujib Medical University, National Institute of Neuro-Sciences and Hospital, Dhaka, Bangladesh; Department of Neurology, National Institute of Neuro-Sciences and Hospital, Dhaka, Bangladesh

Introduction: Shoulder-hand syndrome (SHS) is the post-stroke pain in the paretic limb characterized by regional pain, sensory changes (alldynia), abnormalities of temperature and sudomotor activity, oedema formation, abnormal skin color changes that usually occur between two weeks to five months after stroke.

Incidence: 1.5%–70%.

Clinical criteria: Pain-spontaneous, alldynia, hyperalgesia. Motor disturbances: tremor, weakness, lack of muscular coordination, decreased range of motion, myoclonus, dystonia. Skin changes: Color changes, sudomotor abnormalities, temperature dysregulation, oedema, nail growth, anxiety, depression.

Possible causes: Aetiology of stroke, side affected, sensory impairment, spasticity, shoulder subluxation, the severity and recovery of motor deficit, Phenobarbital use, etc.

Method/objective: The aim of the study was to review the clinical features of SHS.

Study type: Cross-sectional study.

Study Place: Neurology department, Bangabandhu Sheikh Mujib Medical University, Dhaka.

Study Period: July 2009–June 2011 (2 years).

Subjects: Stroke with SHS.

Sample size: thirty cases. Sampling technique: Convenient sampling.

Data collection: By interviewed questionnaire, SHS was diagnosed by clinical criteria.

Result: Age range of the cases was 45–75 years. SHS was more common in 56–65 years of age. Clinical features were Weakness (96.7%), Spontaneous Pain (93.3%), Oedema (86.7%), Raised temperature (63.3%), Tremor (36.7%), Hyperalgesia (33.3%), Color change (30%), Dystonia (30%), Normal temperature (30%), Alldynia (26.7%), Sudomotor change (23.3%), Myoclonus (10%), Decreased temperature (6.7%).

Conclusion: SHS is not very uncommon in our clinical setting. This study aimed at reviewing the clinical features of SHS after hemispheric stroke. It is not related to any type of stroke or any side of stroke affected.

doi:10.1016/j.jns.2013.07.693

Predicators and causes of hospital readmissions after acute ischaemic stroke: Local data from a hospital-based registry

A.C.Y. Chan, Tuen Mun Hospital, Hong Kong, Hong Kong

Background: Acute ischaemic stroke patients have significant neurological deficits, which may lead to increased hospital readmission rates during the first year after index stroke.

Objective: This study looks for the predictors of hospital readmission within the first year of discharge for index ischemic stroke, and investigates for the common causes of hospital readmission.

Methods: 1797 patients were admitted to our hospital from January 1, 2009 to December 31, 2009 for acute ischaemic stroke. Four hundred patients were sampled by simple randomization and they were dichotomized into those with hospital readmission and those without. Their demographics were analyzed with SPSS 16.0, and their causes and times to next hospital readmission were also investigated.

Results: A total of 400 patients were studied in detail, but after exclusion, 334 patients were recruited for this study. 168 patients were found to have hospital readmission within 1 year of discharge for index acute ischaemic stroke. The predictors of hospital readmission include elderly patients with age <72 years, cardioembolic stroke, diabetes mellitus, complications occurring during index admission, and NIHSS > 5. Commonest causes of hospital readmission include infection and recurrent stroke.

Conclusion: Certain patients who are admitted to hospital for acute ischaemic stroke are at increased risk of readmission after the index event. Risk factors for early readmission, i.e. after the first 30 days, and for late readmission, i.e. from the 31st day onwards, can be identified early and readmissions can be prevented. This may minimize the cost brought about to the health care burden.

doi:10.1016/j.jns.2013.07.694

Electrocardiographic maximal P-wave duration in patients with acute ischemic stroke: A novel yardstick in diagnosing ischemic-stroke subtypes

M. Sugie, Y. Shimizu, K. Itaya, Y. Ohnaka, Y. Kamiya, H. Ichikawa, Neurology, Showa University Fujigaoka Hospital, Kanagawa, Japan

Background: P-wave parameters of electrocardiogram (ECG) have associations with atrial fibrillation (AF), myocardial ischemia, or systemic embolism.

Objective: We aimed to evaluate whether maximal P-wave duration (P-max), one of the P-wave parameters, provides additional diagnostic information in determining ischemic-stroke subtypes.

Patients and methods: We enrolled 160 acute stroke patients who showed sinus rhythm on admission. The P-max was defined as the greatest P-wave duration among all 12-leads of ECG measured by calipers manually. The patients were classified into 3 groups by the P-max value; group 1: <80 ms (n = 33), group 2: 90–110 ms (n = 73), and group 3: >120 ms (n = 54). In these 3 groups, clinical background, ECG findings during admission, and ischemic-stroke subtypes were compared. The ischemic-stroke subtypes were classified into large-artery atherosclerosis (LAA), cardioembolism (CE), small-vessel occlusion (lacunar), and others with determined etiology.

Results: In post hoc analysis, chronic kidney disease, development of premature atrial contraction and paroxysmal AF, and dilation of left atrial dimension on echocardiogram were significantly more frequent in group 3, compared with the other groups. In chi-square test, group 3 had CE more frequently than other ischemic-stroke subtypes (P < 0.001). Meanwhile, groups 1 and 2 had CE less frequently than the other ischemic-stroke subtypes (P = 0.04 and 0.006, respectively). In contrast, there was a tendency that the lacunar was more frequently in groups 1 (P = 0.07).

Conclusion: The P-max in acute stroke patients who show sinus rhythm on admission may be a simple, convenient and practical yardstick in diagnosing ischemic-stroke subtypes.

A case of relapse and remitting cerebral infarction associated with polycythemia vera
Department of Neurology, Kyung Hee University Hospital, Seoul, Republic of Korea; Department of Neurology, SM Christianity Hospital, Pohang, Republic of Korea

Background: Polycythemia vera (PV) is a chronic myeloproliferative disorder characterized by increased production of leukocytes, erythrocytes and platelet. We present a case of relapse and remitting ischemic stroke associated with PV, which resulted in aggravation of infarction by hematologic abnormalities.

Objective: The aim of the study was to present a case of relapse and remitting cerebral infarction with PV and discuss the relationship between aggravation of ischemic stroke and hematologic abnormalities.

Patients and methods: A fifty-two-year-old woman visited our department of emergency with transcortical sensory aphasia. Her brain MRI and MR angiography (MRA) showed the acute ischemic stroke in left pterietothemal lobe and mild stenosis of ipsilateral middle cerebral artery (MCA). She was diagnosed with PV according to WHO criteria at the first hospitalization. She was hospitalized five times for recurrent ischemic stroke during about 3 month. The brain DWI, MRA and laboratory test were evaluated at each hospitalization.

Results: The patient’s neurological symptoms got worse and MRA revealed the progression of stenosis and occlusion of proximal left MCA finally. While the level of hemoglobin and hematocrit has been improved in her laboratory test, but the white blood cell (WBC) count and platelet count have been increased despite continued treatment of PV.

Conclusion: In this case, increased WBC and platelet count may play an important role in formation of local thrombus and contribute to the progression of large artery stenosis. Unlike the other cases, we demonstrate the relationship between aggravation of intracranial artery stenosis and hematologic deterioration by serial MRA and laboratory test.

Effects of uric acid levels on outcome in severe ischemic stroke patients treated with intravenous Rtpa
Department of Neurology, Kyung Hee University Hospital, Seoul, Republic of Korea; Department of Neurology of SM Christianity Hospital, Pohang, Republic of Korea

Background: Uric acid (UA) has been known to be a neuroprotective factor by increasing the risk of cardiovascular events. We studied the influence of UA levels in patients with acute ischemic stroke after thrombolytic therapy.

Objective: To confirm the association of admission UA level with clinical outcome in intravenously thrombolysed patients stratified by stroke severity.

Patients and methods: Two hundred eighteen consecutive patients treated with intravenous thrombolysis were included for this analysis in our prospective stroke registry. Early improvement was defined as an improvement from baseline in the National Institutes of Health Stroke Scale (NIHSS) score by ≥ 4 points 24 h after stroke onset and excellent functional outcome was defined as 3-month modified Rankin Scale score by using responder analysis.

Results: There was no significant relationship between serum UA levels and early improvement or excellent functional outcome in total group. However, in the patients with severe baseline stroke deficits (NIHSS score ≥ 15), patients with higher tertile of UA levels had a significant association with excellent functional outcome (p = 0.003). Excellent functional outcome in patients with severe baseline stroke deficits might be associated with serum UA levels particularly in men but not in women.

Conclusions: Increased serum UA levels are significantly associated with better outcome in severe ischemic stroke patients treated with intravenous thrombolysis, but the effectiveness of UA can differ by initial stroke severity and gender.

Characterization of cerebral venous thrombosis in a stroke unit — Cross-sectional study
Department of Neurology, Centro Hospitalar de Setúbal, Setúbal, Portugal

Background: Cerebral venous thrombosis (CVT) is the least common form of acute cerebrovascular disease, 0.5% of all strokes. Diagnosis may be delayed due to large spectrum of clinical symptoms and nonspecific signs on neuroimaging.

Objective: The aim of the study was the characterization of CVT cases diagnosed in our stroke unit.

Patients and methods: 13 patients with CVT admitted in our department from January 2008 to December 2012 were assessed through retrospective, epidemiological characteristics, clinical features, risk factors and prognosis.

Results: Of the 13 patients with confirmed CVT, 10 were female, aged between 21 to 57 years (average 38.25). We found thrombotic risk factors in 10 patients: oral contraceptives use (n = 4), infection (n = 2) and thrombophilia (n = 2). The diagnosis was made by MRI in 11 cases, 1 by brain Veno-CT and another by Angiography. Median time from onset of symptoms to diagnosis was 2 days. In 5 patients, multiple sinuses were affected; the most frequent was lateral sinus (n = 7), followed by superior sagittal sinus (n = 6). Headache, with or without associated deficits, was the most common symptom, occurring in 12 patients. Six patients had a good outcome with complete recovery at early stage of treatment and the rest remained with mild disability.

Conclusion: The data of our patients were similar to literature. However, in our series no deaths occurred and the prognosis was good. This can be explained by rapid diagnosis (only 2 days, less than other studies) and treatment initiation. CVT should be considered in diagnosis of secondary headache even in the absence of other symptoms.

Hematoma size but not Gcs score on admission predicts in-hospital case fatality in the very elderly. A case control study
Department of Neurology, Medical University of Warsaw, Warszawa, Poland; Department of Neurology, King’s College Hospital, London, UK; Department of Informatics and Biostatistics, Medical University of Warsaw, Warszawa, Poland
**Background:** Despite extensive investigations in the stroke medicine, still there is little known about the course of spontaneous intracerebral haemorrhage (SICH) in the very elderly.

**Material and methods:** A retrospective study of 231 consecutive cases diagnosed with SICH was carried out in the Department of Neurology at the Medical University of Warsaw. A case control study included patients with SICH aged ≥80 years. Data on risk factors, clinical presentation, neuroimaging and outcomes were collected and statistically analysed.

**Results:** The whole studied population consisted of 231 patients (52% male): 66 aged ≥80 years and 165 < 80 years of age. There were more female cases among the very elderly (65% vs 46%, p = 0.009). Hypertension was the most common risk factor in both age groups (p = 0.21). Coronary artery disease and atrial fibrillation were statistically more frequent in the elderly (CAD:p < 0.001; AF:p < 0.001). No significant differences were observed in GCS score or the SICH site. Larger hematoma size (3.6 cm vs 3.2 cm, p = 0.04) and more frequent occurrence of intraventricular extension (IVH) (41% vs 24%, p = 0.05) were found in patients aged ≥80 years. The mortality rate was higher in the older patients (in-hospital mortality: 40.9% vs 15.2%, 30-day mortality: 33.3% and 13.3%; both p = 0.02). Hematoma size predicted in-hospital case fatality in the very elderly (p = 0.005), whereas hematoma size and GCS score had predictive value in patients aged ≥80 years (p = 0.001 and p = 0.017, respectively).

**Conclusion:** The very elderly patients with SICH are a high risk group as far as clinical outcomes and prognosis is concerned. Hematoma size seems to be the most powerful parameter in predicting early mortality. Further prospective studies are needed to identify prognostic factors in this subpopulation.

resolution in vivo. The aim of the study was to explore the possibility of the rat mesenchymal stem cells (MSCs) labeled with standard contrast agents (Gd-DTPA) for stem cell tracking. **Methods:** MSCs from bilateral femur of rats were cultured and propagated. Intracellular uptake of Gd-DTPA was achieved by using a non-liposomal lipid transfection reagent (Effectene) as the transfection agent. Electron microscopy was performed to detect the distribution of Gd-DTPA particles in MSCs, and labeling efficiency of Gd-DTPA particles on MSCs was evaluated using spectrophotometric. Viability and proliferation of labeled MSCs were evaluated using MTT assay. Labeled MSCs were detected with T1-weighted MR imaging in vitro and in rat brain. **Results:** The presence of Gd-DTPA particles inside the MSCs was definitely detected by transmission electron microscopy. Labeling efficiency was highly. There was no difference in viability and proliferation between the labeled and unlabeled confirmed by MTT values of light absorption. The labeled MSCs demonstrated the high signal intensity on T1-weighted MRI in vitro and in rat brain. **Conclusion:** Rat MSCs can be labeled with Gd-DTPA particles without changing the cell viability and proliferation. Obviously labeled MSCs can be imaged in vitro and vivo. Gd-DTPA shows no evident adverse effect on the function of labeled MSCs. Gd-DTPA can be used for the MR imaging tracking of labeled MSCs.

**Epidemiology of stroke risk factors in Belarus**  
H. Lushchyk, S. Likhachev. Neurological Department, State Institution ‘Republic Scientific Practical Centre of Neurology and Neurosurgery’, Minsk, Belarus

**Background:** Stroke is one of the leading causes of death. Death from stroke in people of working age is particularly alarming. Studying the prevalence of stroke risk factors will help develop an optimal system for prophylaxis thus reducing morbidity and mortality from stroke.  
**Objective:** The aim of the study was to study prevalence of stroke risk factors among people of working age.  
**Patients and methods:** Using a specially developed standardized questionnaire card we carried out the screening of open population. We examined 189 people aged between 40 and 62 years (mean age 51.68 years) of one of the district polyclinics in Minsk, including 135 women (71.43%) and 54 men (28.57%).  
**Results:** The following risk factors were revealed:  
- Overweight – 128 people (67.72%), including 66 people with a BMI of 26–29 (34.92%) and 62 people with a BMI ≥30 (32.8%);  
- Arterial hypertension – 87 people (46.03%), including 33 people with hypertensive crisis in medical history;  
- Family history of hypertension before the age of 60 years – 98 people (51.85%);  
- Hypodynamia – 71 people (37.57%);  
- Smoking – 46 people (24.34%);  
- Coronary heart disease – 35 people (18.52%);  
- Family history of stroke/heart attack before the age of 60 years – 31 people (16.4%);  
- Diabetes mellitus – 11 people (5.82%);  
- Alcohol abuse – 7 people (3.7%).  
**Conclusion:** The most common stroke risk factors in the studied population are overweight, hypertension and hypodynamia. Particularly disturbing is the fact that only 44 people (50.57%) with hypertension regularly take antihypertensive medication.

**The prevalence and association with cerebrovascular risk factors of cerebral microbleeds in Korean ischemic stroke patients**  
E.J. Choi, T.-W. Kim, J.-S. Kim. Neurology, Seoul St. Mary’s Hospital, The Catholic University of Korea, Seoul, Republic of Korea

**Background and Purpose:** Advanced age, presence of intracerebral hemorrhage or ischemic stroke, dementia, hypertension, and use of antithrombotic therapy have been reported to be associated with a higher risk of cerebral microbleeds. In addition, the severity of white matter hyperintensity (WMH) was known to be associated with cerebral microbleeds. We tried to investigate the frequency and the number of microbleeds in Korean ischemic stroke patients and risk factors as well as their relationship to microbleeds.  
**Methods:** Four hundred subjects (mean age ± SD: 66.5 ± 13.5) visited for acute cerebral infarctions or transient ischemic attacks were enrolled in this study. For each subject, we researched the baseline demographic characteristics, cerebrovascular risk factors, and the number and localization of the microbleeds or WMHs.  
**Results:** The prevalence of microbleeds in this study was 31%. We revealed that male gender, history of heart disease and WMH acted as burdens of microbleeds. After regional subdivision, hypertension was a risk factor for microbleeds especially located in basal ganglia of human brain. Regardless of the location of microbleeds, we understood that WMH was considerably correlated with microbleeds.  
**Conclusion:** A higher prevalence of microbleeds was proved in the Korean ischemic stroke patients than Caucasians. Also, we found that male or WMHs might be the risk factors for microbleeds. Furthermore, hypertension was a risk factor of the microbleeds existed in basal ganglia. WMHs were one of the most important risk factors for microbleeds in spite of bleeding site.

**Clinical characteristics of stroke patients in the Northern Thailand**  
S. Kosachunhanun*, N. Tipayjak*, A. Khunkumb*: *Neurology, Chiang Mai Neurological Hospital, Chiang Mai, Thailand; †Research Unit, Chiang Mai Neurological Hospital, Chiang Mai, Thailand

**Background:** Acute stroke required emergency management.  
**Objective:** This study aimed to analyze the clinical characteristics and management of stroke in the Northern Thailand.  
**Material and methods:** We interviewed patient/relative and analyzed the data of the acute stroke patients admitted to twelve government hospitals in the Northern Thailand during October 2010 to September 2012.  
**Results:** Total of 802 acute stroke patients were recruited, mean age was 65 ± 13.5 years old, 54.1% were female. Most patients had regularly exercise and rarely consumed alcohol. Co-morbidities such as hypertension, diabetes, dyslipidemia were 57.2%, 15.6%, 18.4% respectively. Ischemic and hemorrhagic strokes were 79.7% and 20.3%, respectively. Clinical characteristics of the patients including BP, pulse, GCS, NIHSS, and blood tests were not different between ischemic and hemorrhagic strokes. Patients admitted to general ward were 73% and only 13.1% were admitted to stroke unit. Thrombolytic agent was given in 10.4% of the ischemic stroke patient. The reasons that this agent was not used were unavailable in the hospital for 24.5%, and 75.5% had contraindications including delayed onset
(37.9%). Bleeding complication from thrombolytic agent was 15.4%. Antithrombotic agents for secondary stroke prevention were subsequently used in 94.7% of ischemic stroke patients.

**Conclusion:** Hypertension was the most important risk factor in the Northern of Thailand. Majority type was ischemic stroke. Due to resource limitation, most of the patients were admitted to general ward. Thrombolytic therapy was given in minority of ischemic stroke patients, reasons apart from contraindication were unavailable and delayed onset. Improvement system of care is needed.

**Goal achievement of risk factor control for patient with ischemic stroke in the Northern Thailand**

S. Kosachunhanun, N. Tipayjak, A. Khunkum. 

**Background:** Stroke causes morbidity and mortality.

**Objective:** This study aimed to evaluate the goal achievement of risk factor control of ischemic stroke in the Northern of Thailand.

**Material and methods:** We analyzed the data of the ischemic stroke patients with more than 6 months of onset who regularly followed up during October 2010 to September 2012. The defined goal of the risk factor control was according to ASA 2006, and ADA 2008 in patient with diabetes.

**Results:** Total of 498 patients were enrolled, aged 66 ± 12.4 years old, and 52.1% were male. The proportion of the patients living in the city is 25.1% and 52.1% were male. The proportion of patient with BMI ≤ 25 kg/m² was 72%, regular exercise was 61.2%, and quit smoking or never smoking was 87.2%. Control of HT (SBP/DBP in DM vs. Non DM) was 77.6/91.2%, and 61.6/76.8%, respectively. Dyslipidemia; LDL ≤ 100 mg/dl, DM vs. non-DM was 48.1% vs. 44.7% and diabetes; FBS ≤ 120 mg% and Hba1C < 7.0% was 50.0%, and 31.3%, respectively.

**Conclusions:** Goal achievement of risk factor control for patients with ischemic stroke in the Northern of Thailand is relatively compatible with data from international studies but there is still a quality gap. These findings will be used to encourage participating hospitals to improvement stoke care.

**Transient ischaemic attacks in young adults**

V.K. Oranskaya, M. Barabanova, L.V. Shagal. 

**Background:** Transient ischemic attacks (TIAs) are risk factors for the future development of ischemic stroke.

**Objective:** To analyze predisposing factors of TIAs in young adults.

**Materials and methods:** 50 patients with TIA were examined, the 1st group consisted of patients under 30 years old (10%), the 2nd group consisted of 30–40 years old patients (18%), the 3rd group — 40–50 years old (62%), laboratory and neuroimaging studies were conducted.

**Results:** The risk factors of TIAs revealed in group 1 were: 35% — malformation of cerebral vessels, such as open Willis circle (anterior and posterior trifurcation, posterior communicating artery's aplasia); 20% — sugar diabetes with angiopathy; 20% — non-ischemic cardiac arrhythmias, 10% combined oral contraceptives intake, and 5% hyperhomocysteinemia. In group 2, 46% cerebral vessels malformation, 18% — non-ischemic cardiac arrhythmias, 9% — arterial hypertension (AH) and 9% — cerebral atherosclerosis. In group 3 — 42% AH, 30% — cerebral atherosclerosis, 22% — malformation of cerebral vessels and 6% — non-ischemic cardiac arrhythmias. 25% of patients had both atherosclerosis and other risk factors. Patients with TIA in anamnesis developed ischemic stroke in 60% (group 1), 67% (group 2) and 74% (group 3) of cases.

**Conclusion:** The appropriate screening for cerebral vessels’ malformations (as the major risk factor of TIA at the age under 40 years old), atherosclerosis, metabolic disorders and other risk factors is necessary for the TIA’s prophylaxis.

**Plasma neutrophil gelatinase-associated lipocalin and functional outcome in ischemic stroke**

**Background:** A range of circulating inflammatory reactants have been evaluated as biomarker candidates in acute ischemic stroke. However, no study has shown an additional value of circulating inflammation related proteins for the prediction of the patients’ functional outcome.

**Patients and methods:** At one week from ischemic stroke onset, we measured plasma levels of neutrophil gelatinase-associated lipocalin (NGAL) in 46 consecutive ischemic stroke patients. Protein levels were related to the occurrence of post-stroke infections and the patients’ modified Rankin Scale (mRS) at day 90 after stroke.

**Results:** Plasma levels of NGAL correlated significantly with the mRS at day 90. In predictive models for unfavourable (mRS 3–6) vs. favourable (mRS 0–2) outcomes which included the National Institutes of Health Stroke Scale on admission, the patients’ age, and thrombolytic therapy, the addition of NGAL significantly increased the area under receiver operating characteristics curves. Plasma NGAL levels did not add prognostic information when the occurrence of post-stroke infections was also included into the predictive models.

**Conclusions:** Elevated circulating NGAL levels one week following ischemic stroke are associated with worse functional outcomes at three months and reflect the occurrence of post-stroke infections.

**Plasma midregional pro-adrenomedullin improves prediction of functional outcome in ischemic stroke**

**Background:** No study has shown an additional value of circulating inflammatory reactant proteins for the prediction of the patients’ functional outcome.

**Patients and methods:** At one week from ischemic stroke onset, we measured plasma levels of midregional pro-adrenomedullin (NT-proADM) in 46 consecutive ischemic stroke patients. Protein levels were related to the occurrence of post-stroke infections and the patients’ modified Rankin Scale (mRS) at day 90 after stroke.

**Results:** Plasma levels of NT-proADM correlated significantly with the mRS at day 90. In predictive models for unfavourable (mRS 3–6) vs. favourable (mRS 0–2) outcomes which included the National Institutes of Health Stroke Scale on admission, the patients’ age, and thrombolytic therapy, the addition of NT-proADM significantly increased the area under receiver operating characteristics curves. Plasma NT-proADM levels did not add prognostic information when the occurrence of post-stroke infections was also included into the predictive models.

**Conclusions:** Elevated circulating NT-proADM levels one week following ischemic stroke are associated with worse functional outcomes at three months and reflect the occurrence of post-stroke infections.

doi:10.1016/j.jns.2013.07.709
Background: To evaluate if plasma levels of midregional pro-adrenomedullin (MR-proADM) improve the prediction of functional outcome in ischemic stroke.

Patients and methods: In 168 consecutive ischemic stroke patients, plasma levels of MR-proADM were measured within 24 h from symptom onset. Functional outcome was assessed by the mRS at 90 days following stroke. Logistic regression, receiver operating characteristics (ROC) curve analysis, net reclassification improvement (NRI), and Kaplan–Meier survival analysis were applied.

Results: Plasma MR-proADM levels were found significantly higher in patients with unfavourable (mRS 3–6) compared to favourable (mRS 0–2) outcomes. MR-proADM levels were entered into a predictive model including the patients’ age, NIHSS, and the use of recanalization therapy. The area under the ROC curve did not increase significantly. However, category-free NRI of 0.577 (p < 0.001) indicated a significant improvement in reclassification of patients. Furthermore, MR-proADM levels significantly improved reclassification of patients in the prediction of outcome by the Stroke Prognostication using Age and NIHSS-100 (SPAN-100; NRI = 0.175; p = 0.04). Kaplan–Meier survival analysis showed a rising risk of death with increasing MR-proADM quintiles.

Conclusions: Plasma MR-proADM levels improve the prediction of functional outcome in ischemic stroke when added to the patients’ age, NIHSS on admission, and the use of recanalization therapy. Levels of MR-proADM in peripheral blood improve the reclassification of patients when the SPAN-100 is used to predict the patients’ functional outcome.

Cardio-embolic causes of stroke in young adults
F.M. El-Mabruk. University of Benghazi, Benghazi, Libya

Background: Numerous aetiologies are responsible for stroke in young adults. A fundamental challenge in approaching a young stroke patient is that the cause of the stroke can be one of the many disease processes.

Objective: To determine the frequency of cardioembolic causes in young adults with acute stroke and compare this with other causes.

Methods: Prospective study of young adults presenting with acute first-ever stroke. The cases included people aged between 17 and 55 years, who had acute stroke, during thirty month period. The stroke mechanism was determined on patient’s characteristics, presenting clinical features, risk factors for stroke and the results of the investigations performed.

Results: One hundred and thirty five patients with first-ever stroke aged 17–55 years were identified. The mean age was 45.4 ± 9.0 (SD) for men and 39.8 ± (11.5 SD) for women. The presumed stroke aetiology for men and women was established in 72 (53.5%) patients. Of these, Cardio-embolic causes were presumed in 16/72 (22%). Atherosclerosis accounts for 16 (22%) of cases. Haematological causes were presumed in 10/72 (14%) patients. Other disorders including non-atherosclerotic vasculopathies explained 30/72 (42%) cases. The causes of stroke were undetermined in 63 (46.5%) of the patients.

Conclusions: In this population of young patients, cardiac embolism is a very important cause of stroke. Even after taking an exhaustive history, examining the patient in great details and undertaking numerous investigations, there may still be patients in whom no reasonable explanation for their stroke can be found.

Adipokines level and insulin resistance in abdominally obese patients with primary acute ischemic non-lacunar hemispheric stroke
M. Delva, N. Lytvynenko. Ukrainian Medical Stomatological Academy, Poltava, Ukraine

Background: During the last decade there are numerous reports regarding obesity as a factor that could influence stroke severity and outcome.

Objective: The aim of this study was to determine humoral and endocrine changes among patients with abdominal obesity II class in the acute phase of ischemic non-lacunar hemispheric strokes.

Design and methods: This study evaluated 18 non-diabetic abdominally obese patients (class II) aged 61.3 ± 0.7 years (39% women) with
primary acute ischemic non-lacunar stroke. Patients were matched for infarct volume and co-morbidities. Serum concentrations of adiponectin and leptin, as well as HOMA-IR index were assessed at 1st and at 10th day after stroke onset in fasting state. For comparison, a control group of 9 abdominally obese conditionally healthy humans with chronic lumbalgia has been formed.

**Results:** Abdominally obese patients have significant and sustained reduction of adiponectin level at 1st (23.4 ± 1.5 ng/ml, p < 0.05) and at 10th post-stroke day (2.97 ± 4.2 ng/ml, p < 0.05) in comparison with control group of obese healthy humans (42.0 ± 2.7 ng/ml). Moreover, abdominally obese patients have significant transient elevation of leptin serum level (22.23 ± 3.8 ng/ml, p < 0.05) and HOMA-IR (21.26 ± 5.94, p < 0.05) at 1st day after stroke with subsequent return to basal values on the 10th post-stroke day (11.4 ± 3.4 ng/ml and 2.25 ± 0.49, respectively). Maybe, these peculiarities are interdependent and constitute the syndrome of adipose tissue reaction in stroke.

**Conclusion:** Under the conditions of acute ischemic non-lacunar hemispheric stroke, patients with abdominal obesity II class have significant elevation of leptin serum level as well as indices HOMA-IR.

**The influence of VEGF-A in brain edema on acute ischemic stroke**

I.S. Setyopranoto, S. Wibowo. Neurology, Faculty of Medicine Gadjah Mada University, Sardjito Hospital, Yogyakarta, Indonesia; Neurology, Sardjito Hospital, Yogyakarta, Indonesia; Stroke Unit, Sardjito Hospital, Yogyakarta, Indonesia

**Background:** Hypoxia causes transcription of genes that are controlled by HIF-1, which activates VEGF-A and influence blood brain barrier leakage, causing brain edema. Brain edema can lead to progressive neurological deterioration. The purpose of this study is to prove that the decreased levels of VEGF-A contribute to brain edema in acute ischemic stroke.

**Material and methods:** Design of this study was a case–control in acute ischemic stroke patients treated in Stroke Unit Dr. Sardjito Hospital Yogyakarta Indonesia. To find significant independent factors causing brain edema, logistic regression analysis was used. The significance level used was 0.05 with 95% level of confidence (p < 0.05).

**Results:** There were 37 subjects as a brain edema, and 34 subjects as non-brain edema. The mean levels of VEGF-A on brain edema group is 436 pg/ml, and in non-brain edema group is 746 pg/ml, this difference is significant (95% CI: 5.51–615, p = 0.046). The proportion of VEGF-A levels <638.3 pg/ml in brain edema group is greater than non-brain edema (83.78% vs. 58.82%), this difference is significant. (OR = 3.6; 95% CI: 1.06–13.26). Results of multivariable analysis were lipid profiles (OR = 4.26; 95% CI: 1.28–14.15), MMP-9 (OR = 5.59; 95% CI: 1.58–19.78), and score SSGM (OR = 5.29; 95% CI: 1.47–19.08).

**Conclusion:** The decreased levels of VEGF-A significantly contribute to the brain edema in acute ischemic stroke, and the influence of decreased levels of VEGF-A on the brain edema will increase if considered with unification of lipid profile, levels of MMP-9 and score SSGM.

**doi:** 10.1016/j.jns.2013.07.714
than one episode. The duration between the time of the first TIA episode and the time of onset ranged from 60 to 1320 min with a median duration 369 min (range 160–720 min). The presence of SICH was higher in patients with prior TIA (p = 0.153); however, mortality was lower in this subgroup (p = 0.563). Multivariate analysis showed the impact of prior TIA within 24 h before stroke onset on the presence of SICH. There was no impact of TIA on unfavourable outcomes after three months or on the mortality rate within three months.

**Conclusion:** We found no impact of recent TIA on the safety and efficacy of iv-thrombolysis in patients with AIS.

**Delirium in acute stroke: Frequency and risk factors**

M.A. Kutlubaev, L.R. Akhmadeeva, L.F. Bikbulatov. Neurology, G.G. Kuvato’s Republican Clinical Hospital, Bashkirian State Medical University, Ufa, Russia; Neurology, Neurosurgery and Medical Genetics, Bashkirian State Medical University, Ufa, Russia

**Introduction:** Delirium is common in acute stroke and worsens overall prognosis. The aim of this study was to identify the frequency and risk factors for the development of delirium in acute stroke.

**Methods:** We recruited patients consecutively admitted to neuro-vascular unit of city hospital between 11/05/12 and 30/06/12, within 3 days after stroke onset. Exclusion criteria were subarachnoid haemorrhage, comatose state at admission, TIA and history of psychiatric disease. The criteria of DSM-IV were used to make the diagnosis of delirium. Severity of neurological deficit was assessed by NIHSS, the functional state by Rankin scale (mRS). We assessed frontal lobe reflexes: snout, nasolabial, palmo-mental and grasp reflexes. Stroke lesion location, cortical and central cerebral atrophy and anterior and posterior white matter lesions (WML) were assessed on admission head CT.

**Results:** Ninety six of 271 admitted patients were included in the study. M/F ratio was 50/46, mean age was 68.02 STD 10.52; median NIHSS was 8 with interquartile range (IQR) 5–12.5; mRS – 3, IQR 2–4. Twenty two of 96 patients revealed symptoms of delirium. Patients of older age, those with severe stroke, with prominent atrophy and WML, those with fever, with urine catheter and with positive snout reflex were more likely to develop delirium. Severity of posterior WML was the only independent predictor of delirium according to multivariate analysis.

**Conclusion:** Delirium affected 23% of stroke patients in our cohort. Chronic brain changes and stroke complications were the main risk factors for the development of delirium.

**Could pro-Bnp, uric acid, bilirubin, albumin and transferrin be used in making the distinction between stroke subtypes?**

I.M. Cojocaru, M. Cojocaru, V. Sapira, I. A. Ionescu, S. Barlan, N. Tacu. Neurology, Carol Davila University of Medicine and Pharmacy, Bucharest, Romania; Physiology, Titu Maiorescu University, Faculty of Medicine, Bucharest, Romania; Neurology, Colentina Clinical Hospital, Bucharest, Romania

The importance of establishing the pathogenesis of ischemic strokes in determining an adequate therapy. To observe if certain plasma parameters could be used as biomarkers in distinguishing between stroke subtypes. Plasma pro-BNP (chemiluminescence), serum uric acid, bilirubin (colorimetric assay), albumin and transferrin (nephelometric assay) levels were performed in 168 admitted patients (mean age 68.7 ± 11.6 years, 52 men and 116 women) with different subtypes of acute ischemic strokes within 24 h and at 7 days after stroke onset as TOAST and OCSP criteria, NIHSS and Glasgow Coma Score at baseline and at 7 days were used.

The mean value of pro-BNP level was significantly higher in the cardioembolic stroke (CE), in patients, within 24 h (p < 0.001) and at 7 days (p < 0.001) after stroke onset. A negative correlation between pro-BNP levels and GCS (r = 0.05, p = 0.0002) and a significant difference between pro-BNP levels of NIHSS groups were observed (p < 0.08, respectively p < 0.01). We observed significantly higher values within 24 h of uric acid (p < 0.05), significantly lower values within 24 h of transferrin (p < 0.05), significantly lower values at 7 days of albumin and transferrin (p < 0.001), and significantly higher values at 7 days of uric acid and bilirubin (p < 0.001). No significant statistical differences between the values of oxidative stress parameters and stroke subtypes, GCS and NIHSS score were observed. The level of plasma pro-BNP may be useful in distinguishing CE stroke from other stroke subtypes. Oxidative stress parameters could not be used to differentiate stroke subtypes.

**Col4a2 mutation causing recurrent intracerebral hemorrhage — Importance of screening both Col4a1 and Col4a2 in ICH of unknown origin**

B. Gunda, M. Mine, T. Kovács, C. Hornyák, D. Bereczki. Neurology, Semmelweis University, Budapest, Hungary; Service de Génétique Neuro-Vasculaire, Hôpital Lariboisière, Université Paris Diderot, Paris, France; MRI Research Center, Semmelweis University, Budapest, Hungary

**Background:** Type IV collagen α1 and α2 chains form heterotrimers that constitute an essential component of basement membranes including those of the cerebral vasculature. Mutations in COL4A1, encoding the α1 chain, cause a large spectrum of clinical manifestations, including porencephaly, bleeding prone cerebral small vessel disease, intracranial aneurysms and variable systemic abnormalities. Mutations in COL4A2 have recently been reported in a few porencephaly families.

**Objective:** Herein, we report on a young adult patient with recurrent intracerebral hemorrhage, leukoencephalopathy, intracranial aneurysms, nephropathy and myopathy associated with a novel COL4A2 mutation.

**Methods:** We examined an otherwise healthy 29-year-old male patient with recurrent deep intracerebral hemorrhages occurring after physical exertion. General physical and neurological examination, brain MRI, abdominal ultrasound, ophthalmologic examination, laboratory tests and genetic testing of COL4A1 and COL4A2 were performed.

**Results:** MRI showed deep intracerebral hemorrhages of different ages, diffuse leukoencephalopathy, multiple cerebral microbleeds and small aneurysms of the carotid siphon bilaterally. Laboratory workup revealed significant microscopic hematuria and elevation of creatine-kinase. We found a glycine mutation within the COL4A2 triple helical domain.

**Conclusions:** This study reports the first COL4A2 mutated adult patient with a phenotype very close to the spectrum of manifestations in COL4A1 mutations, and emphasizes the importance of screening both
COL4A1 and COL4A2 in patients showing recurrent ICH of unknown etiology particularly if associated with leukoencephalopathy.

Patent foramen ovale prevalence in patients with acute ischemic stroke and the risk of subsequent events
C. Fernandes, L. Pereira, M. Rodrigues. Neurology Department, Hospital Garcia de Orta, Almada, Portugal

Background: Association between patent foramen ovale (PFO) and stroke is controversial.
Objective: To determine the prevalence of PFO in patients with acute ischemic event (AIE) and recurrence rate.
Patients and methods: Observational retrospective study in patients admitted to a neurology ward with AIE in 5 years. In those with transesophageal echocardiogram (TEE), clinical data, PFO presence, lesion pattern and recurrent events were collected. We present descriptive and inferential statistics with t-test, chi-square and recurrence risk by Kaplan–Meier curves with LogRank, using 95% confidence intervals (95%CI).
Results: Of 1300 subjects, 337 underwent TEE (25.9%), mean age 55.7 years, and 62.9% men. PFO was identified in 69 (20.5%; 95% CI 16.2–24.8%). Prevalence was similar in cryptogenic events (21.1%; 95% IC 17.0–25.3%). There was a negative association with diabetes (p = 0.003), hyperlipidemia (p = 0.03) and smoking (p = 0.047). No association was found with other risk factors or lesion pattern. Paradoxical embolism sources were evaluated in half and found in 23.2%. Six PFO (8.7%) underwent percutaneous closure. In a mean follow-up of 604.7 days, recurrence was low in patients with PFO, indistinguishable from those without PFO (4.8% vs 11.8%, LogRank p = 0.157). Patients with PFO under anticoagulation had fewer recurrent events than those non-anticoagulated (0.0% vs 7.5%), and those without PFO with/without anticoagulation (8.5%/12.8%), although not significant (LogRank p = 0.174).
Conclusion: The prevalence of PFO was similar to the general population, even in cryptogenic events. The negative association with some risk factors and the presence of paradoxical embolism source suggest an implication of the PFO in the event etiology, although not associated with recurrence.

Metabolic syndrome is strongly associated with ischemic stroke and carotid stenosis in non-diabetics
M. Mijailovicc, A. Joticb, N. Sternic, N. Lalicb. cNeurology Clinic, Clinical Center of Serbia and School of Medicine University of Belgrade, Belgrade, Serbia; bInstitute of Endocrinology, Clinical Center of Serbia and School of Medicine University of Belgrade, Belgrade, Serbia

Background: Insulin resistance (IR) with compensatory hyperinsulinemia plays a crucial role in the pathogenesis of atherosclerosis, but their role in ischemic stroke (IST) has not been elucidated. Study was aimed to analyze IR and plasma insulin (PI) levels, dyslipidemia pattern, obesity and plasminogen activator inhibitor-1 in 100 patients with atherothrombotic IST (group A), 100 patients with asymptomatic carotid stenosis (ACAS) ≥50% (group B), 100 patients with lacunar stroke (group C) and 65 healthy controls (group D). Patients with diabetes mellitus and ischemic heart disease were excluded.
Methods: IR was determined by Homeostasis Assessment Model, PI levels by radioimmunoassay, Total-, LDL- and HDL-cholesterol and triglyceride levels were measured in all groups. Central obesity was determined by waist circumference and hypercoagulable state by plasminogen activator inhibitor (PAI-1) levels.
Results: IR was significantly higher in group A compared to groups B, C and D (4.82 ± 0.27 vs. 3.69 ± 0.22, p < 0.05; 19.00 ± 1.2 vs. 11.12 ± 0.19, p < 0.01, 4.82 ± 0.27 vs. 1.50 ± 0.19, p < 0.01). PI levels were significantly higher in group A in comparison to groups B, C and D (19.00 ± 1.2 vs. 15.95 ± 0.88, p < 0.05; 19.00 ± 1.2 vs. 11.12 ± 0.19, p < 0.01, 19.00 ± 1.2 vs. 7.12 ± 1.08). Different patterns of dyslipidemia were observed in ACAS and IST. PAI-1 levels, and waist circumference were significantly higher in groups A, B, and C in comparison to controls (p < 0.01, respectively).
Conclusion: Our results indicate that all subtypes of ischemic stroke as well as ACAS are strongly associated with IR and increased PI and PAI-1 levels. Specific patterns of dyslipidemia between ACAS and IST were observed.

Rotational vertebrobasilar artery occlusion: Mechanisms and long-term outcome
K.-D. Choi1, J.-H. Choi2, J.-D. Seo3, H.-J. Cho2, C.-H. Kim4, J.-H. Bae4, J.-S. Kim5. 1Neurology, Pusan National University Hospital, Busan, Republic of Korea; 2Neurology, Pusan National University, Yangsan Hospital, Yangsan, Republic of Korea; 3Neurology, Dong-A University Hospital, Busan, Republic of Korea; 4Neurology, Dae-Dong Hospital, Busan, Republic of Korea; 5Neurology, Seoul National University, Bundang Hospital, Seongnam, Republic of Korea

Background and objective: To elucidate the mechanisms and prognosis of rotational vertebrobasilar artery occlusion (RVAO).
Materials and methods: We analyzed clinical and radiological characteristics, patterns of induced nystagmus, and outcome in 21 patients (13 men, aged 29–77 years) with RVAO documented by dynamic cerebral angiography over an 8-year period at three University Hospitals in Korea. The follow-up periods ranged from 5 to 91 months (median = 37.5 months). Most patients (n = 19, 90.5%) received conservative treatments.
Results: All the patients developed vertigo accompanied by tinnitus (38%), fainting (24%), or blurred vision (19%). Only 12 (57.1%) patients showed the typical pattern of RVAO during dynamic cerebral angiography, a compression of the dominant VA at the C1–2 level during contralateral head rotation. The induced nystagmus was mostly downbeat with horizontal and torsional components beating toward the compressed VA side. None of the patients with conservative treatments developed posterior circulation stroke, and four of them (21.1%) showed resolution of symptoms during the follow-ups.
Conclusions: RVAO has various patterns of VA compression, and favorable long-term outcome with conservative treatments. In most patients with RVAO, the symptoms may be ascribed to asymmetrical excitation of the bilateral labyrinth induced by transient ischemia and/or by disinhibition from inferior cerebellar hyperperfusion. Conservative management might be considered as the first-line treatment of RVAO.

Dual antiplatelet therapy clopidogrel with low dose cilostazol intensified platelet inhibition in patients with ischemic stroke
H. Maruyama, T. Fukuoka, I. Deguchi, Y. Ohe, Y. Kato, Y. Horiuchi, Y. Nagamine, H. Sano, T. Hayashi, N. Tanahashi. Department of Neurology and Cerebrovascular Medicine, Saitama Medical University International Medical Center, Hidaka, Japan

Objective: We previously reported that antiplatelet action is intensified with combined use of clopidogrel and cilostazol in ischemic stroke patients using the VerifyNow P2Y12 assay. In this study, the relationship between cilostazol dose and platelet function with combination therapy was investigated.

Methods: The subjects were 231 patients with non-cardiogenic ischemic stroke treated at our hospital (18 patients with a combination of clopidogrel 75 mg and cilostazol 100 mg, 52 patients with a combination of clopidogrel 75 mg and cilostazol 200 mg, 126 patients with clopidogrel 75 mg alone, and 35 patients with cilostazol 200 mg alone). Platelet function with 20 μM adenosine diphosphate was measured using the VerifyNow P2Y12 assay. Cilostazol resistance was defined as P2Y12 Reaction Units (PRU) >230 and/or % inhibition <20.

Results: PRU was >230 in 32 patients (25.4%) receiving clopidogrel alone, 1 patient (5.6%) receiving combination therapy with cilostazol 100 mg, and 1 patient (1.9%) receiving combination therapy with cilostazol 200 mg. The percent inhibition was <20% in 41 patients (32.5%) receiving clopidogrel alone, 1 patient (5.6%) receiving a combination with cilostazol 100 mg, and 1 patient (1.9%) receiving a combination with cilostazol 200 mg. The rate of PRU >230 and/or % inhibition <20% was significantly lower in both cilostazol combination groups than in the clopidogrel alone group.

Conclusion: Cilostazol resistance was clearly decreased with combination clopidogrel 75 mg and low-dose (100 mg) cilostazol therapy. The combination therapy with clopidogrel and low-dose cilostazol may be one means to overcome clopidogrel resistance.

Early clinical manifestations in patients with cerebral venous thrombosis
L. Macavei, O. Costache, C. Popa, A. Treaba, A. Macavei, E. Iftene, L. Hermann. "Neurology I Clinic, University of Medicine and Pharmacy Târgu Mures, Romania; "Neurology II Clinic, Clinical County Emergency Hospital, University of Medicine and Pharmacy Târgu Mures, Romania; "Radiology and Imagistic, University of Medicine and Pharmacy Târgu Mures, Romania. "Clinical County Emergency Hospital, Clinical County Emergency Hospital, Târgu-Mures, Romania; "Intensive Care Unit, Clinical County Emergency Hospital, Târgu-Mures, Romania; "Radiology and Imagistic, Clinical County Emergency Hospital, Târgu-Mures, Romania

Introduction: Cerebral venous thrombosis (CVT) has a diverse etiology, sometimes very hard to establish, representing a major neurological emergency.

Objectives: Early recognizing onset symptoms and fast diagnosis in patients with CVT.

Method: This is a retrospective study which included 18 cases with CVT admitted in the Neurology clinic of the Mureș Clinical County Emergency Hospital during 01.01.2012–31.12.2012, noticing the onset, early clinical manifestations, age, sex, demographics and affected venous area. For establishing the diagnosis, the patients have been investigated using paraclinical (electroencephalogram, eye examination, blood test results) and imagistic (computed tomography, magnetic resonance, angio magnetic resonance) investigations.

Results: From the total of 1196 patients with stroke, CVT represented 1.50%. Out of the studied cases, the onset was acute in 50%, 27.77% were subacute and 22.22% were chronic. The most frequent early symptom was headache (44.44%), followed by cranial nerve syndrome (27.77%), seizures (11.11%), aphasia (11.11%), among loss of consciousness, focal neurologic deficit, nystagmus and papilledema (5.55%). Most often, the lesions were located in the superior transverse sinus (33.33%), sigmoid sinus (27.77%), superior sagittal sinus (22.22%), cavernous sinus (11.11%) and deep venous system (5.55%),

Conclusions: The most common form of debut in CVT is the atypical form. Recognizing this pathology is essential for prompt treatment in particular clinical circumstances.

Topic: 3 — Stroke
A novel pathway for atrial fibrillation: Concise, practical, easy-to-use
G. Lai, K.E. Lee. Department of Neurology, National Neuroscience Institute (Tan Tock Seng Hospital), Singapore, Singapore

Background: Atrial fibrillation (AF) is the most common cardiac arrhythmia and increases the annual risk of stroke by five-fold. A recent study at our center demonstrated that a significant proportion of patients (43.6%) with known AF presenting with acute ischemic stroke were not on any antithrombotic therapy, with only 1 of 58 patients at high risk of stroke on therapeutic anticoagulation. While the most common form of debut in CVT is the atypical form. Recognizing this pathology is essential for prompt treatment in particular clinical circumstances.

Material and methods: The latest available guidelines on AF management in USA, Europe, UK, Canada and Singapore were reviewed, with added emphasis on pathways and algorithms in these countries.

Results: A single-page pathway consolidating key components of diagnosis and management of AF was developed. A table juxtaposing the CHADS2 and HAS-BLED score was incorporated for direct comparison and documentation of risk-versus-benefit of anticoagulation. The modified Rankin Scale (mRS) was included, as pre-morbid functional status is an important consideration prior to the commencement of antithrombotic therapy. The pathway was created for use by any general physician, with sections specially color-coded for cardiologist input if needed.

Conclusion: A well-established AF care pathway is currently lacking in clinical practice. Our one-page pathway serves as a ready-to-use guideline-cum-management reference, as well as a possible research and audit tool in all patients presenting with AF.
Results: 505 consecutive patients met inclusion criteria (242 men [47.9%]; median age 71 years; median baseline national institutes of health stroke scale score 12; 37 with sHT [7.3%]). Baseline serum glucose concentrations were independently associated with sHT (adjOR: 1.176 for 1 mmol/l increase; 95 CI: 1.020–1.357: p = 0.025), but not with death (<7 days, <3 months, 8 days to 3 months), and unfavourable outcome at 3 months (modified Rankin scale 2 to 6).

Conclusion: Increased serum glucose concentrations in non-diabetic patients treated by i.v. rt-PA for cerebral ischaemia are associated with an increased risk of sHT, but not with death or unfavourable outcome after adjustment on confounders.

Topic: 3 — Stroke
A prospective study of vascular cognitive impairment in patients with stroke

Background: Cognitive impairment occurs in around 30% patients following stroke. It has been extensively studied in the developed countries recently, especially in the last decade. However, there is few data regarding post stroke vascular cognitive impairment (VCI) from developing countries like India.

Objective: The purpose of this study was to determine various factors including demographic, clinical, neuro-imaging, laboratory parameters which contribute to the development of vascular cognitive impairment (VCI) in patients with stroke.

Material and methods: In the interim analysis of this prospective study, 56 patients fulfilling inclusion criteria were evaluated. All of them underwent clinical examination including cognitive assessment, neuro-imaging in the form of MRI. Repeat assessment was done at 3 and 6 months. Patients with VCI included those with vascular dementia (VaD, as diagnosed by NINDS-AIREN criteria) and VCI-ND (VCI—no dementia).

Results: Of the 56 patients presented in this interim analysis, 22 (39%; VaD = 8, VCI-ND = 14) patients developed VCI. Factors associated with the development of VCI included hypertension (p = 0.012), prior stroke (p = 0.013), strategic site infarction (p = < 0.001), high blood sugar level on admission (p = 0.011), high LDL level levels (p = 0.006) and NIHSS score (p = < 0.001).

Conclusion: Post-stroke cognitive impairment is commonly seen. Our study revealed that post stroke cognitive impairment occurs as a result of stroke itself as well as its risk factors such as hypertension and high LDL levels. Prior history of stroke, high blood sugar level and stroke severity on admission also contribute significantly to post stroke cognitive decline.

Sexual life of post-stroke women with mild or no disability: A qualitative study
S.D. Yilmaz, H. Gumus, H. Yilmaz. "Midwifery, Faculty of Health Sciences, Selcuk University, Turkey; "Neurology, Konya Education and Research Hospital, Konya, Turkey; "Physical Therapy and Rehabilitation, Konya Education and Research Hospital, Konya, Turkey

Objective: To investigate the perspectives and experiences of post-stroke women regarding sexual issues, along with interactions in social life.

Material and methods: A qualitative design was adopted for the study. According to the Rankin score with mild or no disability, a convenience sample of women (n = 16, married and ≥18) with the history of at least 6-month stroke and active sexual life prior to stroke were admitted. Individual and audio-taped interviews were performed. Transcribed interviews were qualitatively and thematically analysed using content data analysis to code and categorize emerging themes.

Results: Four principal themes were identified as follows: physical, emotional and spiritual changes experienced after stroke; negative effects of changes on the roles of post-stroke women as housewives and mothers; changes of sexual life experienced by women in post-stroke period; and, support from healthcare providers in coping with emotional and sexual challenges.

Conclusion: In light of our findings, it is definite that physical, social and emotional challenges commonly influence sexual lives of post-stroke women, and that such women are lack of medical counselling and assistance. Therefore, in the management of post-stroke women, the following recommendations may be suggested:

- To provide stroke women and their spouses with counselling and assistance, healthcare professionals, during in-service training, should concentrate on physical and psychosocial sequelae of stroke related to sexuality.
- To help women cope with their physical, social and emotional challenges in post-stroke period, easily accessible health facilities and opportunities should be formed under the supervision of the ministry of health for stroke rehabilitation.

doi:10.1016/j.jns.2013.07.725
**Background:** Neurologic deficit severity and co-morbidities impact prognosis in patients with stroke.

**Objective:** Comparison of survival, co-morbidity frequencies, complications and length of hospitalization between patients with an acute stroke in either BA or MCA area.

**Methods:** We performed prospective, observational, single-center study on consecutive 69 patients allocated according to stroke area in group 1: BA (30 patients, 23 males); group 2: MCA (39 patients, 24 males). Age, Glasgow coma scale (GCS), The National Institute of Health Stroke Scale (NIHSS), complications as mechanical ventilation (MV), infections, acute myocardial infarction (AMI), hospital length of stay and survival were compared among groups, as well as co-morbidity frequency: atrial fibrillation (AF), diabetes mellitus (DM), hypertension (HTN), and hyperlipidemia.

**Results:** Age was similar in both groups. Women were older than men in group 1 (71.1 vs. 57.2, p = 0.0046). At the admission into ICU, GCS was lower in group 1 than group 2 (8.16 ± 3.92 vs. 10.85 ± 5.37, p = 0.025) and NIHSS was greater (28.79 ± 11.38 vs. 19.17 ± 9.88, p = 0.0006). Complications occurred similarly in both groups: MV, infections, AMI (all p > 0.05), Group 1 had longer ICU length of stay (12.6 ± 20.4 vs. 6.9 ± 5.8, p = 0.17), hospitalization duration (18.9 ± 24.4 vs. 12.8 ± 9.2, p = 0.13) and greater NIHSS at dismissal (14.12 ± 13.55 vs. 10.46 ± 7.07, p = 0.38). Survival was similar in both groups (53% vs. 46%, p = 0.73). Atrial fibrillation was more frequent in group 2 (X² = 3.859, P = 0.044).

**Conclusion:** Acute stroke in region of BA was more severe. There were no differences comparing to MCA stroke for complication rate, ICU length of stay and survival. In MCA stroke AF was more frequent. doi:10.1016/j.jns.2013.07.728

**Gamma-glutamyl transferase levels and cerebrovascular risk factors in patients with acute ischemic stroke**

N. Gurbuzer, E. Gozke, Z. Ayhan Basturk. **Neurology, FSM Teaching and Research Hospital, Istanbul, Turkey**

**Objective:** The aim of this study was to investigate the relationship between gamma-glutamyl transferase (GGT) levels and cerebrovascular risk factors in patients with acute ischemic stroke (AIS).

**Patients and methods:** Sixty patients with AIS and 44 controls who had no cerebrovascular disease were included to the study. The patients were divided into four groups as those with total and partial anterior circulation infarcts (TACI and PACI, respectively), lacunar infarcts (LACI) and posterior circulation infarcts (POCI). All patients and controls were evaluated for GGT levels and the presence of diabetes mellitus (DM), hypertension (HT), and hyperlipidemia (HL). The patients with AIS were classified as normal or those with nonstenotic carotid plaques, internal carotid artery stenosis, and vertebralbasilar insufficiency as evaluated by carotid, and vertebral artery Doppler ultrasound examinations.

**Results:** The frequency of DM, HT, HL, and gender distributions was similar in all groups. The mean GGT levels were significantly higher in patients with AIS. There was no relationship with GGT levels and the largeness and distribution of infarct area. The mean GGT levels were at their nadir in LACI, while at their maximal levels in the POCI group. The lowest GGT levels were detected in patients with nonstenotic plaques.

**Conclusion:** Higher GGT levels in AIS patients support the relationship of GGT with inflammation and oxidative stress. However absence of any correlation among GGT levels, infarct areas and Doppler findings suggests that GGT is not a marker of degree of ischemia.

on the localization of infarction lesion and were different according to Fisher's test (p < 0.05): patients with SCA infarctions presented with dysarthria, limb ataxia due to a lesion of the paravermis and lateral parts of the anterior lobe from lobules II to V; typical signs of PICA infarction included dizziness, gait ataxia, nystagmus associated with a lesion of posterior inferior lobules IX–X of the posterior lobe of the hemisphere; AICA infarctions were manifested with dizziness, vestibular disturbances, nystagmus and associated with affected anterior inferior and medial cortex of the cerebellar hemisphere.

**Conclusions:** The study demonstrated that clinical assessment of the early signs of cerebellar ataxia after isolated infarction, consideration of guiding symptoms of ataxia syndrome and the use of visualization enables to determine vascular territory lesions in the cerebellum.

**Long-term risk of stroke and myocardial infarction in women with low social support in Russia: Monica-psychosexual epidemiological study**

V. Gafarov, D. Panov, E. Gromova, I. Gagulin, A. Gafarova. **Collaborative Laboratory of Cardiovascular Diseases Epidemiology SB RAMS, Russia; FSBI Institute of Internal Medicine SB RAMS, Novosibirsk, Russia**

**Objective:** To study the effect of social support (SS) on relative risk of stroke and myocardial infarction (MI) in female population of 25–64 years in Russia over 16 years of follow-up.

**Material and methods:** Under the third screening of the WHO “MONICA-psychosexual” program random representative sample of women aged 25–64 years (n = 870) were surveyed in Novosibirsk. Berkman-Sym test was used to measure indices of close contacts (ICC) and social network (SNI). From 1995 to 2010, women were followed for the incidence of stroke and MI by using Myocardial Infarction Registry data. Cox regression model was used for relative risk assessment (HR) of stroke, MI.

**Results:** Low levels of ICC and SNI were revealed in 57.1% and 77.7% of women, respectively. Stroke was developed in 5.1% of women, MI — in 2.2%.

HR of MI over 16 years of study was in 4.9-fold (95.0% CI: 1.108–21.762; p < 0.05) and 2.9-fold (95.0% CI: 1.040–8.208; p < 0.05) higher for low ICC and SNI, respectively, compared to higher SS levels. HR of stroke was 4.1 (95.0% CI: 1.193–14.055; p < 0.05) and 2.7 (95.0% CI: 1.094–6.763; p < 0.05) for low ICC and SNI, respectively. Married and unmarried women with low ICC and hard physical laborers with low ICC and SNI had higher rate of stroke development (p for all < 0.05).

**Conclusions:** The prevalence of low SS in women aged 25–64 in Russia is high. Risk of stroke and MI over 16 years of study was significantly higher in women with low ICC and SNI, especially in married ones in manual labor class.

**Brain MRI findings in Fabry Disease**

C. Marchesoni, C. Romero, G. Sevleve, A. Pardal, I. Kisinovsky, A. Quarind, G. Cáceres, R. Reisina. **Neurology, Hospital Británico, Buenos Aires, Argentina; aFundación para la Lucha contra las Enfermedades Neurológicas de la Infancia (FLENI), Ciudad Autónoma de Buenos Aires, Argentina; bInstituto Médico Quilmes, Argentina; cCentro Fabry Pinamar, Buenos Aires, Argentina**

**Background:** Stroke is a serious complication of Fabry Disease (FD) affecting 15% of males and 11% of females. Moreover FD has been identified in 4% of young patients with unexplained strokes. The evaluation of MRI in FD patients without a prior history of stroke may lead to earlier treatment.

**Objective:** To evaluate the presence and distribution of ischemic and hemorrhagic lesions in brain MRI of children and adults with FD lacking history of CVA.

**Patients and methods:** Brain MRI studies in 73 consecutive patients without history of stroke or TIA were evaluated using classic sequences as well as GRE-weighted images, for ischemic lesions and chronic microbleed detection. Of the 62 adult patients, 5 were excluded due to dialysis antecedent. Among the remaining group, 25 were males and 32 females (mean age 34 and 40.3 years old, respectively).

**Results:** Two patients (18.18%) under 18 years of age presented abnormal MRI. Nineteen adult patients (33.33%) had brain MRI evidence of small vessel disease in the basal ganglia, corona radiata, thalamus, brainstem, and periventricular white matter. Patients with MRI abnormalities were older (51.3 vs. 30.6 years old, p = 0.0001). Four patients (mean age 61 years old) presented chronic microbleeds identified by GRE, in the pallidum and thalamus. Moreover, FLAIR and T2-weighted images showed evidence of white matter and deep grey matter involvement.

doi:10.1016/j.jns.2013.07.733
Conclusion: In our group, 33.33% of adult patients with FD lacking history of CVA or prior dialysis had evidence of small vessel disease on MRI and 21.05% of those presented cerebral microbleeds.

Internuclear ophthalmoplegia caused by an isolated ischemic lesion affecting the medial longitudinal fascicule
T. Rahb, I. Vastaghb, V. Várdic, K. Szökéb, G. Bozsikc, G. Várallyayb, G. Rudásb, D. Bereczkb. aDepartment of Neurology, Semmelweis University Faculty of Medicine, Hungary; bMRA Research Center, Semmelweis University, Budapest, Hungary

Background: Internuclear ophthalmoplegia (INO) frequently appears in multiple sclerosis, but is rare as an isolated sign in stroke.
Objective: To present clinical and imaging data of 3 cases of ischemic stroke with uni- or bilateral INO.
Patients and methods: Two patients with unilateral and another one with bilateral INO were investigated by a 3 Tesla Philips Achieva scanner.
Results: A 66-year-old female and a 62-year-old male were admitted with acute right sided and an 80-year-old male with bilateral INO. Diffusion weighted MRI scans (DWI) confirmed restricted water diffusion in the medial longitudinal fascicule (MLF) in all cases. Unilateral INO was associated with unilateral MLF lesion whereas in the patient with bilateral signs the MLF was also affected on both sides. Hypertension was present in all three patients. Two patients had hyperlipidemia, one had diabetes, and one was a heavy smoker. The patient with bilateral INO had malignant melanoma which could also have caused prothrombotic state. Antiplatelets (aspirin or clopidogrel) were administered in all patients. The clinical signs were resolved in the patient with bilateral INO after two months. Patients with unilateral INO also improved during the first month after their stroke and their follow-up is ongoing.
Conclusion: INO due to a small infarct affecting the MLF may cause uni- or bilateral signs. As Fisher proved, signs can be bilateral if the terminal branch of a paramedian artery divides and these vessels supply the MLF on both sides. Such small arteries are not visible however even for a 3 Tesla MRI.

Assessment on preadmission treatment of cardioembolic stroke patient in Malaysian hospital
1Pharmacy Department, Hospital Sultanah Nur Zaharah, Kuala Terengganu, Malaysia; 2Neurology Department, Hospital Sultanah Nur Zaharah, Kuala Terengganu, Malaysia; 3Medical Department, Hospital Seberang Jaya, Seberang Perai, Malaysia; 4Medical Department, Hospital Kepala Batas, Kepala Batas, Malaysia; 5Neurology Department, Hospital Kuala Lumpur, Kuala Lumpur, Malaysia

Background: Atrial fibrillation (AF) increases the degree of stroke risk up to five times and doubled the overall mortality rate. Hence, anticoagulant as stroke primary prevention is vital.
Objectives: We aim to assess the preadmission treatment received by the cardioembolic stroke patients, and review the mortality rate according to pre-treatment received.

Method: This prospective study has been carried out from 1st Jan 2010 to 31st December 2012 by 11 Malaysian hospitals. Data have been collected by using Malaysian National Stroke Registry (NSR) case report form which will then be transferred to web application. For analysis, data was extracted and analyzed by using PASW 18.

Results: There were 126 cardioembolic stroke patients registered to NSR with mean age of 65.97 ± 12.72 years old. Of all, only 45 patients were on Warfarin with 13 (10.3%) of them were within therapeutic and 32 patients (25.4%) received sub-therapeutic Warfarin. 3.2% of patients received dual antiplatelet therapy, 26.2% on single antiplatelet therapy and 34.9% of patient did not received any treatment. The mortality rate was significantly high in no treatment group (34.1%) as compared to Warfarin (13.3%) and antiplatelet group (16.2%) with p value of 0.038. However, the mortality rate between Warfarin therapeutic (7.7%) with sub-therapeutic group (15.6%) and between single antiplatelet (18.7%) with dual antiplatelet were not significantly different.

Conclusion: Our findings warrant greater effort to prevent stroke in AF patients, thus high mortality outcome which was significantly associated with treatment received prior to stroke event.

Topic: 3 — Stroke
Establishing the aetiology of stroke in a young cohort
R. O’Connor, I. Noone, S. O’Riordan, N. Tubridy, C. Mc Guigan. Department of Neurology, St Vincent’s University Hospital, Dublin, Ireland

Background: In 2010 in Ireland, 34.3% of the almost 23,000 strokes diagnosed occurred in patients under 65 years of age. This figure may underestimate the prevalence of stroke in young patients as some may have not been recognised or misdiagnosed.

Materials and methods: A retrospective audit of all patients under age 65 presenting with ischaemic and haemorrhagic strokes to a University Hospital between 1st January 2010 and 31st December 2011. Aetiology was determined using the TOAST criteria.

Results: A total of 80 patients under 65 were treated for stroke (13.6% of the total 586 strokes in 2010/2011). 26% [n = 21] were under 45 years. Average age was 51.1 years (range 20–64 years). 49 were males (61%), and 31 females (39%). 63 were admitted via the emergency department (ED); 10 transfers from other hospitals; 7 existing inpatients. Of 63 ED admissions, 24 (38%) patients received CT Brain within 1 h. Of 80 patients, 56 (70%) had MRI Brain during their inpatient stay. Using TOAST classification of stroke aetiology, 9 (11.3%) strokes were caused by large artery atherosclerosis, 19 (23.7%) cardioembolism, 10 (12.5%) lacunar, 13 (16.2%) other determined aetiology e.g. dissection, 16 (19.9%) undetermined, 10 (12.5%) haemorrhagic and 3 (3.7%) were ischaetogenic. 57.1% of under 45 year strokes were due to other determined aetiology. 12.5% of under 65 years received thrombolysis, compared to 5.8% of all strokes.

Conclusion: The under 65 population accounts for 13.6% of strokes presenting to a tertiary referral hospital. They often require more extensive investigation to determine aetiology.

doi:10.1016/j.jns.2013.07.737
Alice in Wonderland syndrome: A case report

Rehabilitation, Nagasaki Kita Hospital, Nagasaki, Japan; bNeurology, Nagasaki Kita Hospital, Nagasaki, Japan

Objective: Alice in Wonderland syndrome (AIWS), named after a novel that was written by Lewis Carroll, was first reported in 1955 by J. Todd. We herein report a case of AIWS following a cerebral infarction.

Patients: A 61-year-old right-handed male developed a cerebral infarction and was admitted to our hospital for rehabilitation on the 19th day after the stroke. A neurological examination performed on admission revealed no abnormalities, except for mild impairment of the two-point discrimination on the right side and a mild motor aphasia. On admission he complained of a bizarre sensation in his right extremity, which he described as feeling that his right extremity length was half that of the left extremity. He was distress by this bizarre feeling throughout the day, particularly due to a fear of falling down the stairs. The sense of a short extremity disappeared when he looked at his right limb visually. He felt that the weight of his right extremity was lighter than that of the left extremity and stated that the objects grasped tactually in his right hand were lighter in weight and smaller in size than those grasped in the left hand. No prosopagnosia or autotopagnosia were observed. MRI and SPECT images revealed broad hypoperfusion in the left hemisphere.

Discussion and conclusions: The bizarre sensation in the patient's extremity was considered to be consistent with a microsomatognosia, as part of a cluster of symptoms called AIWS. The occurrence of AIWS in stroke patient is extremely rare.

Effect of functional SNPs in UCP2 gene on cerebral infarction among the Korean older male subjects

M.H. Cha, M.M. Ko, H.Y. Go, M.S. Lee, Korea Institute of Oriental Medicine, Daejeon, Republic of Korea; bKorean Oriental Medicine, Semyung University, Chungju, Republic of Korea

Stroke is a serious disease which can cause death. Many genetic polymorphisms in many genes are known to be related with stroke, cerebral infarction and cardiovascular disease. In this study, we investigated the relationship between UCP2 polymorphisms and stroke among the Korean population. A total of 586 normal subjects and 1857 stroke patients (184 ischemic hemorrhage, 1659 cerebral infarction) were enrolled. Three SNPs of UCP2, G-1957A, G-866A and A55V were genotyped by the TaqMan method. Association of the UCP2 SNPs with stroke and blood parameters was statistically analyzed by logistic regression or general linear model using SAS 9.0. The G-866A and A55V UCP2 SNPs were related with stroke (p = 0.029, p = 0.039 in dominant model). These SNPs were significantly associated with cerebral infarction among stroke types. The frequency of subjects with A allele at the −866 position and the V allele at amino acid 55 was, respectively, 71.25% and 70.23% which was significantly lower than the frequencies observed for frequencies observed for G-866A (76.62%) and A55V (75.64%) in the normal group (p = 0.023 and p = 0.028, respectively). This association varied according to gender and age. The G-866A and A55V SNPs were significantly associated with cerebral infarction in male and older subjects. These two SNPs were also linked with decrease of serum triglyceride levels in the normal male subjects. This study showed that the G-866A altering of promoter activity and A55V changing of amino acid were significantly related with stroke, especially cerebral infarction in the Korean male population.

A clinical study of the patients with “ataxia optique”

M. Yamada, Y. Kazu, H. Satoh, A. Satoh, M. Tsujihata. bRehabilitation, Nagasaki Kita Hospital, Nagasaki, Japan; bNeurology, Nagasaki Kita Hospital, Nagasaki, Japan

Objective: So-called “ataxia optique” is a disorder of hand movement in which the patient is unable to grasp objects located in the peripheral visual field. This study was performed to evaluate the neuropsychological and neuroradiological findings of this disorder.

Patients: We studied six patients with ataxia optique, 56–79 years of age. All subjects were able to grasp objects located in the central visual field. Four patients bumped into the contralateral objects due to the presence of lesions.

“Ataxia optique”: Two patients had lesions in the left hemisphere. In one of these patients, reaching with both hands was affected in the contralateral visual field and the right hand in the ipsilateral field. The other patient demonstrated impairment in the ability to reach with the right hand in the contralateral field. Two patients with right hemisphere lesions exhibited reaching impairments with both hands in the right and left visual fields. Two patients had bilateral hemisphere lesions, and their ability to reach with either hand was affected in both the right and left visual fields. The SPECT analysis (vbSEE) revealed the presence of a converging region, including the inferior parietal lobe, angular gyrus, and superior parietal lobe.

Discussion and conclusions: The pattern of the reaching impairments may differ according to the side of the hemisphere lesion. The results of the SPECT analysis indicated that the localization leading to ataxia optique occurs in the above-mentioned converging region, thus leading to an impairment of the visual dorsal stream.

A pure form of amorphognosia: A case report

S. Kubota, M. Yamada, H. Satoh, M. Tsujihata. bRehabilitation, Nagasaki Kita Hospital, Nagasaki, Japan; bNeurology, Nagasaki Kita Hospital, Nagasaki, Japan

Background: Two types of tactile agnosia have been reported, apperceptive and associative. Recently we encountered a patient who showed an amorphognosia, but hylognosis and tactile object recognition were not impaired.

Case report: A 54-year-old, right-handed female suddenly developed a left hand numbness in Jan. 2011. She was admitted to a hospital and pointed out a cerebral infarction in the right frontoparietal region due to Moyamoya disease. On June 22, she was admitted to our hospital for rehabilitation. The neurological examinations revealed no abnormal findings. Neuropsychological examinations such as MMSE, WMS-R, WAIS III, Kohs block design test, BADS, BIT, and CAT were all within normal ranges. The somatosensory functions such as response to light

Seasonal variation in stroke occurrences in Japan
K. Shigematsu, T. Ito, N. Oka, H. Nakano, Y. Watanabe, The Kyoto Stroke Registry Committee. 1Neurology, National Hospital Organization, Minami Kyoto Hospital, Japan; 2Neurosurgery, Kyoto Kidugawa Hospital, Joyo, Japan; 3Epidemiology for Community Health and Medicine, Kyoto Prefectural University of Medicine, Graduate School of Medical Science, Kyoto, Japan

Background: Seasonal variations in stroke were examined from the data in the Kyoto Stroke Registry (KSR).

Methods: We analyzed data on stroke patients identified from January 1999 to December 2009 in the Kyoto prefecture, and registered in the KSR which is administered by the local government. The study cohort had 13,788 patients divided into 9011 cerebral infarction (Celn), 3549 cerebral hemorrhage (CH) and 1197 subarachnoid hemorrhage (SAH) cases. OR and 95% confidence intervals (CI) for stroke occurrence in each season and the effects of risk factor histories (RFH) were calculated for each stroke subtype.

Results: ORs (CI) for stroke occurrence were highest in winter for Celn (1.06; 1.00–1.12) and CH (1.37; 1.25–1.51) and in spring for SAH (1.51; 1.28–1.79), with summer serving as a reference. After adjustments for age, sex and RFH (hypertension, arrhythmia, diabetes mellitus and hyperlipemia), ORs for stroke occurrence were 1.06 (0.93–1.21), 0.90 (0.78–1.03) and 1.05 (0.91–1.20) in spring, autumn and winter for Celn; 1.53 (1.22–1.93), 1.36 (1.07–1.72) and 1.61 (1.28–2.02) for CH; and 1.53 (1.06–2.23), 1.08 (0.73–1.61) and 1.36 (0.94–1.99) for SAH, respectively. Hypertension history had a significant effect on the onset of CH (0.77; 0.62–0.96, p = 0.018) in spring. Arrhythmia history affected the onset of Celn in autumn (1.18; 1.02–1.37) and on onset of Celn (1.29; 1.12–1.48) in winter. Effects of other RFH on the seasonal occurrence of stroke did not reach statistical significance.

Conclusions: Seasonal variation remained significant after adjustments for RFH. However, RFH had significant effects on the seasonal occurrence of some stroke subtypes.

Patients with atrial fibrillation and CHA2DS2-Vasc ≤ 1 still develop stroke — Why so?
O. Rosca, S. Diaconu, N. Diaconu. 1Institut of Cardiology, Chisinau, Moldova; 2Institut of Neurology and Neurosurgery, Chisinau, Moldova

Objective: To determine the influence of AF and of additional thromboembolic risk factors on stroke development and evolution with comparison of several schemas’ stroke predictive value.

Methods: Retrospective study of all ischemic stroke patients admitted during one year in a municipal hospital.

Results: The study included 735 patients with ischemic stroke of whom 519 had primary stroke (70.6%). AF was determined in 206 cases (28.4%), these patients being older (70.1 ± 0.65 vs. 64.3 ± 0.46 years, p < 0.001), mainly females — 57.8% (119/206) and having more vascular risk factors. AF patients have had more severe signs of cerebral lesion on admission (79% vs. 37%, p < 0.01), also with a higher hospital mortality rate (30.6% vs. 13.2, p < 0.001). According to CHADS2 score, about 37.4% of patients with AF and stroke were included in the low and medium stroke risk groups, but still have had stroke. Upon analysis 46% of them were women, 38% were aged between 65 and 75 years, and 36.7% were having coronary heart disease, including 16% old myocardial infarction and 7.7 — intermittent claudication. By including these factors in the CHA2DS2-Vasc score, 0% had a low risk, and 4.1% had a medium one and 95.9% had a high thromboembolic risk.

Conclusions: Patients with AF without previous thromboembolic events have a high risk of stroke with more severe evolution and consequences. Female gender, age between 65 and 75 years and vascular disorders should be taken into consideration when calculating the thromboembolic risk, CHA2DS2-Vasc being the most sensible score in determining thromboembolic risk in patients with non-valvular AF.

Hospitalized patients in the mortality rate from stroke  

N. Vukasinovic, S. Jolic, V. Milosevic, M. Zivkovic. Department of Neurology, University Clinical Center Nis, Nis, Serbia

Hospital registry of the Department of Neurology, Clinical Center Nis, contains information about the treatment of more than 30,000 patients. The aim of our study was to compare the mortality rates of different types of stroke. 

Statistical processing was carried SPSS V19. In the period from 01 January 2000 to 31 December 2010 in-hospital registry of the Department of Neurology, registered 10,739 hospital admissions of patients with a diagnosis of stroke. Since there were 5476 (51%) men and 5263 (49%) were women. The average age of patients was 68.12 ± 11.36 years. Of the total number of recorded hospital admissions, 487 (4.5%) were diagnosed with SAH, 1804 (16.8%) with a diagnosis of ICH, 7553 (70.3%) with a diagnosis of acute ischemic stroke, and 895 (8.3%) with unspecified type of stroke. In the hospital 3285 (30.6%) deaths were registered, while 7454 (69.4%) patients were discharged from the hospital stay. The mortality rate was 19.7% in patients with SAH, 47% of patients with ICH, 23.1% of patients with acute ischemic stroke and 66.5% in patients with an unspecified type of stroke. High mortality rate was registered in the case of patients with unspecified type of stroke and bearing in mind that these are the patients who did not set a definitive diagnosis because they died shortly after admission. Hospital mortality rate patients with ICH is somewhat higher than in the literature, because in our hospital surgery is not indicated in severe illness.

Clinical feasibility and usefulness of three depression scales in acute stroke patients  

S.Y. Kim, M.W. Kim, Dept. Rehabilitation Medicine, Catholic University of Korea, Seoul, Republic of Korea; Catholic University of Korea, Incheon Mary’s Hospital, Incheon, Republic of Korea

Objectives: To investigate clinical feasibility and usefulness of three depression scales, which are Beck depression inventory (BDI), aphasic depression rating scale (ADRS), and emotional behavior index (EBI) in acute stroke patients. 

Methods: Twenty stroke patients, 2 weeks to 4 weeks after onset, were prospectively recruited. BDI was recorded by self or caregiver with yes/no question. ADRS and EBI were checked by observing patient’s behavior for three days. EBI which recorded behaviors most frequently observed, had 7 domains such as sadness, aggressiveness, disinhibition, adaptation, passivity, indifference, and denial. Descriptively we analyzed two rating scales and one behavior index.

Results: 13 patients had left hemisphere lesions, and 7 had right lesions. For BDI, only 9 patients could be evaluated because 11 patients had global aphasia or cognitive dysfunction (MMSE < 20). In 9 patients, three patients had severe depression (BDI score > 16) and 6 patients did not have depression. For ADRS, all patients could be evaluated. Twelve patients had depression by ADRS score (> 10). Among them, 10 were from BDI unfeasible 11 patients and 2 were from feasible 9 patients. For EBI, 6 patients showed sadness, 5 aggressiveness, 2 disinhibition and 1 indifference. Six patients were not observed specific emotional behavior.

Conclusion: It is difficult to assess depression by BDI in patients with communication deficiencies or severe cognitive disorders. ADRS and EBI could help access to emotional changes in these patients. Further research of large sample size and good design is needed for appropriate depression rating scale in acute stroke patients including ADRS and EBI.

Cerebrovascular reactivity and systemic haemodynamics parameters in response to acute hyperoxia in stroke and diabetic patients with stroke  

I. Hegedus, I. Drenjanec, K. Buljan, B. Radanovic. Neurology, Clinical Hospital Center Osijek, Croatia; Physiology and Immunology, Faculty of Medicine, University Josip Juraj Strossmayer Osijek, Osijek, Croatia

Background: The aim was to determine the effect of acute hyperoxia on cerebrovascular reactivity (CVR), thromboxane B2 (TXB2) levels and systemic haemodynamic parameters in acute stroke patients (SP) and diabetic patients with stroke (DPwS). 

Methods: In 26 SP (age 68 ± 6 years) and 26 DPwS (69 ± 6 years) mean blood flow velocity (MBFV) in middle cerebral artery (MCA), index of pulsatility (IP) and index of resistance (IR) were determined by transcranial Doppler before (basal) and during 15 min of hyperoxia (100% O2 via facial mask). Systolic and diastolic blood pressure (SBP, DBP), heart rate (HR), pO2 and TXB2 blood levels were assessed at the same time points. Data are expressed as mean ± SD; p < 0.05 was significant.

Results: During hyperoxia MBFV significantly increased in both groups; SP (from 56 ± 11 to 60 ± 12), DPwS (from 53 ± 13 to 58 ± 16), while IP and IR or HR were not affected in both group compared with basal values. Hyperoxia only caused mild HR increase by 3% in SP and 4% in DPwS (p < 0.05). There was a significant increase in SBP, DBP and pO2 in both groups and 2% decrease in TXB2 levels in SP and 12% decrease in TXB2 in DPwS during hyperoxia (p < 0.001) without significant difference between groups. TXB2 showed weak negative correlation with MBVF in both groups (p < 0.05).

Conclusion: This study demonstrated impairment of CVR accompanied with decrease in TXB2 levels in both groups, suggesting the role of TXB2 in CVR. Haemodynamic parameters were not affected, except for improved oxygenation.

ICH evacuation by MIN techniques  

K.D.M. Resch. Neurosurgery, Klinikum Darmstadt, Darmstadt, Germany

Objective: STICH I and II trials examined a situation that actually is not representing today’s reality regarding MIN strategies and techniques. EndoSTICH trial and MISTIE trial are studying two minimally invasive techniques (endoscopic evacuation and kathereter-lysis) which however do not compete the needs of the majority of hemorrhages. We elaborated a MIN technique with high effectiveness and applied it up to now in 150 cases. We present a retrospectively analysis of this first series.

Material and method: This MIN concept combined several techniques to assist microsurgery: High-end neurosonography with small probes ("burr-hole-probe/ALOKA") and mouth tracking of the microscope, both mandatory. Additionally we added endoscopy (Wolf, Aesculap, Storz) and LASER (Th-YAG Revolix).
150 patients underwent this application within 10 years by the presenting author. The approaches varied from burr-hole to 1€ or 2€ in size depending from the imaging findings and expected difficulties. 

**Results:** In nearly all cases it was possible to evacuate the hematoma within 1 h and the hematoma evacuation decreased the ICP to normal levels. Clinical results were excellent in lobar bleedings with isochoric before surgery. Large and deep-seated hemorrhages needed longer recovery time but in all cases postop CT showed fast reduction of perifocal edema.

**Conclusion:** Combination of ultrasound, mouth tracking, endoscopy and LASER enabled evacuation of all types of hematoma minimal invasively and very effectively in less than one hour.

**The significance of serum gamma-glutamyltransferase in acute cerebral infarction**

J. Son, Boneseng Memorial Hospital, Busan, Republic of Korea

**Background:** Serum gamma-glutamyltransferase (GGT) is known as a possible marker for metabolic syndrome and cardiovascular disease. The relationship between serum GGT and acute cerebral infarction is not well known.

**Objective:** We evaluated the significance of serum GGT in acute ischemic stroke and ischemic stroke subtype.

**Patients and methods:** We included 178 patients with acute cerebral infarction within three days of onset prospectively. Age- and sex-matched 180 controls were enrolled. All patients were performed brain imaging including MRI/MRA or CT/CTA and cardiac workup. Serum GGT in first admission day, C-reactive protein (CRP), uric acid, total cholesterol, high density lipoprotein (HDL), low density lipoprotein (LDL), leukocyte count, fasting glucose, systolic and diastolic blood pressure were measured. Stroke subtype was classified into five groups by the Trial of Org 10172 in Acute Stroke Treatment (TOAST) classification.

**Results:** The mean level of GGT in acute stroke patients was significantly high compared with the control group (p < 0.001). In subgroup analysis, the GGT was high in groups of large artery atherosclerosis, small vessel occlusion and cardiac embolism (all p < 0.001).

**Conclusion:** Serum GGT was elevated in patients with acute cerebral infarction in small vessel disease, atherosclerotic and cardiogenic stroke. There was no association between serum GGT and site of large artery atherosclerosis. Serum GGT may play roles of serum biomarker for acute cerebral infarction.

**Hospital mortality associated with stroke in Southern Iran**

A. Borhani Haghighi, R. Safaria, A. Safarib, S.T.H. Heydari, a bShiraz University of Medical Sciences, Shiraz, Iran; cKazeroon Azad University, Kazeroon, Iran

**Background:** Unlike the western hemisphere, information about stroke epidemiology in Southern Iran is scarce.

**Methods:** A retrospective, single-center, hospital-based longitudinal study was performed at Namazi Hospital in Shiraz, Southern Iran. Patients with a diagnosis of hemorrhagic and ischemic strokes were identified based on the International Classification of Diseases, 9th and 10th editions for the period between 2001 and 2010. Demographics including age, gender, area of residence, socioeconomic status, length of hospital stay and discharge destinations were analyzed in association with mortality.

**Results:** A total of 16,351 patients were included in this analysis with the mean age 63.4 (95% CI: 63.1, 63.6). Males were slightly predominant (53.6% versus 46.4%). Fifty six percent of the total sample were older than 65, 14% were younger than 45, and 0.026% were children younger than 18. The mean hospital stay was 6.3 days (95% CI: 6.2, 6.4). Among all types of strokes, the overall hospital mortality was 20.5%. A higher stroke mortality was associated with females, children, and low socioeconomic status (P < 0.001).

**Conclusions:** In comparison to western countries, a larger proportion of patients are young adults, and the mortality rate is higher.

**Allelic polymorphism of the LMP2 and PSMA6 gene in acute ischemic stroke patients in Ukrainian population**

V. Melnyk, O. Savchuk, V. Dosenko, L. Sokolova, G. Skibo.

**Abstracts / Journal of the Neurological Sciences 333 (2013) e152**

**Background:** The proteasome activity significantly changes in ischemia. Polymorphisms in genes of proteasome subunits have been studied as risk factors of cardiovascular disease but we don’t find any articles concerning role of allelic polymorphism of proteasome genes in the susceptibility to acute ischemic stroke (IS). Different allelic variants of proteasome subunits PSMA6 and LMP2 can have different effects on the susceptibility to acute IS in Ukrainian population.

**Methods:** Fast Real Time PCR was used for determination of LMP2 (rs 4331349) and PSMA6 (rs 1048990) and detection of the various variants of the LMP2 and PSMA6 genes in 102 patients with IS and in 92 control subjects. We tested some risk factors of IS in patients with different variants of these genes.

**Results:** It was shown that the distribution of the major homozygotes, heterozygotes and minor homozygotes for the LMP2 gene (60Arg/His) was 55.5%, 34.3% and 9.8%, respectively (in control group: 53.3%, 43.5% and 6.7%; p = 0.046); for the PSMA6 (−8C/G) polymorphism the percentages were 75.5%, 21.4% and 3.1%, respectively (in control group: 80.2% homozygotes and 19.8% heterozygotes; p = 0.22). We identified that polymorphism of LMP2 gene (60Arg/His) associated with diabetes mellitus (DM) (p = 0.03). The PSMA6 (−8G/C) minor homozygotes was associated with repeated IS (p = 0.06).

**Conclusion:** We found relationship between LMP2 gene polymorphism and we didn’t find relationship between PSMA6 gene polymorphism and risk of IS. We suggest that G/C promoter variant of PSMA6 can be considered as a risk factor for repeated IS and polymorphism of LMP2 gene was associated with previous DM.

Fifty six percent of the total sample were older than 65, 14% were younger than 45, and 0.026% were children younger than 18. The mean hospital stay was 6.3 days (95% CI: 6.2, 6.4). Among all types of strokes, the overall hospital mortality was 20.5%. A higher stroke mortality was associated with females, children, and low socioeconomic status (P < 0.001).

**Conclusions:** In comparison to western countries, a larger proportion of patients are young adults, and the mortality rate is higher.

doi:10.1016/j.jns.2013.07.750
Cerebral venous thrombosis (CVT) is an under diagnosed cause for acute or slowly progressive neurological deficit. It has a wide spectrum of symptoms and signs that may be clinically challenging and great mimicker.

We studied 45 patients with CVT at our centre. 41 were females (91%). The mean age was not different between the sexes (18.55 years in females and 18.35 years in males).

Of the 41 females 15 were postpartum (36.5%); five were pregnant while the other five were on oral contraceptive pills. Two were positive for antiphospholipid antibodies (APLA). Only one patient had protein C deficiency. The associations included, septic abortion (1), non-specific febrile illness (4), SLE (1), neoplasia (2), rheumatoid arthritis on methotrexate therapy (1), and indeterminate cause (2). Amongst the four males one had periportal cellulitis, one had severe dehydration and the last two were of indeterminate cause.

We will present illustrative cases. One patient had a haemorrhagic infarct in the left temporal lobe, misdiagnosed as brain tumour. A second female patient was diagnosed as multiple sclerosis and was planned for disease modifying therapy, the third patient had marked psychiatric disturbance, while a fourth had periportal cellulitis and developed a squint.

We identified 2 patients with venous sub-arachnoid haemorrhage — a unique presentation and 3 with suspected associated viral encephalitis — not previously reported.

MRI/MRV was the examination of choice for confirmation of cerebral venous thrombosis.

Ibudilast inhibits Th17 differentiation
K. Kawabe, T. Takazawa, Y. Yanagihashi, Y. Ishikawa, T. Hirayama, K. Murata, O. Kano, K. Ikeda, Y. Iwasaki. Department of Neurology, Toho University Omori Medical Centre, Tokyo, Japan

Background: T helper cells secreting interleukin (IL)-17 (Th17 cells) play a crucial role in the pathogenesis of autoimmune diseases, such as multiple sclerosis. In addition, Th17 cells are associated with secondary inflammation induced by cranial infarction. Budilast, a nonselective phosphodiesterase inhibitor that suppresses the differentiation of T helper 1 cells. However, it remains unknown whether ibudilast suppresses Th17 differentiation and IL-17 production.

Methods: For the in vitro study, naïve T cells were isolated from 5 healthy volunteers using a magnetic bead kit. These cells were stimulated for Th17 differentiation, with/without ibudilast for 1 week. Population of Th17 was measured by flow cytometry using anti-IL-17 antibodies. For the in vivo study, mRNA were isolated from 5 patients with a history of ischemic stroke before and after ibudilast consumption for 6 weeks. We compared the IL-17 mRNA before ibudilast consumption with those after ibudilast consumption. This study was approved by institutional ethics board.

Results: In vitro, Th17 differentiation was significantly inhibited by ibudilast. In vivo, the IL-17 mRNA were significantly lower in patients treated with ibudilast than in patients not treated with ibudilast.

Conclusion: Ibudilast inhibits Th17 differentiation and may regulate harmful secondary inflammation induced by ischemic changes in the brain.

Minimally invasive removal of intracerebral haemorrhage

I. Kuzibayev. Neurosurgery, Republican Research Center of Emergency Medicine, Tashkent, Uzbekistan

Objective: The main purpose of surgery of intracerebral hemorrhage is minimally invasive removal of hematoma with maximal volume evacuation. For the purpose of increasing the efficiency of surgery of intracerebral hemorrhage, we developed and applied an endoscopy assisted manipulator for minimally invasive evacuation of intracerebral hemorrhage and analyzed the results of treatment of patients using that technique.

Material and methods: The manipulator is consisted from rigid endoscope of Aesculap AG, including irrigation and suction channels, transparent sheath and its holder. The main advantages of the surgical evacuation of intracerebral hemorrhage using of the endoscopy assisted manipulator are:

1) Burr hole approach under local anesthesia.
2) The transparent sheath improves visualization of the border between brain parenchyma and hemorrhage
3) Free-hand surgery without fixing the endoscope.
4) The capability of manipulation in deep area of the brain through narrow surgical approach.

We performed surgery using the manipulator in 78 patients with intracerebral hemorrhage during 24 h after onset. The range of hematoma volume was 18–106 cm³, the mean hematoma volume — 59.2 ± 7.4 cm³.

Results: The main duration time of surgery was 65.4 ± 5.4 min, the mean hematoma removal rate was 95.2 ± 2.6%. The lethal outcome rate was 10.8%. No postoperative recurrence of hemorrhage with deterioration of symptoms occurred.

Conclusion: We consider that evacuation of intracerebral hemorrhage using the endoscopy assisted manipulator allows improving the treatment outcome of patients with intracerebral hemorrhage.

Possibilities of neuroprotection during arterial hypertension and cerebro-vascular disorders

N. Salimova. Republican Specialized Center of Cardiology, Tashkent, Uzbekistan

Aim: Study of comparative effect of two variants of neuroprotection in patients with arterial hypertension (AH) and cerebrovascular disorders (CD).

Materials and methods: 60 I–III level AH patients of both sex were observed (age 55.3 ± 2.8 years) with CD. All patients received basic therapy (BT) (valsartan + ACK + indapamide + atorvastatin). By the character of neuroprotection patients were randomized into 2 groups: 1st (n = 30) received cerebrolysine of 10 ml i/v 10, 2nd (n = 30) — citicoline 1000 mg i/v Nq 10. Before, during and after 3 month therapy all patients' cardiological, neurological and psychological statuses were observed with the use of AH daily monitoring, different psychodiagnostic tests, electroencephalography, CT and MRT of brain, and Doppler of cerebral vessels.

Results: Analysis showed that groups were equally effective for dynamics of cardiological status and AH. But in group of BT + cerebrolysine there was a significant regress of overall (n = 24) and microneurosymptoms (n = 22), anxiety-depressive (n = 27) and cognitive (n = 28) disorders (P < 0.01). During BT + citicoline regressed overall (n = 29) and microneurosymptoms (n = 24) (P < 0.01), but less effective during psychological (n = 18) and cognitive (n = 24) disorders. Cerebrolysine was better for dynamics of neuro-physiological parameters, citicoline — of symptoms liquor hypertension (P < 0.01). This data verifies by variables the neurovisualization methods. Acute cerebrovascular events were not registered during neuroprotection in both groups (P < 0.05).

Conclusion: Cerebrolysine and citicoline demonstrated positive neuroprotective effect in patients with AH and CCVD. Thus, effect of cerebrolysine was significant during neuropsychological and cognitive disorders, and citicoline — local neurological symptoms and liquor hypertension. Combination of citicoline and cerebrolysine is increasing the possibility of neuroprotection during AH.

Surgical therapy of internal carotid artery occlusion (ICAO) in nine patients

1Department of Neurosurgery, First Hospital, Datong Coalmine Group, China; 2Institute of Brain Science, Department of Neurology, Medical School, Shanxi Datong University, Datong, China; 3Department of Encephalopathy and National Major Clinical Department of Ministry of Health, Third Hospital, Shanxi University of Traditional Chinese Medicine, Taiyuan, China

Background: ICAO is a common clinical event. Although the incidence of stroke caused by the occlusion is not high, it leads to the serious change of the cerebral hemodynamics. In particular, when operation of contralateral carotid stenosis is needed, the risk is increasing.

Objective: To explore the indications for operation and recanalized techniques of ICAO.

Patients and method: DSA showed ICAO in 9 male patients, aged 57 to 77 years old. Among them, four patients showed recurrent TIA episodes, three showed dizziness with unilateral weakness, one showed unilateral blindness caused by paroxysmal amaurosis, and one showed paresis of left lower limb. Tail-like gradual occlusion occurred in 6 patients and nearly blunt occlusion in 3 patients. Distal carotid varying degrees of progress occurred in 6 patients.

Results: Six cases showed recanalization, while another three were not. After 2-year follow-up, seven cases did not show further cardiovascular and cerebrovascular events. Two patients died of heart disease.

Conclusion: Hemodynamic analysis is an important part for the operation. Tail-like gradual occlusion and forward or retrograde blood flow developing of the distal carotid artery should serve as strong evidence to choose operation. With regard to ICAO techniques, the length of the hard tough thrombus exceeds the carotid incision by 3 cm, Fogarty catheter was applied to insert into the distal embolization, slowly retracted after filling the balloon, and repeated until blood flows out of the thrombosis. According to the intraoperative angiography, we can decide whether the stent is placed in the distal artery occlusion or not.

Intra-arterial mechanical procedures in treatment of acute stroke
B. Labovic1, S. Culafe2, T. Lepici3, R. Raicevic2. 1Clinic of Neurology, Military Medical Academy, Serbia; 2Radiology, Military Medical Academy, Institute of Radiology, Belgrade, Serbia

Some of the methods of treatment for acute stroke after therapeutic window for intravenous thrombolysis (3–4.5 h) are neuro-interventional procedures: intra-arterial thrombolysis and endovascular potentiating of thrombolytic effect.

Case report: Patient (64), admitted at 13 h, because of stroke, with severe right-sided limbs pyramidal deficit, motor dysphasia (NIHSS 14). First symptoms have appeared abruptly at 7 h. The patient underwent digital subtraction angiography (DSA) due to MSCT malfunction. The DSA finding 7 h after onset was occlusion of temporal branch of left MCA. Following DSA, aspiration thrombectomy was performed, using aspiration catheter size 4Fr, with thromb aspiration with negative pressure using syringe of 60 ml, and procedure is repeated until complete thromb extraction is achieved. Control DSA showed complete recanalization. Patient showed signs of fast recovery, initially in lower limb, immediately followed by recovery of upper limb, maintaining motor dysphasia (NIHSS 5). MR endocanrium on the next day showed hyper density in zone of left MCA, 1 × 1.5 cm.

Discussion: Based on experience in MMA in treatment with intra-arterial thrombolysis and aspiration techniques, of 5 treated patients, full recovery has been achieved in 4, while one resulted in death. It is a fact that patients with time expired on the therapeutic window for intravenous fibrinolysis, but immediately treated with intra-arterial fibrinolysis or mechanical thromb extraction as possible therapeutic option, have much better prognosis.

Conclusion: Blood vessel recanalization in presented patient is achieved by effect of mechanical thromb extraction and it does not represent standard therapeutic procedure. Presented data indicate possibility of widening the therapeutic window.

Low prevalence etiology in a patient with hemispheric stroke
D. Popescu1, A. Mergesan2, B. Dorobat3, O. Bajenaru4, F. Antochi1.
1Neurology, Bucharest University Emergency Hospital, Bucharest, Romania; 2Interventional Radiology, Bucharest University Emergency Hospital, Bucharest, Romania

Objectives: Atherosclerotic intracranial arterial stenosis is an important cause of stroke and it is increasingly being treated with percutaneous transluminal angioplasty and stenting to prevent recurrent stroke. In patients with intracranial arterial stenosis, aggressive medical management was superior to percutaneous transluminal angioplasty and stenting with the use of the Wingspan stent system, but there are no studies that compare transluminal balloon angioplasty to medical treatment.

Methods: We present the case of a 76-year-old patient who presented to our clinic with recurrent syncope for neurologic assessment. The patient has a history of permanent atrial fibrillation, central retinal artery occlusion, and hypertension and has no history of prior neurological deficits. The ultrasonographic examination of cervical vessels was unremarkable for atherosclerotic disease but the CT examination of the head revealed a stroke in the cortical border zone between MCA and PCA. The cervico-cerebral artery digital subtraction angiography revealed an intracranial stenosis of middle cerebral artery in M1 segment.

Results: The patient underwent percutaneous transluminal balloon angioplasty of the stenosis of MCA in M1 segment without neurologic incidents or haemodynamic instability and was discharged with Clopidogrel and oral anticoagulant-cumarin derivate.

Conclusion: We choose to perform percutaneous transluminal balloon angioplasty in a selected case of a patient with middle cerebral artery stenosis and multiple risk factors for stroke with good results and without complications.

stroke in history was higher (9.3; 5.2–19.2 mg/dl) than in the other patients (2.8, 1.8–6.9 mg/dl, p = 0.011).

Conclusion: The increased concentration of IL-6 and CRP in serum is associated with complications of carotid atherosclerosis. CRP is associated with stroke, formed by the mechanism of atherothrombosis.

Stroke in Kenya and its co-morbidities and risk factors in Kenya hospitals
S.W. Mbugua, R.N. Mbugua, J.N. Mwathi. 1Researcher (Global Mental Health), Kenya Medical Research Institute, Kenya; 2Researcher (Global Mental Health), Kenya Association for the Welfare of People with Epilepsy, Kenya; 3Clinical Research/Psychiatry, Kenya Network of Women Living with HIV/AIDS, Nairobi, Kenya

Background: Stroke is the most common causes of morbidity and mortality the world over. Established risk factors such as arterial hypertension, diabetes mellitus, cigarette smoking, hyper-lipidaemia, micro-vascular rupture, gender, age-co-morbidities like sickle cell disease, HIV/AIDS infection and cerebral malaria are encountered in the tropics.

Objectives: To determine pathological, risk factors, in-hospital period prevalence and in-hospital outcome of stroke.

Results: A total of 2629 patients were admitted at the hospital during study period. 80 patients had diagnosis of stroke; giving an in-hospital period prevalence of 3042/100,000. Mean age was 61.3 years, mode; 63 years, range 34–95 years. M to F ratio 1.2:1 stroke sub-types: ischaemic stroke 68 (85%) and haemorrhagic stroke seven (8.8%). Five patients (6.3%) no evidence of stroke sub-type was on-record. Established risk factors are hypertension/diabetes mellitus. Hypertension was found in 64 patients (80%) and diabetes-mellitus in 27 (33.7%). 23 patients (28.8%) had both hypertension/diabetes-mellitus. Co-morbidities were observed and included mitral-stenosis, cardiac-arrhythmias cardio-myopathy, HIV/AIDS, Left Ventricular Hypertrophy (LVH), infective endocarditis, atrial septal aneurysm, carotid plaques with or without stenosis and hyper-homocystenemia. 75 patients (93.8%) were discharged and four (5%) died in hospital. All patients who died had anterior circulation ischaemic stroke as per Trial of Org 10172 in Acute Stroke Treatment (TOAST) classification.

Conclusion: Ischaemic stroke is the most common pathological sub-type observed in this study. Hypertension is the leading observed risk factor for stroke. Hospital period prevalence for stroke of 3042/100,000 was found. 75 patients (93.8%) were discharged and four (5%) died in hospital.

Anterograde amnesia due to fornix infarction
T. Yeoh, G.G. Pulickal, W.-Y. Yu, L.C.S. Tan. 1Department of Neurology, National Neuroscience Institute, Tan Tock Seng Hospital, Singapore; 2Department of Diagnostic Radiology, Singapore General Hospital, Singapore; 3Department of Neuroradiology, National Neuroscience Institute, Tan Tock Seng Hospital, Singapore, Singapore

Background: The fornix serves an important role in human memory. Amnesia resulting from fornix infarction has been rarely reported.

Objective: To describe the clinical and radiological features of a patient who developed anterograde amnesia following fornix infarction and review the published literature.

Patients and methods: A patient who was admitted to the Department of Neurology, National Neuroscience Institute, Singapore.

Results: A 39-year-old lady with poorly controlled diabetes mellitus and dyslipidaemia presented with acute confusion and anterograde amnesia. Neurological examination was normal except for MMSE score of 27 upon 30, with deficits in orientation and recall. MRI brain showed an acute infarction of the columns of the fornices bilaterally. The right septal nuclei and anterior commissure were also involved.

Conclusion: This case illustrates persistent memory impairment following fornix infarction and emphasises the importance of excluding a strategic infarct in a patient presenting with acute amnesia.

Neuroradiological reporting from abroad — Is it possible?
B. Kressa, I. Isfahara, A. Grabowskia, M. Papendiecka, C. Schwareb, A. Gottschalck, U. Meyding-Lamadec, Institute of Neuroradiology, Krankenhaus Nordwest, Frankfurt/Main, Germany; Jerudong Park Medical Center, Bandar Seri Begawan, Brunei; Thesis für Neurologie, Frankfurt/Main, Germany; Meytec Telemedizin, Berlin, Germany; Neurology, Krankenhaus Nordwest, Frankfurt/Main, Germany

Objective: To evaluate whether reporting of emergency examinations is possible over a distance of 12,000 km.

Methods: Evaluation of time duration for the sending process for MR and CT scans under emergency conditions.

Results: 3472 MRI and 1118 CT reports have been prepared between 01.07.2010 and 30.06.2012, median time for sending process for CT was 47.1 s and for MR 252.4 s.

Conclusion: In case of broadband cable capacity and dedicated IT-network specialized reporting of neuroradiological cross sectional imaging examinations is feasible in acceptable length of time even over long distance and in an emergency setting. In any case the requirements of Germany for teleradiological projects are fulfilled. This allows neurological treatment even of intensive care patients according to quality level of European centers.

Myocardial Infarction as an early complication in acute stroke patients: Results from the Austrian Stroke Unit Registry
T. Gattringerk, K. Niederkorna, L. Seyfangb, J. Ferraric, W. Langc, M. Brainind, J. Willeite, F. Fazekasa, C. Enzingera, Institute of Neuroradiology, Krankenhaus Nordwest, Frankfurt/Main, Germany; Jerudong Park Medical Center, Bandar Seri Begawan, Brunei; Thesis für Neurologie, Frankfurt/Main, Germany; Meytec Telemedizin, Berlin, Germany; Neurology, Krankenhaus Nordwest, Frankfurt/Main, Germany

Background: Patients with transient ischemic attack (TIA) and stroke have an increased risk for subsequent cardiac events including myocardial infarction (MI). Information regarding MI as a complication of stroke in the very acute phase is limited.

Objective: To assess the frequency of MI, the characteristics and short-term outcome of such patients in the stroke unit setting.

Methods: 41,619 patients with ischemic stroke or TIA, and 4984 with primary intracerebral haemorrhage (ICH) prospectively enrolled in the Austrian Stroke Unit Registry in the last 6 years were analysed.

Results: 421 patients with ischemic stroke or TIA (1%) and 17 patients with ICH (0.3%) suffered from MI during stroke unit treatment. Patients with ischemic cerebrovascular events were significantly older, had more severe strokes and generally more vascular risk factors, atrial fibrillation and previous MI. Total anterior circulation and left hemispheric stroke syndromes were more often observed in MI patients. Patients with MI not only suffered from a worse short-term outcome at stroke unit discharge (mortality 14.5 versus 2%, p < 0.001), but also acquired more other well known stroke complications. In multivariate analyses factors that remained independently associated with MI were previous MI and stroke severity at admission. Hypercholesterolemia was inversely associated with MI.

Conclusions: Although MI in the acute phase after stroke seems to be rare, it is associated with a poor short-term outcome. Furthermore our results identify patients with previous MI and more severe strokes to be at an increased risk for the early complication of MI.

The cultural acceptance of robotic tele-stroke medicine among patients and healthcare providers in Saudi Arabia: Results of a pilot study
A. Al Khatmaami, S. Al Shahrans, A. El Metwallys, S. Kojans, M. Al Jumahs, King Abdul Aziz Medical City, National Guards for Health Affairs, Saudi Arabia; Department of Epidemiology & Biostatistics, College of Public Health and Health Informatics, King Saud Bin Abdul Aziz University for Health Sciences, Saudi Arabia; King Abdullah International Medical Research Center, Riyadh, Saudi Arabia

Background: The technical feasibility and cultural acceptance toward the use of telestroke technology in Saudi Arabia has not been investigated.

Objectives: To determine the degree of satisfaction toward the use of this technology among stroke patients, their relatives and healthcare providers in Saudi Arabia.

Materials and methods: The remote presence robot (RPR), the RP-7i® (FDA-cleared) provided by InTouch Health was used between October and December, 2012 at King Abdulaziz Medical City in Riyadh, Saudi Arabia. Patients and their relatives were informed that the physician would appear through a screen on the top of a robotic device, as part of their clinical care. A convenient sample of consecutive stroke patients and relatives admitted to the stroke unit through ED and healthcare providers completed a self-administered satisfaction questionnaire following consultation sessions.

Results: A total of fifty participants completed the questionnaire. All agreed or strongly agreed that the consultant interview through robotic tele-stroke was useful and that the audiovisual component of the evaluation was of high quality; 98% agreed or strongly agreed that they did not feel shy or embarrassed during the remote interview, were able to understand the instruction of the remote consultant and recommended its use in stroke management. In addition, 92% agreed or strongly agreed that the use of this technology can efficiently replace the physical presence of a neurologist.

Conclusion: Results suggest that the use of tele-stroke medicine is culturally acceptable among stroke patients and their families in Saudi Arabia and is favorably received by healthcare providers.

Retinal vasoreactivity in patients with ischemic stroke
K. Bettermann, J.E. Slocomb, V. Shivkumar, M.E. Lott, Neurology, Penn State University, Hershey, PA, USA; Neurology, University of Toledo, Toledo, OH, USA; Heart and Vascular Institute, Penn State University, Hershey, PA, USA

Background: As the eye and brain share embryological, anatomical and physiological similarities, studies of retinal blood vessels may
prove useful as a surrogate marker for cerebrovascular disease and help to assess stroke risk. Retinal arteriovenous ratios (AVRs) have been shown to indicate risk of stroke, but the association between retinal vasoreactivity, ischemic stroke, and cerebrovascular function remains unknown. Retinal vasoreactivity assessments may detect early stages of endothelial dysfunction and allow direct assessment of blood vessel physiology.

**Objective:** To examine

1) retinal microvessel behavior in patients with ischemic stroke
2) the relationship between retinal and cerebral vascular reactivity.

**Methods:** Cohort study of 12 patients with ischemic stroke presenting 3 months after the stroke, and 8 healthy controls (44–85 years). Retinal vasoreactivity was measured with the dynamic vessel analyzer following flicker light stimulation. Middle cerebral artery (MCA) vasoreactivity following hyperventilation/breathhold was measured using transcranial Doppler ultrasound. AVRs were obtained using funduscopy photographs.

**Results:** Patients with stroke had significantly attenuated retinal venous (p = -0.0002, CI 95%) and arterial (p = 0.001, CI 95%) vasodilation responses compared to healthy controls, and decreased cerebral vasoreactivity following hyperventilation/breath hold (p = 0.0068, CI 95%). Across all groups an attenuated venous flicker response was associated with an increase in MCA RI (r = -0.5, p = 0.03, CI 95%) and PI (r = -0.5, p = 0.04, CI 95%) and a decrease of MCA vasoreactivity (r = 0.46, p = 0.05, CI 95%).

**Conclusion:** In this study impairment of retinal microvascular function is associated with ischemic stroke and measures of cerebrovascular function. Microvascular dysfunction of retinal blood vessels may predict ischemic stroke risk.

“Mobile Stroke Unit” for stroke treatment at the emergency site

S. Walter, P. Kostopoulos, A. Ragoschke-Schummm, A. Haass, I. Grundwald, W. Reith, K. Fassbender. "Neurology, University Hospital of the Saarland, Homburg, Germany; 2Acute Vascular Imaging Centre, John Radcliffe Hospital, Oxford, UK; 3Diagnostic and Interventional Neuroradiology, University Hospital of the Saarland, Homburg, Germany"

**Background:** Currently only 2–5% of all acute stroke patients receive thrombolytic therapy due to delay in hospital arrival or diagnostic work-up. In this feasibility study, we tested the efficacy of a new approach of stroke diagnosis and treatment starting at the emergency site, rather than after hospital arrival, in reducing delay in stroke therapy.

**Methods:** We constructed a “Mobile Stroke Unit”, an ambulance that delivers imaging, point-of-care-laboratory analysis, and neurological expertise directly at the emergency site. In a prospective, randomised single-centre trial, we compared the time from alarm (emergency call) to therapy decision, between Mobile Stroke Unit (MSU) and standard stroke hospital intervention.

**Results:** As prespecified the trial was stopped after a planned interim analysis at 100 of 200 patients because the primary endpoint showed a clear superiority of the MSU treated group. Prehospital stroke treatment reduced the median time from alarm to therapy decision substantially to 35 min (IQR 31–39) in the MSU group versus 76 min (63–94) in the hospital control group (p < 0.0001). We also detected similar gains regarding times from alarm to end of the different diagnostic steps, although there was no substantial difference in the number of patients who received intravenous thrombolysis or in neurological outcome. Safety endpoints seemed similar across the groups.

**Conclusions:** This first trial demonstrates feasibility of prehospital diagnostic stroke work-up and treatment, with substantially reduced time until therapy decision.

How to use verbal autopsy to study stroke incidence in developing countries

S. Aidi, S. Bellamine, M. Yahyaoui, I. Slassi, F. Mourji, M. El Alaoui Faris. "Neurology, Rabat, Morocco; 2University Mohamed V Souissi, Rabat, Morocco; 3Hassan II University Hospital, Morocco; 4Hassan II University, Casablanca, Morocco"

It is well recognized that good quality population-based studies are the most reliable source of information about stroke incidence on a population level but identifying all new stroke in a population is particularly challenging. However, those criteria may be not practical for stroke studies undertaken in developing countries, where most strokes occur and resources are limited.
In a door-to-door survey in Rabat–Casablanca regions, in Morocco, involving a total of 60,031 individuals (36,756 urban and 3275 rural), investigators identify through the use a specific questionnaire a possible stroke patient and also households where one person died of a possible stroke. In a second step neurologists confirmed the stroke in survivors and stroke death by using a specific verbal autopsy.

We identified 51 first-ever stroke during one year. The incidence rate standardized to Segi’s world population was 97.9 per 100,000 (95% CI 73–123) and the incidence rate in people aged over 55 years was 550.6 per 100,000 (95% CI 381–721) with 467.4 (95% CI 269–666) in urban and 691.4 (95% CI 381–1002) in rural.

Our results show that incidence rate of stroke is significantly high in people aged over 55 years specially in rural area, which are similar to those reported in community studies both in developed countries (Feigin et al, 2003) or in emerging countries (Lavados et al, 2005). We believe that the use of specific verbal autopsy in door-to-door survey of stroke provides good approximation of stroke incidence in developing countries.

Serial hemodynamic and autonomic function studies in acute ischemic stroke: Relation to outcome, stroke type and location
A. Gujjar, D. Jaju, P.C. Jacob, M. Dixit, A.R. Al-Asmi. "Medicine (Neurology), College of Medicine, Sultan Qaboos University, Al Khod, Oman; "Physiology, Sultan Qaboos University, Muscat, Oman; "Medicine (Neurology), Sultan Qaboos University, Muscat, Oman

Background: Hypertension and autonomic changes commonly accompany acute ischemic stroke (AIS); however, their pathophysiology is poorly understood.

Aim: To study serial hemodynamic and cardiovascular autonomic functions among patients with AIS and to explore their relation to stroke outcome, location, type and severity.

Patients and methods: Patients with AIS of ≥96 h duration underwent serial hemodynamic and cardiovascular autonomic function studies using thoracic electrical bioimpedance technology over the first 4 days of admission. Patients with arrhythmias or pulmonary edema were excluded. Correlations between NIHSS scores, outcome at follow-up (mean 10 months), stroke type, location and hemodynamic/autonomic parameters were explored using Mann–Whitney U-test and logistic regression analysis.

Results: 55 patients (M:F=27:28; age:62 ± 12 years) with AIS were studied. 33 had large artery stroke, 18 and 6 patients (11%) died. Mean BP decreased by 8 mm Hg by day 4 (D4); while cardiac output remained stable, systemic vascular resistance (SVR) changes reciprocated BP. Lower NIHSS at admission, SVR (D2), systolic BP (D4), and cardiac index (CI, D1) correlated significantly (p<0.01) with good outcome, as did following autonomic indices: sympathetic activity (LFNU; LFNubPV); parasympathetic activity (HFNU); sympathovagal balance (LF/HF); barareflex sensitivity (BRS) and ventricular loop (LVW)). Systolic BP (D4) predicted outcome independently. Stroke location in the basal-ganglia was related to left ventricular ejection time and sympathovagal balance (LF/HF) (p < 0.05).

Conclusion: Hypertension in AIS may be mediated predominantly by changes in SVR. Hemodynamic and autonomic parameters may predict outcome and possibly stroke location. Further studies among patients with homogenous stroke types may help understand the interaction between focal brain injury and autonomic changes.

doi:10.1016/j.jns.2013.07.772
Tropinin Ths (ThThs, pg/ml) and Pro Brain Natriuretic Peptide (PBNP, pg/ml) were higher in AS (74.61 ± 217.88, p = 0.007; 3809.68 ± 6798.65, p = 0.0004) and CCVD (30.15 ± 49.29, p = 0.0001; 1608.78 ± 3982.99, p = 0.0007), compared to OND (9.66 ± 7.63; 100.76 ± 145.86). A tendency to lower PBNP was found in AS without CCVD (A) compared to AS with CCVD (B) patients.

Echocardiography showed decreased ejection fraction (EF %) and increased pulmonary arterial pressure (PAP, mmHg) in AS (EF 59.52 ± 9.96, p = 0.0001; PAP 43.85 ± 11.47, p = 0.0001) and CCVD (EF 60.02 ± 10.55, p = 0.0001; PAP 40.53 ± 10.89, p = 0.006), compared to OND (EF 64.96 ± 9.66; PAP 34.32 ± 9.45). Significant differences were observed concerning such parameters and left atrial dilatation (LAD, cm) in subgroup B (LAD 4.63 ± 0.72 p = 0.0003; EF 58.52 ± 9.97, p = 0.01; PAP 44.58 ± 11.59, p = 0.05) compared to A (LAD 4 ± 0.41; EF 64.4 ± 8.65; PAP 37.2 ± 6.11). Significant correlations were found between haematological and echocardiographic parameters.

Our data highlight the key role of early identification of cerebrovascular patients with a wider due to restricted therapeutical window because of cardiovascular dysfunctions.

Spinal cord infarction presenting as unilateral diaphragm paralysis
B.J. Ahn, J.H. Jung, Neurology, Soon Chun Hyang University Gumi Hospital, Gumi, Republic of Korea

**Background:** Cervical cord ischemia leads to tetraplegia and pulmonary insufficiency in the case of transverse extension of ischemia. Paralysis of the diaphragm can be experimentally modeled by lateralized, high cervical lesions that interrupt descending inspiratory drive to the corresponding phrenic nucleus. Most reported cases of unilateral diaphragm paralysis were caused by trauma. Paralysis of unilateral diaphragm by spinal cord infarction is rare.

**Case report:** A 79-year-old woman with a history of hypertension visited our hospital with a 2-day history of suddenly developed quadriparesis and dyspnea. On admission her vital signs were normal except for dyspnea. Neurologic examination revealed normal mental state and cranial nerves. Motor evaluation showed weakness of both upper and lower extremities, upper extremities more than lower extremities, right more than left. Sensory evaluation revealed a sensory level at C4. The patient showed no pathologic reflex and deep tendon reflex was hypoactive in all extremities. We ordered cervical spine MRI. It showed an elongated hypointensity on T2WI at the ventral portion of cervical spinal cord from C2 to C6 level without enhancement. The patient was treated with anticoagulation and corticosteroid. Over the next two days, we checked chest fluoroscopy and it showed upward displacement of the right diaphragm with relatively fixation of movement suggestive the right diaphragm paralysis. 2 weeks later we checked phrenic nerve conduction study (MacLean’s method). It showed prolonged latency and lowered amplitude of compound muscle action potentials (CMAPs) of the right phrenic nerve. 2 month later, she discharged with only mild right hemiparesis without dyspnea.

External carotid artery angioplasty and stenting — A good choice for patients with symptomatic ipsilateral internal carotid artery occlusion
A.C. Mergeani, D. Popescu, B. Dorobat, A. Roceanu, O.A. Bajenaru, F.A. Antochi, "Neurology, University Emergency Hospital Bucharest, Bucharest, Romania; Interventional Neuroradiology, University Emergency Hospital Bucharest, Bucharest, Romania

**Background:** In patients with internal carotid artery occlusion (ICA), the ipsilateral external carotid artery (ECA) may supply the cerebral circulation through collateral vessels. Although endarterectomy for ECA stenosis has been described in literature, angioplasty with stent-graft has rarely been reported.

**Objectives:** The aim of our small case series is to present few cases with ECA stenosis and ipsilateral ICA occlusion in which stenting of ECA was performed.

**Patients and methods:** We present four patients with uni- or bilateral ICA occlusion (one of the cases with occlusion secondary to thrombosis after endarterectomy), aged 48 to 69 years old, who presented to our service for neurologic symptoms suggestive for an ischemic event, confirmed by cerebral CT scan or MRI. The ultrasonographic exam of cervico-cerebral arteries showed the presence of ICA occlusion with ipsilateral hemodynamic significant ECA stenosis, so we performed an angiogram which confirmed these findings. The digital subtraction angiography also revealed that the cerebral blood flow was supplied from the ECA collaterals. All the ECA stenoses were ipsilateral to the ischemic stroke or transient ischemic attack.

**Results:** We proceeded to angioplasty with stenting of the ECA with optimal postangioplasty results and improved intracranial cerebral blood flow, without periprocedural incidents. The patients were discharged few days later with double antiplatelet therapy.

**Conclusions:** We chose to present these cases to underline the importance of preventing further ischemic events in patients with occluded ICA and ipsilateral ECA stenoses using angioplasty and stenting of ECA.

Ability reading comprehension in patients with speech and language impairments after stroke
G. Savic, Institute of Physical Medicine and Rehabilitation ‘Dr M. Zotovic’, Banja Luka, Bosnia and Herzegovina

**Background:** Impairments of speaking caused by stroke decreases ability to express and comprehend speaking, reading and writing. Dyslexia is loss or impairment of ability to read brought on by brain damage, in part with the aphasia syndrome or other cognitive neurological impairments.

**Objective:** The aim is to determine age, sex, education level, stroke etiology comorbidity, relation between locations of brain impairment after the stroke with reading comprehension of sentences and paragraphs in patients with impaired speaking communication.

**Patients and methods:** During six months of speaking, 135 patients from neurological ward of the Institute of Rehabilitation “Dr Miroslav Zotovic” in Banja Luka have been analyzed. Subtests of Boston Diagnostic Aphasia Examination were used.

**Results:** The average age of the patients was 66.77 years in samples where there were more males than females. Brain lesions were

Frequency of writing and reading disorders in Bosnia and Herzegovina population of acute stroke patients
O. Sinanovic\textsuperscript{a}, S. Zuki\textsuperscript{c}, Z. Mrkonjic\textsuperscript{b}, M. Vidovic\textsuperscript{c}. \textsuperscript{a}Department of Neurology, University Clinical Center Tuzla, University of Tuzla, Bosnia and Herzegovina; \textsuperscript{b}School of Special Education, University of Tuzla, Tuzla, Bosnia and Herzegovina

Objective: Writing and reading disorders usually followed aphasias but the frequency of acalculia, agraphia and alexia are not often studied. The aim of the study was to determine the frequency of alexia, agraphia and acalculia in acute stroke patients, and determine their relation to the type of stroke (ischemic and hemorrhagic) and lesion site (left or right hemisphere) in Bosnian and Herzegovinan population of acute stroke patients.

Patients and methods: It was analyzed in 194 consecutive hospitalized patients with acute first-ever stroke at the Department of Neurology, University Clinical Center Tuzla. For clinical assessment of alexia, agraphia and acalculia, Minessota test for differential diagnosis of aphasias was used. The patients were evaluated in the first week of stroke onset.

Results: Out of 194 analyzed patients, 59 (30.40%) of them had alexia, agraphia and acalculia or different combinations of these disorders. The frequency of alexia, agraphia and acalculia among patients with stroke in the left (dominant) hemisphere was significantly higher (33; 55.9%) than in the right one (23; 37.7%) ($\chi^2 = 4.003; p = 0.0459$). In 170 subjects with ischemic stroke, there were 53 (31.1%) cases of alexia, agraphia and acalculia, and 6 (42.8%) cases among 14 subjects with hemorrhagic stroke then hemorrhagic and ischemic stroke ($\chi^2 = 0.363; p = 0.394$).

Conclusion: Post-stroke reading and writing disorders are present in one third of stroke cases, and more common in patients with stroke in the left hemisphere, than in the right. There were no significant differences in the frequency of alexia, agraphia and acalculia between hemorrhagic stroke and ischemic stroke.

and specific symptoms that have to be taken into account during the therapy selection.

Cilostazol plus aspirin versus aspirin alone in patients with symptomatic intracranial arterial stenosis: Results of catharsis

The CATHARSIS Study Group

*Department of Neurology, Tokyo Women's Medical University, Tokyo, Japan; *Department of Neurosurgery, Kobe City General Hospital, Kobe, Japan; *Department of Neuroendovascular Therapy, Tohoku University, Sendai, Japan; *National Hospital Organization Kyushu Medical Center, Fukuoka, Japan; *Department of Neurology, Saiseikai Central Hospital, Tokyo, Japan; *National Cerebral and Cardiovascular Center, Suita, Japan; *Department of Neurology, Keio University, Tokyo, Japan; *Saitama Medical University International Medical Center, Saitama, Japan; *Department of Neurosurgery, Mie University, Tsu, Japan; *Department of Neurosurgery, Nagasaki University, Nagasaki, Japan; *Department of Clinical Neuroscience and Therapeutics, Hiroshima University, Hiroshima, Japan

**Background:** The Cilostazol–Aspirin Against Recurrent Stroke with Intracranial Artery Stenosis (CATHARSIS) (Clinicaltrials.gov identifier: NCT00333164) was an investigator-driven nationwide multicenter cooperative randomized controlled trial to compare cilostazol plus aspirin with aspirin alone in patients with symptomatic intracranial artery stenosis (IAS).

**Methods:** Subjects were patients at age of 45–85 years with ischemic stroke after two weeks to six months from onset and >50% stenosis in responsible intracranial arteries on MRA. They were randomly allocated to either group of cilostazol 200 mg/day plus aspirin 100 mg/day (CA group) or aspirin 100 mg/day alone (A group), who were followed up for two years.

**Results:** A total of 165 patients (109 males, average 68 years) were randomized. There was no difference in the progression of IAS between both groups (9.6% in CA group and 7.6% in A group, p = 0.5326). Stroke recurrence occurred in 2.4%/year in CA group (ischemic 6, hemorrhagic 2). After recurrence occurred in 2.4%/year in CA group (ischemic 6, hemorrhagic 2). After correction with background characteristics, rates of stroke plus silent brain infarct (5.8% vs 12.5%, HR 0.34, 95% CI 0.12–0.96, p = 0.04) and all vascular events plus silent brain infarct (10.7% vs 25.0%, HR 0.37, 95% CI 0.14–0.97, p = 0.04) were significantly lower in CA than A group.

**Conclusion:** There was no difference in the progression of IAS between two groups. Rates of stroke plus silent brain infarct and all vascular events plus silent brain infarct were lower in CA than A group.

On the question of the application of silver nanoparticles in antithrombotic therapy

Neurology, Pirogov Russian National Research Medical University (RNRMU), Moscow, Russia

Platelets play a key role in the development of thrombotic lesions. Urgent action to prevent platelet activation affecting the process of fibrin polymerization and slowing clot formation.

**Objective:** To study the effect of silver nanoparticles with 10, 20, 70 nm on the system of cellular and plasma hemostasis in vivo. For the study of platelet aggregation, we used the method of scanning electron microscopy. Silver nanoparticles were pre-incubated with platelet-rich plasma of human blood in the presence of ADP in the control units. The particles do not exceed the diameter of 2.9–3.2 mm. Addition of 60 mM and d = 70 nm nanoparticles in platelet rich plasma, caused the formation of aggregates of a diameter of 3.5–4.2 mm. It caused the decrease in prothrombin time, which indicates additional aggregation and thrombus formation. By chemiluminescence, registered superweak am-

Nonhemiplegic hand strength is weaker in those with deglutition problems at initial one month after stroke

Catholic University of Korea Bucheon St. Mary's Hospital, Bucheon, Republic of Korea

**Background:** Dysphasic stroke patients with nasogastric feeding tubes (NGT) are at high risk of malnutrition, which may lead to prolonged hospital stay and poor functional recovery. Hand grip strength (HGS) is a useful marker of patients' nutritional status at an early stage.

**Objective:** The objective is to determine if HGS of the nonhemiplegic side at one month post-stroke is significantly different in patients with NGT compared to those without NGT and to assess if HGS measurements correlated to serum markers and functional status.

**Patients and method:** We retrospectively reviewed medical record of 218 patients admitted to our department from September 2010 to April 2012.

**Material and method:** We recorded patients’ serum markers (albumin), modified Barthel index scores (MBI), mini mental status examination (MMSE), and Berg balance scale (BBS). Correlations analysis of hand strength to biochemical markers was performed using independent t-test.

**Result:** Mean ± SD values of MBI, BBS, MMSE albumin, with NGT (n = 151) without NGT (n = 67) were 12.5 ± 20.0/51.3 ± 31.3, 6.26 ± 12.2/27.6 ± 20.9, 10.0 ± 10.1/19.1 ± 8.0, and 6.7 ± 0.7/7.4 ± 6.7. The mean lateral pinch and grip strength (lb) of these two groups were 6.5 ± 7.0/11.7 ± 5.3 and 20.1 ± 23.5/42.3 ± 20.6, respectively and all these values showed statistically significant differences (P < 0.05).

**Conclusion:** NGT patients showed weaker grip and lateral pinch strength in nonhemiplegic hand and this correlated to functional status and serum markers. Initial assessment of grip and lateral pinch strength of the contralateral hand may be useful to evaluate the functional nutritional status in those with prolonged NGT from an early stage.

α-Lipoic acid treatment is neurorestorative and promotes functional recovery after stroke in rats
K. Choi, J. Kim, H. Kim. Chonnam National University Hospital, Gwangju, Republic of Korea

Background: A considerable body of evidence suggests that oxidative stress is a fundamental mechanism of brain damage in stroke. A recent study suggests that the antioxidant properties of alpha-lipoic acid (aLA) correlate with its ability to promote neuroproliferation. However, there have been no reports of comprehensive studies examining the neurorestorative effects of aLA administered after the onset of ischemia.

Purpose: Here we report the role of aLA as a neurorestorative agent in focal cerebral ischemia.

Methods: The middle cerebral artery (MCA) of adult rats was occluded for 2 h and then reperfused. aLA (20 mg/kg) was administered in 71 animals (aLA group) through the left external jugular vein immediately after reperfusion. An equivalent volume of vehicle was administrated to animals (control group). A neurological deficit score (NDS) was obtained, and motor impairment was assessed by the accelerating rotarod test. Levels of endogenous neural precursor and glial cell were analyzed by immunohistochemistry.

Results: Immediate aLA administration group after reperfusion significantly reduced the mortality, infarct size, and NDS than control group (n = 71, P = 0.005, P = 0.002, and P = 0.001, respectively). Long-term functional outcomes by rotarod test were also markedly improved by aLA treatment (P = 0.013). And aLA treatment enhanced the earlier proliferation of endogenous neural precursor and glial cell using nestin- and GFAP-antibody along the infarct and infarct core regions.

Conclusions: These results indicate that urgent treatment with aLA after ischemic injury may have significant neurorestorative effects through enhanced neuroproliferation. Thus, aLA may be a useful intervention for the treatment of acute ischemic stroke.

Recurrent stroke from free-floating carotid artery thrombus: 14-year experience from a tertiary institute in Singapore
H.C. Chua, Z. Phua. National Neuroscience Institute (Tan Tock Seng Hospital), Singapore, Singapore

Background: Free-floating carotid artery thrombus is a rare cause of cerebral infarcts. Current understanding is limited to small case-series. Recurrent stroke in free-floating thrombus is believed to be due to delayed embolism from the tail of the carotid thrombus to the intracranial circulation.

Objective: To review recurrent stroke mechanism in free-floating carotid artery thrombus.

Patients and methods: All patients admitted from 1999 to 2012 for cerebral infarcts were included. Cases were retrospectively identified from carotid ultrasound reports showing free-floating carotid artery thrombus. Case notes, neuroimaging and electronic records were retrieved and patients with recurrent stroke were studied.

Results: A total of 28,126 carotid ultrasound reports were screened and 61 patients with free-floating thrombus were identified. Of these, recurrent stroke occurred in 4 patients. Age range: 60 to 83 yrs. Clinical syndrome: pure motor stroke (n = 2), sensorimotor stroke (n = 1), hemispheric stroke (n = 1). BP on admission ranged from 145/75 to 210/80 mm Hg. In 3 patients, neurological deterioration occurred in the first week of admission coinciding with a drop in BP. Etiology of hypotension included dehydration, anemia and inadvertent administration of anti-hypertensive. Brain scan showed watershed infarcts, which collaborated with hypotension as the underlying cause. Recurrent stroke due to embolism from the tail of the carotid thrombus occurred in only one patient with hemispheric syndrome. All patients were treated with heparin and warfarin.

Conclusion: Hypotension is the cause of recurrent stroke in 75% of patients with free-floating carotid artery thrombus. Clinicians treating such patients must be vigilant to this potentially preventable complication.

Degree of recovery in motor functions of patients with CVI in relation to the degree of damage on speech comprehension
V. Buzadzija, G. Savic, J. Satara, D. Djuric, D. Prtina. Institute of Physical Medicine and Rehabilitation ‘Dr M. Zотович’, Banja Luka, Bosnia and Herzegovina

Background: Patients with brain damage brought on by cerebrovascular insult (CVI) with damage to the motor function system, often have difficulty in comprehension of speech and language.

Objective: To research the degree of functional impairment and recovery of patients following CVI in relation to the degree of speech and language comprehension by patients with present speech and language disability.

Method: The functional ability was estimated with Barthel index for 102 patients with present speech and language impairments after CVI, also an estimate on speech and language status with the subtest auditory comprehension BDAE. A correlation was observed between speech comprehension and functional ability.

Results: Average age of the patients was 64.94 years in samples where there were more males than females. The most common type of stroke was ischemic. The most numerous were multifocal lesions in the area of left ACM.

At the beginning stages of rehabilitation the average Barthel index of the patients was 47.95 and after rehabilitation the index was 65.09.

Patients with average comprehension complex ideational material (KIM) under 50% of the test had a starting Barthel index of an average of 39.02, and after rehabilitation it was 55.91.

Patients with average comprehension KIM above 50% of the test had a starting Barthel index of 55.45 and after rehabilitation 72.07. A low correlation was found between the results of auditory comprehension KIM and functional ability of patients. The results are statistically significant.

Conclusion: Patients with larger impairments of comprehension KIM had a lower degree of functional repair in relation to patients with better comprehension of speech and language.

Stroke and leucoencephalopathy  

N. Radojkovic Gligic, K. Kacar. Hospital for Cerebrovascular Diseases Sveti Sava, Belgrade, Serbia  

Background: Encephalopathy means brain disease, damage and malfunction. It presents broad spectrum of symptoms such as memory loss and subtle personality changes to severe such as dementia, seizures, coma, and death. Posterior leucoencephalopathy syndrome was first described in 1996. It is a condition where diagnosis depends on clinical and radiological features. Leukoencephalopathy seen in association with severe hypertension, disease leading to failed out regulation, hyperperfusion, and endothelial injury vasogenic edema. Vasocostricion and hyper-perfusion lead to brain ischemia and vasogenic edema. MRI scan is useful in giving prognosis.  

Material: We have in stroke unit for 225 consecutive patients with ischemic stroke investigated systematically with MRI. Imaging 156 patients (69.33%), MRI shows edema involving the white matter in the posterior portions of the cerebral hemispheres, especially in the parieto occipital regions. Diffusion weighed sequences can be differentiated between edema from leaking capillaries and cell.  

Conclusion: In 78% (123 patients) of patients, the acute infarct was deep. And leucoencephalopathy was more frequent in patients with a deep infarction than in patients in whom the cortex was involved. Hypertension was the most common risk factors 87% and was more frequent in study than in control group. This study suggests that hypertension may be more strongly associated with leukoencephalopathy than with deep infarction.

Effect of short-term changes of air pollution on the development of acute ischemic stroke  

Neurology and Stroke, Szent Janos Hospital, Hungary; Climatology Division, Hungarian Meteorological Service, Hungary; Department of Meteorology, Eötvös Loránd University of Sciences, Hungary; First Department of Pediatrics, Semmelweis University, Budapest, Hungary  

Background: Thrombolytic treatment (TT) of acute ischemic stroke (AIS) requires a highly organized hospital service due to the strict therapeutic protocol. All data that can be used to predict the demand on the healthcare system have practical benefit. According to literature data, air pollution (AP) plays a role in the development of stroke.  

Objective: We examined the role of short-term changes of AP in the development of AIS. Our previous results did not confirm the effect of AP averaged by season on the development of stroke. Analysis of TT-s — due to their narrow therapeutic window — allowed us to determine the onset of stroke events, which is important for the examination of short-term meteorological effects. We had to reduce the sample size in order to assess highly localized environmental effects.  

Patients and method: Stroke onset dates and times of 80 patients who received TT at our department between 2009 and 2012 were compared with measurement data (PM10, NO, NO2, NOx, SO2, O3, CO) from nearby meteorological stations. Correlation was analyzed with SPSS software, Pearson’s, Kendall’s tau-b and Spearman’s tests, and Student’s t-test.  

Results: There was a significant correlation between the increase of concentration of most polluting materials (NO: 0.1050, NO2: 0.0490, NOx: 0.1060, CO: 0.1140) and the development of stroke. A negative correlation was found with sulfur-dioxide and ozone-levels (SO2: −0.0670, O3: −0.0900) and no correlation with PM10-levels. The t-test did not show significance due to the low number of cases.  

Conclusion: Higher air pollution only slightly increases the short term risk of stroke.

Kinetics of inflammatory markers in acute ischemic stroke and their relevance in stroke-induced immunosuppression  

Neurology and Stroke, Szent Janos Hospital, Semmelweis University, Budapest, Hungary; First Department of Pediatrics, Semmelweis University, Budapest, Hungary; Department of Laboratory Medicine, Semmelweis University, Budapest, Hungary  

Background: Stroke-induced immunosuppression syndrome (SIIS) leads to severe complications in stroke patients. Infection is the most common of these complications and the chief cause of morbidity and mortality in stroke survivors.  

Objective: We aimed to identify an inflammatory marker for the distinction between the inflammatory response evoked by stroke and inflammation later caused by infection due to SIIS.  

Patients and method: We investigated the kinetics of CRP, WBC, neutrophil count, suPAR, CD4 + CD25high Tregs, CD64 + and CD177 + neutrophils and monocytes in 12 acute ischemic stroke (AIS) patients within 6 h (Stroke 1) and one week after the insult (Stroke 2). Patients with infection after stroke were excluded. As controls, 14 age-matched healthy individuals with similar cardiometabolic risk factors, but with a negative history of stroke or other neurological disorders were included.  

Results: CRP, WBC and neutrophil count values were comparable in Stroke 1 and controls; however, they were elevated in Stroke 2. suPAR levels were higher in both stroke groups compared to controls. The prevalence of CD64 + neutrophils was higher in Stroke 1 than in controls and it decreased in Stroke 2 below the level in controls. The prevalence of CD64 + neutrophils was higher in both stroke groups compared to controls.  

Conclusion: Our pilot study identified the prevalence of CD64 + neutrophils as an inflammatory marker that best represents immunological alterations in AIS. Its level is a suitable candidate for the indication of the developing inflammatory response due to infection.

Dysphagia tests and intensive special neurorehabilitation should be regular part of diagnostic and neurorehabilitation algorithmus in stroke unit  

B. Bunová, D. Bartko.  

Out-patient Department for Dysphagiology and Speech Language Disorders, LOGOMEDIK s.r.o., Skalica, Slovak Republic; Institute of Medical Sciences, Neurosciences and Military Health, Department of Neurology, Central Military University Hospital, Ružomberok, Slovak Republic
Background: Dysphagia is a frequent symptom of ischaemic or haemorrhagic cerebral stroke (iCi, ICH). The incidence of dysphagia is ranging from 25% to 81%. The most often complication of dysphagia is aspiration which often leads to pneumonia. The reason why the determination and therapy of dysphagia and aspiration is so important is that the aspiration (especially silent aspiration) contributes to higher mortality as well as to the increase of costs.

Aim:
1. To analyse the occurrence of dysphagia and its complication: aspiration “silent” aspiration.
2. To evaluate the results of intensive special neurorehabilitation.

Material and methods: Material consists of 113 subjects. Whole group was divided into two subgroups: the 1st iCi patients with neurorehabilitation by certified dysphagologist (iCi-d, n = 66), mean age 68.08 ± 11.41 years, male 59.09%, the 2nd subgroup with different neurological disorders (n = 47), mean age 65.09 ± 15.52 years, male 62.62%. iCi with various degree of neurolological deficit (NIHS) was confirmed by CT/MRI. For confirmation of dysphagia clinical swallowing examination and instrumental evaluation—videoendoscopy was used. For evaluation of aspiration Rosenbeck P/A scale was used.

Results: The occurrence of dysphagia was documented in 57 from 66 iCi patients (86.36%) and 29 (43.93%) of them had aspiration, and “silent” aspiration was found in 10 (15.15%) patients. Significant improvement following neurorehabilitation was documented in all stroke patients with dysphagia. From the 47 patients 2nd subgroup (non-stroke patients) we have found out 20 patients (42.55%) with dysphagia and 6 (12.76%) of them had aspiration. 1 (2.12%) patient had “silent” aspiration.

Conclusions:
1. Special tests for dysphagia should be the obligatory part of diagnostic algorithm.
2. Special neurorehabilitation by certified dysphagologist should be part of therapeutic algorithm in stroke patients.

Predictors of early efficacy of thrombolytic therapy in patients with ischemic stroke
L. Volkovaab, E. Prazdnichkovab, A. Alasheevb, O. Shalaginaa, O. Cyganenkoa, aUral State Medical Academy, Russia; bSverdlovsk Regional Clinical Hospital #1, Ekaterinburg, Russia; cDemidovskaya Hospital, Nizhni Tagil, Russia

The aim of the study was to evaluate association of age, smoking, atrial fibrillation and time from symptoms onset with early efficacy of thrombolytic therapy in patients with ischemic stroke.

Materials and methods: We conducted retrospective analysis of 44 cases of systemic and intraarterial thrombolytic therapy in patients with ischemic stroke that are admitted at Sverdlovsk Regional Clinical Hospital and Demidovskaya Hospital in Nizhni Tagil in 2011. Neurologic deficit was evaluated according to NIHSS on admission and at the 7th day of hospitalization. Early effectiveness of thrombolytic therapy was defined when NIHSS at the 7th day decreased in ≥ 4 points.

Results: Median age was 59.5 (IQR 53.0–70.0) years. 19 (43.2%) patients smoked. Atrial fibrillation was noted in 34.1% (15) of patients. Median time from symptoms onset to beginning of rtPA infusion was 187.5 (IQR 152.5–217.5) min. Median NIHSS on admission was 11.5 (IQR 9–16.5), NIHSS at the 7th day of hospitalization was 6.0 (IQR 4–12). Patients with cardioembolic stroke were noted to have more severe neurologic deficit on admission, median NIHSS was 14.0 (IQR 12.0–18.0). Improvement at the 7th day of hospitalization was achieved in 29 (66%) patients. Statistical analysis revealed significant association of early neurologic improvement and time from symptoms onset, Spearman’s coefficient of rank correlation was −0.424 (95% CI, −0.640 to −0.145, P = 0.0042).

Conclusion: Early efficacy of rtPA infusion depended on time from symptoms onset to rtPA infusion. Statistical analysis didn’t showed significant correlation of other factors with early improvement after rtPA infusion due to insufficient sample size.

Severe stress and post-stroke depression
T. Kherkheulidzea, D. Eliaurib, E. Devidzeb, M. Beridzea, aNeurology, Tbilisi State Medical University, Georgia; bNeurology, Tbilisi State University, Tbilisi, Georgia

Purpose: To identify the main factors assisting to the development of post-stroke depression.

Patients and methods: Totally 75 ischemic stroke patients are investigated. Stroke severity is assessed by NIHSS. Stroke risk factors are studied retrospectively: age, ethnicity, previous stoke/TIA, atherosclerosis, hypertension, atrial fibrillation, diabetes mellitus, recent infection, smoking, alcohol abuse, severe social and psychological stress. Patients are divided as right hemispheric stroke (1st group—18 patients), left hemispheric stroke (2nd group—26 patients), brainstem stroke (3rd group—15 patients), and cerebellar stroke (4th group—16 patients). Ischemic lesion is evaluated on conventional CT at 24 h after onset. Stroke outcome is evaluated by mRS at 1 month. Depression is assessed by Zung Depression Scale at 1 month. Statistics are performed by SPSS-11.0.

Results: In the 1st group initial NIHSS was 21.5 ± 4.5. Severe depression was found in (46.15%), moderate depression in (76.9%), and mild depression in (15.3%) of patients. In the 2nd group the initial NIHSS was 14.0 ± 3.5. Severe depression was found in (33.3%), moderate depression in (13.4%), and mild depression in (6.7%) of patients. In the 3rd group initial NIHSS was 16 ± 4.5. Severe depression was found in (44.5%), moderate in (11.2%), and mild in (16.7%) of patients. In the 4th group the initial NIHSS was 12 ± 2.5, and severe depression was found in (12.5%), and mild depression in (6.2%) of patients. The initial NIHSS positively correlated with depression (r = +0.25; p < 0.05). Correlation was not found between lesion location and depression. Multivariate logistic regression revealed the significance of initial NIHSS in conjunction with severe stress for depression at 1 month post-stroke.

Conclusion: Probably, the pre-stroke psychological instability and stroke initial severity predispose toward post-stroke depression.

Venous infarction in young female patients

D. Eliauri, M. Alpaidze, T. Kherkheulidze, E. Devidze, M. Beridze

Neurology, Emergency Neurological Clinic 'Neurologist', United States; Neurosonology, Tbilisi, GA, United States; Neurology, Tbilisi State Medical University, Tbilisi, GA, United States

Purpose: To investigate the risk of venous infarctions in young females with ischemic stroke.

Patients and methods: Totally 57 female stroke patients aged from 35 to 55 years investigated. Stroke Etiology determined according to TOAST. Stroke severity assessed by NIHSS. Risk factors investigated retrospectively. Brain visualized by MRT (1.5 T) at 24 h. Dopplerography conducted in all patients. Statistics performed by SPSS-11.0.

Results: Cardioembolic stroke found in 19 patients (33.3%), lacunar stroke — in 12 patients (21%), other etiology — in 26 patients (45.7%), where 17 cases (65.4%) were venous infarction. Main risk factors in cardioembolic stroke were congenital cardiac valve deficiency — 9 patients (47.3%), cardiac post-operational period — 5 patients (26.3%), and acute myocarditis — 5 patients (26.3); in lacunar stroke—hypertension due to chronic kidney pathology in 6 patients (50%), heredity hypertension — in 3 patients (25%), chronic vasculities — in 2 patients (16.6%), and diabetes mellitus — in 1 patient (8.4%). Other etiology stroke risk factors included long term (>10 years) oral contraceptives usage — in 21 patients (80.7%), smoking — in 20 (76.9%) patients, systemic lupus — in 4 patients (15.3%), Fabry disease — in 2 patients (7.6%), and anti-phospholipids — in 3 patients (11.7%). Multivariate logistic regression revealed the significance of long term oral contraceptives application in conjunction with smoking and chronic venous insufficiency (blood flow velocity in cavernous and transverse sinuses >30 cm/s) for brain venous infarctions.

Conclusion: Presumably, the long-term application of oral contraceptives in conjunction with chronic venous insufficiency crates the risk for venous infarctions in females.

Decompressive hemicraniectomy worth in patients with cerebral infarction in the territory of the middle cerebral artery and treated with rt-PA

M. Wiszniewska, H. Kasprzak, G. Waliszek, B. Woźniak

Neurological Department, Specialist Hospital, Pila, Poland; Neurosurgery Department, Specialist Hospital, Pila, Poland

Background: The aim of this paper is presentation of patients with malignant MCA infarction treated concomitant therapy rt-PA and decompressive hemicraniectomy.

Method: In 2009–2012, 215 patients were treated with rt-PA. Malignant brain edema diagnosed clinically and CT occurred in 6 of them (2.3%), aged up to 61, treated with decompressive hemicraniectomy. Analysis included: the time of the beginning malignant edema after the beginning of the stroke, mortality (at 30 and 90 days), quality of recovery evaluated with the mRs.

Results: Among 6 patients with malignant MCA infarction with space-occupying edema there were two women and four men aged 40–61. On the average, the patients scored 15.8 point in NIHSS on admission. On day one of brain edema was present in all the patients. At the moment of qualifying a patient for hemicraniectomy the NIHSS score deteriorated by 9 points, on the average. CT showed brain swelling, and in 2 secondary hemorrhagic cerebral infarction. One patient died on day 11 following hemicraniectomy (the surgery was performed when one pupil was dilated and nonreactive), one — died on day 40. The other four patients survived and are still alive.

Conclusions:
1. Decompressive hemicraniectomy in malignant MCA patients treated with rt-PA is a safe procedure, which improves their chances for survival.
2. Secondary hemorrhagic cerebral infarction should not be a contraindication for decompressive hemicraniectomy.
3. Decompressive hemicraniectomy should be performed as promptly as possible.
4. Good cooperation between a neurologist and a neurosurgeon is necessary to successfully perform hemicraniectomy.

The dissemination and conditions for endovascular treatments in acute ischaemic stroke in Europe

A. Kobayashi, A. Czlonkowska, EFNS Stroke Scientist Panel.

Interventional Stroke Treatment Centre, Poland; 2nd Department of Neurology, Institute of Psychiatry and Neurology, Poland; Department of Experimental and Clinical Pharmacology, Medical Center Aviva University of Warsaw, Warsaw, Poland

Introduction: Endovascular approaches are new emerging methods in the management of acute stroke. The aim of this study is to establish the organization of endovascular treatments for stroke in European countries.

Material and methods: A structured questionnaire regarding stroke unit (SU) organization and usage of endovascular treatments for acute stroke in the years 2009–2011 was acquired from representatives of the European countries, mostly being members of the EFNS Stroke Scientist Panel or local opinion leaders.

Results: Data from 19/47 (40%) European countries was received. The number of comprehensive SU overall was 181 (mostly — 100 in Germany). Intraarterial thrombolysis was reimbursed in 13/19 and

Cerebrovascular risk factors and depression: Report from National Ambulatory Medical Care Survey 2002–2009
H. Egila, B. Rahim, M.A.K. Suri, M.F.K. Suri, A.I. Qureshi. Neurology, Zeenat Qureshi Stroke Research Center, Minnesota University, Minneapolis, MN, USA

Background: Depression is a common psychiatric disorder that can occur as a result of many factors. Recently, a link between cerebrovascular risk factors and depression has been suggested. We performed this study to identify the association between depression and cerebrovascular risk factors.

Method: We analyzed nationally representative data derived from patients enrolled in the National Ambulatory Medical Care Survey (NAMCS) between 2000 and 2009. Data analyzed included patients’ age, gender, race/ethnicity, presence and control of cerebrovascular risk factors and self-reported depression.

Results: During the 9-year study period, an estimated 148,857 patients enrolled in this study. There were 14,849 (7.4%) of 148,857 patients who reported depression. Of the patients with depression, 2.8% had a history of cerebrovascular diseases. Among patients with depression (compared with those without), frequency of body-mass index >30 (41.1% versus 31.9%, P < 0.05), cigarette smoking (33.8% versus 25.2%, P < 0.05), hypertension (28.4% versus 23.6%, P < 0.05), diabetes mellitus (12.3% versus 10.1%, P < 0.05), and hyperlipidemia (18.1% versus 13%, P < 0.05), was significantly higher.

Conclusion: High frequencies of cerebrovascular risk factors were identified among persons with depression despite absence of any overt cerebrovascular disease. Further studies need to identify whether cerebrovascular risk factors have a causative role in depression or are a consequence of depression.

Epidemiological and prognosis aspects of stroke in the elderly in the neurological clinic of Fann Teaching Hospital, Dakar — Senegal

Background: Strokes are a vital emergency and functional. Their frequency increases with the aging population so that the senior pays a heavy price for this condition.

Objective: The objective of this study was to describe the epidemiological and prognosis of stroke in the elderly at the Fann Teaching Hospital, in Dakar.

Patients and methods: This is a retrospective study from 1st January 2001 to 1st November 2003 on patients aged 55 and older with stroke and had a brain CT scan. Sociodemographic data, medical history and surgical signs of severity associated with neurological symptoms and the prognosis were collected.

Results: Records of 314 patients with stroke collected, 228 were aged 55 and over for a prevalence of 72.6%. The patient population consisted of 54.8% of women with a mean age of 67.9 years (± 8.5). Risk factors were dominated by high blood pressure (74.1%), diabetes (11.8%), the previous stroke (10.1%) and heart disease (3.1%). Ischemic stroke accounted for 65.8%. Coma (22.4%) and high blood pressure (21.9%) were associated with neurological symptoms. Lethality of 26.3% was observed with the main predictor coma (OR = 33.3, confidence interval 95% of 13 to 83.3).

Conclusion: It should develop and implement a health education program to reduce morbidity and mortality from stroke in the elderly.

Neuroplasticity in neurodegenerative diseases and stroke
V. Demarin. Medical Center Aviva, Zagreb, Croatia

Neurodegenerative diseases and stroke are foremost causes of medical, as well as socioeconomic problems in modern society leading to quality of life impairment of patients and caregivers. Disorders like stroke, dementia, Alzheimer’s and Parkinson’s disease, Huntington disease, multiple sclerosis and acquired brain trauma contribute to the decline of cognitive, motor, and sensory abilities.

Neuroplasticity, also known as cortical remapping, challenges the idea that brain functions are fixed in certainnow. It refers to changes in neural pathways and synapses which are due to continuous stimulation and practice enhanced by previous experience. Mirror-neurons system is activated both in action and observation. Practicing mental stimulation improves memory and attention. Neuroplasticity can act through two possible mechanisms on motor deficit and cognitive impairment, by forming new, or improving existing pathways. The changes in the cortex organization include an increase in the number and density of dendrites, synapses and neurotrophic factors. After damage has been afflicted to the motor cortex, changes of activation in other motor areas are observed. These changes occur in homologue areas of the non-affected hemisphere which can substitute for the lost functions or in the intact cortex adjacent to the damage. Thanks to these cortical reorganizations the patients can recover, at least in part, their lost abilities.

Brain health is maintained through control of conventional vascular risk factors, practice of physical activity, healthy nutrition, stress management and mental stimulation. Challenging the brain with different tasks creates new neural connections and intensive exercise leads to improvement in neuroplasticity.

**Neuroimmune correlations in acute ischemic stroke**

I. Solodovnikova, A. Son. Odessa National Medical University, Odessa, Ukraine

**Background:** Neuroinflammation and neuronal apoptosis play important role during early brain injury in acute ischemic stroke (AIS).

**Objective:** The aim of this study was to analyze the correlations between CD4+/8+, CD7+, CD25+, CD95+, CD25+/95+, and CD54+ cell counts and clinical outcome in patients with AIS.

**Patients and methods:** 56 males (63.2 ± 4.7 years) with AIS were examined. CD4+/8+, CD7+, CD25+, CD95+, CD25+/95+, CD38+, and CD54+ cell counts were measured using immunoenzymometric PAP method. The clinical outcomes were assessed by the modified Rankin Scale (mRS).

**Results:** Patients with CD4+/8+ 1.70–4.50 and CD7+ 151.00–591.00 cells/Mcl or CD4+/8+ 1.70–4.63 and CD38+ 122.00–726.00 cells/Mcl cell counts during first 24 h after AIS showed mild disability (mRS ≤1) (p < 0.01). Patients with CD25+/95+ 0.29–1.15 and CD7+ 238.00–330.00 cells/Mcl/Mcl cell counts by 8–10th day after AIS showed severe disability (mRS ≥4) (p < 0.01). Patients with CD4+/8+ 1.90–2.71 or CD25+ 382.00–652.00 cells/Mcl cell counts by 21st day after AIS showed mild disability (mRS ≤2) (p < 0.01). Patients with good outcome (mRS ≤1) three weeks after AIS had 545+ cell counts 473.00–748.00 cells/Mcl during first 24 h after AIS (p < 0.01).

**Conclusion:** Neurological deficit and clinical outcome in patients with AIS correlate with CD4+/8+, CD7+, CD25+, CD95+, CD25+/95+, CD38+, and CD54+ cell counts.

**Effects of afobazole on brain tissue under the conditions of new model of local ischemia**

K. Alikhanyan, M. Balasanyan, A. Mkhitaryan.  
1Department of Clinical Pharmacology, Muratsan Hospital of Yerevan State Medical University, Yerevan, Armenia; 2Department of Pharmacology, Yerevan State Medical University after M. Heratsi, Yerevan, Armenia; 3Department of Clinical Pathology, Muratsan Hospital of Yerevan State Medical University, Yerevan, Armenia

Investigations with neuroprotective drugs have shown great promise in preclinical testing but disappointment in clinical trials. So, the aim of our investigation was to develop new local ischemia model more precisely reflecting the clinical picture of stroke, when the acute ischemic disorders develop on the background of chronic ischemization of cerebral tissue and to study neuroprotective effects of afobazole in this model.

White inbred rats were used. Chronic ischemization of brain tissue was caused by hypokinesia (rats were individually housed in narrow cages for 15 days). Local ischemia was caused by the ligation of middle cerebral artery (MCA).

Data obtained have shown local ischemia caused in hypokinetic rats was conducted by big areas of laminar neuronal necrosis in cortex, accumulation of neutrophiles, massive glial scars, focal hemorrhages, which were more significant after 12 days of MCA occlusion compare with 6th day of MCA ligation. Histopathological analyses of brain of rats treated with afobazole (twice daily, 5 mg/kg, i.p.) during 6 and 12 days have shown diminished subarachnoidal edema, macrofagal reaction was manifested without infiltration of brain tissue, the short areas of laminar necrosis of brain cortex and single areas of pancortical necrosis were mentioned. Afobazole has shown also ability to limit the size of ischemic zone after 6 and 12 days of MCA occlusion. Thus, afobazole evidently displays neuroprotective effect in the new more relevant to clinical stroke experimental model of local ischemia. It opens new possibilities for afobazole as a potent neuroprotective agent for the treatment of stroke.

**The recent trends of the change of risk factors with stroke patients at the hospital in Central Tokyo**

T. Takemi, T. Kimura, A. Unaki, H. Okayasu. Neurology, St. Luke's International Hospital, Tokyo, Japan

**Background:** In recent years, stroke patients with dyslipidemia as their risk factor have been increasing at our hospital. We assumed the changes in lifestyle and environment of modern times to explain this trend.

**Objective:** Regarding the above clinical question, we consider it is important to examine the change of risk factors prevalence in the younger patients compared with the elder patients, for the prevention of stroke.

**Patients and methods:** This study involved consecutive 1853 patients admitted to our hospital with the diagnosis of ischemic stroke from April 2001 to March 2013, and was conducted by comparative review on patients of two groups about the common risk factors (hypertension, diabetes mellitus, dyslipidemia, and atrial fibrillation). Group A includes patients aged less than 60 years old. Group B includes patients aged 60 and over.

**Result:** Group A has 415 patients and Group B has 1438. The percentage of patients with hypertension, diabetes mellitus, dyslipidemia, and atrial fibrillation as their risk factor was 48.7%, 27.5%, 45.5%, and 9.4% in the Group A, and in the Group B, 63.9%, 29.8%, 34.4%, and 23.7%, respectively.

**Conclusion:** In the Group A, the percentage of patients with dyslipidemia is higher than in the Group B. However, in recent several years, it has been increasing also in the elder patients. Our result indicates the importance of vigorous control of dyslipidemia for the prevention of stroke. To get national trends, it is requested to expand further study throughout all of Japan.

**Quality of life in aphasia after stroke in Cotonou, Benin**

1Neurology, CNHU-HKM, FSS/UAC, Cotonou, Benin; 2Neurology, Faculté de Médecine de Brazzaville, Brazzaville, Congo; 3Neurology, Université de Parakou, Parakou, Benin

**Background:** Aphasia, a consequence of stroke is an inability to understand, formulate language or combination of both.

**Objective:** The aim is to report the perceived quality of life among aphasic patients in Cotonou.

**Methods:** It is transversal, prospective study of descriptive and analytic aim conducted in extern neurological department of CNHU-HKM and orthophonie clinic in liberal consultation, from October to December 2012, including all patients with aphasia after stroke by dating six months at least. For each patient, the Sickness Impact Profile or SIP-65 was administered. The demographic characteristics
and the clinic data were the variables studied. Statistical analysis was performed by Epi info 3.5.

**Results:** Forty one patients were enrolled including 27 males and 14 females. The age varied from 36 to 72 years with of a mean of 55.3 ± 2.5 years. The mean duration of disease was 10 months. The Broca's aphasia was predominant (68.3%) and also the ischemic stroke (58.5%). Most of our patients answered "false" to more than half of the questions, except for communication, resumption of work and distraction.

Bivariate analysis showed that: the age, the sex, the mode of home, the support, the profession, the type of stroke and of the aphasia and the orthotrophic treatment were associated to the quality of life.

**Conclusion:** The aphasia is a common condition after stroke, affecting the quality of life, especially the resumption of work and the speech. Those items must be considered in order to get a good reeducation.

**Clinical significance of vertebral artery hypoplasia in lateral medullary infarction**

H.G. Oh, E.J. Rhee. aDepartment of Neurology, Soonchunhyang University College of Medicine, Cheonan, Republic of Korea; bDepartment of Endocrinology and Metabolism, Kangbuk Samsung Hospital, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea

**Background:** It is controversial whether vertebral artery hypoplasia (VAH) is a risk factor for stroke in the posterior cerebral circulation or not. The aim of our study was to investigate the frequency and clinical relevance of VAH in lateral medullary infarction (LMI).**Methods:** In total of 40 patients with LMI, the frequency of VAH, defined as a diameter of ≤2.2 mm by contrast-enhanced magnetic resonance angiography, was measured. We assessed the risk factors for stroke in each patient. In all LMI patients, transcranial Doppler was performed.

**Results:** Among them, 13 patients (32.5%) had VAH. It was detected in 6 patients (28.6%) of the 21 patients with age range of 15–64 years and in 7 patients (36.8%) of the 19 patients with age range of 65–99 years. In 3 young patients with age range of 15–40 years, all patients had VAH (100%) but had no additional risk factors for stroke. In very elderly patients (5 with age range of 80–99 years), 3 patients (60%) had VAH and had only hypertension as an atherosclerotic risk factor. 13 patients with VAH demonstrated low mean flow velocity (20–35 cm/s) in distal symptomatic vertebral artery.

**Conclusion:** The clinical significance of VAH is not yet clearly defined. But VAH, which shows decreased flow velocity, might be more susceptible to pro-thrombotic or atherosclerotic processes than normal or dominant vertebral artery in young or very elderly patients with few risk factors.

**Extensive cerebral sinus thrombosis involving bilateral internal jugular, sajittal, sigmoid and transverse sinuses with clinical presentation of subarachnoid hemorrhage**

H. Hashim, S. Alrukn, A. Almadani. Neurology Department, Rashid Hospital, Dubai, United Arab Emirates

**Introduction:** Cerebral sinus thrombosis is less common than most other types of strokes and is thousand times less prevalent than arterial stroke. Causative factors are different from arterial stroke that includes infection, dehydration, local trauma, rheumatologic diseases, hypercoagulable states, cancer and use of oral contraceptives. We are presenting an unusual case with extensive cerebral sinus thrombosis.

**Case description:** This case is about a 36 year-old Indian male who was working in Dubai as a laborer for the last 9 years. He presented with sudden onset severe thunderclap headache with some vomiting but without any other neurological or medical complaints. On clinical examination he was a little confused but no other neurological signs except neck stiffness and bilateral papilloedema. Plain CT brain showed evidence of subarachnoid hemorrhage in bilateral frontal and parietal areas. CT venogram showed extensive thrombosis involving bilateral internal jugular veins, posterior two third of superior sajittal sinus, sigmoid sinus and bilateral transverse sinus thrombosis. Further workup including thrombophilia profile, vasculitic profile, thyroid function, coagulation profile, paraneoplastic workup was negative. There was no evidence of any underlying neoplastic process and any hypercoagulable state.

**Discussion:** This case is interesting and unusual as his clinical presentation resembles subarachnoid hemorrhage and secondly patient is very stable except headache in spite of extensive involvement of the sinus thrombosis. And finally all workup for sinus thrombosis was negative except mild relation to dehydration.

Bedside dysphagia screening after acute stroke: Incidence, screening, and clinical outcomes
J.A.S. Vatanagul, C.P.V. Gallemit. Internal Medicine, Perpetual Succour Hospital, Cebu City, Philippines

Background: Dysphagia is a common finding in the clinical setting of a patient with acute stroke, which can give rise to a risk of aspiration, pulmonary infections, fluid depletion, and malnutrition. Therefore, early identification of dysphagia is crucial to avoid these adverse health consequences.

Objectives: To determine the incidence and clinical outcomes of acute stroke patients with dysphagia admitted at a tertiary hospital in Cebu City from December 2011 to July 2012.

Study design: Prospective, single center, descriptive study.

Materials and methods: The study population included all patients aged 18 years old and above admitted during the study period due to an acute stroke, whether an ischemic infarct or hemorrhage who underwent dysphagia screening test within 24 h of admission and with no previous documented dysphagia. Patients who passed the screening test were fed orally and those who failed were inserted with nasogastric tube for feeding and oral medications.

Results: A total of 74 patients with acute stroke admitted at a tertiary hospital in Cebu City from December 2011 to July 2012 were enrolled in this study. Out of the total 74 respondents, 38 patients passed the dysphagia screening test and 36 patients failed. Eight (22%) of the 36 patients developed pneumonia, and only one patient died of pneumonia.

Conclusion: Early identification of dysphagia with a simple and inexpensive bedside screening procedure can certainly decrease the risk of pneumonia to develop among patients who have failed the dysphagia screening test, as well as reduce mortality and overall healthcare expenditure.

Cerebral venous sinus thrombosis (CVST): Study of four Filipino patients and literature review
J.A.S. Vatanagul, I.A. Rulona. Internal Medicine, Perpetual Succour Hospital, Cebu City, Philippines

Research design: Case series study.

Background: Cerebral venous sinus thrombosis (CVST) is rare, with estimated 3–4 cases per million annual with the introduction of venography. Most cases of cerebral venous sinus thrombosis are due to hypercoagulability. Other important risk factors include pregnancy, primary antiphospholipid syndrome, and hereditary thrombophilias.

Objective: To present four Filipino patients with radiologically-proven cerebral venous sinus thrombosis (CVST) and discuss their demographic, etiologic and clinical characteristics and clinical outcomes.

Methods: A retrospective and descriptive analysis of the medical records of four patients with CVST, who were admitted to a single tertiary hospital.

Results: Four patients were identified with a mean age of 36.25 years old. The youngest patient was 22 years old. All of the patients were women. Two of the cases had previous use of oral contraceptives. The most frequent clinical manifestations were headache as seen in all patients (100%), dizziness (50%), vomiting (25%), motor weakness (50%) and seizures (25%). Three patients (75%) presented with thrombophilia – protein C deficiency.

Cranial CT scan revealed subarachnoid hemorrhage in 50% of the patients while parenchymal hemorrhage was present in the other 2 cases. Superior sagittal sinus (50%) and transverse sinus (50%) were the most common locations. All cases received oral anticoagulation with warfarin. All patients were discharged stable and without any neurologic deficits and adverse outcomes.

Conclusions: Venous sinus thrombosis may present to the physician in a number of clinical presentations. Early recognition of the condition and investigation of appropriate therapy probably reduce mortality and morbidity.

Expression profile of microRNAs in the peripheral lymphocyte of acute stroke patients
H. Zhaoa, P. Liub, R. Wangc, X. Liud, X. Wud, C. Xu, X. Ji, L. Gaof, Y. Luoa, *Cerebrovascular Diseases Research Institute, Xuanwu Hospital of Capital Medical University, Beijing, China; bDepartment of Neurology, The First Affiliated Hospital of Lanzhou Medical University, Jinhua, China; cDepartment of Neurology, Xuanwu Hospital of Capital Medical University, Beijing, China

MicroRNAs (miRs) profile of whole blood in acute stroke patients has been reported, but the profiling of peripheral lymphocyte has not been characterized. Since the key role of immunity and inflammation in stroke pathology, we currently profiled peripheral lymphocyte miRs of acute stroke patients and healthy persons with Agilent human microarray. We identified 70 down-regulated and 35 up-regulated miRs (>2-fold change) in lymphocyte by differential analysis. Next, 7 deregulated miRs (miR-99a, −99b, −181c, −181d, −212, −424, and −532-5p) were selected randomly and detected in patients’ plasma by qRT-PCR, and we found their trends were just the same as their counterparts in peripheral lymphocyte. Pathway analysis indicated 58 significantly changed KEGG pathways targeted by the deregulated miRNAs including MAPK pathway, ubiquitin mediated proteolysis and focal adhesion pathways concerning molecular mechanisms of cell apoptosis and inflammation response. Moreover, a miRs-miRNAs network was created based on bioinformatics analysis of pathways related with immune cell proliferation, chemotaxis and adhesion, presenting 22 critical miRs and their 139 targets to visualize hypothetical interactions. Taken together, except for profiling miRs of lymphocyte in acute stroke patients, we also showed that some miRs in lymphocyte might be related with plasma miRs, and further provide important miRs as therapeutic targets of regulation of lymphocyte function in acute stroke patients.

Circulating beta-antithrombin glycoform increases during the acute ischemic cerebrovascular event
A.M. García, M. de la Morena-Barrio, J. Corral, J. Iniesta, A. Mifiano, *Neurology, Reina Sofia Hospital, Spain; bCentro Regional de Hemodonación, Servicio de Hematología y Oncología Médica, Hospital Morales Meseguer, Universidad de Murcia, Murcia, Spain

Despite control of thrombin is crucial in the development of atherosclerosis, antithrombin, the main endogenous inhibitor of
thrombin, has been classically considered to play a role only in venous thrombosis. Available methods to study antithrombin do not discriminate between the two main glycoforms present in plasma. We have developed a method able to specifically distinguish b-antithrombin (higher heparin affinity, predominant vascular localization and less abundant in plasma, 10%) from a-antithrombin. We used this novel method and the classical one that determines the whole antithrombin anticoagulant activity (a + b) in plasma of patients with ischemic cerebrovascular disease during the acute event and one year later. We recruited 117 consecutive patients (mean age 73 years, 52% males). Total levels of antithrombin did not significantly differ from that of a cohort of 97 healthy control subjects (97.6 ± 12.7% vs. 99.9 ± 6.4%, respectively p = 0.105) and did not significantly change one year after the event (100 ± 13.1%). Plasma b-antithrombin of patients during the acute event was significantly higher than the control cohort (105.0 ± 17.7% vs. 97.1 ± 12.2%, respectively; p < 0.001). We observed a significant decrease of b-antithrombin over time (p = 0.04), one year after the thrombotic event, levels reached values observed in controls. Results might be explained by the release of b-antithrombin from the vascular compartment to the circulation during the acute event.

Conclusions: Data sustain a role of antithrombin in stroke and show new knowledge on b-antithrombin, one potentially relevant glycoform that might be studied in thromboembolic diseases using the method that specifically detect this glycoform.

Risk factors for the progression of cognitive impairment after ischemic stroke
D. Matcau. Neurology Clinic Timisoara, Timisoara, Romania

Background: Vascular cognitive decline appears in 20–30% of ischemic stroke patients, being in the same time a risk factor for recurrent stroke and mortality. The arterial changes in the ageing brain are associated with hypoperfusion in periventricular regions, basal ganglia and hippocampus. The age, systemic hypertension episodes, low diastolic blood pressure and previous cognitive impairment are main risk factors for neurodegenerative and vascular dementia after ischemic stroke.

Objective: The objective of this study is to assess the risk factors associated with the progression of cognitive impairment in patients after ischemic stroke.

Patients and methods: We studied 56 patients (65 to 75 years old) with ischemic stroke, with and without previous cognitive impairment, admitted into the Neurological Clinic Timisoara between October 2012 and March 2013. All patients were clinically, metabolically (glycemic and lipidic profile), IRM and MMSE assessed. The patients were followed up on 3 and 6 months after stroke onset. IRM performed showed small infarcts, cerebral atrophy, medial temporal atrophy and leukoaraisis. Cognitive impairment was diagnosed according to the score of MMS test (mild >21, moderate 10–20, severe <9).

Results: After 3 months: no cognitive decline 28 patients (50%); mild decline 15 patients (26.7%); moderate impairment, with previous cognitive decline, 10 patients (17.8%); and severe impairment-dementia, with previous cognitive decline, 3 patients (5.3%). After 6 months: no cognitive decline 19 patients (33.9%); mild decline 18 patients (32.1%); moderate impairment 14 patients (25%); and severe impairment 5 patients (8.9%).

Conclusions: The risk factors of progression of cognitive impairment after 3 and 6 months from stroke onset are older age, previous cognitive decline, genetically predisposed to brain vessel damage, insufficient control of vascular diseases and low systemic blood pressure (hypotension episodes).

Free radical formation in patients with cerebrovascular accidents and comorbid cardiovascular pathology
E. Silina1, S. Rumiantseva2, A. Orlova3, S. Bolevich4, I.M. Sechenov First Moscow State Medical University, Russia; 2The Russian National Research Medical University named after N.I. Pirogov, Moscow, Russia

Background: Cerebrovascular accidents (CA) are associated with an increase of free radical production, which leads to oxidative stress and contributes to brain damage. Comorbid cardiovascular diseases (CVD) aggravate the condition.

Objective: To evaluate the disturbances in free radical balance and their prognostic value in patients with CA and comorbid CVD.

Patients and methods: 141 patients with CA (Male — 72 (51.1%), mean age 65.48 ± 13.44 years) and history of CVD (coronary artery disease (CAD), myocardial infarction (MI), atrial fibrillation (AF)), free radical formation was assessed in plasma based on oxidative (chemiluminescence intensity index — basal (CIB) and zymosane-stimulated (CIs)) and lipid peroxidation markers (anti-peroxide plasma activity (APA), malondialdehyde (MDA)).

Results: In patients with CA and CAD Clb was 1.97-fold lower (64.24 ± 7.18 vs. 126.5 ± 17.19 mV/s × 106 leu) and Cls 1.55-fold higher (1106.71 ± 107.34 vs. 716.21 ± 93.37 mV/s × 106 leu) compared to patients with no CA or CAD (p < 0.05). In MI patients APA is 1.41-fold (2.92 ± 0.24 vs. 3.54 ± 0.13) higher than in patients with no MI (p < 0.05). We observed a marked increase in free radical formation on admission as demonstrated by Clb 1.23-fold (64.75 ± 11.94 vs. 94.31 ± 10.00 mV/s × 106 leu) in patients with AF compared to patients with CA only (p < 0.05).

Conclusion: In patients with CA and CVD there is an increased free radical formation even in the first 24 h, which justifies adjunctive antioxidant therapy.

Stroke awareness in Munich and Moscow
Y. Fris, P. Kamchatnova, R. Kalla. The Russian National Research Medical University, Moscow, Russia; Ludwig–Maximilians-University Munich, Klinikum Großhadern, Munich, Germany

Background: Different data of public stroke awareness in several researches may result from different methods of investigations.

Objectives: We aimed to compare the stroke awareness among patients in Moscow and Munich.

Material and methods: 180 patients in Moscow (48% female, mean age 63.09 ± 13.83) and 180 patients in Munich (47.8% female, mean age 61.12 ± 14) hospitals, divided into three groups (after stroke, high risk of stroke and without risk of stroke) answered 33 questions, including 4 open-ended questions about stroke symptoms (SS) and risk factors (RF).

Results: In group of patients without risk of stroke the difference in number of SS named was not significant. In group of patients with high risk of stroke the awareness of SS (1.96 ± 1.28 in Munich and 1.03 ± 1.07 in Moscow, p = 0.000) and the awareness of stroke RF (2.25 ± 1.29 in Munich and 1.34 ± 1.2 in Moscow, p = 0.000) were better among patients in Munich. In group of patients with stroke in anamnesis the awareness of SS (2.08 ± 0.99 in Munich and 1.25 ± 0.89 in Moscow, p = 0.000) was also better among patients in Munich. The difference in awareness of stroke RF in this group was not significant. The direct dialogue with the doctor and specialized brochure was named as most preferable forms of increasing the knowledge of risk factors and stroke symptoms.

Conclusion: The educational activities in Moscow should be focused on patients with high risk of stroke and should increase the recognition of stroke onset and highlight the importance of early hospitalization.

Cancer patients are at increased risk of recurrent stroke and cardiovascular mortality
K.K. Lau, Y.-K. Wong, K.-H. Chan, K.-C. Teo, S.F.-K. Hon, W. Mak, R.T.-F. Cheung, S.-L. Ho, L.S.-W. Li, H.-F. Tse, C.-W. Siu. The University of Hong Kong, Hong Kong, Hong Kong Special Administrative Region

Background: Cancer patients are at increased risk of cardiovascular and cerebrovascular events. However, the risk of recurrent stroke or cardiovascular mortality amongst cancer patients with stroke is currently unknown.

Objective: To determine the risk of recurrent stroke and cardiovascular mortality in cancer patients with ischemic stroke.

Patients and methods: This is a single center, observational study comparing the clinical characteristics and outcome of 58 ischemic stroke patients with cancer to 1047 ischemic stroke patients without cancer recruited from 2004 to 2008. Mean follow-up period was 76 ± 18 months. Primary endpoint was recurrent stroke and secondary endpoint was cardiovascular mortality.

Results: The three most common malignancies were breast (17%), colorectal (14%) and nasopharynx (13%). 26% of cancer subjects had active malignancy and 7% had metastatic disease. 22 patients with cancer (38%, 13.94 per 100 patient-years) and 219 patients without cancer (21%, 4.65 per 100 patient-years) developed a recurrent stroke (p < 0.01). 13 patients with cancer (22%, 4.3 per 100 patient-years) and 143 patients without cancer (14%, 2.35 per 100 patient-years, p = 0.08) died due to cardiovascular causes. After adjusting for age, gender, cardiovascular risk factors and co-morbidities, cancer was an independent predictor for recurrent stroke (HR 2.68; 95% CI: 1.58 to 4.54, p < 0.01) and cardiovascular mortality (HR 2.17; 95% CI: 1.12 to 4.22, p = 0.02).

Conclusion: Stroke patients with underlying cancer are at increased risk of developing recurrent stroke and cardiovascular mortality.

Application of chemical exchange saturation transfer (CEST) MRI in acute stroke to visualize tissue acidosis and infarction risk  
J. Blicher, A. Tietze, J.K. Mikkelsen, L. Østergaard, M. Strother, S. Smith, M. Donahue. cCFIN, Neuroradiology, Aarhus University Hospital, Aarhus, Denmark; bNeuroradiology, Aarhus University Hospital, Aarhus, Denmark; 4Radiology and Radiological Sciences, Vanderbilt University, Nashville, TN, USA

Background: In stroke patients with uncertain symptom onset or patients beyond the current time window for ivTPA there is a need for better imaging modalities to guide clinical decision making. Currently, MRI (perfusion weighted imaging) can be used to assess acute cerebral hyperperfusion. However, the technique is invasive, limited to some patients, and distinguishing penumbra from benign oligemia remains difficult. Amide Proton Transfer (APT) MRI is a non-invasive technique sensitive to the exchange of protons between amide-groups and water. The exchange rate is base-catalyzed and thus pH-sensitive.

Objective: To investigate the potential for APT imaging, which is sensitive to lactate formation and reduced pH in tissue at risk for infarction, in human acute stroke patients.

Patients and methods: 10 patients with acute stroke were scanned on a Phillips 3 T system using our standard acute MRI protocol (including DWI and PWI) as well as a 3-minute APT-sequence. Patients were offered a follow-up scan and a clinical evaluation one month post-stroke.

Results: We found a large variation in APT effect between patients. However, in patients with penumbra, based on DWI/PWI mismatch, we found a lower APT effect compared to the ischemic core pointing to early lowering of pH in the penumbra, and possibly changes in protein and water content in the ischemic core.

Conclusions: These first results of APT in human acute stroke patients show that the technique could serve as a tool to show early tissue acidosis, and thus guide clinical decision making in stroke care.

Clinical and radiologic characteristics of RCVS (Reversible Cerebral Vasocostriction Syndromes) in 23 patients  
Y. Ito, H. Moriyoshi, A. Ogura, N. Nakai, S. Nishida, T. Yasuda. Stroke Center, Department of Neurology, TOYOTA Memorial Hospital, Toyota, Japan

Background: Reversible cerebral vasocostriction syndrome (RCVS) is a clinicoradiologic syndrome believed to be benign conventionally, however it is pointed out that cerebrovascular events including infarction and hemorrhage are not rare, suspecting that this syndrome is not necessarily in good prognosis.

Subject and method: We have experienced 23 patients of RCVS corresponding to the diagnostic criteria from April, 1988 to December, 2012. The background disease included 17 obstetrical disease (eclampsia/preeclampsia/PCA), posttransfusion 1 case, idiopathic 4 cases and nephrotic syndrome 1 case. We examined cranial CT/MRI and MRA in all 23 cases, cerebral angiography in 8 cases in the acute phase and followed up clinical and radiological findings up to 3 months.

Results: Headaches was recognized in 18 cases convulsion in 16 cases. Radiological examination showed posterior reversible encephalopathy syndrome (PRES in 20 cases, cerebral infarction in 5, subcortical subarachnoid hemorrhage in 2, cerebral hemorrhage and subdural hematomas in 1 case). MRI at 3 months later was 0–1 in 22 cases, but one case was 3. We recognized asymptomatic irreversible change in MRI in six cases at 3 months later.

Discussion: RCVS has various symptoms and background disease in addition to a headache. Our patients had larger portions of gynecologic related RCVS patients. This may reflect higher incidence of PRES in acute phase. Hemorrhagic complications were not rare. Although outcome was favorable in most of our cases, some cases showed irreversible lesion in MRI images, suggesting that reversibility was not always true in radiologic images.

Is anger a precipitating risk for stroke?  
Y.L. Danga, J.Y. Hora, Y.K. Chiaa, T.T. Lima, P.E.S. Easawa, P.S. Easawb, M.H. Rafa. aDepartment of Neurology, Penang General Hospital, Malaysia; bDepartment of Medicine, Penang Medical College, Penang, Malaysia; cDepartment of Neurology, Kuala Lumpur General Hospital, Kuala Lumpur, Malaysia
Background: Emotional well-being is closely related to health. A lot of medical illnesses are closely linked to disrupted mental health. Men with introvert personality are particularly at high risk of ischemic stroke.

Hypothesis/objective: Suppressed anger within the past 2 weeks is a risk for stroke. Patients with introvert personality are more likely to develop ischemic stroke, whereas those with bad temper and recent rage outburst tend to present with intracranial haemorrhage.

Patients and methods: Patients admitted to the ward with stroke (both ischemic and haemorrhagic) were interviewed about whether they have suppressed anger over the past 2 weeks.

Results: More than 50% of strokes admitted that they have suppressed anger or upset within the past 2 weeks. The suppressed anger intensified to maximum just 1–2 weeks prior to onset of the disease. In cryptogenic young stroke group who has no other medical risks, suppressed anger was clearly identified.

Conclusion: Our findings suggest that suppressed anger is a clear risk for stroke. We hope that the public will become aware these finding. In order to prevent recurrent stroke, it is advisable not to suppress the anger and instead try to channel out the suppressed anger.

Stroke campaign: An experience report
C.D. Rochaa, J.A.D. Oliveira Júniorb, L.A.A. Reisa, F.K.M.S. Pintoa, F.O. Comesa, D.J.D. Silvab.  *Faculdade de Medicina, Universidade Federal de Goiás, Goiânia, Brazil; bHospital das Clínicas, Universidade Federal de Goiás, Goiânia, Brazil

Background: Cerebrovascular accident (CVA) is the second cause of mortality in Brazil and third in the world. Data from the World Health Organization (WHO) predict a 1.4% increase in stroke mortality in men and 0.3% in females by 2030. It is possible to reduce stroke mortality and disability through decreasing incidence and lethality of the disease and that is why stroke campaigns are indispensable.

Objectives: Experience report on campaign to promote health and prevent stroke.

Material and methods: In the campaign about stroke, medical students teach about the FAST test to recognize earlier the symptoms. The FAST test consists of “F”. Face (to smile), “A”, arm (any arm drifts downward?), “S”, Speech (speech sound slurred or strange?) and “T”, Time (if any of signs are observed) to call emergency immediately. Blood pressure measurements were also made to identify the main risk factor for hemorrhagic stroke — hypertension.

Results: People were instructed to the prevention of stroke, following stroke prevention, guidelines make aware of blood pressure, smoking, control alcohol abuse, check cholesterol levels, control diabetes, manage exercise and diet, and act FAST test at the first warning sign of stroke. The population empowerment from campaigns like this can reduce the interval between symptoms and diagnosis, reducing stroke morbidity and mortality.

Conclusion: Objectives were achieved and from primary attention to harm reduction, health promotion was entirely contemplated. It is a health promotion experience to be perpetuated.

Adult on set moyamoya like atherosclerotic disease with spontaneous revascularization
M.F. Oztokin, N. Oztokin, F. Efendizade, E. Bilgi, O. Ergun.  *Neurology, MOH Ankara Yildirim Beyazit Education and Research Hospital, Ankara, Turkey; aNeurology, MOH Ankara Numune Education and Research Hospital, Ankara, Turkey; bNeurology, MOH Ankara Yildirim Beyazit Education and Research Hospital, Ankara, Turkey

Background: Moyamoya disease is characterized by chronic occlusion of internal carotid arteries with development of fragile new vessels at the base of the brain with unknown etiology. It is often presented with ischemic vascular events in children and intraventricular or intraparenchymal hemorrhages in adults. Adult onset moyamoya disease must be differentiated from atherosclerotic disease. We presented an adult onset moyamoya like atherosclerotic disease with spontaneous external revascularization.

Case presentation: 57 year old female patient was admitted in emergency clinic with sudden loss of consciousness and vomiting. Her systemic examination revealed mild hypertension. Neurological examination revealed a drowsy patient with stiff neck, and no cranial nerve dysfunction was found. She had no motor and sensory lateralizing deficit. Bilateral extensor planter reflexes and brisk tendon reflexes were found. She had normal blood count and screening tests. Computerized tomography revealed intraventricular hemorrhage filling all ventricles. She gained her consciousness in the next day and informed that she had had another intracerebral eight years ago with full recovery. Cranial angiography revealed bilateral occlusion of carotid arteries at the level of suprACLoid segment and stenosis of right internal carotid artery after bifurcation from common carotid artery and moyamoya vessels at the base of the skull. There was also anastomosis of right external carotid and right middle cerebral artery at the dural level convexity of the right hemisphere.

Conclusion: This case demonstrates that spontaneous revascularization of dural anastomosis may be a part of the moyamoya like syndrome due to atherosclerosis.

Isolated oculomotor nerve palsy: A rare manifestation of spontaneous internal carotid artery dissection

Introduction: Internal carotid artery (ICA) dissection commonly presents with headache, neck pain, Horner syndrome or with focal cerebral ischemic symptoms. Cranial nerve palsies can also be found, accounting for 12% of spontaneous ICA dissection cases and usually presenting as a syndrome of lower cranial nerve palsies. Therefore, an isolated oculomotor nerve involvement is extremely rare.

Case report: A 58 year-old man complains of a sudden-onset double vision for 3 days. He denies recent inflammation/infection, headache, cervical pain and trauma. He had well-controlled diabetes, hypertension and dyslipidemia. He was apyretic, without ocular erythema, proptosis or palpable orbital mass. Neurologic examination: left-sided ptosis and binocular horizontal diplopia in dextroversion without apparent extraocular-muscle paralysis or pupillary involvement. Other cranial pairs, motor, sensory and coordination systems were spared. The laboratory screening was negative for infections and immunologic diseases. The brain-MRI revealed a crescent-shaped mural hyperintensity in left ICA at the skull base extending to intrapetrous segment, implying reduced caliber/flow on MRI-angiography — left ICA dissection. The patient started antiaggregation therapy and progressively recovered. A year later he was asymptomatic and CT-angiography confirmed ICA recanalization.

Discussion: An ICA dissection presented only by an incomplete oculomotor nerve palsy is extremely rare. According to the literature, this can be explained by a blood supply impairment to vasa nervorum (embolic/hemodynamic) as the distal III is supplied by the inferior cavernous sinus and meningohypophyseal arteries, both derived from the intracavernous ICA. This case report enhances the importance of considering a cervicocerebral dissection in less typical clinical presentations.

Stroke in the very elderly patients in Albania
University Service of Neurology, UHC Mother Theresa, Tirana, Albania

Aim: To evaluate vascular risk factors, stroke subtypes and clinical outcomes in very old patients admitted at our hospital with acute stroke.

Methods: We included in this study 252 stroke patients admitted to 4th Ward in the Clinic of Neurology in University Hospital Centre “Mother Teresa”, Tirana, Albania from February 2011 to December 2012. All of them were male. We assess if there were any significant differences between patients under 80 years old compared with older patients (80 years or older), with regard to vascular risk factors, stroke type and clinical outcome.

Results: Of 252 patients, 189 patients were less than 80 years, 63 were 80 years old and older. Younger patients were more likely to have diabetes (30, 6% versus 16, 2%, p < 0.001).

Older patients were more likely to have ischemic heart disease (38% versus 30, 1%, p = 0.02), or atrial fibrillation (34, 5% versus 15, 2%, p < 0.001).

Older patients were more likely to have Total Anterior Circulation Infarcts (TACI) strokes (17, 6% versus 11, 1%, p = 0.009) or Partial Anterior Circulation Infarct strokes (PACI) (30, 1% versus 23, 5%, p = 0.04).

Outcome data, which was available for 91% patients, showed that older patients stayed longer in the hospital (median length of stay 23 days versus 18 days (p = 0.008)) and had a higher inpatient mortality (14% versus 3, 7% (p < 0.001)).

Conclusion: Very elderly patients have a different risk factor profile, have more anterior circulation infarcts and have a worse prognosis with increased mortality and increased length of stay in the hospital.

CRP in the patients with ischemic stroke compared with controls. We didn’t find a direct correlation between neurological status and oxidative stress markers, instead NIHSS score correlated significantly with CRP levels at the onset of stroke.

**Conclusion:** These results prove once more the implication of oxidative stress and inflammation in the pathogenesis of ischemic stroke.

**Management of multiple intracerebral hemorrhages due to myxomatous aneurysms — A case report and literature review**

G. Puttinger1, G. Schwarz2, J. Trenkler1, A. Gines1, J.T. von Oertzen2.

1Neurology, Landesnervenklinik Wagner-Jauregg, Linz, Austria
2Neuroradiology, Landesnervenklinik Wagner-Jauregg, Linz, Austria
Radiation Oncology, University Hospital, Innsbruck, Austria

**Background:** The natural history of cerebral aneurysms which derived from metastatic spread of cardiac myxomas is not well known and their management may prove very difficult.

**Objective:** Description of a patient’s history with multiple intracerebral hemorrhages due to myxomatous aneurysms and progression who underwent whole brain radiotherapy.

**Patients and methods:** Case report and literature review.

**Results:** A 35-year-old woman presented with headache due to multiple intraparenchymal hemorrhages five months after resection of an atrial myxoma. Angiography showed several small fusiform aneurysms. During the following four months the patient developed a worsening of her neurological deficits correlating with a progression of the amount as well as the size of the hemorrhages. Since undergoing a whole brain radiotherapy with 30 Gy/2 Gy the patient has been clinically and radio logically stable over a 15 month period up to now.

**Conclusions:** Myxomatous cerebral aneurysms are important entities for neurologists to recognize which can present before, but also months to years after diagnosis of a cardiac myxoma. So far there are only a few case reports about the management of intraparenchymal hemorrhages of this etiology published: most of them recommend an observational procedure. In one case radiotherapy with 50 Gy and chemotherapy has been described.

To our knowledge this is the first report about a whole brain radiotherapy with 30 Gy/2 Gy in a patient with multiple intracerebral hemorrhages due to myxomatous aneurysms.

**Efficacy of carotid endarterectomy performed by urgent indications**

A. Zakhidov. Neurology, Republican Scientific Research Center of Emergency Medicine, Tashkent, Uzbekistan

**Background and purpose:** Carotid endarterectomy (CEAE) is a standard method of primary or secondary ischemic stroke (IS) prevention. In our days there is no common consensus concerning the period when to perform CEAE. Majority of authors consider that CEAE should be performed after acute period of IS. But some authors’ opinion is to perform CEAE to patients who need it by urgent indications. We estimate efficacy of CEAE by urgent indication in acute period of stroke.

**Methods:** 54 patients with acute IS developed due to occlusive and stenotic lesion of carotid arteries were investigated. Males were 45 (83.3%), females were 9 (16.8%). Average age was 60.7 ± 2.6 years. The period from the IS sign appearance to CEAE operation performance ranged from 2 h to 18 days. CEAE was executed when hemodynamically significant stenosis of carotid arteries with embolically dangerous atherosclerotic plaque occurred. Indications for CEAE were minor stroke — 36 patients (66.6%), transient ischemic attacks (TIA) — 4 patients (7.4%), stroke progression — 11 patients (20.4%) and floating embolus — 3 patients (5.6%). In 37 patients (68.5%) classic CEAE and in 17 patients (31.5%) eversion CEAE were performed.

**Results:** Regression of neurological deficiency in 2–3 days was observed in 48 (88.9%) patients in post operative period. Among these 48 patients full neurological recovery occurred in 36 (66.7%) patients. Obtained data testified about efficacy of CEAE in acute period of IS when urgent indications presented.

**Conclusions:** CEAE performed at the stage of reversible ischemic and neurological lesions (minor stroke and TIA) had better results.

**Mortality trends by stroke in Uruguay**

H.J. Hackembruch, A. Perna, C.N. Ketzoian. Neuroepidemiology Section, Institut of Neurology, School of Medicine, Montevideo, Uruguay

**Background and purpose:** Intravenous tissue plasminogen activator (tPA) application within 3 h after onset of acute ischemic stroke (AIS) is established therapy. The alternative for thrombolysis in patient admitted within 3–6 h after onset is intra-arterial thrombolysis (IAT). The purpose was to evaluate the efficacy of IAT with tPA in AIS due to middle cerebral artery (MCA) occlusion.

**Methods:** Cerebral angiography (CA) and standard Seldinger technique were applied in IAT. After angiographic detection of MCA occlusion IAT with tPA in dose 15–25 mg was performed. 10 patients (7 male, 3 female, aged 48–75 years, average age 64.4 ± 8.6) were investigated. All patients were selected by the National Institute of Neurological Disorders and Stroke recommendations. National Institutes of Health Stroke Scale (NIHSS) and modified Rankin scale (mRS) were used.

**Results:** MCA occlusion was detected by CA in all patients. NIHSS average score at admission was 14.7 ± 3.9, 272 ± 36.5 min elapsed from symptom onset. We obtained the following clinical results: 5 patients (50%) had excellent outcome (mRS score 0 to 1), 3 patients (30%) a good outcome (mRS score 2), and 2 patients (20%) had no changes (mRS score 3 to 4). In this patient brain ischemic zone was detected on control CT. In the group with excellent and good outcomes 3 patients had asymptomatic hemorrhagic transformation (HT) with small petechiae along the margins of infarct zone.

**Conclusions:** IAT with tPA performed under CA control can be considered as an effective method in patients with AIS. Thrombolysis-related HT is a marker of successful recanalization.
**Background:** Stroke is one of the major death causes in Uruguay and in the world.

**Objective:** For this motive, we have designed this study to describe and to analyze stroke mortality tendency in Uruguay between 1950 and 2008. Its relationship with gender, imaging techniques, intensive treatments, gross domestic product (GDP), and mortality in other countries was analyzed.

**Methods:** An ecologic study of mortality trends, standardized gender and age rates, and Poisson regression models and autocorrelation was performed.

**Results:** The mortality trend has decreased throughout the studied time, with two periods, an increasing one until 1971, and then a decreasing period until 2008. The female gender presented higher mortality. The decreasing period coincides with the introduction of intensive care units (ICU) and the computerized tomography (CAT) scan. The GDP showed a negative correlation with the decrease of stroke mortality.

**Conclusions:** Uruguay has had a decline in stroke mortality placing itself in an intermediate position in comparison to other countries. CAT scan techniques, ICU centers and an increase in the GDP seem to have had a positive effect in the decline of stroke mortality.

**Multidisciplinary stroke early supported discharge program in a local hospital: Outcome and safety**

W.C. Fong, S.T. Chan, C. Chao, T. Fung, V. Kwok, A. Tsoi, P. Lau, K.F. Leung, J.H.M. Chan, P.C.K. Li, aDepartment of Medicine, Queen Elizabeth Hospital, Hong Kong, Hong Kong Special Administrative Region; bDepartment of Physiotherapy, Queen Elizabeth Hospital, Hong Kong, Hong Kong Special Administrative Region; cDepartment of Occupational Therapy, Queen Elizabeth Hospital, Hong Kong, Hong Kong Special Administrative Region

**Background:** Recent meta-analysis had demonstrated that early supported discharge is equally effective as compared with prolonged inpatient rehabilitation. Stroke Early Supported Discharge (SESD) Program was then implemented since Dec. 2011. Timely home based rehabilitation and caregivers’ training would be provided to those patients eligible for early discharge.

**Objective:** This study aims to show whether our SESD program can be effective and safe outside clinical trial setting.

**Method:** This study reviewed the outcome and safety parameters after the introduction of the program. Data were prospectively collected and compared before and after the introduction of the program.

**Results:** From Dec. 2011 till Sept. 2012, 283 patients were recruited into the SESD program. Their mean age was 70. Half of the patients had Modified Barthel Index (MBI) less than 85. After the program was implemented, the proportion of acute stroke patients directly discharged without transfer to rehabilitation unit, was significantly increased from 43.5% to 49.2% (p = 0.005). The average length of stay of those patients was 5.08 days. For the functional recovery, the MBI and Berg Balance Scale (BSS) were significantly improved after home based rehabilitation as compared with their baseline upon discharge (mean MBI from 81.2 to 91.9, p < 0.001, mean BSS from 40.4 to 46, p < 0.001). Their unplanned readmission rate, within 4 weeks from discharge, was 10.2%, which was lower than that of all the stroke patients (12.3%) in the same period (p = 0.055).

**Conclusions:** The SESD program was effective and safe to facilitate direct discharge of acute stroke patients from acute hospital.

**Predictive value of imbalance grade and F-score to identify stroke in dizziness patients**

J. Seo, H. Jung, E. Kim, Neurology, Inje University, Paik Hospital, Busan, Republic of Korea

**Background:** In patients presenting dizziness, there is no definite criterion to distinguish between the central and peripheral etiology based on their symptom quality. Although dizziness is usually considered to be benign etiologies, not infrequently acute dizziness cases could herald a cerebrovascular disease. But lack of objective risk stratification schemes of cerebrovascular disease makes clinicians perplexed. At this point, we aimed to assess the effectiveness about the cerebrovascular disease risk stratification systems such as hard coronary heart disease 10 year risk score in Framingham heart study (F-score) and specialized examinations such as imbalance grade.

**Methods:** We performed retrospective study presenting symptom with whirling/non-whirling type dizziness, vertigo or disequilibrium. Peripheral type vertigo was excluded. MRI was taken in all included patients to define ischemic lesions. ABCD2, CHADS2, F-Score, and imbalance grade (0 to III) were calculated using clinical information from the medical records. Statistical analysis was done with chi square and logistic regression.

**Results:** Among the 145 patients (mean age, 59.8 ± 10.3), ischemic stroke was diagnosed in 27 (18.6%). Univariate analysis revealed that F-score (13.6 ± 9.1 vs 7.4 ± 7.5, P = 0.001), imbalance grade (P = 0.014), male (70.4% vs. 39.8%, P = 0.004), smoking (40.7% vs. 10.2%, P = 0.000) and low high density lipoprotein (HDL) cholesterol (47.7 ± 16.3 vs. 52 ± 13.8, p = 0.05) were associated with stroke. In multivariable analysis, imbalance grade only (p = 0.037) was associated with stroke. Most common lesion in stroke patients with isolated dizziness was PICA territory.

**Conclusion:** Those patients with isolated dizziness, imbalance grade could be helpful to predict central origin.

So prompt evaluations were needed to define stroke to those patients with high imbalance grade score presenting with dizziness.

**Isolated right hand palsy due to cortical ischaemia**

H. Yasar, V.S. Bek, R.E. Togral, aNeurology, Ankara Mevki Military Hospital, Ankara, Turkey; bNeurology, GATA Haydarpasa Educational Hospital, Istanbul, Turkey

**Case:** 75 year old male patient with no known previous illness, noted a weakness on his right hand one day before his presentation to our polyclinic. He consulted the physical therapy and rehabilitation polyclinic and an ENMG study was ordered with a preliminary diagnosis of entrapment neuropathy. The ENMG was found to be normal, and a control ENMG was ordered 10 days later. The patient consulted medical advice from the neurology polyclinic 1 day after the beginning of his complaints. His neurological examination at the time of his application was as follows: Right hand fingers were in flexion posture, the motor strength of the opposition and flexion of the right hand first finger, abduction and adduction of the other fingers were 0/5. The strength of the right hand extension was 4/5. Hoffmann sign was (+) on the right side. The other neurological examination signs were normal. Cranial MR imaging revealed widespread bilateral periventricular chronic lacunar ischaemia as well as an acute ischaemic
infarct area in the sol cortical area corresponding to the motor area of the right hand. Ultrasonographic investigation showed 75% stenosis in the left carotid artery and 50% stenosis in right carotid artery. No ischaemic cardiac pathology was detected on cardiac examination.

**Discussion:** Isolated hand palsy due to cerebral ischaemic pathology is rarely seen and is usually confused with acute entrapment neuropathies. Usually cortical ischaemic lesion is seen and cerebral atherosclerosis is present in the etiology.

**Hemorrhage into a gastrointestinal stromatumor (GIST) under Dabigatran at a patient with stroke caused by a paroxysmal atrial fibrillation**

R. Schimana. Geriatry, Clinic Vilshofen, Vilshofen, Germany

**Background:** An 87 year old patient had a stroke with a hemiparesis left under aspirin. In their anamnesis she had an arterial hypertension and a benign gastrointestinal stromatumor. Should we treat the patient with new oral anticoagulation therapy or Warfarin? After information the patient agreed to therapy with Dabigatran.

**Methods:** The classical diagnostics in neurology and internal medicine.

**Objectives:** Sensomotoric hemiparesis left.

**Results:**

- MRI brain: Several ischemic lesions in the region of right middle cerebral artery.
- Holter EKG: Paroxysmal atrial fibrillation.
- 24 h blood pressure measure: Arterial hypertension I.
- CT abdomen: Great hemorrhage into the GIST.
- Gastroscopy and colonoscopy: No hemorrhage.
- Laboratory 1: Regular finding.
- Lab II: Hb 6.7 mg/dl, following leukocytosis of 12000 and CRP 30 mg/dl.

**Conclusions:** At patients with a stroke caused by atrial fibrillation and a benign tumor in the history the indication for therapy with Dabigatran should be done carefully or under monitoring.

3 days after starting the therapy with Dabigatran (2 × 110 mg/daily) the patient had a decrease of hemoglobin to 6.7 g/dl and a hemorrhage into the GIST, but not a cerebral hemorrhage. After finishing the therapy with Dabigatran the hemorrhage stopped slowly without a special coagulation management. A therapy with Imatinib, which should melt down the tumor, needed to be stopped because of side effects. A urosepsis, the next complication, faded away under a special antibiotic. After 6 weeks the patient left the hospital with a Barthel index of 60 points; the same as at the admission.

**Atherosclerotic carotid artery diseases and atrial fibrillation in ischemic stroke patients**

D. Necioglu Orken, N. Kuloglu-Pazarci, E. Turgut. Neurology, Sisli Etfal Education and Research Hospital, Istanbul, Turkey

**Introduction:** Atrial fibrillation (AF) is the most common sustained cardiac arrhythmia, affecting 1–2% of the general population. The most common causes of AF are ischemic heart disease and atherosclerosis. The aim of this study is to determine the frequency of atherosclerotic cervical carotid disease with Doppler ultrasonography (USG) in patients with AF.

**Material and methods:** Ninety-three patients who had AF, treated with warfarin and being followed-up in the Cerebrovascular Diseases outpatient clinic were included to this prospective study. Seventy-one subjects were chosen as control group among warfarin treated patients with indications other than AF. Patients and controls were evaluated with carotid Doppler USG.

**Results:** The mean age of patients and controls were 71.5 and 64.2 years, respectively. Fifty of the 93 patients (54%) had atherosclerotic changes in carotid Doppler USG compared with 40 of 71 (56%) control patients (p = 0.74). Among the 93 patients who had atherosclerotic changes 27 had an increased intima-media thickness, 15 had atherosclerotic plaques causing <50% of lumen stenosis, 2 had 50–69% of lumen stenosis, 5 had >70% of lumen stenosis and 3 had internal carotid artery (ICA) occlusion. Proportion of patients who had greater than 50% stenosis or ICA occlusion was 11%.

**Discussion:** Carotid artery stenosis of 50% or more occurs in about 11% of ischemic stroke patients with AF, due to other risk factors like hypertension, diabetes mellitus and hyperlipidemia. This patient group must be followed-up carefully for the progression of carotid artery disease for the prevention of new stroke due to large artery disease.

Cognitive functioning in ischemic stroke patients with physical disability

J. Ma1, Y. Zhang2, Q. Guo3, R. Jin4, X. Zhen5. 1Stroke Unit, Yueyang Hospital of Integrated Traditional Chinese and Western Medicine, Shanghai University of Traditional Chinese Medicine, China; 2Department of Neurology and Institute of Neurology, Huashan Hospital, State Key Laboratory of Medical Neurobiology, Fudan University, China; 3Department of Preventive Medicine and Medical Statistics, Shanghai University of Traditional Chinese Medicine, Shanghai, China

Background: Stroke is a major cause of disability in the elderly. It is also related to a wide spectrum of cognitive deficits. Post-stroke cognitive impairment is particularly important and frequent. Whether there is relationship between cognitive functioning and physical disability in ischemic stroke patients is unclear.

Objective: To access the relationship between cognitive functioning and physical disability in ischemic stroke patients.

Patients and methods: We prospectively evaluated consecutive patients with acute ischemic stroke. 145 patients were administered by tests of Modiﬁed Rankin Scale (MRS), Mini-Mental State Examination (MMSE) and National Institute of Health Stroke Scale (NIHSS) and the Barthel Index (BI). We accessed the relationship between MRS and MMSE and compared the cognitive functioning with mild to moderate physical disability (MRS ≤ 3) and severe physical disability (MRS > 3) in ischemic stroke patients across 4 weeks while observing the changes both in MMSE and NIHSS/BI.

Results: MMSE scores were significantly different among different degree of MRS over time with p < 0.05. The change of MMSE in MRS ≤ 3 group was different from that in MRS > 3 group after 2 and 4 weeks (p = 0.01), the improvement of MMSE scores was 0.75 ± 3.78 in MRS ≤ 3 group and 3.10 ± 5.68 in MRS > 3 group after 2 weeks (p = 0.001), and 0.58 ± 4.10 in MRS ≤ 3 group and 3.71 ± 5.59 in MRS > 3 group after 4 weeks. The change of MMSE was linear for NIHSS or BI scores after 2 and 4 weeks.

Conclusion: Physical disability correlated with cognitive functioning in ischemic stroke patients. The improvement in cognitive functioning correlated with the degree of physical disability.

Ischemic stroke and migraine

N. Radojkovic Gligic1, S. Atic2, R. Amanovic Curuvija3. 1Stroke Unit, Belgrade, Serbia; 2Hospital for Cerebrovascular Disease Sveti Sava, Belgrade, Serbia

Background: Migraine is recognised as a cardiovascular risk factor and connection with stroke especially migraine with aura.

Objectives: Relationship between migraine and stroke and compared to other types of headache.

Methods: The study included 135 patients with stroke and headache. After statistical adjustment for age, gender and affected vascular brain system, we formed two groups 15 patients with stroke and migraine and second 17 patients with stroke and other types of headache. All of them had MRI. Welch criteria were applied for the relationship between migraine and stroke.

Results: 1 group 15 pts, mean age 45 ± 11 years, 9 pts had migraine with aura and 6 pts without aura. The II group 16 pts, mean age 53 ± 8 years, 12 pts tension tape headache, 3 headache attributed to HTA and one unclassified. There were no differences between groups on main vascular risk factors (blood pressure, cholesterol level and ischemic cardiopathy). According to Welch criteria 2 pts had stroke which occurs in patients with migraine but not during an attacks, 9 pts had migraine induced stroke with risk factors. Migraine with aura produced stroke in the presence of another risk factor and 5 pts had uncertain history of migraine without aura and stroke during a migraine attack. The Rankin disability scale was significantly worse compared to stroke and other types of headache.

Conclusion: A patient with migraine had high probability to have severe stroke than other types of headache. Relationship between migraine and stroke is complex and difficult.

Insular and caudate lesions release abnormal yawning in stroke patients

H. Krestel1, C. Weisstanner2, C.W. Hess3, C.L. Bassetti4, R. Wiest5. 1Neurology and Pediatric Neurology, Inselspital, Bern, Switzerland; 2Neuroradiology, Inselspital, Bern, Switzerland; 3Neurology, Inselspital, Bern, Switzerland

Background: Abnormal yawning (chasm) is a rare phenomenon in patients in anterior circulation stroke.

Objective: We aimed at identifying core regions involved in abnormal yawning in an attempt to assign abnormal yawning to lesions in the anterior circulation.

Patients and methods: We analyzed the extent of brain areas encompassing restricted diffusion after ischemic stroke in ten patients presenting with at least three yawns per 15 min associated with stroke symptoms. All patients were classified according to the NIH stroke scale (NIHSS), daytime of symptom onset, yawning duration, Glasgow Coma Scale (GCS), partial oxygen pressure, body temperature, blood pressure, pulse, and modified Rankin scale. Lesion maps were segmented on diffusion weighted images in native space using MRicron and spatially normalized using the unified segmentation algorithm in SPM5. The extent of overlap between the different stroke patterns was calculated.

Results: Abnormal yawning persisted for 2.8 ± 1.3 days. Average GCS and NIHSS scores were 12.8 ± 2.6 and 10.5 ± 6.5, respectively. Oxygen saturation, body temperature, blood pressure, and heart rate were within normal limits. Ischemic brain lesions overlapped in eight out of ten patients: in six patients in the insula and in six in the caudate nucleus. The decrease of the apparent diffusion coefficient within the lesions correlated moderately with the duration of abnormal yawning (insula; r2 = 0.58; caudate nucleus; r2 = 0.32).

Conclusion: The intensity of targeted ischemic lesions in the insula and the caudate nucleus correlates with the duration of abnormal yawning in anterior circulation stroke.

Poststroke depression

A. Alajbegovic1, J. Djelilovic-Vranic2, L. Todorovica, S. Alajbegovic3. 1Neurology and Pediatric Neurology, Inselspital, Bern, Switzerland; 2Neurology Clinic, Clinical Center of Sarajevo University, Sarajevo, Bosnia and Herzegovina; 3Cantonal Hospital Zenica, Zenica, Bosnia and Herzegovina

Background: Abnormal yawning (chasm) is a rare phenomenon in patients in anterior circulation stroke.

Objective: We aimed at identifying core regions involved in abnormal yawning in an attempt to assign abnormal yawning to lesions in the anterior circulation.

Patients and methods: We analyzed the extent of brain areas encompassing restricted diffusion after ischemic stroke in ten patients presenting with at least three yawns per 15 min associated with stroke symptoms. All patients were classified according to the NIH stroke scale (NIHSS), daytime of symptom onset, yawning duration, Glasgow Coma Scale (GCS), partial oxygen pressure, body temperature, blood pressure, pulse, and modified Rankin scale. Lesion maps were segmented on diffusion weighted images in native space using MRicron and spatially normalized using the unified segmentation algorithm in SPM5. The extent of overlap between the different stroke patterns was calculated.

Results: Abnormal yawning persisted for 2.8 ± 1.3 days. Average GCS and NIHSS scores were 12.8 ± 2.6 and 10.5 ± 6.5, respectively. Oxygen saturation, body temperature, blood pressure, and heart rate were within normal limits. Ischemic brain lesions overlapped in eight out of ten patients: in six patients in the insula and in six in the caudate nucleus. The decrease of the apparent diffusion coefficient within the lesions correlated moderately with the duration of abnormal yawning (insula; r2 = 0.58; caudate nucleus; r2 = 0.32).

Conclusion: The intensity of targeted ischemic lesions in the insula and the caudate nucleus correlates with the duration of abnormal yawning in anterior circulation stroke.

Comorbidty of depression and stroke significantly reduces quality of patient’s life after stroke. Squeal after stroke also determines quality of life and impact on the occurrence of depression after stroke. In our study we investigated occurrence of depression in patients after different types and subtypes of stroke measured by Hamilton scale compared to the level of disability on NIHSS scale.

The goal was to make comparative analysis of depression after stroke, according to gender and age, side of lesion and severity of neurological deficit.

Material for our work is 210 patients with stroke treated at the Neurology Clinic, Clinical Center of Sarajevo University in 2012, 105 male and 105 female. The mean age of patients was 67.12 with SD of 9.5 years. Ischemic stroke was present in 65% cases. There was no statistical significant difference between ischemic and hemorrhagic stroke according to gender (chi-square = 6.563, p = 0.082). Depression was more prevalent among younger patients (52–60 g) with 39.2% then in the group of older patients (61–70 g) with 32% of depressed. In relation to gender there was significantly more patients with depression among women compared to men (63:8:27.2%) (chi-square = 14.38, p = 0.00019). Depression was more frequent in patients with stroke in the left hemisphere medial localization (63%). NIHSS scale average was 16.07 with the minimum of 11 and maximum of 22, F = 52.56, p = 0.001.

We can conclude that depression after stroke is more frequent in younger patients, female patients, patients with localized stroke in the medial left hemisphere and with higher disability score.

Is treatment with alteplase beneficial in elderly patients or patients with mild deficit?

S. Greiseneggera, J. Ferrari, L. Seyfangc, W. Lang; aDepartment of Neurology, Medical University of Vienna, Austria; bDepartment of Neurology, Krankenhaus Barmherzige Brüder Wien, Austria; cDanube University Krems, Gesundheit Österreich GmbH/BIQG, Vienna, Austria

Background: Treatment with iv thrombolysis is not approved for patients with ischaemic stroke (IS) over 80 years or patients with mild deficit despite subgroup analyses from randomised studies and observational data pointing to a benefit for these patient groups.

Objective: To analyse efficacy of iv thrombolysis in matched-pairs of patients (with and without iv thrombolysis) over all age groups and the whole range of stroke severity in a large cohort of prospectively enrolled patients with ischemic stroke (Austrian Stroke Unit Registry).

Methods: Patients with and without therapy with iv tPA were matched for age, sex, the pre-stroke modified Rankin scale (mRS), stroke severity (according to the NIH stroke scale (NIHSS)), hypertension, diabetes, hypercholesterolemia, etiology and clinical stroke syndrome. The outcome was assessed by the mRS at 3 months. Means of outcome differences in matched pairs were used for interpretation. For data-visualization weighted averages of outcome differences were computed for all age–severity combinations along a grid and mapped to a colour.

Results: 60230 patients with IS 7615 were treated with iv tPA. Of those 25.3% were 80 years and 18.1% had a mild deficit (NIHSS ≤ 4). 2124 matched pairs were included into the analysis. Colour mapping showed a beneficial effect on outcome in thrombolized patients as compared to matched cases over all ages and the whole range of stroke severity. In patients with mild stroke effect sizes were smaller but still present.

Conclusion: Treatment with iv tPA might be beneficial in elderly patients and patients with mild deficit.

Clinical presentation of internal carotid artery dissection in series of 28 patients

I. Divjakab, S. Slankamenac, B. Radovanovicb, Z. Zivanovicb, A. Jescib, aClinical Center of Vojvodina, Neurology Clinic, Medical Faculty, University of Novi Sad, Serbia; bClinical Center of Vojvodina, Urgent Neurology, Medical Faculty, University of Novi Sad, Novi Sad, Serbia

Background: Cervical artery dissection is defined by the existence of a hematoma in the arterial wall. Internal artery dissection (ICAD) is an important cause of stroke among young and middle-aged patients.

Objective: The aim was to analyze the spectrum of clinical presentation in 28 ICAD patients.

Patients and methods: 28 patients with ICAD, 26 with unilateral and 2 with bilateral, aged 35–59 (mean age 47.6) were evaluated in the last 12 year period. The ICAD diagnosis was established in all cases using MRI, MRA and duplex sonography.

Results: Facial and neck pain and Horner’s syndrome were the only presenting symptoms in 5 patients; headache and visual disturbances in 2; facial pain, Horner’s syndrome and contralateral sensorimotor deficit in 7; headache and contralateral sensorimotor deficit in 5; and contralateral sensorimotor deficit in 9. ICAD was triggered by mild trauma in 7 patients (1 while unloading sacks of corn, 2 following sudden head turning, 1 during sports activity, 1 during sexual intercourse, 1 during roller-coaster ride, and 1 in car accident), and spontaneous in 21. MRI revealed infarction in 21 patients, while in the 5 patients presenting with facial and neck pain and Horner’s syndrome and in 2 patients with headache and visual disturbances MRI did not show evidence of infarction. Good outcome (defined as modified Rankin score of 0–2) was seen in 26 patients (92.8%).

Conclusion: The clinical presentation of ICAD is variable and can be similar to other stroke etiologies. ICAD is not always associated with brain infarction.

Cerebral venous thrombosis: Clinical, genetic and neuroradiological study

Background: Cerebral Venous Thrombosis (CVT) is a rather uncommon cerebrovascular disease with a wide spectrum of clinical presentations and a variable prognosis.

Objective: To study the CVT clinical presentation and outcome.

Patients and methods: We investigated clinical and imaging features of twenty-three consecutive patients with CVT (17 F, 6 M; mean age 39.8 yrs) admitted to our department from August 2005 to February 2013. Diagnosis of CVT was confirmed by brain MRI and MR-venography. All patients underwent an extensive systematic etiological and genetic work-up at admission. Treatment was based on intravenous unfractionated heparin, followed by oral anticoagulation for six months or longer. Outcome was evaluated by modified Rankin Scale (mRS) at three months.

Results: Genetic risk factors were identified in twelve out of twenty patients. Patients presented with the following clinical syndromes: focal syndrome (12/23, 52.1%), isolated headache (8/23, 34.7%) and isolated intracranial hypertension (3/23, 13.0%). Headache was the most
frequent symptom, present in twenty out of twenty-three patients (86.9%). Other often occurring symptoms were seizures (9/23, 39.1%), motor deficits (7/23, 30.4%) and aphasia (6/23, 26.0%). The sinus most frequently involved was the lateral sinus (22/23, 95.6%), either isolated or in association with other sinuses. A complete recovery (mRS = 0–1) was observed in 16/23 (69.5%) cases. One patient died of heart failure. **Conclusion:** Our results confirm that headache is the most frequent symptom and may be the only clinical presentation of the CVT in a high percentage of cases. CVT seems to have a more benign prognosis than previously considered.

**Prediction of tissue outcome in acute stroke with perfusion CT**

D. Sergeeva, A. Suslinb, A. Sergeeva, M. Piradova, M. Krotenkovab.
Intensive Care, Research Center of Neurology, Russian Academy of Medical Sciences, Moscow, Russia; bRadiology, Research Center of Neurology, Russian Academy of Medical Sciences, Moscow, Russia

**Background:** Perfusion CT allows assessment of tissue viability in acute cerebral ischemia.

**Objective:** To evaluate the outcome of ischemic tissue depending on the initial perfusion deficit.

**Patients and methods:** Thirty patients (21 men, median age 59 years) with acute hemispheric stroke in the first 24 h of symptoms onset underwent perfusion CT on admission and non-contrast CT on Day 10. Relative (intact/affected side) values of perfusion parameters within hyperperfused area on initial perfusion CT scan in the regions corresponding to hypodense and normal tissue zones on non-contrast CT were studied with ROC analysis. No patients were eligible for recanlization therapies, and received standard antiplatelet treatment and supportive care.

**Results:** Median initial NIHSS score was 8.1. Thresholds for relative values of perfusion parameters indicating tissue survival (i.e., no infarction on final CT scan) were 5.06 for rCBF, 1.13 for rCBV, and 0.41 for rMTT. Despite no difference was found between areas under ROC curves (p > 0.05), AUROC value was numerically higher for rCBV (0.84 vs 0.80 vs 0.59 compared with values for rCBF and rMTT, respectively). The rCBV threshold had sensitivity of 88.9% and specificity of 75.0%.

**Conclusion:** In patients with acute stroke who did not receive thrombolysis the viability of tissue can be best predicted with the change of CBV parameter relative to intact tissue on initial perfusion CT, with decrease of CBV > 13% indicating worse tissue outcome.

**Specification of amino acid neurotransmitters in the cerebrospinal fluid in intracerebral hemorrhage**

Y. Musaeva, F. Saidvalley, S. Kuranbaeva.
Tashkent Medical Academy, Tashkent, Uzbekistan; Neurology, Tashkent Medical Academy, Tashkent, Uzbekistan

**Introduction:** Current knowledge of the mechanisms of neuronal death in stroke shows that the damaged nerve cells play an important role in imbalanced neurotransmitter amino acids, set in motion a cascade of calcium glutamate.

The purpose of the study is to evaluate the content of excitatory (glutamate and aspartate) and inhibitory (GABA, glycine) neurotransmitter amino acids (NTA) in the cerebrospinal fluid (CSF) of patients with intracerebral hemorrhage (ICH), and give a comparative description with ischemic hemispheric stroke (IHS).

**Materials and methods:** The study included 75 patients: 40 with ICH, 20 with IHS and 15 dyscirculatory encephalopathy (DE) under sub-compensation (control group).

All patients with ischemic acute stroke had severe disease severity (according to clinical scales). Determining the level of excitatory and inhibitory NTA in the CSF was performed by liquid chromatography (Cohen’s method).

**Results:** These studies have shown that in patients with ICH, the average content of glutamate was 402.0 ± 11.60 nmol/ml, aspartate – 345.0 ± 13.83 nmol/ml, glycine – 316.5 ± 10.4 nmol/ml and GABA – 100.3 ± 4.8 nmol/ml. In the early days of ICH, average content of excitatory amino acids increased dramatically, significantly surpassing both the control group (4.14 times), and patients with IHS (2.65 times).

**Conclusions:** Thus, the ICH and IHS accompanied by significant changes in the content of both excitatory and inhibitory amino acids in the acute phase of the disease.

A pooled analysis identifies the potential and limitations to improve upon intravenous rt-PA

T.A. Kent, P. Mandava. Neurology, Baylor College of Medicine, Houston, TX, USA; Stroke Program, Michael E. DeBakey VA Medical Center, Houston, TX, USA

**Background:** Intravenous thrombolysis (IVT) remains the most effective therapy for ischemic stroke. While non-randomized series suggested better outcomes for add-on and other approaches, larger randomized clinical trials (RCTs) were mostly negative. Because imbalances in important baseline factors between treatment and control arms affect all but the largest trials and may have produced misleading results, we developed techniques to identify potentially efficacious therapies by providing a pooled comparison sample to test against.

**Objective:** To accommodate imbalances by testing outcomes of trials intended to improve upon IVT against pooled models at each trial’s own baseline NIH Stroke Scale and age.

**Patients and methods:** We generated outcome models (modified Rankin Scale 0–1 & 0–2) with the novel feature of multi-dimensional statistical intervals pooled from the thrombolytic arms of all published IVT RCTs. A function was fitted and individual trial results were tested against this model to determine whether outcomes surpassed the p < .05 surface. We analyzed IVT add-on and endovascular/thrombectomy trials.

**Results:** Functions derived from 14 IVT RCT thrombolytic arms representing 1785 subjects were generated (r2 ≥ .67). Nineteen trials were analyzed representing 1748 subjects. Only TUCSON (3 hour IVT/ultrasound with microspheres), CLOTBUST (3 hour IVT/ultrasound), and SYNTHESIS (3 hour IA rt-PA) achieved significant improvement, but notably SYNTHESIS-EXPANSION (4.5 hour IA rt-PA) did not. No extended window endovascular/thrombectomy trial showed benefit.

**Conclusion:** Three hour treatment with adjunctive ultrasound or IA rt-PA appears to be the most promising approach, indicating that there remains little evidence that the therapeutic window can be extended other than by IV rt-PA.

Intracranial carotid artery dissection in puerperium

**Introduction:** Arterial dissection occurs as a result of penetration of the blood vessel wall, which leads to the separation of the layers of the wall and formation of intramural hematoma, or dissection aneurysm.

**Objective:** To determine the correlation of ultrasound findings with MR angiographic diagnosis of unilateral vertebral artery (VA) dissection.

**Materials and methods:** We retrospectively examined 12 patients, 4 men and 7 women aged 33 to 60 years (mean age 48 years) with unilateral vertebral artery dissection who were hospitalized at our institution during the period from 2010 to 2012. All patients had undergone echo sonographic examination of neck blood vessels, followed by MRI with MR angiography of the head and neck.

**Result:** Echosonography of neck blood vessels showed a significant asymmetry with reduced flow in 9 patients, 4 of whom had stenosis of a longer segment of VA1, VA2 and/or VA3 segment. In two patients occlusion of VA1 segment was registered. In one patient normal findings were registered. MR angiography of blood vessels of the head and neck showed dissection of the extracranial segment in 8 patients, craniovertebral transition in two patients and VA4 segments of three patients. Ten patients had stenosis of blood vessels (50–90%) in the field of dissection and occlusion in two patients.

**Conclusion:** Ultrasonography is also highly sensitive to the disturbance of hemodynamic flow characteristics in the vertebral arteries, which further indicates the MR angiographic diagnosis.

The importance of ultrasound in the early diagnosis of vertebral artery dissection

**Introduction:** Intracranial artery dissection is an important cause of stroke in young adults, but it has rarely been reported as a cause of stroke in puerperium.

**Case report:** We report a case of a 27-year-old female with a past history of migraine, who presented with unilateral left headache and transient episode of dysphasia and right hemiparesis, 30 days after vaginal delivery. The first symptom started six days after the uncomplicated childbirth.

She was admitted to our department, with strong headache, confusion, and right hemiparesis. CT and laboratory tests were all unremarkable. Cervical ultrasonography revealed a different flow in the distal part of the internal carotid artery, with low flow velocity in the left ICA. MRI revealed some high signal abnormalities, with one predominant lesion in the left parahippocampal region suggestive of ischemia,
MRA with 3D TOF confirmed supraclinoid carotid artery subocclusion and suggested intracranial carotid artery dissection. After 5 days she was impaired and we did DSA that showed a left intracranial ICA occlusion. The patient was placed under oral anticoagulation and one month after she was discharged, control ultrasonography showed good flow in the left internal carotid artery that suggests recanalization.

**Conclusion:** The pathophysiology of intracranial artery dissection appears multifactorial, with evidence suggesting traumatic and genetic contributions. Vessel wall injury related to the Valsalva maneuver during labor, with pressure vessel wall on skull bones as well as hemodynamic and hormonal changes related to pregnancy may be the cause of peripartum spontaneous intracranial artery dissection.

**The importance of localization of dissection of the internal carotid artery on clinical outcome**

Introduction: Carotid artery dissection occurs as a result of the split of the vessel wall with the formation of intramural hematoma that leads to narrowing of the lumen and is usually localized in the extracranial internal carotid artery (ICA).

**Objective:** To determine the importance of localization of the internal carotid artery dissection on clinical outcomes.

**Materials and methods:** We retrospectively studied 30 patients, 20 men and 10 women aged 27–66 years (mean age 48.8 years) hospitalized in our institute in the period of 2009–2012. A total of 29 patients had unilateral and 1 patient had bilateral dissection of ICA. Before the hospital discharge all patients had undergone assessment through the National Institute of Health Stroke Scale (NIHSS) and magnetic resonance imaging (MRI) with MR angiography of the head and neck.

**Results:** MR angiography in 23/30 patients showed dissection of the extracranial segment of 11 (48%) with occlusion of a blood vessel, and 12 (52%) in the long segment stenosis. 7/30 patients had dissection of the intracranial segment of the ICA, of which 6 (86%) had occlusion, and 1 (15%) had stenosis of the vessel. The average NIHSS at discharge was 8 in patients with extracranial ICA dissection, and 4 in patients with intracranial dissection.

**Conclusion:** Dissection of the intracranial segment of the ICA often goes with occlusion of a blood vessel, but with better clinical recovery compared to dissection of the extracranial segment of the ICA.

**Topic: 3 — Stroke**
**Rheumatic stroke**

S. Aslanova, F. Yunusov.

**Introduction:** Cerebrovascular pathology in rheumatic fever has a variety of clinical manifestations. Stroke can be caused by rheumatoid vasculitis of cerebral vessels.

**Purpose:** To study the clinical, immunological, and neurophysiological changes in the diagnosis of stroke in rheumatic fever.

**Materials and methods:** Rheumatic probes, ECG, echo-cardiography, immunological methods.

The study included 44 patients with stroke in rheumatic fever. The age of patients range from 20 to 68 years (mean age 46.6 ± 1.3 years), 9 of them (20.5%) men and 35 (79.5%) women.

**Results:** Stroke was more frequent between the ages of 30 and 60–37 (84%). All cases revealed marked changes in the heart rate by type of atrial fibrillation, arrhythmia. Stroke more often (91%) occurred on the background of an existing visceral rheumatic fever. The following forms of rheumatic stroke were observed: transient ischemic (5 patients), ischemic (37) and hemorrhagic (2) strokes. The majority of patients had changes in the peripheral blood and immunobiochemical indicators: increasing titer of Asl-O, positive C-reactive protein, and increased haptoglobin.

The study of the immune status in patients with RI showed a significant deficit of T-lymphocytes in the 1.6 and 1.9-fold (relative and absolute content, respectively), T-suppressor cells in 1.9 and 1.8 times the level of B-cells — 1.2 and 1.3 times compared with the control.

**Conclusions:** Thus, acute rheumatic stroke tends to occur in young and middle-aged individuals, 3.9 times more often in women, against rheumatic fever activity and gross lesions of cardiac rhythm disturbances, with immunodeficiency. These methods have diagnostic and prognostic values.

**Public awareness of the main risk factors of stroke and its primary prevention**

D. Farmonova, G. Rakhimbaeva, Y. Musaeva. Neurology, Tashkent Medical Academy, Tashkent, Uzbekistan

**Background:** In the effectiveness of prevention of stroke the primary role played by the awareness of the population about the problem and ways to prevent it.

**Objective:** To study the state of public awareness of risk factors of a stroke and measures for its primary prevention.

**Methods of research:** This continuous study interviewed the population of Toy-tepa town using a questionnaire whose question list is specially formulated by us, consisting of 28 questions, covering main risk factors of stroke.

**Results and discussion:** 1346 people were interviewed, the average age was 42 ± 3.2 years. Women comprised 67.6%, while men comprised 32.4% of the respondents. 49.71% of the respondents didn’t know the level of their blood pressure. 87 people were suffering from arterial hypertension. 20.68% of them regularly take hypotensive drugs, 22.98% take only at an increased level of blood pressure, and 56.32% didn’t take antihypertensive drugs. The most common group of hypotensive drugs taken by the population were ACE inhibitors, rauanutin, and dibasolum. 2% of respondents know their level of cholesterol in the blood. 17.16% of the patients knew their blood glucose level, with increased levels in 7.2% of them. 17.75% of respondents smoke, with smokers accounting for 48.5% of all men, and 3.07% of all women. 29.92% of patients responded that they suffer from being overweight.

**Conclusions:**

1) Analysis points to the lack of knowledge of the population about risk factors of stroke, such as arterial hypertension, cerebral atherosclerosis, and diabetes mellitus.
2) The population is not sufficiently actively engaged in non-drug prevention of the diseases, which consists of smoking refusal, the struggle with physical inactivity, and overweight.

Peculiarities of the etiology of ischemic stroke (IS) in young patients
D. Farmonova. Neurology, Tashkent Medical Academy, Tashkent, Uzbekistan

Background: Stroke is becoming increasingly medico-socially and economically significant. Stroke in young patients is becoming an everyday reality.

Objective: Explore and compare the etiology of ischemic stroke in young people and the elderly.

Materials and methods: The study included 40 patients (20 young people; 20 elderly) with IS. We used the descriptive method and entered data on a special form.

Results: All patients were divided into two groups: the main group of young patients (50% men and 50% women) with ages ranging from 23 to 44 years, the average age was 40.5 years; and the control group of elderly patients (70% men, 30% women) with ages ranging from 61 to 78 years, the average age was 67.35 years.

Etiological factors of IS in young patients were: essential arterial hypertension (AH) — 65%; atrial fibrillation — 15%; cerebral atherosclerosis + AH — 10%; symptomatic AH — 5%; neuro-rheumatism — 5%; AH + the use of combined oral contraceptives — 5%; AH + the use of psychoactive substances — 5%; AH + alcohol abuse — 5%. Etiological factors of IS in the elderly were: the essential AH — 55%; cerebral atherosclerosis + AH — 25%; diabetes mellitus type II + AH — 15%; and atrial fibrillation — 5%.

Conclusions: 1. Young patients met the following causes of IS, which were not found in elderly patients: neuro-rheumatism, symptomatic arterial hypertension, a combination of arterial hypertension with the use of psychoactive substances, the use of combined oral contraceptives, and abuse of alcohol.

The effect of opium addiction on carotid intima media thickness
M. Saadatnia1, H. Ebrahimi2, M. Tajmirriahia. 1Isfahan Neurosciences Research Center, Isfahan University of Medical Sciences, Iran; 2Islamic Azad University, Najafabad Branch, Isfahan, Iran

Background: The hazardous effects of smoking on the progression of atherosclerosis have been well studied, but little is known about the effect of opium addiction on the progression of atherosclerosis.

Methods: A total of 202 subjects who were screened for brain disease (at annual medical checkups) between April 2010 and March 2012 were studied to clarify the effects of smoking and opium addiction on maximum carotid intima media thickness (IMT).

Univariate analyses were performed to investigate the relationships between maximum IMT and independent variables, such as smoking, opium addiction, age, gender, hypertension, and diabetes.

Results: Although maximum IMT was significantly higher in the opium addiction group (7.9%) in comparison with the non-addicted group (p = 0.02), univariate analysis revealed that age (p = 0.000), diabetes (p = 0.004), hypertension (p = 0.006), and smoking (p = 0.02) had a significant relationship with maximum IMT. Opium addiction (p = 0.22) and sex (p = 0.43) had no significant relationship with maximum IMT.

Conclusions: Opium addiction has no hazardous effects on the progression of atherosclerosis. Prospective studies with a larger sample size are needed to confirm this hypothesis.

A reversible cause of bilateral thalamic infarct and cognitive impairment
Y.S. Ng, J. Downer, P. Keston, C. Derry. Department of Clinical Neurosciences, Western General Hospital, Edinburgh, UK

Background: Bilateral thalamic infarct is rare and associated with cognitive impairment, gaze palsy and altered consciousness. We report a patient who had a reversible cause of bilateral thalamic infarct and his cognitive function improved significantly following an intervention.

Result: A 61 year old right handed man presented with one-day history of acute confusional state to the emergency department. He then developed intermittent agitation, anterograde amnesia and increased drowsiness three days after the hospital admission. His CT head showed bilateral thalamic haemorrhagic infarct. His CT venogram raised a suspicion of venous hypertension and possible recannalisation as there was irregularity in the right internal cerebral vein and hypoplastic straight sinus although no thrombus was seen. He was given intravenous heparin initially even though CT venogram was not diagnostic of cerebral venous sinus thrombosis. Subsequently a digital subtraction angiography was performed which revealed a vein of Galen dural arteriovenous fistula. It was treated successfully with embolisation. His consciousness level stabilized and cognitive function improved significantly. He was discharged home with mild short-term memory deficit, impaired executive function and visual-spatial awareness two months later.

Conclusion: Investigating bilateral thalamic infarct requires a careful workup. When standard imaging is inconclusive, digital subtraction angiography should be considered as highlighted in this case which showed that the detection of vein of Galen dural arteriovenous led to definitive treatment and improvement of the cognitive function.

Poststroke pain: A prospective study of the association and risk factors in patients presenting with stroke
S. Naija, S. Ben Amor, I. Chatti, Z. Saied, N. Karmeni, M. Ben Hlima. Sahluol Hospital, Sousse, Tunisia

Introduction: Pain is a significant part of many stroke patients’ experience. Although pain is defined as an individualised experience, specific types of pain which commonly occur following stroke are well described.

Aims of this study were: To determine prevalence; intensity and risk factors of pain after stroke.
Methods: It is about a prospective study in a Tunisian population containing 121 patients with stroke who were selected from Sahloul Hospital in Sousse going from January 2012 till December 2012. The criteria of inclusion: Diagnosed stroke by the regular doctor. The criteria of exclusion: Cognitive disorders (confusions), aphasia.

Measuring Instrument: Neuropathic pain was evaluated by DN4. A score upper or equal to four “4/10” defines a positive test, which confirms the positive diagnosis of a neuropathic pain.

Worst pain intensity during the previous 48 h was assessed on a visual analogue scale (VAS), ranging from 0 to 100: a score of 0 to 30 was defined as no or mild pain; and 40 to 100 as moderate to severe pain. Screening for depression was done using HAD-S. SF36 was used to evaluate quality of life.

Results: Moderate to severe pain was reported by 63% of patients (VAS median = 70). The DN4 was positive in 52%. Predictors of pain were younger age, male sex, worse HAD-S score and short disease duration. Pain impaired quality of life in 2/3 of cases.

Conclusion: Pain following stroke is common and may have a considerable effect on the everyday life of the patient.

Juvenile stroke as presenting manifestation of essential thrombocytosis with JAK2V617F mutation
L. Fancellu, P. Canu, P. Doneddu, P. Falchi, G.A. Soro, G. Sechi. Department of Clinical and Experimental Medicine, University of Sassari, Sassari, Italy

Thromboses of cerebral veins or arteries may herald a latent/subclinical essential thrombocytopenia (ET), which is a myeloproliferative disorder (MPD) with sustained elevated platelets. Juvenile stroke as presenting manifestation of ET has rarely been reported.

Case report: A 31-year-old man, without cardiovascular risk factors, presented with acute onset of gait ataxia and transient mesial disturbances. Brain MRI showed multiple acute ischemic lesions in the cerebellum and in the right occipital lobe.

Blood tests were normal except for an elevated platelet blood count (600,000/mm3).

The acquired Janus kinase 2 V617F mutation (JAK2V617F) resulted positive. Bone marrow examination showed cluttered hyperlobulated megakaryocytes. He was diagnosed with ET. The patient had complete recovery from stroke and underwent therapy with antiplatelet agents and hydroxyurea.

Discussion: MPD are hematologic malignant conditions that include: ET, polycythemia vera (PV), primary myelofibrosis (PMF) and chronic myeloid leukemia.

Detection of the JAK2V617F mutation is a useful tool for early MPD diagnosis: it is present in over 90% of patients with PV, 50–70% with ET and 30–58% with PMF, while it is absent in healthy subjects.

An early diagnosis of MPD, especially in patients with thrombotic events in the latent MPD phase, would be beneficial for preventing further morbidity.

Special attention must be given to patients with acute stroke at juvenile onset, especially in the absence of cardiovascular risk factors. Therapeutic decision can be based on recent literature data where administration of antiplatelet agents, in combination of hydroxyurea, has been shown to be beneficial for MPD patients with thrombotic events carrying the JAK2V617F mutation.

Aspergillus fumigatus ethmoidal sinusitis invading cavernous sinus responsible for cerebral infarction: A case report
G.C. Garcia1, V. Sudacevski2, F. Bruneel3, M.-L. Chadenat4, M. de Malherbe5, S. Genty6, F. Pico6. 1Department of Neurology and Stroke Center, Versailles Saint Quentin en Yvelines University, Versailles Hospital, France; 2Intensive Care Unit, Versailles Hospital, Le Chesnay, France; 3Department of Radiology, Versailles Hospital, Le Chesnay, France

A 56-year-old immunocompetent man presented to the emergency department with a right hemiplegia of sudden onset. He reported a history of recent protracted fever after a surgery for ethmoidal chronic sinusitis. MRI showed an ischemia of the left lenticular-caudate nucleus and a tight stenosis affecting the supraccavernous segment of the left internal carotid artery and the first segment of the left middle cerebral artery. Stenosis was due to a surrounding T2-hypersignal structure, enhanced by gadolinium injection, wrapping and compressing both arteries and infiltrating the left cavernous sinus. Blood cultures, transesophageal echocardiogram and PET scan were normal. Aspergillus antibodies were positive with high titer. CSF analysis revealed lymphocytic meningitis with elevated eosinophils. Beta-d-glucans were positive in CSF and negative in serum consistent with a fungal infection limited to CNS. Aspergillus fumigatus was identified after cultures on surgical ethmoidectomy samples.

The diagnosis is an external compression of the left internal carotid secondary to an aspergilloma coming from a remaining postethmoidectomy skull-base breach leading to cerebral infarction. An antifungal treatment by 800 mg per day of oral voriconazole has been started for 6 months. A slight lesion regression was noted after 2 months of treatment with stable blood flow in the carotid and serum antiaspergillus IgG drop. CSF analysis improved with a decrease in beta-d-glucans level and white cell count.

This case emphasizes the possibility of a local arterial damage, in an immunocompetent patient, due to A. fumigatus without systemic infection or cerebral vasculitis commonly described.

Number of patients and current use of antithrombotic agents before the onset of intracerebral hemorrhage
T. Watari, T. Mori, K. Nakazaki, Y. Miyazaki, T. Iwata. Department of Stroke Treatment, Shonan Kamakura General Hospital Stroke Center, Kamakura, Japan

Background: Antithrombotics are widely used to treat some vascular diseases. Intracerebral hemorrhage is the major risk associated with antithrombotics.

Objective: To assess how many patients had taken antithrombotic agents and the type of agent used before onset of hemorrhagic stroke transferred to a suburban emergency hospital in Japan. The antithrombotic agent most used annually was also assessed.

Patients and methods: This retrospective analysis focused on patients who were transferred to our institution due to intracerebral hemorrhage (ICH) from January 2009 through December 2012, inclusive. Antithrombotic agents were classified into three groups: antiplatelets (P), anticoagulants (C) and both agents (PC).

Results: There were 492 consecutive patients with ICH. Mean age was 74 ± 12.67 years (males 270, female 220), including 128 (26.02%)
patients previously treated with antithrombotic agents. Groups consisted of the following: P (69.5%; 89/128), C (20.3%; 26/128) and PC (10.16%; 13/128). In group P, aspirin was used in 64 of 128 patients (50%), and thienopyridine agents in 19 patients (14.8%). In group C, warfarin was only used in 26 patients (20%) and no new oral anticoagulants. In the PC group, every patient took warfarin (13 patients; 10%) and many patients also used aspirin. Aspirin was the most widely used agent (~60% annually) followed by warfarin (~30% annually).

**Conclusion:** Over one-quarter of ICH patients had taken antithrombotic agents before hospitalization annually and these agents included aspirin and/or warfarin. Our results suggest that new antithrombotics, with fewer bleeding risks, may decrease the incidence of ICH.

**Relationship of brachial-ankle pulse wave velocity and cerebral microbleeds, lacunar infarcts and white matter lesions in acute ischemic stroke**

Kosin University College of Medicine, Busan, Republic of Korea

**Background:** Brachial-ankle pulse wave velocity (BaPWV) is a representative and simple method for evaluating arterial stiffness. Increased arterial stiffness may lead to vessel damage and atherosclerosis. Vessel wall damage in relation to arterial stiffness develops more frequently in the microvessels of end organs.

**Objective:** We investigated the relationship between arterial stiffness, as measured by BaPWV and cerebral small vessel disease, visualized on MRI as white matter lesions (WMLs), lacunar infarcts (LIs), and cerebral microbleeds (CMBs).

**Patients and methods:** A total of 88 patients with acute ischemic stroke who had undergone BaPWV measurement and brain MRI were enrolled. The number of CMBs and LIs were rated. The locations of CMBs and LIs were divided into infratentorial, lobar and deep regions including the basal ganglia, thalamus and internal capsule. The WMLs were separated into deep and periventricular regions and the severity of WMLs was assessed.

**Results:** Patients with higher BaPWV tended to have more LIs and more severe WML in both deep and periventricular regions (p < 0.05). There was no significant association between the number of CMBs and BaPWV. Patients with higher BaPWV had more number of CMBs and LIs in the deep regions than in the lobar or infratentorial regions (p < 0.05).

**Conclusion:** These findings suggest that increased BaPWV is associated with the severity of cerebral small vessel diseases. Moreover, deep regions, such as the basal ganglia and thalamus, are more related with systemic arterial stiffness.

**Comparison between multiphasic perfusion CT guided selection and perfusion MRI selection of patients with acute ischemic stroke for endovascular treatments**

H.-S. Yeom1, N.-C. Choi1, S.-K. Kim2, Gyeongsang National University Hospital, Jinju, Republic of Korea; 3Gyeongsang National University School of Medicine, Jinju, Republic of Korea

**Background:** The objective of this study was to compare between multiphasic perfusion computed tomography (CTP) selection and perfusion MRI (MRP) selection of patients with acute ischemic stroke to identify those patients who stand to benefit most from endovascular recanalization.

**Methods:** We reviewed acute stroke patients who received intra-arterial thrombolysis initiated within 6 h of stroke between October 2009 and August 2011. In acute ischemic stroke patients within 4.5 h from symptom onset, tPA of 0.45 mg/kg was infused intravenously after exclusion of hemorrhage by CT screening, and subsequently a further decision on intra-arterial recanalization was made after CTP or MRP screening.

**Results:** A total of 98 patients received intra-arterial thrombolytic therapy within 6 h of stroke onset during the study period, 54 patients with the CTP guided group and 44 patients with the MRP guided group. The CTP guided group had a shorter door-to-imaging time (P = 0.07) and door-to-procedure time (P = 0.05), compared with the MRP guided treatment group. The post thrombolysis outcome of the CTP guided group (difference of NIHSS from initial to post thrombolysis; CTP guided −2.59, MRP guided −2.39) is better than that of the MRP guided patients (P = 0.03) but favorable outcome at 7 days after onset was similar in 47 (79.2%) of the CTP guided versus 45 (70.3%) of the MRP guided patients (P = 0.737).

**Conclusion:** These results suggest that CTP guided endovascular treatment could provide useful information when deciding upon intervention in hyper-acute ischemic stroke patients. If MRI equipment is not available or patients are contraindicated for MRI, the perfusion CT can be used as an alternative tool.

**CYP2C19 genotype and risk of in-stent restenosis among vertebral artery stent patients treated with clopidogrel: A retrospective study**

Y. Xu. Affiliated Drum Tower Hospital of Nanjing University Medical School, Nanjing City, China

Preventing stroke through endovascular treatment with vertebral artery stenting (VAS) remains a great challenge due to the occurrence of an in-stent restenosis (ISR) and a lack of randomized controlled trials. In this study, a retrospective analysis was conducted involving 163 patients who had been treated with VAS between January 2004 and December 2011 in the Drum Tower Hospital of Nanjing University Medical School. Patients were followed-up at 3, 6, and 12 months after treatment and annually thereafter. The cumulative long-term incidence of ISR was evaluated and risk factors for ISR were identified. DNA was extracted from blood for genotyping CYP2C19 (636G>A, 681G>A), CYP3A4 (894C>T), and P2Y12 (34C>T, 52G>T). The results demonstrated that in-stent restenosis occurred at a higher rate, mainly within the first year after VAS treatment (4.05%) during long-term follow-up. A multiple binominal regression analysis showed that patients with smoked, or hypertension or hyperlipidemia or CYP2C19 (*2 or *3), were more likely to develop ISR. The strongest statistically significant predictors of subsequent ISR was hyperlipidemia (OR 4.305, 95% CI 2.988–6.321, p = 0.042), CYP2C19 (OR 0.521, 95% CI 0.171–0.979, p = 0.04) by multivariable regression analysis. 21.4% patients had stroke with an ISR, 8.3% patients had stroke without ISR during a median of 54 months follow-up time (OR: 0.331, 95% CI: 0.112–0.975). CYP2C19 with *2 or *3 alleles had a higher incidence of restenosis (P = 0.004) and stroke (Kaplan–Meier analysis) than that with *1 allele.
Conclusion: Hyperlipidemia and CYP2C19 impotency are risk factors for the development of ISR in VAS treated ischemic patients.

Isolated infarction of medullary pyramid: Its clinical features and pathology
S. Kajii, H. Katada, S. Sato, H. Shibayama, T. Fukuiz, Y. Kikuchi, S. Murayama, aNeurology, Kameda Medical Center, Kamogawa, Japan; bRadiology, Kameda Medical Center, Kamogawa, Japan; cNeuropathology, Tokyo Metropolitan Institute of Gerontology, Itabashi, Japan

Background: Medial medullary infarction (MMI) is caused by hypoperfusion of the anteromedial territory in which blood flow is supplied by bilateral vertebral arteries and the anterior spinal artery. MMI usually causes hemiparesis, deep sensation disturbance, and hypoglossal nerve palsy. Isolated infarction of medullary pyramid (IIMP) is considered an incomplete form of MMI. Its etiology and pathophysiology are unknown due to its rarity. We report the clinical characteristics, prognosis, and one autopsy finding of IIMP.

Patients and methods: We checked MRI reports of all the patients with ischemic stroke (n = 3185) hospitalized between January 2005 and October 2012. We reviewed the medical records of patients diagnosed with IIMP by brain MRI-DWI taken 48 h after onset to obtain information about the distribution of muscle weakness, concomitant symptoms, TOAST classification, and 3-month prognosis.

Results: Seventeen (14 males/3 females) patients (0.53%) had IIMP, and all presented with contralateral hemiparesis with the weakness more prominent in the lower extremities (n = 15). Six patients (35%) had ipsilateral hypoglossal palsy. When applying TOAST classification, twelve cases (71%) were classified as large-artery atherosclerosis and four (24%) as small-artery occlusion. Thirteen patients (76%) have become independent with stable walking and had a modified Rankin Scale score of 2.3 ± 1.4 three months after stroke onset. An autopsy case of a 77-year-old man exhibited necrotic cells restricted to the left medullary pyramid and severe arteriosclerosis of the vertebral arteries.

Conclusion: IIMP more often causes leg dominant hemiparesis and generally has a good 3-month prognosis. Its etiology closely associates with arteriosclerosis of the vertebral arteries.

The predisposing factors to hematoma enlargement in spontaneous intracerebral hemorrhage
H. Zhang, J. Feng, D. Han, L. Cui, R. Wang, P. He, Y. Luo, aDepartment of Neurology, Affiliated Shengjing Hospital, China Medical University, China; bCerebrovascular Diseases Research Lab, Xuanwu Hospital, Capital Medical University, Beijing, China

Hematoma enlargement occurs commonly in patients with spontaneous intracerebral hemorrhage and worsens their clinical outcome. This study analyzed the main predisposing factors of hematoma enlargement in spontaneous intracerebral hemorrhage through a retrospective study data of 268 patients. All patients underwent their first CT scan within 24 h of arrival and a second CT scan within 72 h of admission. These factors that were assumed to affect the growth of hematoma, such as consciousness level, blood pressure, clinical outcome, hematological parameters, and CT findings (hematoma shape, location, midline shift and broken into the ventricles), were analyzed by means of univariate and multivariate logistic regression analyses. Univariate analyses indicated that Glasgow coma scale (GCS), hematoma shape, midline shift, breaking into the ventricle, thrombin clotting time (TT), white blood cells, neutrophil percentage, serum creatinine, and fasting plasma glucose (FPG) were significantly different between the patients with or without hematoma enlargement (P < 0.05). Multivariate analyses revealed that the following four factors were independently associated with hematoma enlargement: the midline shift, the GCS score, the FPG, and the breaking into the ventricles. Therefore, timely review of CT findings and dynamic monitoring of peripheral blood biochemical indicators should be taken in patients who have a risk of developing hematoma enlargement, which is very important for further therapy.

Ambient air pollution and emergency department visits for stroke
J. Sohn, J. Cho, S.-K. Cho, H. Kim, C. Kim, D.-C. Shin, S. Seo, aDepartment of Preventive Medicine, Yonsei University College of Medicine, Republic of Korea; bDepartment of Neurology, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea

Background: Many epidemiological studies have shown the short-term effects of air pollution on cardiovascular diseases. Several studies have investigated the relationship between air pollutant exposure and stroke but the findings have been inconsistent.

Objective: We conducted a time-series study to assess the association between ambient air pollution and emergency department (ED) visits for stroke in Seoul, Republic of Korea.

Materials and methods: The ED data from 2005 to 2009 were obtained from the Health Insurance Review and Assessment Service, and the number of ED visits for stroke was 118,171. We used a generalized additive model with Poisson distribution, adjusting for temperature (cubic spline, df = 6), relative humidity (cubic spline, df = 3), day of the week, and national holidays. The risk was expressed as a RR with one standard deviation increase and its 95% CI. We explored the lag effects with cumulative lag models (lag0–lag7).

Results: In the same day exposure, the RRs of ED visits for stroke were 1.016 (95% CI, 1.011–1.023) per 12.04 ppb increment of NO2 and 1.014 (1.007–1.020) per 0.24 ppm increment of CO. In lag0–7, the RRs for stroke were 1.009 (1.002–1.017) per 2.33 ppb increment of SO2, 1.009 (1.004–1.015) per 36.70 μg/m3 increment of PM10, 1.018 (1.010–1.026) per 10.04 ppb increment of O3, 1.012 (1.006–1.018) for NO2, and 1.010 (1.003–1.017) for CO. Positive correlations were observed in PM10 (p = 0.029) and O3 (p < 0.001) for hemorrhagic stroke and all pollutants for ischemic stroke in lag0–7.

Conclusion: Ambient air pollutants are significantly correlated with ED visits for stroke.

Psychosis after thalamic infarcts: Is it just post-stroke delirium or does the thalamus have a pivotal role to play?
M. Pipis, B. Dewan, J. Young, Royal Free London NHS Foundation Trust, London, UK
Background: As the 'gatekeeper' of information and stimuli from the outside world reaching the brain, the thalamus plays a key role in the processing and conveyance of this information. The prevalence of post-stroke psychotic disorders is rare and apart from an association with frontoparietal lesions, they have also been described after infarcts in the thalamus.

Objective: We describe the case of a 51 year-old gentleman who suffered acute bi-thalamic infarcts. By describing the sequence of events from presentation to the subsequent development of cognitive sequelae, as well as the changing nature of his psychotic episodes, we are able to make a distinction between post-stroke delirium and psychosis.

Patients and methods: We undertook a retrospective analysis of the medical notes (including entries from the medical, psychiatric and therapy teams) and investigations performed in the London Hyper-Acute and Acute Stroke Units.

Results and conclusion: The patient's post-stroke delirium developed shortly after the bi-thalamic infarcts, had a strong diurnal component to it and was also associated with disorientation in time and place, whereas the psychotic disorder evolved over a period of weeks and included worsening paranoid ideas and delusions. A possible link between thalamic dysfunction and psychosis is explored after considering the neuronal networking of thalamic relays with the reticular brainstem formation as well as layers 6 and 5 of the cerebral cortices.

Do cervical spine spondylodyisis and osteophytes influence dysphagia in stroke patients? Case–control study
Y.I. Seo1, I. Sun1, G.Y. Park1, S.Y. Kim1. 1The Catholic University of Korea, Yeouido St. Mary's Hospital, Seoul, Republic of Korea; 2The Catholic University of Korea, Bucheon St. Mary's Hospital, Bucheon-si, Republic of Korea

Introduction: Although there are many risk factors that influence dysphagia outcome, the role of cervical spine abnormalities in stroke patients has not been reported, yet. This study was carried out to determine whether the presence of cervical spine abnormalities can influence the severity and outcome of dysphagia in stroke patients.

Method: We retrospectively reviewed 800 patients' medical records and video fluoroscopic swallowing study (vfss) reports performed at our department. We identified 120 stroke patients with severe cervical spondylosis. Among these, 19 patients were identified who had single brain lesion. We case matched these 19 patients according to their lesion site, gender and age, to a control stroke group with dysphagia, with normal cervical spine findings (total n = 38, mean age = 71.6 ± 10.9). We compared the two groups’ dysphagia severity scale scores, the parameters recorded at their initial vfss and swallowing outcomes at follow-up.

Result: Compared to controls, the case group showed a more severe degree of dysphagia (P < 0.005) than the control group from their dysphagia severity scale. The case group also had more cases who showed residues at the vallecular (68%, P < 0.008) and pyriform sinuses (100%, P < 0.000) and were more likely to have poorer dysphagia outcome (P = 0.004) at follow-up than the control group.

Conclusion: Cervical spine abnormalities can influence the initial severity and outcome of dysphagia in stroke patients. Although cervical spine abnormalities do not cause more severe aspiration, it seems to have an adverse effect on swallowing, by causing greater amounts of residues with reduced clearing of bolus.

Comparative study of combination therapy of Korean–Western medical treatment versus Western medical treatment only in acute ischemic stroke patients

Background: Stroke is one of the 3 major causes of death worldwide and can leave irreversible neurological deficits, which is why appropriate treatment is important.

Objective: The objective of this study is to report the effectiveness of Korean and Western medicine combination therapy on cerebral infarction.

Patients and methods: Subjects were patients diagnosed with acute cerebral infarction within 10 days of onset, admitted to Kyung-Hee University Medical Center (KMC) and Kyung-Hee University Korean Medical Center (KKMC) from 2010.3 to 2011.10. Patients admitted to...
KMC were set as the Western Medical Treatment Only (W-Tx) group. Patients admitted to KKMC were set as the Combination Treatment (C-Tx) group. Morbidity Index (MI) score and Scandinavian Stroke Scale (SSS) were checked at the start of treatment, and 3 weeks after.

**Results:** 15 patients were included in the W-Tx group, and 30 patients were included in the C-Tx group. After 3 weeks, the MI arm score of the W-Tx group increased from 87.0 ± 21.2 to 88.3 ± 20.9 (p = 0.480), and the leg score increased from 86.8 ± 23.1 to 89.5 ± 20.5 (p = 0.210). The MI arm score of the C-Tx group increased from 81.4 ± 12.6 to 85.9 ± 12.1 (p < 0.001), and the leg score increased from 78.2 ± 18.6 to 86.7 ± 17.7 (p < 0.001). Only the C-Tx group showed significant MI score increase. The SSS of the W-Tx group increased from 51.6 ± 9.1 to 53.1 ± 7.9 (p = 0.034), and the SSS of the C-Tx group increased from 44.8 ± 8.9 to 50.0 ± 5.8 (p < 0.001). Both groups showed significant SSS improvement.

**Conclusion:** This study implies that receiving Korean medical treatment with Western medical treatment may have a positive effect on improving the motor function of stroke patients.

**Abdominal obesity and body mass index as a risk factor for stroke in transient ischemic attacks**

G. Izyumova a, D. Izyumov b, E. Izyumova a. aRepublican Scientific Centre of Emergency Medical Aid, Khorezm Branch, Uzbekistan; bNeurology, Khorezm Regional Multifield Medical Centre, Urgench, Uzbekistan

**Background:** Transient ischemic attack (TIA) is a proven risk factor for stroke, but on the liaison with a body mass index (BMI) is little known.

**Aim:** To study abdominal obesity and BMI as risk factor for stroke in TIA.

**Methods:** The study conducted on a “case—control”. Individuals with diagnosis of TIA (study group—“cases”) were compared with patients with arterial hypertension (AH) and control group.

**Results:** In total, 87 patients of the main group were examined, 84 with arterial hypertension (AH), and 94 individuals from the control group. There was a general relationship between TIA and large waist circumference (independent of BMI) compared with controls (OR = 2.23, 94% CI: 1.18–3.98, waist circumference >80 cm vs <80 cm). There could be a “plateau of risk” with an increased risk for circumference >80 cm, but in the absence of a reliable trend tended to regard as compared to patients with hypertension (p value for trend = 0.03). There was no connection between TIA and BMI. Waist circumference was associated with the hypertension severity of symptoms (OR = 1.78, 94% CI: 1.04–3.37, the risk of heavy weekly high blood pressure — 10 cm circumference) correction by AH partially reduced the liaison between TIA and circle waist.

**Conclusions:** Waist circumference, not BMI, has moderate independ-ent association with the risk of TIA. These data partially favor the hypothesis that abdominal obesity promotes hypertension, which in turn may increase the risk of TIA.

**Endovascular treatment for acute ischemic stroke: Is immediate post-procedural extubation a new prognostic factor?**

M. Chia a, J.J. See b, K.E. Lee c. aYong Loo Lin School of Medicine, National University of Singapore, Singapore; bDepartment of Anaesthesiology, Intensive Care and Pain Medicine, Tan Tock Seng Hospital, Singapore; cDepartment of Neurology, National Neuroscience Institute (Tan Tock Seng Hospital), Singapore, Singapore

**Background:** Endovascular therapy may benefit selected patients with acute ischemic stroke. Yet, it remains uncertain which factors directly influence functional outcome. Following general anesthesia (GA), stable patients are extubated before transfer to Neurointensive Care Unit.

**Objective:** We aim to study if immediate post-procedural extubation correlate with functional outcome at 3 months after stroke.

**Material and methods:** We retrospectively reviewed and analyzed the medical records of 38 consecutive patients treated between December 2006 and June 2011 in our institution, including their GA records.

**Results:** 22 and 16 patients suffered acute ischemic stroke in the anterior and posterior circulations respectively. Atrial fibrillation was present in 36.8%. Mean time from symptom onset to therapy was 370 min. 7 patients were not successfully recanalized due to unfavourable anatomy. 16 patients were extubated immediately after endovascular procedure, 9 of whom enjoyed favourable functional outcome (mRS ≤ 2) at 3 months, compared to 3 of 22 who had remained intubated (p = 0.0116). Time to therapy, location of stroke and presence of AF were not significantly correlated with favourable functional outcome at 3 months poststroke. Mortality was 36.8%, the odds being 8.4 times higher in those who were not extubated immediately after endovascular procedure.

**Conclusion:** Acute ischemic stroke patients under GA for endo-vascular therapy are immediately extubated when they are assessed to be breathing well, able to maintain their own airway and haemodynamically stable. These patients are observed to have significantly better functional outcome at 3 months after stroke. Immediate post-procedural extubation may be an important prognostic factor.

**An evaluation of neuroendocrine dysfunction following acute aneurysmal subarachnoid hemorrhage: A prospective study**

A.K. Jaiswal a, S.B. Yadav b, R.N. Sahu c, S. Behari d, A.K. Mahapatra e. aDepartment of Neurosurgery, Sanjay Gandhi Post Graduate Institute of Medical Sciences, Lucknow, India; bDepartment of Neurology, Sanjay Gandhi Post Graduate Institute of Medical Sciences, Lucknow, India

**Background:** Evidence that aneurysmal subarachnoid hemorrhage (SAH) is associated with neuroendocrine dysfunction comes mainly from case reports or small series of patients.

**Objective:** To investigate the incidence and pattern of neuroendo-crine changes in cases of acute aneurysmal subarachnoid hemorrhage (SAH).

**Methods:** Endocrine assessment was performed in 100 consecutive cases of acute aneurysmal SAH presenting within 7 days of ictus. The gonadotropin, somatotropic, thyrotropic, and corticotropic axes and prolactin were evaluated for their possible dysfunction.

**Results:** A total of 100 cases (38 males, 62 females; age range—17–76 years; mean age—43.6 years) of acute SAH were studied. The aneurysms were located in the anterior circulation (n = 95) and posterior circulation (n = 5). The commonest hormone deficiency was of growth hormone (n = 67) followed by gonadotropin (n = 50), corticotropin (n = 49) and thyrotropin (n = 35). Hyperprolactinemia was noted in 10 cases. One pituitary hormone axis deficiency was noted in 26 cases while 67 cases had two or more pituitary hormone axes
deficiency. A total of 93 cases had hormonal deficiency in one or more pituitary hormone axes and 7 cases had no hormonal deficiency. **Conclusions:** Endocrine dysfunction occurs in 93% of cases of acute SAH and multiple pituitary hormone axes deficiency occurs in 67% of cases. It is suggested that hormonal evaluation should be considered as a part of management of acute SAH.

**Factors involved in the outcome of ischemic stroke among the Asian population: A Chinese study**  
T. Sosorbaram, L. Zhang, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China

**Background:** Ischemic stroke (IS) is an issue in many countries and the outcome depends on the events, causation and the medical care facilities present in the health centers. The aim of this study was to evaluate the outcome of IS among patients presenting in the rural area of Eastern China.

**Methods:** This study was conducted in Hubei province, over a period of 1 year. A total of 335 cases of IS and suffering for the first time were recruited. The mean age was 55 ± 8 years, 60% were males. Information was obtained using a standardized questionnaire including demographic details, symptoms and signs, risk factors, Glasgow Coma Score, stroke severity, admission baseline investigations and presence of complications. The end point was mortality or survival at 1 month from the day of stroke.

**Results:** Strong factors predicting mortality were ruled out to be stroke severity on admission (74%), hypertension (67%), admission hyperglycemia (54%), and presence of complications (94%) especially concomitant renal or cardiac failure and chest infections during the hospitalization period. Of these factors, the presence of complications had the strongest correlation with fatality (r = 0.52; p = 0.001). Overall, 1 month fatality was 31%.

**Conclusion:** Our study clearly reflected that the overlapping complications seem to be the strongest factor for mortality among patients of ischemic stroke in the hospital. Early detection and prompt treatment can easily prevent these conditions and responsibility lies primarily on the physician and paramedical staff to monitor these complications in every case of ischemic stroke while taking care of the general stroke management.

**Topic: 3 — Stroke**  
**State of coronary bed in patients with acute ischemic stroke with reversible and irreversible neurological impairment**  
D. Izyumova, G. Izyumova, “Khorezm Regional Multifield Medical Centre, Uzbekistan; “Republican Scientific Centre of Emergency Medical Aid, Khorezm Branch, Urgench, Uzbekistan

**Purpose:** To examine the state of coronary bed in patients with acute ischemic stroke with reversible and irreversible neurological deficits.

**Material and methods:** 48 patients with reversible (group 1) and 44 patients (group 2) with an irreversible neurologic deficit (57 males and 35 females) were involved in the study.

**Results:** Vessel disease of coronary arteries was revealed in all the patients. Group 1 patients showed lesion of main branches, and in group 2 the frequency of lesions was less. This fact requires a detailed study of the degree of coronary lesions. Identified: in group 1 — the prevalence of stenotic coronary lesions more than 50%, stenosis of the anterior interventricular branch, particularly, in 77% cases, stenosis of circumflex branch — at 75% cases, stenosis of the right coronary artery — in 53% cases. In group 2 there is dysfunction-occlusion. A greater percentage of hemodynamically significant lesions were found in females of group 1 — 41.8%, in comparison with males — 13%.

Distal localization of lesions and large length of lesions were found in group 2, more often in women — 67%. In group 2 a sharp deterioration in hemorheology, hemostasis and fibrinolysis in acute period of ischemic stroke was detected.

**Conclusions:** We hope that the research results will attract the attention of physicians in choosing new ways of prevention strategies of cardio-cerebrovascular diseases. Timely and qualified early diagnosis with earlier pharmacologic therapy will reduce mortality in young people.

**Metamorphopsia restricted to the nose and mouth with right medial temporooccipital lobe infarction**  
D. Kim, J. Han. Neurology, Korea Veterans Hospital, Seoul, Republic of Korea
Background: Metamorphopsia includes a broad spectrum of visual perceptual distortions, such as alteration of perceived object size or, rarely, altered perception of faces, termed prosopometamorphopsia. The fusiform face area is known to play a key role in face perception.

Case: A 75-year-old right-handed woman was admitted for a sudden onset of nausea, dizziness, and blurred vision. She complained of dimmed vision, and the central part of faces, particularly the nose and mouth, appearing out of shape. She claimed, “The nose looks very narrow as well as lengthened toward the mouth, which looks small and round in shape”. Her description of how she saw faces seemed as if viewed through a convex lens. She had no prosopagnosia. She had no impairment in her visuoperceptual performances (describing a complex scene, drawing figures, reading and writing) or in color perception. Left homonymous quadrant anosia was seen. Diffusion weighted MRI and T2-weighted brain MRI revealed an infarction in the right medial temporoparietal lobe, including the parahippocampal gyrus.

Conclusions: In light of recent empirical evidence, face perception is thought to be mediated by a distributed neural system including all regions of the core and extended systems of which the major entry node is the lateral fusiform gyrus. We speculated that any injury on this pathway could bring about prosopometamorphopsia involving whole or unilateral face perception, or very rarely, such as in our case, distortion restricted to the central area of the face.

Anaemia as a predictor of the severity and functional outcome of ischaemic stroke

T. Chang, T. Vithange, P. Weeratunga, C. Arambepola, P. Wijewickrama, S. Kularathne, S. Fernando. Clinical Medicine, Faculty of Medicine, University of Colombo, Colombo, Sri Lanka

Background: Korea Veterans Hospital lower haemoglobin levels may impair cerebral oxygen delivery and predispose to infarct expansion and impaired neuronal survival in the ischaemic penumbra following stroke. Whether anaemia is associated with greater stroke severity and worse outcome remains unestablished.

Objective: To identify the association of anaemia with stroke severity and functional outcome among patients with ischaemic stroke.

Methods: A cross-sectional study was conducted among 190 prospectively-recruited patients with newly-diagnosed ischaemic stroke at the National Hospital of Sri Lanka. Their socio-demography, co-morbidities, stroke type (Oxford Community Stroke Project classification), stroke severity by NIHSS, and functional outcome by Modified-Rankin-Score (MRS) and Barthel index (BI) were assessed within 48 h of stroke onset. Anaemia was defined as Hb < 13 g/dl in males and < 12 g/dl in females.

Results: Mean age was 63.1 years (SD = 12.0); 75.8% were males. Mean NIHSS was 11.07 (SD = 7.04); 27.4% had moderate–severe stroke. NIHSS score > 15). Mean MRS was 3.63 (SD = 1.19); 68.3% had dependent mobility (MRS > 3). Mean BI was 38.26 (SD = 30.6); 85.8% had moderate–severe dependent mobility (BI < 75). 58.4% had anaemia (59.0% males; 56.5% females). Mean Hb was 11.7 (SD = 2.2) [males = 11.7 (SD = 2.3); females = 11.65 (SD = 1.9)]. Compared to non-anaemic patients, anaemic patients had significantly higher functional disability based on MRS (77.3% vs. 55.7%) and BI (90.1% vs. 79.7%) but showed similar stroke severity (27.8% vs. 27.0%). When adjusted by gender, co-morbidities and stroke subtypes, functional disability by MRS was significantly associated with anaemia [adjusted odds ratio = 2.17 (95% CI: 1.13–4.17)].

Conclusions: Anaemia is independently associated with increased functional disability, as measured by MRS.

Results of Russian prospective controlled multicentral clinical study “SOKOL” (comparable efficacy of Cavinton in standard acute stroke treatment)

J. Azimova1, G. Tabeeva2, 4Neurology and Clinical Neurophysiology, Moscow Medical Academy, Russia; 1st Moscow State Medical University, Moscow, Russia

Background: The protective effect of vinpocetine (Cavinton) was demonstrated using in vitro models of oxidative stress. In vitro data supports additional clinical trials of vinpocetine to be carried out.

Objectives: The aim of the study was to evaluate the efficacy of Cavinton with standard acute stroke therapy as compared to standard therapy.

Patients and methods: 661 patients with acute stroke (7–14 day) were enrolled in the study. One group (334 patients) received standard therapy and intravenous infusions of Cavinton (4 days — 25 mg, 3 days — 50 mg) and then Cavinton 30 mg/day in tablets for 90 days. The other group (327 patients) received only standard therapy. Patient disability was the primary endpoint (the Oxford handicap scale) accessed at baseline (visit 1), after infusions (visit 2) and after 1 (visit 3), 2 (visit 4) and 3 (visit 5) months of treatment.

Results: In the Cavinton group Oxford handicap scale score was 2.9 points at the 1st visit, 2.4 points at the 2nd, 1.8 points at the 3rd, 1.6 points at the 4th and 1.3 points at the 5th visit. In the control group this rate was 2.9 points at the 1st visit, 2.5 points at the 2nd, 2.2 points at the 3rd, 2.0 points at the 4th and 1.8 points at the 5th visit. The significant difference between groups (p < 0.05) was at the 3rd, the 4th and the 5th visit.

Conclusions: Addition of Cavinton to standard treatments lowers patients’ disability and may be considered as an option for long term treatment.

Long-term natural history of intracranial arterial stenosis: An MRA follow-up study
Y. Kim, W.S. Ryu, S.S. Park, Y.S. Kim, S.H. Lee, K. Kang, C. Kim, C.H. Sohn, B.W. Yoon, Neurology, Seoul National University Hospital, Republic of Korea; Neurology, Seoul Medical Center, Republic of Korea; Neurology, Hanyang University Medical Center, Republic of Korea; Neurology, Seoul Daehyung Hospital, Republic of Korea; Neurology, Euiji General Hospital, Seoul, Republic of Korea; Neurology, Hallym University Sacred Heart Hospital, Chuncheon, Republic of Korea; Radiology, Seoul National University Hospital, Seoul, Republic of Korea

Objective: Intracranial arterial stenosis (ICAS) is a major cause of ischemic stroke in Asian populations. In the present study, we demonstrated the results of a long-term follow-up of ICAS and comparisons between symptomatic and asymptomatic stenosis.

Methods: A series of 102 subjects underwent follow-up MR angiography (MRA) five years after initial MRA. Because the sample size is too small to adjust for multiple confounders, we applied propensity score. We used a logistic regression analysis with adjustment for the propensity score. In addition, we matched the patients by propensity scores and built the second logistic regression model.

Results: The median time interval between initial and follow-up MRA was 5.7 years (range 3.6–8.5 years). The progression rate of ICAS differed significantly between symptomatic and asymptomatic patients (22% vs. 8%), indicating that symptomatic stenosis had a 3-fold risk of progression compared with asymptomatic stenosis [OR 3.27, 95% confidence interval (CI) 1.08–9.95]. After adjustment for propensity score, the OR was 4.84 (95% CI, 1.40–16.7). In the propensity score matched cohort, the relative risk of stenosis progression was 5.20 compared with asymptomatic stenosis. Furthermore, the progression rate of concomitant asymptomatic stenosis in subjects with symptomatic ICAS was largely comparable to that of asymptomatic stenosis; 3% progressed, 65% were stationary, and 32% regressed.

Conclusion: We found that symptomatic stenosis had a greater risk of progression compared with asymptomatic stenosis. In addition, our results suggested that concomitant asymptomatic stenosis in symptomatic patients also had a benign course.

Cervical medullar infarction in multileveled discopathy
J. Stricker, R. N’Gbo Ikazabo, R. Hourez, P. Seeldrayers. Neurology, CHU de Charleroi, Charleroi, Belgium

Spinal cord infarction is a rare but devastating pathology causing acute neurological deficits. The incidence has been estimated to 1% of all strokes. In that case report, our patient has presented anterior spinal artery infarction in C5 and C6. The only risk factor found was a multileveled discopathy which is known to be an uncommon cause of anterior spinal artery syndrome.

Neurocnectomy by MIN techniques versus craniectomy in stroke
K.D.M. Resch. Neurosurgery, Klinikum Darmstadt, Darmstadt, Germany

Objective: In the series of 150 hematoma evacuations some cases were hemorrhagic infarctions. In these cases additional to the hematoma the center of the necrosis was evacuated also. As these patients made a much better recovery than craniectomy cases we developed a novel concept.

Methods: Hemorrhagic infarctions were operated through key-holes under ultrasound control (burr-hole probe, Alpha 7, ALOKA) and by mouth-switch tracked microscope. Before surgery CTA or TCD was made to see if the infarction showed reperfusion, because in the latter condition the operation may be more difficult. Perfusion CT determined the center of the necrosis.

Results: In all cases we saw a much better course of recovery than in craniectomy cases. The patients were not disabled additionally by stigma like craniectomy defect, big scarf, loss of hair and psychological trauma. The beginning of rehabilitation therapy could start within one week only, the wound of 3 cm was not visible and during rehabilitation there was no fear by the rehabilitation clinics to soon start the full training program. We did not see any complications due to the MIN strategy. It is worthwhile to study this novel concept by trials. The-operative technique, however is much more sophisticated and also much faster and economic than a simple craniectomy.

Neural coupling of cooperative hand movements in stroke patients
M. Schrafl-Altermatt, V. Dietz. Balgrist University Hospital, Spinal Cord Injury Center, Zurich, Switzerland

The neural control of cooperative hand movements reflecting “opening a bottle” has been studied in healthy subjects. It revealed a task-specific neural coupling of the upper limbs resulting in bilateral EMG responses following unilateral ulnar nerve stimulation. In contrast, during control conditions (e.g. pro-/supination) only ipsilateral reflex responses were detected.

The objective of this study was to examine this neural coupling in chronic stroke patients. Mildly affected post-stroke patients were included 6.4 years (±2.5) after stroke. Patients had a mean age of 53.3 years (±7.9), were right-handed and had a left hemispheric insult resulting in a right hemiparesis. The average Fugl-Meyer score for the upper limb was 49.1 (±7.7) out of 66. Unilateral ulnar nerve stimulations were randomly delivered during three conditions, a dynamic cooperative movement, an isometric and a dynamic pro-/supination control condition. EMG of forearm extensors and flexors was analyzed.

Stimulation of the right (affected) arm led in both conditions in ipsilateral muscles to an early response followed by segmental EMG responses. Contralateral no reflex response could be recorded in neither one of the conditions. Stimulation of the left (unaffected) arm resulted in bilateral EMG response patterns similar to the ones found in healthy subjects during the dynamic cooperative movement. Only ipsilateral responses appeared during the control conditions.

The results indicate that the task-specific neural coupling during cooperative hand movements is partially impaired after stroke corresponding to movement performance. This has consequences for rehabilitation of upper limb function of these patients.

Impact of prior IV thrombolysis on early recanalization and clinical outcome after endovascular treatment in acute ischemic stroke
D. Sanale1, D. Skoloudik1, T. Veverka1, M. Kuliba1, M. Kra1, M. Kocher1, M. Roubec1, K. Langova1, V. Prochazka2, M. Nevrly2, D. Franc2, K. Mensikova2, R. Marak2, P. Otruba2, P. Kanovsky2.
1Department of Neurology, Comprehensive Stroke Center, University Hospital, Olomouc, Czech Republic; 2Department of Neurology, Comprehensive Stroke Center, University Hospital, Ostrava, Czech Republic; 3Department of Radiology, Comprehensive Stroke Center, University Hospital, Czech Republic; 4Department of Medical Biophysics, Palacký University Medical School and Institute of Molecular and Translational Medicine, Olomouc, Czech Republic; 5Department of Radiology, Comprehensive Stroke Center, University Hospital, Ostrava, Czech Republic

Background: Although different endovascular approaches are now largely used for acute intracranial arterial occlusion (IAO) in ischemic stroke (IS), intravenous thrombolysis (IVT) is standard option within first 4.5 h after stroke onset. The aim was to assess the impact of prior IVT before endovascular treatment (EVT) on early recanalization and clinical outcome.

Methods: In retrospective study, 372 consecutive acute IS patients with IAO were treated with EVT and divided into 2 groups according to the presence/absence of prior IVT. Stroke severity was assessed using National Institutes of Health Stroke Scale (NIHSS), 90-day clinical outcome using modified Rankin Scale (mRS) with good outcome defined as 0–2. Early recanalization was quantified using Thrombolysis in Cerebral Ischemia scale and symptomatic intracerebral hemorrhage (SICH) using SITS-MOST criteria.

Results: Group 1 consisted of 193 patients (51% males, mean age 62.9 ± 13.8 years) treated with IVT and Group 2 of 179 patients (60% males, mean age 65.5 ± 12.4 years) without IVT. Patients treated with IVT had higher baseline NIHSS (18 vs. 15 points, p < 0.001). No difference was found in recanalization rate (80.9 vs. 87.6%, p=0.089) including complete (41.6 vs. 46.4%, p=0.403), occurrence of SICH (4.1 vs. 4.0%, p=1.000), good clinical outcome (43.8 vs. 51.7%, p=0.146) and 3-month mortality (22.7 vs. 23.0%, p=1.000).

Conclusion: Prior IVT probably does not increase the chance for early recanalization and good clinical outcome after EVT of IAO in acute IS patients.

Correlation of electrophysiologic abnormality with motor recovery in stroke

E.Y. Han. Jeju National University Hospital, Jejusi, Republic of Korea

Objectives: The objective was to determine whether the abnormal findings of somatosensory evoked potentials (SEPs) and motor nerve conduction study correlate with Motor Recovery in Stroke.

Methods: Eighty-two stroke patients were enrolled in this study from January, 2011 to December, 2011. The initial clinical data were reviewed including age, gender, main type of stroke (ischemic or hemorrhagic), lateralization of the lesion (right, left, or bilateral), location, motoricity index, MBI and hand function test. SEP tests (N20 in median nerve, P37 in posterior tibial nerve) and motor nerve conduction study (median, lateral, common peroneal, and tibial nerve) were performed. The amplitude of hemiside motor amplitude was compared with that of sound side and confirmed the relationship among other parameters.

Results: Relative value of median and tibial motor amplitude correlated significantly with the hemiside median SEP, posterior tibial SEP, and initial MBI. And the absent median SEP was correlated significantly with MFT (p < 0.05). Binary logistic regression analysis of factors showing significant correlations with final MBI indicated with relative value of motor amplitude.

Conclusion: In conclusion, relative value of motor amplitude as well as SEP was a primary predictor of motor recovery in the sub-acute phase of stroke.

Septic hydatid cerebral embol with a subarachnoid hemorrhage: A case report

L. Yildirim Caprar, a, H.Z. Batur Caglayan, b, N. Nazliel, b, D. Vuralli, b, Y. Öner, a, b
aNeurology, Gazi University Faculty of Medicine, Ankara, Turkey; bRadiology, Gazi University Faculty of Medicine, Ankara, Turkey

Introduction: Hydatid disease is a parasitic disease caused by the larval stages of Echinococcus granulosus and the most common sites of involvement are the liver and lungs. Hydatidosis is a rare disease even in the endemic areas and though most of the patients may remain asymptomatic, a number of serious and lethal complications have been described.

Case report: We present a patient with cardiac hydatidosis leading to a septic cerebral embolus accompanied by a subarachnoid hemorrhage, probably due to the rupture of a mycotic (embolic–septic) aneurysm.

Discussion: Cerebral hydatid cysts are relatively rare and account for up to 2% of cases. Cerebral involvement generally occurs secondary to dissemination from a cardiac source. Mycotic aneurysms also known as infective or microbial aneurysms are rare inflammatory neurovascular lesions that count for 0.7–6.5% of all intracranial aneurysms. Because their spontaneous rupture results in subarachnoid and intracerebral hemorrhage, they are associated with significance and morbidity. The possibility of hydatid disease should be kept in mind, especially in endemic zones.

Acute stenting in treatment of acute ischemic stroke
L. Hajdukova¹, L. Loudova¹, L. Martinikovic⁶, J. Kasík⁴. ¹Neurology, Military University Hospital Prague, Czech Republic; ²Neurology, 2nd Faculty of Medicine, Charles University Prague, University Hospital Motol, Prague, Czech Republic

Background: Acute stenting alone or in combination with other modalities is one possibility for acute stroke treatment in certain indications.

Objective: The purpose of our study is to demonstrate the results of acute stenting in 44 patients with acute ischemic stroke during January 2006 and December 2012 in our hospital.

Patients and methods: We retrospectively reviewed 44 patients (36 males, 8 females, median 58 years) with acute stroke caused by occlusion or severe stenosis of large artery of anterior (35 patients) or posterior circulation (9 patients). Patients underwent acute stenting alone or in combination with intravenous thrombolysis (IVT), percutaneous angioplasty (PTA), intraarterial thrombolysis (IAT) or mechanical thrombectomy (MT). The procedure was performed within 8 h after stroke onset. We determined median score of National Institute of Health Stroke Scale (NIHSS) at baseline and after 24 h and modified Rankin score (mRS) in 3 months. The Thrombolysis in Myocardial Infarction (TIMI) recanalization score was assessed by angiography performed immediately after each procedure.

Results: The median NIHSS score at baseline was 14 (range 4–25), after 24 h 8 (range 0–35). Good clinical outcome in 3 months (mRS 0–2) had 29 patients (65.9%). The mortality rate was 22.7% (mRS 6). Complete recanalization (TIMI 3) was achieved in 23 patients (52.3%). Symptomatic intracranial hemorrhage occurred in 8 cases (18.0%).

Conclusion: Acute stenting has a high recanalization rate. In our study late stent implantation did not show higher risk of complications.

Peroxyynitrite could regulate proliferation and neuronal differentiation of neural stem/progenitor cells through activating WNT/β-catenin signaling pathway
J. Shen, X.-M. Chen, T.-T. Yan. School of Chinese Medicine, University of Hong Kong, Hong Kong Special Administrative Region

Background: Hypoxia/ischemia could mediate the differentiation of neural stem/progenitor cells (NSCs) into mature neurons. In hypoxic/ischemic brain, nitric oxide and superoxide are simultaneously produced and they rapidly react to form peroxynitrite. Whether peroxynitrite can regulate neurogenesis is unknown yet.

Objectives: Present study aims to understand the roles of peroxynitrite in regulating self-renewal, proliferation and differentiation of NSCs.

Materials and methods: Primary cultured NSCs were subjected to different stimulations including peroxynitrite donor SIN-1, synthesized peroxynitrite and hypoxia treatment. For visualizing the formation of peroxynitrite, we developed a highly sensitive and specific fluorescent probe and detected the formation of peroxynitrite in the NSCs. We applied different biomarkers including Ki67, BrdU, Tuj1 and DCX, etc. to identify the self-renewal proliferation, and neuronal differentiation of NSCs respectively.

Results: Low concentrations of extraneous peroxynitrite (<1 μM) promoted NSC proliferation, self-renewal and neuronal differentiation but high level of peroxynitrite (>5 μM) induced cytotoxicity. Hypoxic treatment induced the production of peroxynitrite and promoted NSC proliferation and self-renewal, and neuronal differentiation. Treatments of peroxynitrite decomposition catalysts (PDCs, FeTMPyP and FeTPPS) reduced hypoxia-induced peroxynitrite formation, NSC proliferation, self-renewal and neuronal differentiation. The neurogenesis promoting effects were partly mediated through activating Wnt/β-catenin signaling pathway.

Conclusion: Low concentration of peroxynitrite may serve as a cellular signaling for promoting NSC proliferation, self-renewal and neuronal differentiation.

Perfusion defect and initial clinical status might predict the poor prognosis of DWI-negative ischemic stroke
H.-K. Park⁵, J.-H. Rha⁶, S.-B. Ko⁷. ⁵Neurology, Seoul, Republic of Korea; ⁶Inha University Hospital, Incheon, Seoul, Republic of Korea; ⁷Seoul National University Hospital, Seoul, Republic of Korea

Purpose: Clinically acute stroke is not always accompanied by positive lesion on the diffusion-weighted image (DWI). In this diffusion negative ischemic stroke (DNIS), the clinical prognosis might be related to the symptom persistence after seven days, and analyzed the differences in clinical and imaging factors between two groups.

Methods: We retrospectively reviewed data from prospectively collected Inha University Hospital Stroke Registry from January 2007 to December, 2010. We identified and divided the DNIS into two groups, according to the persistence of symptoms after seven days, and analyzed the differences in clinical and imaging factors between two groups.

Results: A total of 1398 subjects were enrolled and 142 DNIS patients were identified. Compared to DWI(+) group, the patients with DNIS were younger, and had the low frequency of atrial fibrillation and hypertension. Among DNIS, the patients with fully recovery within seven days, had the lower ABCD2 score, the lower NIHSS on admission, and the lower frequency of perfusion delay on perfusion MRI, compared to the patients with persistent symptoms. In the multivariable analysis, initial NIHSS(≥ 1) and perfusion delay were independently associated with persistent symptoms (NIHSS, p < 0.001, OR 17.2, 95% CI 5.5–54.0; perfusion delay, p = 0.03, OR 36.7, 95% CI 1.4–977.0).

Conclusions: Our results suggested that the perfusion defect and focal neurological deficit might be related to the symptom persistence in the DNIS.

Unusual central nervous system hemorrhagic complications associated with dengue fever  
aNeurology, King George Medical University, Lucknow, India;  
bNeurosurgery, King George Medical University, Lucknow, India  

Background: Dengue viral infection is emerging as significant public health problem, particularly in developing world. The dengue infection mainly presented with classical dengue fever, dengue hemorrhagic fever, and dengue shock syndrome.  
Objectives: We intended to report spontaneous intracranial hemorrhage, associated with dengue virus infection without other bleeding manifestations.  
Patient and methods/material and methods: The clinical details and outcome were described in two patients of CNS hemorrhagic manifestations with dengue fever. Both the patients were serum positive for IgM capture ELISA for dengue fever and showed fourfold increase in titer subjected one week apart. There was no history of trauma.  
Results: In Case-1, a 28 years old male was admitted with complaint of high grade fever, malaise and severe bone pain for 15 days. Later on, he developed acute headache, vomiting and altered sensorium with the presence of thrombocytopenia. The computerized tomography head demonstrated acute subdural hematoma with associated subarachnoid hemorrhage. Bilateral fronto-parietal craniotomy with right sided evacuation of acute SDH was done. The patient recovered completely at follow-up. In Case-2, a 19 years old male reported with complaints of fever, retroorbital pain, arthralgia and thrombocytopenia. He subsequently developed headache, seizures and unconsciousness. Magnetic Resonance Imaging of the brain revealed acute extradural hematoma. The patient was managed conservatively and was completely improved at follow-up after 3 months.  
Conclusion: Our case series illustrate that spontaneous CNS hemorrhage associated with dengue fever can occur without other bleeding manifestations and it required a high index of suspicion to have good clinical outcome.

Cerebral vascular accident caused by intracranial aneurysm: Evaluation of fifteen cases  
H.H.S. Matozinho, M.F. Rodrigues, N.S. Dias, V.F.V. Júnior, T.A.G.J. Ribeiro, F.O. Gomes, Faculdade de Medicina, Universidade Federal de Goiás, Goiânia, Brazil  

Background: Hemorrhagic stroke due to intracranial aneurysm (HS-IA) is caused by the rupture of aneurysms predominantly formed in the anterior circulation (90%), which leads to subarachnoid hemorrhage. HS-IA has a higher incidence around the age of 50, and it is more common in women than in men. The clinical features are sudden headache, dizziness, hemiplegia, and nausea, among others. Complications are frequent: vasospasm, seizures, rebleeding, and hydrocephalus.  
Objectives: Investigate the characteristics of patients with HS-IA, comparing with literature.  
Methods: A retrospective review of 15 patients admitted with the diagnosis of HS-IA in Santa Monica Hospital, Goiânia — Brazil, from July 2008 to January 2009 was performed.  
Results: Among the 15 cases of HS-IA analyzed, a peak occurrence between 51 and 60 years was observed. There were 9 women and 6 men. The most common affected arteries were: middle cerebral (23%), ophthalmic (23%), anterior communicating (18%), posterior communicating (18%), internal carotid (12%), and posterior inferior cerebellar (6%). The most common symptoms were: 86.7% headache, 33.3% vomiting, 33.3% change in the consciousness, 33.3% visual impairment, and 20% nuchal pain. Of the 14 patients undergoing surgery, 8 patients had no complications, while the other 6 had different frames: headache, facial nerve paresis, neck hematoma and hypertensive peak; spasm, motor impairment and atrophy of the left temporal muscle, and paresis of the lower limbs.  
Conclusion: In this study, the data obtained are consistent with the epidemiological literature, except in the category of postoperative complications, proving that the profile of the patient is important to recognize a HS-IA.

Cranial nerve syndromes and vision loss in cerebral venous thrombosis: A rarity  
S. Ramakrishnan, G.B. Kulkarni, M. Veerendrakumar.  
Neurology, NIMHANS, Bangalore, India  

Background: Cerebral venous thrombosis (CVT) can present as raised intracranial tension, focal deficits, cavernous sinus thrombosis, sub-acute encephalopathy and cranial nerve syndrome. Cranial palsy may be seen in 10–12%. CVT presenting as cranial nerve palsy and vision loss is rare.  
Objective: To analyse patients of CVT presenting with cranial nerve palsy and vision loss due to raised intracranial tension.  
Patients and methods: Retrospective analysis of CVT patients admitted in stroke unit from 2004 to 2012 was performed from medical records of our university hospital.  
Results: Among 405 patients, 8 patients of CVT had combination of visual loss and cranial nerve palsies. Mean age at presentation was 27.6 years. Male:Female: 5:3. The most common risk factor was elevated homocysteine levels (n = 4). Duration of presentation ranged from 4 days to 1 year. Patients presented with headache (n = 7), neck pain (n = 7), seizures (n = 4), papilledema (n = 8), visual impairment (n = 8), visual field defects (n = 5), bilateral 3.4 and 6th cranial nerve palsy (n = 5), LMN facial palsy (n = 4), bilateral 6th nerve palsy (n = 3) and radiculopathy (n = 4). None had focal deficits. CSF pressure ranged from 235 to 400 mm of Hg. Superior sagittal sinus and transverse sinus thrombosis were the commonest sites of thrombosis by MR venography. Treatment included anti-oxide measures, methyl prednisolone (n = 4) and 5000 IU subcutaneous heparin 6th hourly followed by acenocoumarol. Optic nerve fenestration (n = 3) followed by thecoperitoneal shunt (n = 4) was undertaken in those with significant vision loss and headache, though the outcome remained poor.

Conclusion: Cerebral venous thrombosis can have diverse presentations. CVT with vision loss and cranial nerve palsy may be misdiagnosed as chronic meningitis, pachymeningitis or vasculitis.

Recovery of bimanual coordination is delayed after left hemispheric and/or purely cortical stroke lesions

L. Morlet1, D. Mottet1, H.-Y. Bonnin-Koang1, L.E. van Dokkum2, I. Laffont3,4, Movement to Health Laboratory, EuroMov, Montpellier-1 University, Montpellier, France; 2Physical and Rehabilitation Medicine, CHU Nîmes, Le Grau du Roi, Nîmes, France; 3Physical and Rehabilitation Medicine, CHRU Montpellier, France; 4Movement to Health Laboratory, EuroMov, Montpellier-1 University, Montpellier, France

Background: One-fit-all post-stroke rehabilitation has limited plausibility. Better understanding the effects of lesion location on the recovery process may help to develop rehabilitation strategies adapted to individual patients’ needs.

Objective: The purpose of this study was to assess the natural evolution of bimanual coordination over standard rehabilitation aiming to identify a potential responder-profile for bimanual-oriented therapy.

Patients and methods: 12 hemiparetic, moderately impaired patients were included within 30 days after a first unilateral stroke. Kinematic and clinical assessments were performed once a week for 6 weeks and at 3 months after inclusion. Patients performed a synchronous bimanual reach-to-grasp task. Clinical evaluation included Fugl-Meyer Assessment, Box and Block test, 9-Hole Peg test and Barthel Index.

Results: Although no clinical difference was found between groups, left-hemisphere damaged (LHD) patients tended to reach less smooth than right-hemisphere damaged (RHD) patients (p = .07). Moreover, it was found that patients with purely cortical damage moved slower than patients with subcortical lesions (p < .01). These kinematic inter-group differences disappeared, respectively, after 4 and 6 weeks of standard therapy, likely indicating a shift in the recovery phase.

Conclusion: Because patients with a subcortical lesion/and or right hemispheric lesion were naturally more coordinated during bimanual movements over recovery, they may benefit more from bimanual rehabilitation.

Troponin-T in acute ischemic stroke patients — Results of the prospective history study

M. Kral1, D. Šaňák1, T. Veverka2, M. Hutyr3, D. Vindiš4, A. Bártková4, T. Dorňák4, M. Švobová5, V. Kubíčková5, J. Zapletalová6, R. Herzig5, D. Školoudík5, P. Kaňovský6, 1Comprehensive Stroke Center, Department of Neurology, Czech Republic; 2Department of Internal Medicine I — Cardiology, University Hospital and Faculty of Medicine and Dentistry, Palacký University, Czech Republic; 3Department of Clinical Biochemistry, University Hospital, Czech Republic; 4Department of Biophysics, Faculty of Medicine and Dentistry, Palacký University and Institute of Molecular and Translational Medicine, Olomouc, Czech Republic

Background: Multiple interactions are considered to occur between the various forms of cardiovascular and cerebrovascular diseases. The aim of the study was to assess the serum level profile of cardiac troponin T (cTnT) in acute ischemic stroke (AIS) patients to evaluate factors associated with increased serum level of cTnT.

Methods: AIS patients admitted within 12 h from stroke onset were enrolled in this prospective study. Neurological examination and brain CT or MRI at admission, standard laboratory tests, including cTnT and other cardiac markers, at admission and 4 h later, and repeated electrocardiograms (ECGs) were performed. Correlations between cTnT and several baseline parameters were tested and multivariate regression analysis was used to assess the predictors of cTnT elevation.

Results: In total, 107 consecutive AIS patients (65 males, mean age 67.2 ± 14.2 years) were enrolled. 39 (36.4%) patients presented with elevated cTnT above the upper limit. The cTnT levels correlated significantly with age (r = 0.448) and the levels of NT-proBNP (r = 0.528), cystatin C (r = 0.457), CK-MB mass (r = 0.253), urea (r = 0.281), and albumin (r = −0.219). Multiple logistic regression analysis found creatinine >90 μmol/L (OR = 3.45; 95% CI: 1.09–10.85), NT-proBNP (OR = 1.09 per 100 μg/L increase; 95% CI: 1.03–1.16) and CK-MB mass (OR = 1.45 per 1 μg/L increase; 95% CI: 1.04–2.04) to be associated with cTnT elevation in AIS patients.

Conclusion: Elevated cTnT can be relatively frequently detected in AIS patients. To reliably identify the patients with current acute myocardial impairment, more in-depth clinical investigation is needed.

Stroke outcome after endovascular treatment: Influence of the site of occlusion

H. Henon1, P. Aguetz2, M. Bodenat1, M. Aggour2, D. Leys3, X. Leclerc2,3, Stroke Unit, CHRU of Lille, Lille, France; 2Neuroradiology, CHRU of Lille, Lille, France

Background: After IV thrombolysis, patients with occlusion of both M1 and ICA (tandem occlusion) have a worse outcome than patients with isolated M1 occlusion (I1M occlusion).

Objective: We aimed to evaluate the influence of the site of occlusion on stroke outcome after endovascular treatment.

Patients and methods: We included consecutive patients treated by endovascular procedure because of a stroke related to an occlusion of M1, isolated or associated with an ICA occlusion. Mechanical
thrombectomy was performed using a stentraver (Solitaire FR). We evaluated clinical severity of stroke (NIHSS), lesion volume (pre-treatment diffusion MRI), haemorrhagic complications (T2*MRI at 24 h (ECASS II)), recanalisation at the end of the procedure (TICI criteria), and 3-month outcome (mRS). Favourable outcome was defined as a mRS ≤ 2 or identical to pre-stroke mRS.

**Results:** Among 28 consecutive patients (median age 58.5 years, 8 men, median NIHSS 18, 21 treated by IV rtPA), 14 had IM1 occlusion, 14 tandem occlusion. Demographics, NIHSS, stroke volume, delay and duration of endovascular procedure, and number of patients with IV rtPA did not differ between groups. The rates of recanalisation of M1, of haemorrhagic complications and of favourable outcome at month-3 (57% in IM1 occlusion and 64% in tandem occlusion) were similar in the 2 groups of patients. Multivariate analysis found infarct volume to be the only independent predictor of 3-month outcome.**Conclusion:** After endovascular treatment, 3-month outcome was similar in patients with tandem occlusion compared to patients with IM1 occlusion, without clear influence of the site of occlusion.

**Alcohol attributable fraction of stroke mortality in Russia**

Y.E. Razvodovsky, Psychiatry, Grodno State Medical University, Grodno, Belarus

**Background:** Stroke is an international health problem with high associated human and economic costs. The mortality rate from stroke in Russia is one of the highest in the world. Risk factor identification is therefore a high priority. Epidemiological evidence suggests that binge drinking increases the risk for ischemic and hemorrhagic stroke.

**Objectives:** The aim of the present study was to estimate the premature stroke mortality attributable to alcohol abuse in Russia on the basis of aggregate-level data of stroke mortality and alcohol consumption.

**Methods:** Age-standardized sex-specific male and female stroke mortality data for the period 1980–2005 and data on overall alcohol consumption were analyzed by means ARIMA time series analysis.

**Results:** The results of the analysis suggest that 26.8% of all male stroke deaths and 18.4% female stroke deaths in Russia could be attributed to alcohol. The estimated alcohol-attributable fraction for men ranged from 16.2% (75+ age group) to 57.5% (30–44 age group) and for women from 10.3% (75+ age group) to 43.5% (30–44 age group).

**Conclusions:** The outcomes of this study provide support for the hypothesis that alcohol is a major contributor to the high stroke mortality rate in Russian Federation. Therefore prevention of alcohol-attributable harm should be a major public health priority in Russia. Given the distribution of alcohol-related stroke deaths, interventions should be focused on the young and middle-aged men and women.

**Perilesional and subcortical plasticity after focal ischemic stroke is associated with motor recovery: A tensor-based morphometry study**

E. Abela1, A. Seiler2, J. Missimer3, A. Federspiel4, C. Hess5, M. Sturzenegger5, R. Wiest3, B. Weder2,3, 1Neurology, Third Faculty of Medicine, Charles University and University Hospital Royal Vineyards, Prague, Czech Republic; 2Cardiology, Third Faculty of Medicine, Charles University and University Hospital Royal Vineyards, Prague, Czech Republic

**Background:** In preclinical models of cortical sensorimotor stroke, extensive remodeling of perilesional and subcortical gray matter (GM) has been described. It is unknown whether these morphological changes can be detected in clinical populations as well.

**Objective:** To measure the longitudinal GM plasticity in stroke survivors using MRI, and to identify its relationship with motor recovery.

**Patients and methods:** We tracked motor recovery in 28 patients suffering from hand paresis after cortical sensorimotor stroke with a detailed battery of hand function tests. We used a longitudinal principal component analysis to quantify and classify recovery subgroups. To assess GM volume change, we performed tensor-based morphometry and statistical parametric mapping on high-resolution T1-weighted MRI scans acquired between 3 and 9 months post-stroke. Significance was estimated using threshold-free cluster enhancement. Cytoarchitectonic regions-of-interest were used for structure–behavior correlations and subgroup comparisons.

**Results:** Multivariate classification yielded three recovery subgroups. We found significant GM expansion in perilesional premotor cortex, ipsilesional caudate and ipsilesional medio-dorsal thalamus, and GM atrophy in the contralesional cerebellum. A 3 × 2-ANOVA with recovery subgroup (fast, slow, impaired) and site of plasticity (premotor, thalamic) as between-subject factors revealed a significant interaction effect (F(2,106) = 3.837, p = .025): fast recoverers showed more perilesional, impaired recoverers more thalamic GM expansion. Thalamic GM change was significantly correlated with chronic motor impairment (r = .829, p = .011).

**Conclusions:** Subcortical GM plasticity can be detected non-invasively during subacute phases of recovery, and correlates with post-stroke motor outcome. This might reflect an adaptive, but insufficient, shift of motor control from pyramidal to extrapyramidal circuits.

**Acute ischemic stroke with medial cerebral artery hyperdense sign — Comparison of intravenous thrombolysis and catheter-based therapy: A pilot study**

T. Peisker1, P. Vaško2, B. Kožnar2, P. Widimský3, I. Štětěnková4, 1Neurology, Third Faculty of Medicine, Charles University and University Hospital Royal Vineyards, Prague, Czech Republic; 2Cardiology, Third Faculty of Medicine, Charles University and University Hospital Royal Vineyards, Prague, Czech Republic

**Introduction:** Acute ischemic stroke due to occlusion of medial cerebral artery (MCA) has an unfavourable prognosis in spite of intravenous rtPA administration. Alternative treatment options are still a matter of debate. In this study, we compared the results of rtPA and mechanical thrombectomy in the matched study groups.

**Material and methods:** Ten patients underwent a direct mechanical thrombectomy (catheter-based therapy, CBT group) of MCA occlusion and were compared to 10 matched individuals, who were treated for acute ischemic stroke by intravenous thrombolysis (IVT group). All 20 patients had hyperdense sign on initial non-contrast CT scan. IVT group (8 females, average 58 yrs, range 38–79) had an initial NIHSS of 15 points. CBT group (8 females, average 59 yrs, range 32–79) had the initial NIHSS of 14 points. Mean onset to needle time was 124 min in IVT group and 140 min in CBT group.

Scherrer Institute, Villigen, Switzerland; 2Psychiatric Neurophysiology, University Hospital of Psychiatry, Switzerland; 3Neurology, University Hospital Inselspital, Bern, Switzerland; 4Neurology, Kantonsspital St. Gallen, St. Gallen, Switzerland.
Results: Early MCA recanalization was reached in nine subjects in the CBT group and in three patients in IVT group as assessed by ultrasound. Symptomatic intracerebral haemorrhage occurred in one subject in CBT group and in two patients in IVT group. Favourable outcome (mRS 0–2) on acute hospital discharge was achieved in five individuals treated by CBT and in two persons, who received IVT.

Conclusion: This pilot study showed promising outcomes (angiographic and clinical) after direct CBT when it is initiated with minimal delay. Further research comparing direct CBT versus IVT is warranted.

Functional condition of central and cerebral hemodynamic in patients with coma caused by acute ischemic stroke
O.O. Ivanova, M.G. Zhestikova, Y.A. Churliaev, K.V. Lukashev, O.V. Rudenkova, D.G. Dantsiger, A.G. Chechenin, V.M. Aliferova, N.G. Zhukova, I.A. Zhukova. "Neurology, City Clinical Hospital № 1, Russia; "Neurology, State Educational Establishment of Additional Medical Education 'Novokuznetsk Post-Graduate-Medical Institute' Russian Health Care, Russia; "Reanimatology, City Clinical Hospital № 1, Novokuznetsk, Russia; "Management, City Clinical Hospital № 1, Novokuznetsk, Russia; "Neurology, State Educational Establishment of High Professional Education Siberian Medical University, Tomsk, Russia

The aim of study was to evaluate the functional condition of central hemodynamic and cerebral blood flow in acute ischemic stroke comatose patients.

Objective: The continuous simultaneous assessment of invasive central hemodynamic and intracranial pressure (ICP), transcranial Doppler measurement of cerebral hemodynamic was performed in 35 comatose ischemic stroke patients on 1, 3, 5 and 7th day of acute period.

Material and methods: The cardiac index (CI) was significantly higher on 3rd and 7th day of acute period. The mean arterial pressure (MAP) was increased.

Results: The systemic vascular resistance index (SVRI) was higher than normative value. ICP was significantly higher on 3rd and 5th day in comparison with 1st day (p < 0.05–0.001) and was higher than normative range value. Cerebral perfusion pressure (CPP) was assessed in normative range value and on 7th day it was 96.6 ± 2.12 mmHg. Time average maximum velocity (TAMX) in middle cerebral artery on stroke side increased significantly on 7th day (p < 0.05–0.001). Pulsatility index (PI) on 3rd day was 1.2 time higher than 1st day value and was 1.16 ± 0.07 and it was a result of increased ICP. The maximal value (0.64 ± 0.02) of the resistive index (RI) was on 3rd day (p < 0.05–0.001).

Conclusions: The reaction of central hemodynamic was aimed to provide an adequate cerebral perfusion. The elevation of cerebral blood flow and mean arterial pressure on 7th day of acute period of ischemic stroke was a result of cerebral autoregulation impairment.

Quality of care registry of cerebrovascular disease in Veneto region: One year of experience in monitoring and implementing stroke care

Objective: To pilot and promote the use of a regional "quality of care register" for cerebrovascular disease to document procedures, treatments, compliance with evidence-based indications, and to guide improvements in ischemic stroke patient management.

Materials and methods: The multicentric, observational prospective study, funded by the Regional Government of Veneto with the participation of Pfizer Italia, was designed to collect data on patients admitted to Ist and IInd level SU’s for cerebrovascular diseases in the Veneto Region from 1/09/2011 to 31/8/2012. Patients’ complete care pathway was assessed from the pre-hospital phase, to the emergency department, to admission to SU, discharge and follow-up.

Results: During the collection period 3357 admissions for cerebrovascular diseases were recorded. Of the ischemic stroke patients, 75% reached the ER and underwent a brain CT within 4.5 h of symptoms onset and were thus in time to undergo reperfusion therapy, but thrombolyis involved only 18% of all ischemic stroke. In terms of compliance with the main guidelines, the study revealed poor use of the leading standardized neurological assessment scales (Rankin and NIHSS), and that a high percentage of patients were not taking adequate preventive treatment, a significant percentage of patients were not recommended to take statins after ischemic stroke (46%), and patients with cardioembolic stroke were not discharged with anticoagulant therapy (46%).

Conclusions: The system for monitoring of patients with cerebrovascular pathology is designed both to identify structural weaknesses in the stroke pathway requiring organizational/legislative intervention, and to evaluate the quality and standardization of the care pathway.

Predictors of early post-stroke seizures in patients with spontaneous intracerebral hemorrhage

Background: Seizures are common in patients with spontaneous intracerebral hemorrhage (ICH). Understanding of the risk factors of seizures following ICH is needed to predict which patient will require treatment.

Objective: To determine the factors predicting the occurrence of early post-stroke seizures in patients with spontaneous ICH.

Methods: Seventy patients (43 males and 27 females) with first time spontaneous ICH were included in the study. Their age ranged from 27 to 90 years (mean 58.5 ± 11.1). All the patients were subjected to clinical examination, laboratory investigations (including early morning serum cortisol level), computed tomography brain scan at the time of admission and after 48 h, and electroencephalography. Patients were followed up for 7 days for the occurrence of early seizures.

Results: On the follow-up period, 13 patients (18.6%) developed early post-stroke seizures. Of them, 4 patients (30.7%) had focal seizures and 9 patients (69.3%) had generalized seizures. Patients with early post-stroke seizures were significantly more likely to have Glasgow Coma Scale (GCS) < 12, high systolic and diastolic blood pressure, high body temperature, high random blood glucose level, lobar cortical hematoma, hematoma volume > 30 cc, peri-hematoma edema, midline shift, hematoma expansion after 48 h and periodic lateralized epileptiform discharges (PLEDs) than patients without seizures.

Conclusions: GCS < 12, high systolic and diastolic blood pressure, high body temperature, high random blood glucose level, lobar cortical hematoma, hematoma volume > 30 cc, peri-hematoma edema, midline shift, hematoma expansion after 48 h and PLEDs can be considered as predictors of early post-stroke seizures.

A case of anterior spinal artery syndrome (ASAS) demonstrated by angiography
1Neurology, Bakirkoy Prof. Dr. Mazhar Osman Mental Health and Neurological Diseases Training and Research Hospital, Turkey; 2Radiology, Bakirkoy Training and Research Hospital, Istanbul, Turkey

A 27-year-old woman experienced pain, paresthesia and weakness after her mother made massage to her neck. Nearly 1 after, her upper extremities became plegic and her lower extremities became weaker and 5 h later she became totally quadriplegic. Neurological examination revealed extreme neck pain, quadriplegia, decreased deep tendon reflexes, sensory disturbance of pain and temperature below the neck and urinary incontinence. MRI T2 weighted images showed a high-intensity lesions which did not enhance after contrast and could also be demonstrated by angiography. Echocardiography was normal. Serum viral markers were negative. In CSF, cell account and biochemistry was normal, viral markers were also negative. ASAS was diagnosed according to the owl’s eye appearance which is large, round, single, central lesion locating in the anterior side of the spinal cord supporting an ischemic disease in cervical diffusion MRI. Angiography was performed and it showed that vertebral arterial flow was intact but there was an interruption in the blood flow of anterior spinal arteries at the 4–7th cervical segments. ASAS is a very rare entity and its MRI findings such as the “owl’s eye” appearance is specific and demonstrative and angiographic demonstration of occlusion of anterior spinal arteries is relatively rare. We report this case because it has typical clinical and MRI findings and could also be demonstrated by angiography.

Quality control of carotid stenting with digital subtraction angiography and computed tomography angiography: Similarities and differences
W. Freund1, M. Dornacher2, T. Stubera, M. Juchema, B.L. Schmitzb.
1Diagnostic and Interventional Radiology, University Hospitals Ulm, Ulm, Germany; 2Neuroradiology, University Hospitals Ulm, Ulm, Germany

Background: The effect of carotid stenting must be continuously monitored to ensure good patient outcomes. Mostly this is done by means of digital subtraction angiography DSA. Increasingly, computed tomography angiography CTA is used as an alternative. To assess differences between both methods, we retrospectively compared DSA and CTA after carotid stenting.

Patients and methods: Retrospective analysis of pre- and post-interventional CTA and DSA in carotid stenting patients. We found 59 patients with complete records. Two readers independently assessed the images on PACS workstations and measured carotid diameters according to NASCET criteria. Stenosis as well as technical success rates (improvement over 20% and less than 50% residual stenosis) and interrater reliability and correlations were computed for both methods.

Results: Mean preinterventional stenosis rates were 69.9% for CTA vs 59.3% for DSA, postinterventional stenosis was 20.5 vs. 17.4% respectively. Technical success rates were calculated for DSA to be 97.5% and for CTA 85.6%. The correlation of both methods was higher preinterventionally (r = .49, p < .0001) than postinterventionally (r = .48, p = .0001). Interrater reliability was mostly moderate to good (lambda = .46–.79).

Conclusion: Due to the volumetric dataset with the possibility to perform measurements orthogonal to the vessel and to assess the minimal diameter independent from projection angles of DSA, the measurement of preinterventional stenosis was deemed more accurate than DSA.
accurate with CTA, thus giving higher stenosis rates. Postinterventional assessment with DSA is prone to a bias since the intervention is performed under control in one projection. CTA however demonstrated regularly less optimal results in other projections.

Optimized amide proton transfer imaging of ischemic stroke
Z. Dai, G. Yan, S. Li, G. Xiao, Z. Shen, G. Zhang, R. Wu.
2nd Affiliated Hospital of Shantou University Medical College, Shantou, China; 3Hanshan Normal University, Chaozhou, China

Objective: The identification of ischemic penumbra is very important to guide the treatment in ischemic stroke. Amide proton transfer (APT) imaging, a new MRI technology, is expected to detect the ischemic penumbra more precisely than PWI–DWI mismatch in hyperacute cerebral infarction. But APT effect is typically small and sensitive to pre-saturation power, which needs to be optimized in the first 3 h after stroke.

Material and methods: Twelve adult male Sprague Dawley rats underwent permanent middle cerebral artery occlusion by thread embolism. MRI experiments were conducted under an Agilent 7T scanner. Parameters were used: Offset at 3.5 ppm and −3.5 ppm, TR/TE = 26/2.5 ms, FA = 5°, slice thickness = 2 mm, FOV = 34 × 34 mm2, NEX = 64, matrix = 64 × 64 and bandwidth = 50 kHz. APT MRI was optimized as functions of pre-saturation power. The pulse power (Gauss pulse, 15 ms) was serially set from 0.4 μT to 1.6 μT with intervals of 0.2 μT. Amide proton transfer imaging and contrast to noise rate (CNR) were processed in Matlab.

Results: The optimized pre-saturation power in the first 3 h was 0.6 μT, which had better spatiotemporal resolution and contrast than others. The best CNR was about 4. Moreover, the APT effect almost disappeared when the pre-saturation power was varied more than 0.4 μT.

Conclusion: Our study demonstrates the optimized APT imaging in the first 3 h of ischemic stroke, which showed the ischemic lesion precisely and be promising for an accurate gauge of ischemic penumbra.

Influence of acute aneurysmal subarachnoid hemorrhage on subpopulations of mononuclear cells
J. Pera, R. Morga, E. Grzywna, T. Dziedzic, M. Moskala, A. Szczudlik, A. Slowik, 3Neurology, Jagiellonian University Medical College, Poland; 4Neurosurgery and Neurotraumatology, Jagiellonian University Hospital, Poland; 5Neurosurgery and Neurotraumatology, Jagiellonian University Medical College, Krakow, Poland

Background: Aneurysmal subarachnoid hemorrhage (aSAH) causes specific changes in transcription profiles of peripheral blood cells with a downregulation of transcripts related to T lymphocytes and an upregulation of transcripts related to monocytes and neutrophils. However, it is uncertain whether those changes reflect changes in cell count or in their activities.

Objective: To analyze changes in subpopulations of mononuclear cells in the acute phase of aSAH.

Patients and methods: Nine patients with acute nontraumatic aSAH (7 females) and 10 control subjects (8 females) were recruited into the study. Flow cytometry method was used to analyze following subpopulations of leukocytes: T lymphocytes (CD3+, CD4+, CD8+), invariant natural killer T cells (iNKT) and monocytes (classical CD14+, CD16−, intermediate CD14+CD16+, nonclassical CD14+CD16+).

Results: Significant changes in leukocyte composition with an increase of granulocyte percentage (85.3% vs 63.3%) and a decrease of monocyte (4.9% vs 6.2%) and T lymphocyte (10.0% vs 26.3%) percentages were noted in aSAH patients comparing with controls (p < 0.05). Among monocytes a significant decrease only of nonclassical monocyte count was observed in aSAH patients (p < 0.05). Analysis of subsets of T lymphocytes revealed significantly lower count of CD3+, CD4+, and iNKT in aSAH patients comparing with controls.
Conclusion: Acute aSAH strongly influences the composition of leukocytes in the peripheral blood. In particular, we found a decrease of nonclassical monocyte count concomitantly with decreased numbers of CD3+, CD4+ and iNKT cells.

Is thrombolysis realizable at the Department of Neurology, Fann Teaching Hospital, Dakar-Senegal?

Background and purpose: Stroke is a real health problem with a high morbidity and mortality in developing countries. This figure is increasing and worsening because of a problem of management. Nevertheless, the organization of care in the acute phase significantly reduces the cost, morbidity and mortality of stroke. Among these treatments, thrombolysis is the most effective therapeutic means to prevent lasting disability. However neurological clinics exist in Africa, thrombolysis in stroke patients is not updated. The study focused on the feasibility of thrombolysis in our neurological department.

Methods: This is a prospective study from September 2010 to April 2012 in a population of patients attending the Department of Neurology, Fann Teaching Hospital of Dakar-Senegal for stroke. Data on sociodemographic, lifestyle, delay to attend the clinic and to realize the CT scan of the brain were collected. We performed univariate and multivariate comparing the time of consultation and achievements of brain scan with socioeconomic data.

Results: Data of 285 patients was collected. They had a mean age of 56.5 years, male (50%), and ischemic stroke (73%). The main risk factors for stroke were: hypertension and diabetes. The consultation period was within 3 h for 19.8% and within 6 h for 15.1%. 23.3% came by ambulance and 66.7% by public transport. 9% had the CT scan performed within 3 h and 18% within 6 h. No statistically significant difference between time compared to variables of interest before 6 h was observed.

Conclusions: Thrombolysis appears feasible in our clinic.

Time is brain: Stroke thrombolysis in Brunei Darussalam
G.C. Chan,a, U. Meyding-Lamade,b,c. "Department of Neurology, Neuroscience Stroke and Rehabilitation Centre, Bandar Seri Begawan, Brunei; "Department of Neurology, Krankenhaus Nordwest, Frankfurt/Main, Germany

Background: Stroke is emerging as a major public health problem for Brunei Darussalam. The Neuroscience, Stroke and Rehabilitation Centre (NSRC) has established a dedicated stroke unit since 2010.

Objective: To assess the demographic of patients admitted with ischaemic stroke into NSRC who were within the 4.5 hours thrombolytic window.

Methods: Medical case-notes of all patients admitted with stroke (ischemic or haemorrhagic) from July 2010 to October 2012 were reviewed. Data collected included age, gender, referral centres, time of symptoms, time of arrival in NSRC, time of thrombolysis and length of stay.

Results: Out of 456 charts reviewed, 21 patients (5%) received intravenous thrombolysis with Alteplase. There were 13 (62%) males and 8 (38%) females. 86% of patients were referred from Brunei Darussalam main hospital (RIPAS) while 14% were referred from Jerudong Park Medical Centre. The mean age of patients was 56 ± 12 years (range 23–88).

The mean time from onset of symptoms to iv needle thrombolysis was 179 ± 62 min. The mean door to iv needle thrombolysis was 48 ± 22 min. Thus the mean time from onset of symptoms to reaching our unit (door) was 131 min.

Conclusion: In our preliminary study (with small number of patients), there is a quick and efficient door to needle thrombolysis time of 48 min. However there is a need to improve the time delay (131 min) from the onset of symptoms to reaching our stroke unit.

Cortical deafness as a sole manifestation of ischemic cerebrovascular disease
E. Papageorgiou, G. Matikas, X. Papastergios, V. Koukouni, G. Gekas. Neurology Department General Hospital of Nikaia, Athens, Greece
**Background:** Cortical deafness is a very rare condition characterized by the complete disruption of central auditory processing with intact peripheral auditory function.

**Objective:** To describe a case of cortical deafness associated with ischemic cerebrovascular disease.

**Patients and methods:** A 61 year-old female with a history of arterial hypertension presented to our department complaining of a sudden complete hearing loss. On examination, she was alert but slightly confused and agitated. Her spontaneous speech was fluent with occasional paraphasic errors. She was unable to follow verbal commands, but could understand simple written information. She appeared totally deaf, with no startle response to loud sounds. The rest of the neurological examination was unremarkable. Brain CT scan demonstrated a chronic right temporo-parietal ischemic infarct. Otorhinolaryngologic examination revealed no evidence of external or middle ear disease. Audiometry showed normal middle ear reflexes. Brainstem auditory evoked potentials were normal, consistent with normal auditory processing up to and including the inferior colliculus. An MRI scan demonstrated the old right temporo-parietal infarct and an additional hyperacute ischemic infarct in the left posterior parietal area, extending into the Heschl’s gyrus, the superior temporal gyrus and the Sylvian fissure. In three months' follow-up, the patient showed no improvement and she was able to communicate only through reading and writing.

**Conclusion:** Our case emphasizes on cortical deafness as a rare sole manifestation of ischemic cerebrovascular disease associated with bilateral damage of the primary auditory cortex.

**Central obesity in the poorest region in Chile**  
*Neurology Department, Universidad de La Frontera, Chile; Stroke Unit, Clínica Alemana de Temuco, Temuco, Chile; Neurology Department, Clínica Alemana de Temuco, Temuco, Chile; Nutrition Department, Clínica Alemana de Temuco, Temuco, Chile*

**Background:** Stroke is the first most common specific cause of death in Chile, since 2008. The increased risk in our region is explained by the prevalence of poverty, diabetes, a sedentary lifestyle and overweight.

**Object:** To assess the waist circumference (WC) in Clínica Alemana de Temuco, Temuco, Chile.

**Methods:** One hundred and eighty-one patients were included. Mean WC: 102.3 (SD: ±13.6), BMI: 29.9. LR: 3%; MR: 28.4%; and HR: 61.7% (CO).

**Conclusion:** Central obesity is a major risk factor for cardiovascular disease. This series of cases only shows that the problem is very important in Chile. The obesity and central obesity are epidemic. We should perform behaviors to lower these indicators, with much education and government guidelines.

**Preliminary evaluation of diffusion kurtosis imaging in acute stroke patients**  
Y.-L. Guo, S.-J. Li, P. Zhe Sun, R.-H. Wu.  
*Department of Radiology, The Second Affiliated Hospital, Shantou University Medical College, Shantou, China; Athinoulia A. Martinos Center, Department of Radiology, Massachusetts General Hospital and Harvard Medical School, Boston, MA, USA*

**Aims:** To translate and evaluate diffusion kurtosis imaging (DKI) in stroke patients.

**Methods:** Four patients underwent DKI and conventional MRI (including T1WI, T2WI, FLAIR and DWI) using a GE 1.5T HDx echo speed plus an MRI scanner. Mean kurtosis (MK), radial kurtosis (Kr) and axial kurtosis (Ka) were derived using DKI software in GE ADW4.3 workstation. Fourteen regions of interest (ROI) were outlined in infarction regions of stroke patients, including 2 ROIs in super-acute, 3 ROIs in acute, 6 ROIs in subacute and 3 ROIs in chronic lesion. The stroke duration was determined from onset time and DWI signal intensity. Stroke prognosis was evaluated by follow-up MRI and clinical manifestations.

**Results:** During super-acute stroke, regions of hyperintensive MK and Kr progressed to infarction with mild bleeding without noticeable DWI and ADC abnormalities. For the case of sub-acute stroke, DKI (MK and Kr) appeared hypointensive without significant change in DWI and ADC maps. In addition, 10 ROIs showed abnormality in both DKI and DWI/ADC maps.

**Conclusions:** DKI displayed contrast different from the standard DWI and ADC maps. DKI remains promising to address false negative signals in the standard DWI and ADC maps, and complement existing stroke MRI for improved stroke diagnosis.

New prognostic score for the prediction of 30-day outcome in spontaneous supratentorial cerebral hemorrhage

L. Csiba, I. Széll, R. Szepesi, L. Láncai, E. Berényi, K. Nagy, D. Bereczki, L. Kardos, a Neurology, Debrecen University, Debrecen, Hungary; bBiomedical Laboratory and Imaging Science, Debrecen University, Debrecen, Hungary; cNeurology, Semmelweis University Faculty of Medicine, Budapest, Hungary; dIndependent Statistician, ANTSZ, Debrecen, Hungary

Objectives: The purpose of the present study was to evaluate predictors of outcome in primary supratentorial cerebral hemorrhage. Furthermore, we aimed to develop a prognostic model to predict 30-day fatality.

Methods: We retrospectively analyzed a database of 156 patients with spontaneous supratentorial hemorrhage to explore the relationship between anamnestic, clinical and CT characteristics, and fatal outcome within 30 days using multiple logistic regression analysis. The analyzed factors included volumetric data assessed by neuropathological and CT volumetry. A second CT scan in survivors, or neuropathological ABC/2 volumetry in non-survivors was used along with the baseline CT to assess the growth index of hematoma.

Results: Systolic blood pressure, serum potassium and glucose levels, platelet count, absolute and relative hematoma volumes, presence and size of intraventricular hemorrhage statistically significantly predicted the fatal outcome within 30 days. Based on our results we formulated a six-factor scoring algorithm named SUSPEKT to predict the outcome.

Conclusions: After validation the SUSPEKT Score may be applicable in general clinical practice for early patient selection to optimize individual management or for assessment of eligibility for treatment trials.

Association between metabolic syndrome and homocysteinaemia in ischemic stroke

M. Vujnic, N. Raseta, S. Miljkovic, D. Raci, V. Djajic, O. Perazic, S. Peric. a Department for Pathophysiology, Faculty of Medicine, University Clinical Center in Banja Luka, Bosnia and Herzegovina; b Neurology Clinic, University Clinical Center in Banja Luka, Bosnia and Herzegovina; c Institute for Occupational and Sport Medicine of the Republic of Srpska, Banja Luka, Bosnia and Herzegovina; d Neurology Clinic, Clinical Center of Serbia, School of Medicine, University of Belgrade, Belgrade, Serbia

Background: Stroke is one of the leading causes of morbidity and mortality worldwide. The role of metabolic syndrome and homocysteinaemia as risk factors for ischemic stroke is not completely clear.

Aim: To determine the frequency of metabolic syndrome and homocysteinaemia, as well as their association in patients with ischemic stroke.

Method: The research included 53 subjects being on rehabilitation after stroke and 40 clinical controls without vascular disease that were on rehabilitation due to the back pain problems.

Results: The frequency of metabolic syndrome was much higher in patients with stroke compared to control group (88.7% vs. 70.0%, p < 0.05). The level of homocysteinaemia and the frequency of hyperhomocysteinaemia were increased in the patients with stroke (15.0 ± 5.50 μmol/L vs. 11.2 ± 2.51 μmol/L, p < 0.01 and 39.2% vs. 11.4%, p < 0.01, respectively). Among patients with stroke, those with metabolic syndrome had higher frequency of hyperhomocysteinaemia (42.2% vs. 16.7%, p < 0.05) and the serum level of homocysteine was significantly higher in patients with more individual components of metabolic syndrome (11.1% in patients with 3 components, 36.8% in patients with 4 components and 64.7% in patients with 5 components, p < 0.05).

Conclusion: Our results suggest that metabolic syndrome and homocysteinaemia represent significant risk factors for ischemic stroke. It seems that there is an association between these two factors in pathogenesis of the ischemic stroke, but further analyses are needed to confirm this hypothesis.

doi:10.1016/j.jns.2013.07.924
deposition in the leptomeningeal and cortical vessels, with frequent intracerebral hemorrhagic stroke (IHS).

**Conclusion:** Although with TTR Val30-Met mutation IHS is not common, in our liver transplanted patient the local and remote parenchymal hemorrhage after thrombolysis raises the hypothesis that cerebral amyloid angiopathy might develop in the long-term in these patients, due to maintained abnormal transthyretin production in the choroid plexus. Brain pathological studies are necessary to confirm this hypothesis in the TTR Val30-Met liver transplanted patients.

**Methods:** All consecutive acute stroke patients admitted to our department between September 2006 and September 2011 were included. We distinguished between patients:
1) with active malignancy (the diagnosis of cancer within 12 months before stroke, AM);
2) with non-active malignancy (non-AM);
3) cancer-free patients (CF), used as a reference.

**Results:** Of 1558 acute stroke admissions, 90 (5.8%) had an additional diagnosis of cancer, including 41 cases of AM (2.6%) and 49 cases of non-AM (3.1%). Compared to CF group, non-AM patients did not differ in terms of vascular risk factors; they more frequently had stroke due to small vessel occlusion (18.4% vs 7.0%, p = 0.003). AM patients less frequently had atrial fibrillation (7.3% vs 23.5%, p = 0.016) and history of previous stroke (2.4% vs 24.9%, p = 0.018). The most frequent stroke etiology in the AM group was undetermined (61.0%) and they had higher levels of serum inflammatory parameters. Stroke severity and outcome were similar across all groups.

**Conclusions:** Compared to the CF patients, the pattern of stroke in non-AM patients appears similar. However, stroke pattern in patients with AM may be different from the conventional one, but it does not affect the short term prognosis.

**No:** 2319  **Topic:** 3 — Stroke  **Setting up a neuroscience stroke and rehabilitation centre**

12,000 km away with the help of telemedicine

**Neurology, Krankenhaus Nordwest, Frankfurt/Main, Germany;**

**Brunei Stroke and Rehabilitation Centre, Jerudong, Brunei;**

**Neuroradiology, Krankenhaus Nordwest, Frankfurt/Main, Germany**

**Background:** Due to world-wide aging population neurologists are urgently needed for stroke/non-stroke. In Brunei Darussalam we set up a national stroke unit, intensive care unit, neurorehabilitation on-site including tele-neurology and tele-teaching.

**Objective:** The aim of this project to teach to treat was to set up a world class centre of neurology.

**Methods:** In 7/2010 set-up of the Bruneian Neuroscience Stroke and Rehabilitation Centre (BNSRC) has started. To overcome the distance of 12,000 km a telemedical network between the Department of Neurology (KHNW) and BNSRC started. This international cooperation includes a “specialist neurology” training program, accredited in Brunei Darussalam by an international advisory board. Daily tele-teaching, 24/7 tele-neurology service, as well as all neurological laboratories have been set up on site by tele-cytology, and tele-electrophysiology including EEG and ultrasound. Awareness campaigns and telerehab have been successfully started.

**Results:** The BNSRC already has been successfully audited according to the STU requirements of the German Stroke Society. Over 200 patients have been treated so far. Several Bruneian doctors are enrolled in the specialist curriculum.

**Conclusion:** The program to teach to treat resulted in a local set up of a BNSRC, being built up by KHNW. This outstanding project of a cooperation between the KHNW and BNSRC succeeded in building up a centre of excellence of high end acute neurological department including a stroke unit and neurorehabilitation.

**Abstract — WCN 2013**

**No:** 2355  **Topic:** 3 — Stroke  **Late cerebrovascular complications of radiation therapy for pediatric primary central nervous system tumors**

**Neurology, Instituto Português de Oncologia de Lisboa Francisco Gentil, Lisbon, Portugal;**

**Neuroradiology, Hospital de Faro EPE, Faro, Portugal;**

**Neurology, Instituto Portugues de Oncologia de Lisboa Francisco Gentil, Lisbon, Portugal;**

**Pediatric Neuro-Oncology, Instituto Portugues de Oncologia de Lisboa Francisco Gentil, Lisbon, Portugal**

**Background:** Radiation therapy (RT) plays an important role in the management of primary central nervous system tumors (PCNST) in children. Despite field and dose optimization, late cerebrovascular complications (LCCs) still occur. However, the number of studies assessing the burden of these complications is limited.

**Objective:** To describe the occurrence of LCCs in adult survivors who underwent RT for PCNST during childhood.

**Methods:** Retrospective consecutive case series description of LCCs from a cohort of adult survivors of pediatric PCNST. Diagnosis of hemorrhagic LCCs was confirmed by gradient-echo MRI sequence.

**Results:** We identified LCCs of RT in 35 of a total of 103 patients (34.0%); median age at RT was 8.4 years; and median follow-up was 18.7 years. Histological diagnoses were: medulloblastomas/primitive neuroectodermal tumors (16/45.7%), gliomas (15/42.9%) and germ cell tumors (4/11.4%). The most frequent PCNST site was the posterior fossa (21/60%). Mean total radiation dose was 48 Gy (18–54 Gy); most patients received focal plus entire neuraxis RT (23/65.7%). Thirty-three patients had microbleeds, all asymptomatic; cavernomas occurred in eleven patients, causing epilepsy in 2; two patients had a symptomatic ischemic stroke (6 and 25 years after RT); two patients presented with symptomatic superficial siderosis (15 and 26 years after RT) and one patient developed symptomatic moyamoya syndrome 4 years after RT. In some patients, microbleeds and cavernomas increased in number during follow-up.
Conclusions: LCCs are very common after RT for pediatric PCNST, with microbleeds and cavernomas being more frequent in a continuous and dynamic pathophysiological process.

Long-term imaging follow-up in patients with adequately coiled basilar tip aneurysms is essential to timely detect late reopening

M. van Eijck, W.J. van Rooij, M. Sluzewski, G. Roks. St. Elisabeth Ziekenhuis, Tilburg, The Netherlands

Background and objective: Reopening after coiling at mid-term follow-up is more frequent in basilar tip aneurysms than in aneurysms at other locations. To quantify this phenomenon of late reopening, we performed MRA at 3 T in a cohort of patients with basilar tip aneurysms coiled between 1994 and 2005, that were adequately occluded at short- or mid-term and had no imaging follow-up in the last 7 years.

Patients and methods: Between 1994 and 2005, 148 patients with basilar tip aneurysms were coiled. In 2012, 29 were deceased and 56 had prolonged imaging follow-up after previous reopening and/or retreatment. Of the remaining 63 patients, 11 were untraceable, 11 were not eligible because of contra-indications for MRI or poor clinical condition, and 9 refused follow-up MRA. Finally, 32 patients with adequately coiled basilar tip aneurysms and without imaging follow-up in the last 7 years were scheduled for MRA follow-up after a mean of 12.8 years (median 12.7, range 7–19 years).

Results: Of 32 patients, 31 had MRA and 1 patient had angiography after a rebleed 5 days before scheduled MRA. Four of 32 patients (12.5%) had late reopening of the coiled basilar tip aneurysm requiring additional coiling.

Conclusions: Basilar tip aneurysms that are adequately occluded at short- or mid-term after treatment may reopen (and rebleed) many years later with a frequency of 1 in 8 in this cohort. In patients with coiled basilar tip aneurysms, prolonged imaging follow-up at regular intervals is recommended to timely detect late reopening.

The association between routine serum C-reactive protein and outcome in ischemic stroke patients treated with intravenous alteplase

M.A. Karlinska1, J. Bembenek1, K. Grabska2, A. Kobayashi3, A. Baranowska3, T. Litwin1, A. Czlonkowska3,4, 2nd Department of Neurology, Medical University of Warsaw, Warsaw, Poland; 2Interventional Stroke Treatment Centre, Institute of Psychiatry and Neurology, Medical University of Warsaw, Warsaw, Poland; 3Department of Experimental and Clinical Pharmacology, Medical University of Warsaw, Warsaw, Poland

Background: The clinical usefulness of blood biomarkers in acute stroke is not yet fully established, especially after intravenous thrombolysis.

Objective: Our aim was to investigate the association between routine serum C-reactive protein (CRP) measured very early after stroke and outcome in patients treated with intravenous thrombolysis, adjusting for a history of recent infection.

Patients and methods: We analyzed the data of consecutive patients treated with intravenous alteplase in our center between October 2003 and December 2011. The information was prospectively collected in a detailed registry. Patients or their proxies were additionally interviewed for a history of an infectious event during 7 days before stroke onset. Routine serum CRP was measured within 24 h from admission, concentration >5 ng/ml was considered elevated.

Results: Serum CRP was measured in 341/406 patients treated with intravenous rt-PA. Patients with elevated CRP (135/341, 42.5%) compared to those with normal CRP values, were significantly older, more frequently presented with a pre-existing disability, comorbidities and suffered more severe strokes. They had a higher proportion of symptomatic intracranial hemorrhage according to ECASS II definition (7.2% vs 1.6%, p = 0.010), higher 3-month mortality (25.6% vs 11.3%, p = 0.001), and were less frequently alive and independent after 3 months (45.9% vs 63.7%, p = 0.002). However, those associations were not confirmed in a multivariate analysis.

Conclusions: Routine serum CRP determined very early after stroke may be helpful in establishing long-term prognosis for patients treated with intravenous thrombolysis. Elevated CRP seems to coexist with other factors associated with poor outcome.

Post-partum angiopathy: A challenging clinical-case
R. Loureiroa, R. Samõesab, T. Rodriguesb, I. Moreiraa, R. Felgueirasa, C. Correiaa. aNeurology Department, Centro Hospitalar do Porto, Porto, Portugal; bNeuroradiology Department, Centro Hospitalar do Porto, Porto, Portugal

Background: Postpartum angiopathy is one of the reversible cerebral vasoconstriction syndromes. It usually presents as a combination of symptoms such as severe headache, seizure, encephalopathy, motor deficit or ataxia. Intraparenchimal or subarachnoid hemorrhage, ischemic stroke and vasogenic brain edema have been reported.

Clinical case: Three days after an uncomplicated delivery, a 36 yo woman developed progressively intense holocranial headache. Within 1 h of headache onset, she was aphasic and had right motor deficit. Her past medical history included migraine and aplastic anemia. Her pregnancy was complicated by anemia, so she needed transfusion support. Blood pressure was normal and she did not develop albuminuria or preeclampsia throughout pregnancy. Cerebral CT scan showed left basal ganglia hemorrhage. Angiography showed multiple bilateral stenosis involving large and medium size cerebral arteries. Transcranial Doppler showed bilateral flow accelerations in all intracranial cerebral arteries, more severe on the right anterior circulation. She was treated with oral nimodipine, endovenous magnesium sulphate and mild hypervolemia. On day 16 she had a focal seizure, with right temporal paroxistic activity on interictal EEG. A cerebral MRI scan showed acute cerebral infarction involving right anterior cerebral artery. Due to the lack of clinical recovery, a presumptive diagnosis of non-convulsive status epilepticus was made and levetiracetam perfusion was started, with clinical and electroencephalographic response. The patient neurological status and cerebral vasospasm gradually improved.

Conclusion: We illustrate a challenging clinical case of postpartum angiopathy that presented with several of the possible complications of this syndrome: intraparenchimal cerebral hemorrhage, seizures and ischemic stroke.

Retrospective evaluation of patients with oral anticoagulant treatment introduced for secondary prevention

Background and objective: Warfarin reserves an important role for secondary prevention. The purpose of the study was to determine the efficacy of anticoagulation for secondary prevention in our clinical practice in strokes of different etiology.

Material and methods: We enrolled 181 ischemic stroke patients categorized according to TOAST classification. These patients started as either only with warfarin or warfarin and antiagregan combination were examined as retrospectively (1 month–16 years) for recurrent vascular incident and bleeding complication.

Results: Patients that are grouped according to their warfarin use period (first 1 year, 1–5 years, more than 5 years), minor bleeding complication was found statistically significant (p = 0.023) in more than 5 years warfarin using group and there was no other difference between the groups. During the follow, recurrent vascular incidence was determined in 17 patients, 13 of these patients (7.2%) had recurrent ischemic strokes. 6 (3.3%) major and 23 (12.7%) minor bleeding complications were observed. Average INR value was 1.69 ± 0.31 during the recurrent ischemic stroke, on the other hand it was 3.15 ± 1.30 during major bleeding complication. There was no significant difference between only warfarin using and warfarin with antiagregan using patients in terms of recurrent ischemic stroke and bleeding complications. During the diagnosis, ECG showed that patients had normal sinus rhythm, 48.8% of these patients’ Holter results showed PAF.

Conclusion: This study is important as it reflects clinical practice and we can say that our department is successful with INR follow on the strength of the similarities from our study with the literature.

Thrombolysis or anticoagulation for cerebral venous thrombosis (TO-ACT trial)

Background: Endovascular thrombolysis (ET), with or without mechanical clot removal, may be beneficial for a subgroup of patients with cerebral venous sinus thrombosis (CVT), who have a poor prognosis despite treatment with heparin. Published experience with ET is promising, but only based on case series.

Objective: The objective of the TO-ACT trial is to determine if ET improves the functional outcome of patients with a severe form of CVT.

Methods: The TO-ACT trial is a multi-centre, prospective, randomized, open-label, blinded endpoint (PROBE) trial. Patients are eligible if they have a radiologically proven CVT, a high risk of poor outcome (defined by presence of one or more of the following: mental status disorder, coma, intracranial hemorrhagic lesion, or thrombosis of the deep cerebral venous system) and if the responsible physician is uncertain whether ET or standard treatment is better. 164 patients will be included.

Intervention: Patients are randomized to receive either ET or standard treatment (therapeutic doses of heparin). ET consists of local application of rt-PA or urokinase within the thrombosed sinuses. Mechanical clot removal, such as thrombectomy, is allowed, but not mandatory.

Outcomes: The primary endpoint is the modified Rankin score (mRS) at 12 months, with a score ≥2 defined as poor outcome. Secondary outcomes are 6 months mRS, mortality and recanalization rate. Principal safety outcomes are major intra- and extracranial hemorrhagic complications. Results will be analyzed according to the “intention-to-treat” principle. Blinded assessors not involved in the treatment of the patient will assess endpoints with standardized questionnaires.

Clinical characteristics and short term mortality ischemic stroke patients with atrial fibrillation
S. Mihajlovic, V. Stojkovic. Department of Neurology, Health Centre Vranje, Vranje, Serbia

Background: Ischemic stroke (IS) accounts for 85% of all strokes. Atrial fibrillation (AF) is a strong independent risk factor for stroke. Objective: AF is responsible for about 25% of all IS and the risk of stroke attributed to AF increases with age. This study investigated the clinical characteristics and case fatality for the first-ever IS patients with AF.

Patients and methods: 102 patients were included in the study. A stroke was classified as IS when intracranial hemorrhage was excluded by a CT. AF was defined as a history of persistent AF or paroxysmal AF, supported by past ECG or diagnosed based on ECG and/or 24-hour ECG monitoring during admission. Short-term mortality was assessed as 30-day case-fatality rate.

Results: Of the 102 patients included in this study 21 (20.6%) had AF. Compared to patients without AF, patients with AF were older (71.2 vs. 68.3) and had higher frequency of coronary heart disease (15.1 vs. 12.3%) and myocardial infarction (4.1 vs. 1.2%), but a lower incidence of hypertension, diabetes mellitus, and hyperlipidemia. These patients had a higher NIHSS score on admission (median 12 vs. 7) and hemorrhagic transformation (16.2% vs. 7.8%). Within AF patients, only 3 (14.3%) received oral anticoagulants before stroke onset. 9 subjects with AF died within 30 days with an overall mortality of 42.9%.

Conclusion: Our results indicate that patients with AF have a higher frequency of cardiovascular comorbidities, stroke-related complications and a higher early death than patients without AF. The oral anticoagulants are rarely used in stroke prevention.

Clinical observations have suggested that splenectomy can contribute to an increased susceptibility to thrombosis attributed to the presence of high platelet counts following splenectomy and to increased number of abnormal RBCs. The higher incidence of thrombotic events in thalassemia intermedia compared to thalassemia major patients is mainly attributed to transfusion naiveté and splenectomy, both of which promote an underlying procoagulant activity.

doi:10.1016/j.jns.2013.07.940
differences. However, in cancer patients, several clinical conditions appear to increase the risk of stroke.

**Objective:** Compare ischemic stroke in cancer and non-cancer patients according to common modifiable vascular risk factors, etiology and outcome at discharge and three months later.

**Material and methods:** Retrospective case–control study conducted in a stroke unit, between January 2007 and December 2012. Cases: diagnosis of cancer and acute ischemic stroke; controls: only stroke. Groups were compared based on: vascular risk factors, etiology (TOAST classification) and outcome at discharge (NIH Stroke Scale, modified Rankin Scale scores).

**Results:** 56 cases were identified: 64.3% men, mean age of 71 years (31–92 years); 37.5% had evidence of active cancer. Gastrointestinal cancer (25.9%) was the most common; 151 controls, matched for gender and age. Vascular risk factors were not significantly different, except diabetes mellitus, more frequent in the control group [16.07% vs 33.77%, p = 0.02]. Cancer cohort had more previous thrombotic events [8.93% vs 0.66%, p = 0.007]. Another determined etiology subtype was more frequent in the cancer patients [17.86% vs 0.66%, p < 0.001], with no significant differences on the other TOAST subtypes. Functional outcome, both at admission and discharge were not significantly different. Mortality rate was higher in cancer patients at discharge and three months later [16.07% vs 3.31%, p < 0.01].

**Conclusion:** Results reveal similar vascular profile, although ischemic stroke in cancer patients seems to be more frequently associated with a hypercoagulable state and poorer outcome.

**Treatment possibilities of basal ganglia hemorrhage:**  
Retrospective trial of fifty-four patients

Neurology, Clinical Hospital Center Osijek, Osijek, Croatia;  
Neurosurgery, Clinical Hospital Center Osijek, Osijek, Croatia

**Background:** Intracerebral hemorrhage presents a challenge for both neurologists and neurosurgeons and constitutes up to 15% of the total number of cerebrovascular incidents.

**Objective:** The aim of this trial is to present an outcome of conservative and surgical treatment of intracerebral hemorrhage in our hospital.

**Patients and methods:** All patients underwent CT on admission. The treatment depended on CT confirming intracerebral hemorrhage and regarding progressive neurological deterioration of consciousness, brain edema or shift effect. These patients underwent a prompt surgical treatment with decompressive craniotomy and clot removal or external ventricular drainage as standard approach. The other patients underwent conservative treatment which consisted of antiedematous therapy and blood pressure regulation.

**Results:** In a group of fifty-four patients, fifty-one patients were treated conservatively and three patients were treated surgically. Conservatively treated patients and three patients treated surgically showed clinical improvement with satisfying additional postoperative CT scan within 48–72 h.

**Conclusion:** The trial showed that there is no difference between conservative and surgical treatment, although surgical treatment was superior in cases of progressive neurological deterioration with GCS 5–11. According to our retrospective trial, we can conclude that there was no significant difference between conservative and surgical treatment during the follow-up period of three months.

**Impact of heat shock protein on ischemic stroke risk**

Department of Neurology, Medical University of Gdansk, Poland;  
Department of Molecular and Cellular Biology, University of Gdansk, Gdansk, Poland;  
Department of Microbiology, University of Szczecin, Szczecin, Poland

Heat shock protein 72 (HSP72) has been found to reduce ischemic injury. HSP72 itself may be a marker for neuroprotection in ischemic stroke.

The aim of the study was to investigate the association between HSP plasma concentration and risk of ischemic stroke. We also investigated MTHFR and CBS genotypes.

**Methods:** We have measured the level of antibodies against HSPs in vitro, in serum of ischemic stroke patients and control group using ELISA. We study the prevalence of MTHFR (C677T, A1298T) and CBS (T833C, insertion 68 bp in position 844) genotypes.

**Results:** Heterozygotic genotype C677T of MTHFR was detected in 45% of patients, and A1298T in 43%. 5% of homozygotic C677C and 8% of T1298T were detected. In 87.5% of subjects at least one heterozygotic mutation was detected. Hyperhcy was correlated with mutations in either gene (p = 0.04). The level of antibodies against one of the bacterial HSPs, GroEL, correlates with the level of serum hcy. It points at the possible significance of autoimmune reactions contributing to atherosclerosis. We have also purified MTHFR and tested the influence of HSPs of the KJEB system in vitro, using spectrophotometric test for MTHFR activity. We found that MTHFR is partially protected from the effect of heat shock by KJEB system and that KJEB proteins can restore that activity of the enzyme when it is lost due to thermal denaturation.

**Conclusions:** Our study confirms diagnostic significance of antibodies to HSP in stroke. HSPs can be involved in the development of atherosclerosis, as well as protection against stroke.

**Tympanic temperature matches the brain temperature, fact or fiction?**

P. Kordestani Moghadam, P. Miravand, F. Manteghi, ICSS, Institute for Cognitive Science Studies, Tehran, Iran;  
LUMS, Lorestan University of Medical Sciences, Iran;  
ICU of Shohada Hospital, LUMS, Lorestan University of Medical Sciences, Khorramabad, Iran

This study is a case series, which was conducted on 10 CVA patients who were admitted in the ICU ward. These subjects consist of unilateral or bilateral ICH.

GCS, vital sign and tympanic temperature were controlled for the subjects within one week. Tympanic temperature measured from the left and the right ear. After this time we observed the meaningful difference between the left and the right tympanic temperature in patients with a unilateral lesion, but this difference was not seen in patients with bilateral lesions.

Based on these results, it seems that we used tympanic temperature in early diagnosis of hemorrhagic lesion in the affected side of the brain, just as the case in unilateral hemorrhagic lesion in patients with different etiologies.

Isolated right carotidynia: CT, MRI, FDG-PET and contrast-enhanced ultrasound carotid examination findings
Department of Neurology and Stroke Center, Versailles, France; Angiology and Ultrasound Unit, Versailles, France; Department of Radiology, Versailles Saint Quentin en Yvelines University, Versailles Hospital, Versailles, France

Introduction: Carotidynia as a distinct nosological entity is a controversial issue. Some authors have described consistent MRI findings in patients with carotidynia. We report a patient with this MRI pattern and present findings of contrast-enhanced ultrasound carotid examination.

Case description: A 52 year-old woman was admitted in the Stroke Unit for a suspected carotid artery dissection, after a 3-day history of intense, sudden and isolated right-neck pain. Clinical exam was strictly normal except for the tenderness at the right-carotid bifurcation. Ultrasound carotid examination depicted a hypoechoic tissue thickening around the right-carotid bifurcation, with an enhancement after injection of a microbubble contrast agent, without evidence for dissection or plaque. CT and MR findings evidenced a T1 isosignal, T2 hypersignal, and CT isodense infiltration around the right-carotid bifurcation, together with a gadolinium enhancement, without argument for artery dissection. The MR-angiography was normal except for a mass effect on the homolateral intern jugular vein, also observed on ultrasound. A 3-day follow-up examination confirmed the disappearance of initial abnormalities.

Discussion: We provide a full clinical/imaging/biological report of an isolated and remittent right carotidynia, arguing for idiopathic carotidynia as a distinct radio-clinical syndrome. MRI findings in this case are consistent with previous descriptions. To our knowledge, this is the first report of contrast-enhanced ultrasound aspects of idiopathic carotidynia.

Profile impact of depressive symptoms after stroke
Z. Adwan.
Privat Clinic, SMS HOSP, Swaida, Syria

Objective: The impact of the profile of depressive symptoms after stroke using the Stroke Impact Scale (SIS).

Background: Stroke effects have impacts on memory and thinking, communication, and social functioning. The effect of depression on functional outcomes.

Methods: A total of 287 stroke patients recruited from acute and sub-acute facilities in a community were followed prospectively from stroke onset till 3 months post-stroke. All subjects were assessed with standardized stroke outcome measures. Subjects were also assessed with SIS about 90–120 days after stroke.

Results: An average age 73 ± 10.1 years and 47% men. 94% were ischemic stroke patients and the median baseline NIHSS was 6. On average, this stroke cohort has 4.2 depressive symptoms. Mean scores of SIS domains were 62, 78, 74, 81, 60, 67, 56 and 59 for strength, memory/thinking, emotion, communication, mobility, ADL/IADL, upper extremity and participation, respectively, with 0 being the worst and 100 being the best. The baseline GDS scores (number of depressive symptoms) significantly correlated with strength; memory and thinking; communication; ADL/IADL; mobility; hand function; and social participation. Mean SIS domain scores were significantly different between subjects who were considered depressive (GDS ≥ 6) and subjects who were not depressive (GDS < 5) (all p < 0.0005). Mean scores of communication domain were significantly different between the two groups at the 0.0119 level.

Conclusions: Depressive symptoms affected more than just the physical aspects of functioning. They also restricted memory and thinking, communication, emotion and social participation.

Arterial stiffness and small vessel disease in patients with obstructive sleep apnea
Department for Vascular Neurology, Ljubljana Medical Center, Ljubljana, Slovenia; Department for Neurophysiology, Ljubljana Medical Center, Ljubljana, Slovenia

Background: Obstructive sleep apnea (OSA) is a common sleep disorder associated with increased body mass index, metabolic syndrome, hypertension etc. Stroke and in particular small vessel disease (SVD) is common in OSA patients. Pathophysiology of SVD is not well known. Increased arterial stiffness seems to play an important role. The aim of this study was to show that OSA is an independent risk factor for increased arterial stiffness. We hypothesized that patients with OSA have increased arterial stiffness compared to controls with similar cerebrovascular risk factors.

Methods: 32 subjects with OSA (average AHI 53.9) and 28 age and gender matched controls with similar risk factors were included. Common carotid artery stiffness was determined using β index. Magnetic resonance tomography of the head was performed in all patients and Fazekas scale was used to assess the stage of SVD.

Results: The two groups did not differ in cerebrovascular risk factors except for BMI (OSA: 35.0 ± 4.0 vs. controls: 31.2 ± 4.1) (p < 0.01). Less OSA patients had a normal MRI exam but the difference was not significantly different between subjects who were considered depressive (GDS 5) (all p < 0.01). Logistic regression model has shown a significant relationship between BMI and OSA but not between AS and OSA.

Conclusions: Arterial stiffness in OSA patients does not differ significantly from controls with similar risk factors. OSA patients frequently have small vessel disease but there is no significant difference compared to controls.

Milton Keynes General Hospital, Milton Keynes, UK; Histopathology, Milton Keynes General Hospital, Milton Keynes, UK

Background: CAA is caused by deposition of amyloid in the walls of small cortical and meningeal vessels. Clinical presentations include...
cognitive decline, cerebral haemorrhages and TIA like episodes. Early diagnosis is important to avoid catastrophic bleeding with antiplatelet or anticoagulant medication.

**Objective:** To demonstrate practical difficulties in diagnosis and management of CAA in patients with vascular risk factors.

**Patients and methods:** We present a case of pathologically proved CAA. Clinical presentation and investigation results are discussed.

**Results:** This gentleman initially presented to psychiatric services with memory problems at the age of 76. Brain MRI showed evidence of small vessel disease. Other vascular risk factors included hypertension, previous smoking and IHD. His medication included aspirin, clopidogrel, citalopram and ramipril. At the age of 79 he had a brief episode of language difficulties lasting for a few hours. One month later he developed a similar but longer episode. CT of the brain showed a right frontal subarachnoid haemorrhage. MRI of the brain 2 days later showed a further left superficial parietotemporal bleeding. Antiplatelets were stopped and the patient made a good recovery.

Further fatal intracranial bleeding occurred 2 months later. Pathological examination confirmed CAA.

**Conclusion:** CAA is common in older patients who may have other vascular risk factors. Cognitive impairment and changes on CT or MRI are often attributed to ischemic small vessel disease. This case demonstrates the importance of obtaining specialised MRI sequences in older patients before decisions are made on the use of several antiplatelet agents or oral anticoagulation.

**Conclusions:** Our first results show a favourable outcome of stroke patients with failure of iv thrombolysis successfully recanalised by thrombectomy.

doi:10.1016/j.jns.2013.07.950
stroke symptoms is an independent predictor of early stroke risk and provides prognostic information when included in the ABCD²–1 score. Little information exists on other MRI biomarkers for stroke risk.

**Objective:** We aimed to investigate the association between candidate new MRI biomarkers and early stroke risk in the Dublin BIO-TIA study.

**Patients and methods:** The BIO-TIA Study is a multi-hospital registry of TIA cases over a 5-year period. Patients with stroke-physician confirmed TIA and MRI within 72 h of TIA onset were included and followed prospectively for early recurrent stroke, confirmed by a stroke physician. Standardized blinded MRI assessment was performed by a neuroradiologist.

**Results:** 230 patients met inclusion criteria, of whom 14 had stroke. Early recurrence was associated with any acute DWI lesion (71.4% vs. 35.6%, p = 0.007, c-statistic = 0.68, OR = 4.53, CI = 1.27–14.87). Among candidate MRI biomarkers, 90-day recurrent stroke was associated with FLAIR Vascular Hyperintensity (16.7% vs. 3.4% in non-stroke patients, p = 0.03, c-statistic = 0.57, OR = 5.7, CI = 1.04–30.9), focal stenosis on intracranial MRA (25% vs. 3.7%, p = 0.01, OR = 8.8, CI = 1.22–63.1) and FLAIR chronic ischaemic lesions (28.6% vs 11.6%, p = 0.065).

**Conclusion:** In addition to acute DWI lesions, other MRI biomarkers were associated with stroke risk after TIA, including FLAIR Vascular Hyperintensity, focal intracranial stenosis, and FLAIR chronic infarcts. If validated, these non-DWI biomarkers may improve identification of patients at high early risk for intensive stroke prevention therapy in clinical practice or randomized trials.

**Perfusion computed tomography in the diagnosis of acute focal neurological symptoms: Ischaemic stroke vs. seizures**

K. Kubiač Balcerewicz, a J. Fiszer, a,b E. Nagańska, a C. Siemianowski, b A. Sobieszek, a A. Witak-Grzybowska, a A. Kosińska-Sztosa, a

**Medical Centre of Postgraduate Education, Warsaw, Poland; Independent Public Clinical Hospital in Warsaw, Warsaw, Poland**

**Background:** Mislauigning stroke may lead to unnecessary thrombolytic therapy. There are contradictory reports about the role of perfusion computed tomography (PCT) in differentiating stroke and seizures as causes of acute focal neurological symptoms.

**Objective:** To define the role of PCT in differentiating between those two conditions in acute setting.

**Patients and methods:** The study covered 35–85 year old patients with acute focal neurological symptoms, who underwent PCT and EEG within 12 h after symptoms onset. Presumptive ischaemic focus would be revealed in non-contrast CT in the 3rd day after symptoms onset or, when no CT changes appeared, in MRI. Neurological status was evaluated according to the National Institutes of Health Stroke Scale (NIHSS). Perfusion parameters were set up as asymmetry indices for corresponding regions of brain hemispheres. EEG was described in a 5-stage scale.

**Results:** Statistical analysis covered 17 patients with ischaemic stroke and 12 patients with focal neurological symptoms in the course of seizures. Those groups, taking potential effect of sex and age into account, were significantly statistically different for two parameters of PCT: MTT (mean transit time) and TTP (time to peak) in lateral middle cerebral artery territory (linear regression, p-value < 0.05). TTP revealed to be the most significant parameter (logistic regression, p < 0.05). Analyzed groups were not significantly statistically different in NIHSS evaluation (T-test, p-value > 0.05) and EEG (Mann–Whitney test, p-value > 0.05).

**Conclusion:** PCT may differentiate between ischaemic stroke and seizures as causes of acute focal neurological symptoms.

**The association of BclI gene polymorphism and −148C/T promoter β fibrinogen with plasma fibrinogen level in acute ischemic stroke**

A.B. Baharuddin, Neurology, Hasanuddin University, Makassar, Indonesia

**Background:** Stroke is a leading cause of disability and death. High fibrinogen levels are a risk factor for ischemic stroke and are associated with interaction of genetic and environmental factors.

**Objective:** To analyze the relationship of gene polymorphism BclI and −148C/T β fibrinogen with elevated levels of fibrinogen in acute ischemic stroke.

**Method:** This is a case control study with acute ischemic stroke patients and non-stroke in the Neurology Department of Dr. Wahidin Sudirohusodo Hospital, Makassar, Indonesia. The sample was determined based on their sex, age group, risk factor, and taken by consecutive sampling technique. All samples of stroke were conducted, fibrinogen level, DNA isolation, PCR and RFLP, using the HindIII and BclI restriction enzymes. Furthermore, these were analyzed by electrophoresis and sequencing.

**Result:** There were a total of 216 samples consisting of 106 stroke and 110 non-stroke patients. The average fibrinogen level of the sample group is 423.48 (SD ± 131.07) mg/dl, while in the control group was normal. There was significant correlation of high fibrinogen level and ischemic stroke with RO 16:50 (95% CI 7.72–35.26). The Chi-square analysis result proves that fibrinogen (cut off 375 mg/dl) plays a significant role in causing ischemic stroke (OR 16:50 p = 0000). The polymorphisms of BclI gene and of −148C/T have a correlation with stroke incidence (BclI gene: p = 0.000 and OR 2.16, as for −148C/T: p = 0.000 and OR 6.84).

**Conclusion:** BclI gene and −148C/T were significantly associated with an elevated plasma fibrinogen level, both genes are also risk factors for stroke ischemic events.

**Capability of navigated repeated transcranial magnetic stimulation in stroke rehabilitation (Randomized blind sham-controlled study)**

(A clinicaltrials.gov identifier: NCT01652677)

A. Cheryvakov, M. Piradov, L. Chernikova, M. Nazarova, V. Gnezditsky, N. Savitskaya, P. Fedin. Research Center of Neurology, Russian Academy of Medical Sciences, Moscow, Russia

**Background:** Among several noninvasive brain stimulation techniques repetitive transcranial magnetic stimulation (rTMS) demonstrates beneficial effect in motor recovery after stroke. The transcranial magnetic stimulation with MRI navigation (nTMS) permits to take into account individual brain anatomy and to repeat stimulation focally.

**Objective:** Examine effectiveness, safety and tolerability of different regimens of nTMS for stroke rehabilitation.
Patients and methods: The randomized blind sham-controlled study of repetitive nTMS of primary motor cortex for motor stroke rehabilitation was started. 22 patients have been recruited (mean age — 55.15 ± 8.77 years). Patients were randomly assigned to one of the four groups:

1) sham group (n = 4);
2) low-frequency stimulation group (n = 6);
3) high frequency stimulation group (n = 9);
4) both hemispheric stimulation: low-frequency to unaffected hemisphere than high-frequency to affected (n = 3).

For nTMS we used NBS exImia Nexstim and Magstim Rapid2. Clinical condition of patients was assessed with a set of scales before and after stimulation.

Results: Patients in the fourth group have significant better clinical output: Fugl-Meyer scale distinction — 27.00 ± 12.50 (p = 0.003, U-test). Preliminary results show the relief of the post-stroke spasticity and pain after high-frequency stimulation of the unaffected M1. Motor improvement was demonstrated for low-frequency stimulation of the unaffected M1. Headache appeared at 6 patients (27%) after stimulation which held itself. Four patients had an increase of epileptiform discharges on EEG (45%). Generalized epileptic seizure occurred in 2 patients (9%) during TMS.

Conclusion: Repeated nTMS is a safe and effective add-method in post-stroke rehabilitation, but continuous study and forming protocols are necessary to validate this method.

Clinical and radiologic imaging study of patients with ruptured and unruptured cerebral aneurysms submitted to the endovascular or microsurgical treatment
F.D. Lima, M.C. Vieira, A. Araújo Júnior, J.C.M. Rodrigues. Universidade do Estado do Pará, Belém, Brazil

Introduction: Endovascular therapy is an effective method to treat cerebral aneurysms due to it being a low invasive procedure and causes less complication than microsurgical technique, the standard approach.

Objective: Perform a clinical and radiologic imaging study of patients with ruptured and unruptured cerebral aneurysms submitted to the endovascular or microsurgical treatment.

Material and methods: Patients treated between 2001 January and 2009 December were analyzed through protocol including sex, age, subarachnoid hemorrhage presence or absence, aneurysm variety, size and more frequently localization, multiplicity, clinical complications regarding hemorrhage and embolization, associated diseases, dome-to-neck ratio, sort of treatment, retreatment, angiographic control and Fischer, Hunt–Hess and Glasgow Outcome scales. We studied 105 patients and discovered 146 aneurysms using transversal observational study. Statistic study has p < 0.05.

Results: Aneurysms were most common in the posterior communicating artery of women in the sixth decade. Patients submitted to the endovascular treatment had satisfactory evolution when analyzed by Glasgow Outcome Scale in 3 months and by angiographic control in 1, 3 and 5 years.

Conclusion: Endovascular therapy is an effective method comparing with microsurgery to therapeutic approach of cerebral aneurysms and its symptoms.

Tissular and motor analysis of neuroprotective and anti-inflammatory effects of copaiba oil (Copaifera reticulata Duclkea) after focal cortical ischemia
A.A.V.O. Sousa, F.D. Lima, A.A. Machado, M.O. Vera, L.M.P. Fernandes, R.R. Lima, C.D.S.F. Maia, Universidade do Estado do Pará, Belém, Brazil; Universidade Federal do Pará, Belém, Brazil

Background: Cerebrovascular diseases are a common cause of mortality worldwide and brain ischemia is its main manifestation, inducing a large variety of injuries and neurological processes.

Objective: Evaluate the antiinflammatory and neuroprotective effects of Copaiba oil, in tissue and motor preservation after focal ischemia in the motor cortex, with Endothelin-1 (ET-1).

Material and methods: 16 Wistar adult rats were distributed in groups of ischemia + tween (GIT), ischemia + Copaiba (GIC) and nonischemic (GNI), examined microscopically and by behavioral tests, with emphasis on locomotor activity, motor coordination and balance of the animals.

Results: Microinjection of ET-1 induced tissue loss, with necrotic features and tissue edema, accompanied by intense inflammatory response and ischemic penumbra area in the GIT animals. In GIC the reduction of inflammatory response, lesional edema and ischemic penumbra with tissue preservation were observed. Evaluated locomotor activity in the GIT noticed a significant reduction when compared to GNI (p < 0.0001). Comparing the GIC with the GIT, there was a statistically significant difference between the two groups (p < 0.0001). For the evaluation of GIC compared with GNI, a significant difference (p < 0.05) was found. In the evaluation of coordination and balance, the result reveals that the groups showed no statistical difference.

Conclusion: It was found that copaiba reduced the inflammatory response, with repercussions on the improvement of behavioral performance of the animals in locomotor aspect, setting it as a neuroprotective factor.

An ominous disease mimicking multiple sclerosis

Background: Multiple sclerosis is a CNS demyelinating inflammatory disease defined by clinical demonstration of disease dissemination in space and time, after excluding other etiologies that could explain the neurologic manifestations (2010 McDonald criteria). Paraclinical evidence (MRI, visual evoked potentials, CSF analysis) also support the MS diagnosis. The attempts to fulfill the criteria could mislead clinical investigation, forcing an equivocal MS diagnosis while disregarding the correct etiology.

Objective: To present a case of severe cerebrovascular disease first diagnosed as multiple sclerosis.

Case report: A 50-yr-old, hypertensive, smoker, Caucasian male was referred to our reference center for treatment of CNS demyelinating diseases for consultation. He had received the diagnosis of multiple sclerosis relapsing–remitting in the month before, and was sent to us for the purpose of human immunoglobulin therapy — since a 5 day course of methylprednisolone was ineffective. The neurological examination revealed severe ataxia of limbs and trunk, slighted decreased muscle strength, brisk deep tendon reflexes in all limbs and bilateral Babinski sign, left internuclear ophthalmoplegia, right hemifacial...
hypesthesia. He also exhibited frequent presyncopes when standing in upright position. The symptoms started around 50 days earlier, and were evolving. Five years before, he noticed episodes of sudden weakness of his left leg, with instantaneously improvement.

Gadolinium-enhanced brain MRI showed T2-hyperintense lesions in the inferior thalamus, cerebral peduncles, pons, cerebellum and a small periventricular lesion. Brain angiography pointed complete occlusion of basilar artery and irregular pericallosal arteries.

**Conclusion:** We reported a case of total basilar occlusion confounded with multiple sclerosis presentation.

**Ischemic stroke revealing a celiac disease: A case report and review of the literature**

N. Slimani, D. Hakem, B. Mansour, A. Berra

*Internal Medicine, Dr Mohammad-Lamine Debaghine Hospital, Bab El Oued University Hospital Center, Algiers, Algeria; *Radiology, Dr Mohammad-Lamine Debaghine Hospital, Bab El Oued University Hospital Center, Algiers, Algeria

**Objective:** To report a case of celiac disease ‘CD’ revealed by ischemic stroke.

**Case report:** A 38-year-old woman is investigated for ischemic stroke associated with generalized convulsive crisis which are stabilized by medical antiepileptic drugs. The examination does not show any sign of clinical call suggesting a disease thrombosis (systemic, neoplastic...). We noted an iron deficiency anemia (hemoglobin at 9 g/100 ml microcytic hypochromic anemia). The levels of calcemia, cholesterol, glyceria, prothrombin index, and albumin are normal. The cardiovascular morphological assessment (Holter ECG, echocardiography, Doppler of the supra-aortic trunks ‘SAT’) do not objectify any abnormalities (patent foramen ovale, stenosis, thrombosis...). In addition the homocysteinemia, C, S, and antithrombin protein levels are normal. Leiden factor’s mutation, antiphospholipid antibodies, anti nuclear antibodies, the flux cytometry etc. are without abnormalities. The anti-gliadin and antitransglutaminase of the type (IgA) antibodies are strongly positive and of this fact the diagnosis of the CD is established.

**Discussion:** The absence of cardiovascular diseases or the metabolic risk factor of young’s stroke and the negativity of the immunological assessment plead in favor of the existence of a causal link between the CD and the ischemic stroke. The most widely incriminated factor is autoimmune central nervous system vasculitis, in which tissue transglutaminase, the main auto-antigen contributing to maintaining the integrity of endothelium tissue, plays a major role like reporting in our observation.

**Conclusion:** Being a potentially treatable cause of stroke, CD disease must appear among the etiologies to seek in front of stroke of unknown cause especially in young patients.

**Sports-related ischemic stroke**

H. Delgado, S. Calado, M. Pinto, A. Lourenço, Neurology Service, Centro Hospitalar Lisboa Ocidental, Hospital de Ega Moniz; *Stroke Unit, Centro Hospitalar Lisboa Ocidental, Lisbon, Portugal

**Background:** Ischemic stroke symptoms installation during usual sports activity (Sports-related stroke) has been rarely reported, with only small case series in the literature.

**Objective:** Describe clinical cases of patients with acute stroke during installation during usual sports. We analyzed the clinical features, imaging and prognosis.

**Results:** We identified 3 patients (2 men) with a mean age of 54 years (47–59). First patient was 47 years old, with a history of hypertension, stroke during gym manifested by paresis of the left upper limb, in the ER with NIHSS 4, OSCP-PACI, TOAST indeterminate; outcome: mRS NIHSS 3 and 2. Second patient was 57 years old with a history of dyslipidemia, stroke during football practice manifested by imbalance and right hemiparesis, in the ER with NIHSS 13, OSCP-PACI, TOAST indeterminate; outcome: mRS NIHSS 5 and 2. Third patient was 59 years old, with a history of hypertension and dyslipidemia, stroke during running manifested by imbalance and right hemiparesis and global aphasia in the ER with NIHSS 17, OSCP-PACI, TOAST cardioembolic; outcome: mRS NIHSS 5 and 1.

**Conclusion:** Although our case series is too small, we can observe that patients had good functional recovery. It will also be taken into account that patients had low risk factors. We cannot correlate etiology with incidence or prognosis.

Survival of intracerebral hemorrhage in Chile. A population based register
V. Diaz a,b, I. Delgado a, S. Illanes a,b, J. Antinao a, V. Olavarri a, D. Carcamo c, P. Lavados b, aNeurology and Neurosurgery, Universidad de Chile, Independencia, Chile; bMedicine, Clínica Alemana de Santiago, Santiago, Chile

Background: The average incidence of intracerebral hemorrhage (ICH) is 25 per 100,000 inhabitants in the world; in Chile is 20 per 100,000. The mortality of hemorrhagic stroke is between 30 and 45%.

Objective: To study intrahospital mortality and survival of ICH through the country.

Method: Is a descriptive and ecological study of national discharge database from 2003 to 2007 from ICD-10 category I 61.0 (0 to 9) and I 62.9 of the National Health Ministry (MINSAL) and National Socioeconomic Survey (CASEN). A survival analysis estimated long term survival. Kaplan–Meier survival curves and Cox proportional hazard models were used to demonstrate predictors.

Result: 13,256 registered and 10,267 persons were identified, 93.6% had only one event. 37% died during the hospitalization, 44% the first day and 70% before five days. The survival is higher in female than in male (p = 0.02). The higher case-fatality rates are in IV, VI, VIII and Metropolitan regions (≥40 per 100,000). The lethality has been decreasing from 42.6% to 36.4%. The correlation of lethality rates was only with poverty (r = 41%, p = 0.0001).

Conclusions: The lethality was decreasing during the study period. Most of the patients died during the first five days, survival is higher in women.

doi:10.1016/j.jns.2013.07.964
was cutaneous myxoma. Though the patient met the diagnostic criteria for Carney complex, PRKAR1A sequencing was negative for the presence of mutations in the coding region and flanking intronic regions.

**Conclusion:** We report a case of cardioembolic ischemic stroke in a young patient leading to Carney complex diagnosis. Recognizing this rare situation is important since specific patient follow-up must be planned for early detection of potentially fatal tumors, including atrial myxoma.

**Topic:** 3 — Stroke

**Red blood cell distribution width (RDW) association with ischemic stroke among adults younger than 55 years**

**Background:** Red blood cell distribution width (RDW) measures the size variability of these cells. It has been recently reported as a novel independent marker of macrovascular disease, including stroke, even at normal range values.

**Objective:** Evaluation of RDW values in adults younger than 55 years presenting with ischemic stroke.

**Patients and methods:** All patients aged under 55 years and presenting with ischemic stroke during 2012 were enrolled. Socio-demographic information was registered before clinical examination in addition to RDW, cholesterol, triglycerides, smoking, alcohol use, presence of diabetes and arterial hypertension. Cases with anemia were excluded.

**Results:** 158 patients (133 males, 25 females), aged 16–55 years (mean 48.4 years, SD 7.22) presented with ischemic stroke. RDW values were 14.27% (SD 1.1%, normal range being 10–15%). No case presented with RDW under 12%. Cases were divided in quartiles: 9.6% had 12–13% RDW value (1st quartile), 30.8% had 13–14% RDW value (2nd quartile), 34.6% had 14–15% RDW value (3rd quartile), and 25% had >15% RDW value. Hypertension was present in 90 patients (57%). Diabetes was present in 42 patients (26.6%). 58 patients (36.7%) were smokers. 48 patients (30.9%) were alcohol users. Mean cholesterol level was 211.4 mg/dl (SD 66.71 mg/dl). Mean triglyceride level was 170.3 mg/dl (SD 95.32 mg/dl).

**Conclusions:** Adults under 55 years of age presenting with ischemic stroke have upper normal or over the range RDW values, therefore RDW may be of great help as a future risk marker for ischemic stroke, being a cheap and readily available clinical laboratory examination.

**Risk factors and etiology of ischemic stroke in young adults admitted to the stroke unit of Policlinico “Gemelli” of Rome**

R. Renna, F. Pilato, P. Proifice, V. Di Lazzaro.

**Background:** Approximately 10–14% of ischemic strokes occur in young adults.

**Objective:** To investigate risk factors and etiologies of young adults admitted to the “Stroke Unit” of Policlinico “Gemelli” of Rome from December 2005 to January 2013.

**Patients and methods:** 150 consecutive patients aged ≤50 years diagnosed with ischemic stroke. Clinical evaluation consisted of a complete neurologic examination and the National Institutes of Health Stroke Scale. Diagnostic work-up consisted of anamnesis, extensive laboratory, radiologic, and cardiologic examination. Stroke etiologies were classified according to the Trial of Org 10172 in Acute Stroke Treatment (TOAST).

**Results:** Patients’ mean age was 41 ± 8 years. The most common risk factors were dyslipidemia (52.7%), smoking (47.3%), hypertension (39.3%), and patent foramen ovale (32.8%). Large-artery atherosclerosis (TOAST 1) was diagnosed in 17 patients (11.3%). Cardioembolism (TOAST 2) was presumed in 36 patients (24%), most of them presented a PFO at transesophageal echocardiography. Small-vessel occlusion (TOAST 3) was diagnosed in 12 patients (8%); all of them were hypertensive and most of them presented additional risk factors. 41 patients (27.3%) presented a stroke of other determined etiology and 44 (29.3%) presented a stroke of undetermined etiology. 3-year survival was 96.8%; recurrent strokes occurred in only 3 cases.

**Conclusions:** Traditional vascular risk factors are very common also in young adults with ischemic stroke, but probably they increase the susceptibility to stroke being dependent on other causes, as TOAST 1 and 2 represent less than 20% of cases. Prognosis quad vitam is good, being characterized by low mortality and recurrence rate.

Optimum site for cTBS in stroke-patients: A quantitative evaluation
T. Matsuda, A. Manji, K. Amimoto, A. Inaba, Y. Nakajima, I. Nishimura, S. Watanabe, T. Hirashima, Y. Wada, Uekiwa Gakuen University, Chiba, Japan; Rehabilitation, Saitama-Misato Sogou Rehabilitation Hospital, Saitama, Japan; Tokyo Metropolitan University, Japan; Kanto Central Hospital, Japan; Nissan Tamagawa Hospital, Japan; Rehabilitation, The Jikei University School of Medicine, Tokyo, Japan

Background and objective: Continuous Theta Burst Stimulation (cTBS) is a new trans-cranial magnetic stimulation protocol that transiently alters cortical excitability in the human brain. We aimed to test the proper stimulation for the recovery of the target site.

Subjects and methods: Two stroke patients at the restorative stage (A: 68-year-old female; B: 74-year-old male) were treated with informed consent (Uekiwa Gakuen University and Nissan Tamagawa Hospital Ethics Committee approved the study). cTBS was applied to the non-affected side of M1 (hand, shoulder area) for 200 times consecutively for 40 s. Motor evoked potential (MEP) before and after cTBS was compared. The motion of the paretic arm was analyzed by motion capture method with Frame-DIASIV (DKH) software. The changes in angle and velocity of the movement of several U/E joints were measured.

Results: Both patients showed decreased MEP after cTBS. Patient A showed moderate improvement at the fingers but poor at the shoulder. cTBS targeting the fingers showed more effects than when targeting the shoulder. Of the fingers, the thumb had better outcome. Patient B showed moderate improvement at the shoulder but poor at the fingers by both stimulations targeting the fingers or shoulder. The targeting site of cTBS is not corresponding to the recovery site. The mechanism of the improvement is not only from regaining the affected M1 but also from the change of the spasticity, associated reaction and the other factors.

Conclusion: cTBS is a potential tool for the treatment to the stroke patients. Our results showed cTBS can regain the motor function through several mechanisms.

Topic: 3 — Stroke
Kinesiological evaluation after cTBS to contralesional motor cortex in restorative stage stroke patients
A. Manji, T. Matsuda, K. Amimoto, A. Inaba, Y. Nakajima, I. Nishimura, T. Hirashima, Y. Wada, Uekiwa Gakuen University, Chiba, Japan; Rehabilitation, Saitama-Misato Sogou Rehabilitation Hospital, Saitama, Japan; Tokyo Metropolitan University, Japan; Kanto Central Hospital, Japan; Nissan Tamagawa Hospital, Tokyo, Japan

Background and objective: Continuous theta burst stimulation (cTBS), is a repetitive trans-cranial stimulation technique that causes significant inhibition of synaptic transmission for over 1 h when applied to the primary motor cortex (M1). cTBS studies for the stroke related symptoms such as motor paralysis and neuropsychological dysfunctions at the chronic phase were reported. We aimed to investigate whether cTBS over the unaffected site of the M1 can induce an improvement of the upper arm at the restorative phase. For the evaluation of the improvement, the shoulder joint angle and velocity of the movement were measured by the motion capture analysis.

Subjects and methods: Five stroke patients (mean age: 74.9 yrs) were treated under the informed consent (Uekiwa Gakuen University and Nissan Tamagawa Hospital Ethics Committee approved the study). cTBS was applied to the unaffected side of M1. Paretic shoulder motion during flexion and abduction was analyzed with Frame-DIAS VI software. Baseline maximal angle and velocity prior to cTBS (600 stimuli, at 80% active motor threshold) or sham stimulation were set at 100 and post-stimulation change was calculated. Pre- and post-scores were compared by Mann–Whitney test.

Results: cTBS improved shoulder movements. In particular, cTBS significantly improved shoulder joint abduction angle and flexion velocity (p < 0.05).

Conclusion: The findings demonstrated the feasibility and efficacy of cTBS on the restorative stage recovery. Even at the restorative stage, the inhibitory effect of cTBS resulted in improved paretic arm movement with faster time and wider range. The results have important implications for the use of cTBS for stroke rehabilitation.

Topic: 3 — Stroke
Balance and gait measures as predictors of cognitive function in post-stroke patients
E. Ben Assayag, S. Shenhar-Tsarfaty, E. Kliper, H. Hallevi, L. Shopin, N.M. Bornstein, A. Korczyn, A. Mike, N. Giladi, A. Mirelman, A. Weiss, J.M. Hausdorff, Tel Aviv University, Tel Aviv, Israel

Background: Stroke patients are at risk for developing cognitive impairment. While motor function changes and decline in physical performance may precede the onset of cognitive impairment, it is not easy to identify which stroke patients are likely to develop cognitive impairment.

Objectives: To test whether quantitative balance and gait parameters can enhance the prediction of post-stroke long-term cognitive outcome.

Methods: The TABASCO is a prospective study of first-ever mild-moderate ischemic stroke patients who were cognitively intact at baseline. Quantitative movement, balance and cognitive tests were obtained at admission, 6, 12 and 24 months later.

Results: Data obtained from 211 patients. During 2 years of follow-up, 15.6% were found to have clinically significant cognitive decline (CD). The CD group and cognitively intact group did not differ in their neurological deficits 6 months after the index event. Nonetheless, at 6 months, timed up and go (TUG) test times were longer and Berg Balance Scale (BBS) scores were lower in the CD group, compared to the cognitively intact group (p < 0.001). Multivariate regression showed that the TUG and BBS below 45 were significant independent predictors of cognitive decline (p = 0.002 and p = 0.021, respectively).

Conclusions: Our results show that balance and mobility are significant predictors for cognitive status after stroke. Relatively simple, performance-based measures of balance and mobility may enhance the identification of patients who have a heightened risk of developing cognitive decline. Using these tests may enable early adaptation of rehabilitation strategies to delay the onset of cognitive decline and dementia in post-stroke patients.

The volume DWI method increases detectability of small ischemic lesions in patients with transient global amnesia
T. Yuasa1, K. Mutsukura2, Y. Nakao3, K. Ichinose3, I. Tomita3, H. Satoh4, A. Satoh5, M. Seto1, M. Ochi6, M. Tsujihata3. 1Neurology, Nagasaki Kita Hospital, Nagasaki, Japan; 2Radiology, Nagasaki Kita Hospital, Nagasaki, Japan; 3Research Institute for Neurointervention, Salzburg, Austria; 4Laboratory of Cerebral Infarction, RAMS, Moscow, Russia; 5Department of Neurology, St. Marianna University School of Medicine, Kawasaki, Japan; 6Department of Cerebrovascular Medicine, National Center Hospital, Nagasaki, Japan

Background: Transient global amnesia (TGA) is a clinical syndrome of reversible anterograde amnesia that occurs acutely. One of the possible causes of TGA is an ischemic deficit in the hippocampus.

Objective: We studied the acute ischemic changes in the hippocampus following TGA onset using magnetic resonance imaging (MRI).

Patients and methods: A total of 13 patients who visited our hospital within three days after the onset of acute amnesia were clinically diagnosed with TGA. The patients were evaluated using the conventional diffusion-weighted imaging (DWI) with a 6-mm slice thickness and the volume DWI method to generate three-dimensional images with 1.6-mm isotropic voxels.

Results: The initial MRI study of each patient was performed within three days after TGA onset. High signal-intensity lesions in the hippocampus were detected in six of the 13 patients (46.2%) on conventional DWI, and seven of 11 patients (63.6%) using the volume DWI method. Subsequent MRI studies were performed in six patients within two days after the initial MRI examination. In three patients, the volume DWI method revealed high signal-intensity lesions in the hippocampus that were not detected on the initial MRI examinations. The conventional DWI was unable to detect these lesions at the subsequent MRI examinations. Ultimately, we detected hippocampal lesions in 11 out of the 13 patients (84.6%).

Conclusion: The volume DWI method and repeated MRI examinations are useful for detecting small ischemic lesions in the hippocampus after TGA onset. The results suggest the presence of a relationship between TGA and hippocampal ischemic deficits.

Anxiolytic effects of 5-hydroxiadamantane-2-on under the conditions of local ischemia of brain in rats
V.S. Meliksetyan1, K.B. Alikhanyan1, A.G. Stepanyan1, A.A. Hakobyan2, A.M. Kukhtarova2. 1Clinical Pharmacology, Yerevan State Medical University after M. Heratsi, Yerevan, Armenia; 2Laboratory of Microrcirculation, The Institute of General Pathology and Pathophysiology RAMS, Moscow, Russia

Stroke is the most common life-threatening neurological disease, one of the major causes of death and disability worldwide. Prevalence of anxiety remains a common problem several years after the stroke. 5-hydroxiadamantane-2-on an adamantane derivative has cerebrovascular activity and improves cerebral blood flow by activating GABA-ergic system.

The aim of this study was to reveal and evaluate anxiolytic effect of 5-hydroxiadamantane-2-on after local ischemia.

White inbred male rats were used. Anxiety was evaluated by two main parameters of elevated plus-maze (EPM) test: percentage of entries to open arms (OA) and time spent on OA. As a model of acute local ischemia, the middle cerebral artery (MCA) occlusion was chosen. The control group didn’t receive any drug, while the experimental group has received 5-hydroxiadamantane-2-on immediately after MCA occlusion and on the following 6 days (100 mg/kg, i.p., once daily).

In both groups the neurobehavioral changes have been tested through EPM test a day before and on the 6th day after MCA occlusion. The percentage of entries to OA and time spent on OA of control group before occlusion were 27.25 ± 9.69 and 33.52 ± 3.86 and on 6th day — 19.38 ± 14.2 and 17.25 ± 11.1, respectively. For experimental group the percentage of entries to OA and time spent on OA were 12.55 ± 7.1 and 21.0 ± 5.8 before occlusion and 36.66 ± 9.12 and 69.0 ± 22.33 on the 6th day.

Thus, the results have shown that 5-hydroxiadamantane-2-on displays anxiolytic-like effect in animals with anxiety caused by local ischemia and can be suggested for further investigation of its anxiolytic activity.

Correlation between anti-thrombotic drugs and hematoma expansion in acute intracerebral hemorrhage under strict blood pressure-lowering management: SAMURAI-ICH study
H. Akiyama1, Y. Hasegawa2, M. Koga3, H. Yamagami1, S. Okuda4, Y. Okada5, K. Kimura6, Y. Shiokawa7, J. Nakagawara8, E. Furui9, K. Kario10, K. Toyoda11. 1Department of Neurology, St. Marianna University School of Medicine, Kawasaki, Japan; 2Department of Cerebrovascular Medicine, National Center Hospital, Kawasaki, Japan; 3Department of Cerebrovascular Medicine, National

Background: Endovascular mechanical recanalization (EMR) is the most effective therapeutic strategy regarding large artery occlusion in stroke. Advanced age has been identified as one of the strongest predictors of poor outcomes.

Objective: The aim of this study is to analyze the clinical outcomes after thrombectomy in elderly patients in comparison to younger ones.

Methods: Patients treated with EMR were registered prospectively. Patients eligible for treatment received either intravenous thrombolysis (IVT) as a bridging concept and/or intra-arterial thrombolysis (IAT) in addition to EMR. Outcome parameters and recanalization of the occluded vessels were documented using the National Institutes of Health Scale (NIHSS), the modified Ranking Scale (mRS) and the Thrombolysis in Cerebral Infarction (TICI) score, respectively. Follow-up evaluations were performed up to 90 days. Patients were divided into three groups: age ≤60 (n = 53); age 60–79 (n = 92); age ≥80 (n = 33).

Results: The baseline NIHSS score of all patients was 18. TICI 2b and TICI3 were documented in 70% of patients <60, in 74% of patients 60–79 and in 70% of patients ≥80. At 90 days follow up we documented 59% for patients who aged <60, 39% for patients who aged 60–79 and 18% for patients who aged ≥80 with mRS ≤2. The highest mortality rate was documented in patients aged ≥80.

Conclusion: Recanalization results were equal in all patient age groups. Despite a higher mortality rate, successful revascularization is strongly associated with improved outcome in elderly stroke patients treated with thrombectomy.

Background: Few reports have documented the effect of pretreatment of anti-thrombotic agents on hematoma expansion in patients with intracerebral hemorrhage (ICH) under strict blood pressure-lowering management in the acute phase.

Methods: Patients (n = 211) with hematoma in the supratentorial region were enrolled. Continuous intravenous administration of the anti-hypertensive drug nicardipine was commenced within 3 h of ICH onset at 10 hospitals in Japan, and systolic blood pressure was controlled between 120 and 160 mm Hg. The correlation between pretreatment of anti-thrombotic agents and hematoma expansion (growth volume and rate 24 h after admission) was analyzed.

Results: Subjects (n = 211; 81 females, mean age, 65.6 ± 12.0 years) had a median NIHSS score on admission of 13. Twenty-four patients were taking anti-thrombotic agents on admission, 14 aspirin alone, 1 aspirin + dipyridamole, 2 aspirin + clopidogrel, 2 ticlopidine alone, 2 clopidogrel alone, and 2 warfarin. When divided into 3 groups according to hematoma volume on admission (≤3.0 ml, 3.1–11.9 ml, >11.9 ml), a significant difference (p = 0.008) was observed between patients with and without pretreatment of anti-thrombotic agents (mean growth volume 24 h after admission: not taking anti-thrombotic agents, 4.73 ml; taking anti-thrombotic agents, 12.15 ml) only in the 3rd tertile group (volume >11.9 ml). By three months after discharge, four deaths unrelated to anti-thrombotic agents had occurred.

Conclusions: Pretreatment of anti-thrombotic agents is likely significantly related to hematoma expansion in ICH patients with higher hematoma volume (>11.9 ml) on admission under strict blood pressure management in the acute phase.

A case of acute cerebral infarction in young adult associated with the polycythemia vera

I.S. Ahn, Neurology, Dong-Eui Medical Center, Busan, Republic of Korea

Background: Several primary hematologic disorders have been associated with ischemic stroke. The main cause of stroke in the hematologic disorders is coagulopathy or thrombosis.

Purpose: We report one patient of acute cerebral infarction associated with polycythemia vera.

Patients and methods: A 44-year-old man admitted to our hospital was complaining of left extremity weakness. His symptoms occurred suddenly 2 days ago. He had been well before admission and his past medical history was unremarkable. He had no history of any medical or neurological illness. Vital sign was stable at admission. In the neurological examination during admission, he was alert and well oriented. In motor examination, left hemiparesis was Medical Research Council(MRC) grade 3. He had no sensory abnormality and no ataxia. Diffusion weighted imaging showed hyperintense signal on right MCA territory. Brain CT angiography showed no evidence of definitive intra and extra cranial aneurysm or stenosis. Laboratory studies revealed normal serum electrolytes and renal function except for elevated hemoglobin, which shows decreased erythropoietin. An ultrasound scan of the abdomen revealed splenomegaly and mild fatty liver. PBS revealed moderate polycythemia. Phlebotomy and BM biopsy were performed. Then he was diagnosed with polycythemia vera. He took hydroxyurea 500 mg bid daily.

Results: Based upon clinical manifestation and radiologic findings, we diagnosed right middle cerebral artery infarction. Laboratory studies and bone marrow biopsy revealed polycythemia vera.

Conclusions: The case presented herein is characterized by an association between acute cerebral infarction and hematologic disorder. We should be curious of other causes except for cerebral atherosclerosis when young adult patient without other risk factors was diagnosed with ischemic infarction.

Swallow therapy for dysphagia

A. Malik, S. Azam, T.T. Latifi, S. Noureen, A. Neuro Clinic & Falij Care, Pakistan; Liaquat National Hospital, Pakistan; Department of Neurology, Liaquat National Hospital, Karachi, Pakistan
Swallowing disorder is a difficulty in moving food from mouth to stomach. After any cerebrovascular accident, 90% of patients encounter some form of swallowing disorder. Swallow therapy techniques reduce any delay in triggering the oral, pharyngeal swallow & improve pharyngeal transit time. Therapy procedures were designed to improve five areas of swallowing.

- Position of food in mouth
- Manipulating food in the mouth with tongue
- Chewing the bolus of varying consistencies
- Recollecting bolus in oral cavity
- Organizing lingual action to propel the bolus posteriorly.

Case: A 57 years old male patient came with a history of pontine infarct 15 days back, complaining of slurring of speech and dysphagia. He was fed by NG tube.

MRI findings: Acute pontine infarct
Barium swallow: Right pyriform fossa pooling.
Dysphagia assessment: A detailed assessment of swallowing revealed:
- Delayed bolus transit time.
- No anterior and posterior propulsion
- Food residue after eating
- Gurgly and wet voice quality
- The patient had pharyngeal dysphagia with all diet and liquid levels.
- Frequency of therapy was decided four times a week.

Treatment plan: Therapy plan consists of three important techniques
- Oral motor stimulation, postural maneuvers and diet modifications.

Result: With the help of these techniques he was able to take partial oral feed within one week. After 2 weeks he was able to take regular food but felt a little difficulty in thin liquid diet. This clearly shows that swallow therapy works well for patients who have difficulty in swallowing.

Silent cerebral infarctions and MR perfusion imaging in children with sickle cell anemia
M. Arkuszewski1,2, J. Krejza3, R. Chen1, M. Bilello2, E.R. Melhem2.
1Department of Neurology, Medical University of Silesia, Katowice, Poland; 2Department of Radiology, Division of Neuroradiology, University of Pennsylvania, Philadelphia, PA, USA; 3Department of Diagnostic Radiology & Nuclear Medicine, University of Maryland School of Medicine, Baltimore, MD, USA; 4Al-Imam Muhammad Ibn Saud Islamic University, Riyadh, Saudi Arabia

Objectives: Children with sickle cell anemia (SCA) and clinically “silent” cerebral infarcts (SCI) have poorer academic performance and lower intelligence quotients compared to healthy peers, and are at higher risk of stroke. Mechanisms that lead to SCI, however, remain poorly understood. Here we determined whether occurrence and volume of SCI in a neurologically intact children with SCA who did not have intracranial stenosis were related to alterations in cerebral blood flow (CBF).

Methods: We studied prospectively a cohort of 62 children with SCA without prior clinically overt stroke or TIA (median age, 8.8 years; range limits, 2.3–14.4 years; 33 females) and mean velocity <170 cm/s on transcranial Doppler ultrasound. They underwent MR-angiography of intracranial arteries, anatomical MR-imaging and continuous arterial spin labeling (CASL) MR-perfusion imaging of the brain.

Results: We found silent infarcts in 20 children (32.3%, 95% CI: 21.9–44.7%). The median volume of SCI in relation to total brain volume was 0.020% (range limits, 0.001–0.101%). Total CBF mean value was 81 ± 18 ml/100 g/min. CBF in the right hemisphere (79 ± 19 ml/100 g/min) was significantly lower than in the left hemisphere (82 ± 18 ml/100 g/min, p = 0.025). Low CBF was associated with high volume of SCI (p = 0.042; F = 4.33; R² = 0.07). Low hemispheric CBF was associated with high occurrence (p = 0.021; ρ² = 0.036), number and volume of SCI (Spearman R = −0.199, p = 0.027 and R = −0.210, 0.021 respectively). Also, systolic blood pressure was an independent predictor of high occurrence of SCI and their bigger volume.

Conclusion: High occurrence of SCI and their bigger volume are associated with low CBF and high systolic blood pressure in children with SCA.

The effect of nasogastric tube in stroke patient with swallowing disorder
R. Chobchuen, P. Wattanapan, P. Keithmaleesatti, A. Srikhan, N. Sangjuan. Khon Kaen University, Khon Kaen, Thailand

Background: Nasogastric (NG) tube is common route of feeding in stroke patient with swallowing problem. The size of tube has an effect on both patient and food passage.

Objective: To determine the effect of NG tube size on feeding in stroke patient.

Material and methods: A randomised cross-over study was conducted among 10 stroke patients (eight male, median age 66 years) in rehabilitation ward, Sirinarind hospital. All participants were fed via small-bore tube (10 F) and large-bore tube (14 F) for separate session (7 days for each session). Total feeding time, the event of tube obstruction, and patient satisfaction were recorded.

Results: Despite reports of patients being more comfortable in using small-bore tube, there was no significant difference between tube sizes in satisfaction (P = 0.13). There were 4 patients who experienced tube obstruction during placing of small-bore tube, whereas no report of obstruction in those placing large-bore tube. Median feeding time was longer while feeding via small-bore tube (49 min VS 29 min, P = 0.03).

Conclusion: Small-bore NG tube (10 F) may be used to improve patient comfort. Modified diet and well drug preparation should be used to reduce tube obstruction.

Vascular risk factors predisposing to white matter hyperintensities: Cross-sectional study
A. Amintaeva1, M. Kravchenko1, O. Andreeva1, Y. Varakin1, G. Gornostaeva1, M. Prokopovich1, E. Gnedovskaya1, R. Konovalov1, M. Krotenkova1, N. Lazareva2, E. Oshepkova2. “Research Center of Neurology, Russia; 1Russian Cardiology Complex, Moscow, Russia

Objective: To analyze risk factors predisposing to white matter hyperintensities (WMH) in patients.

Methods: 284 participants (mean age 50 +/− 5) were enrolled from local community and stratified into two groups: group 1 (without
WMH) and group 2 (with WMH), MRI studies were done on 1.0 Tesla (Philips panorama) with a slice thickness of 0.5 cm; T1 and T2, T2d—fluid attenuated inversion recovery (FLAIR) scans were reviewed.

Results:
Group 1 was consisted of 193 participants (age 48 ± 5; 124 women and 69 men).

Group 2 included 91 participants (age 53 ± 5; 55 women and 36 men).

Participants from group 2 were significantly older (p < 0.02).

The analysis for risk factors showed the prevalence of these factors in group 2 vs group 1, respectively: coronary artery disease (CAD) (11% vs 4%, p = 0.03); Diabetes Mellitus (DM) (6% vs 1%, p = 0.005); arterial hypertension (AH) (60% vs 33%, p = 0.007); and family history of vascular diseases (CVD) (25% vs 14%, p = 0.03) were associated negatively without WMH participants.

Thus, CAD, AH, DM and family history of CVD were significantly more common in participants with WMH.

Participants in group 2 were noticed to have AH grade 1 (140–159/90–99 mmHg) more often than were participants in group 1 (30% vs 19%, p < 0.05).

There was found no significant difference in prevalence of smokers and cardiac arrhythmia between the two groups (30% vs 28%, p > 0.5) and (1% vs 2%, p > 0.5).

Conclusion: We found that in our patient cohort WMH were associated with cardiac ischemia, diabetes, arterial hypertension, and family history of vascular diseases.

A Brain-Computer Interface for rehabilitation after stroke
R. Ortner, A. Schnürer, M. Bruckner, C. Guger. g.tec medical engineering Gmbh, Guger Technologies OG, Schiedlberg, Austria

Brain-Computer Interface (BCI) technology has not only been used widely for communication but also for control purposes in a closed loop setup [1]. Recently, it has been shown that exercising motor imagery (MI), i.e. the mental rehearsal of movement execution, could be used as an effective therapy in stroke rehabilitation [2] even if no feedback about the performance is given to the user. However, when providing additionally a real-time feedback, the Hebbian plasticity can be elicited that is likely to result in an increased cortical plasticity, and has the potential to improve the functional recovery.

In this manuscript a MI based Brain-Computer Interface (BCI) is connected either to an upper limb rehabilitation robot or a Virtual Reality (VR) system. Both, the VR system and the rehabilitation robot provide online feedback about the performed MI to the user. A total of eleven post-stroke patients and a control group of eleven healthy people took part in the VR based experiment and the first results on 4 healthy users performing the experiment with sensory feedback from the rehabilitation robot are available. Additionally, five of the stroke patients agreed to participate to further sessions, allowing to observe the possible improvements in accuracy due to training effects.

Vestibular evoked myogenic potentials in cerebellar and brainstem strokes
F. Gulec¹, N. Celebisoy², Y. Zorlu². ªNeurology, Izmir Tepecik Education and Research Hospital, Turkey; ªNeurology, Ege University Faculty of Medicine, Izmir, Turkey

Objective: Cervical vestibular evoked myogenic potential (cVEMP) is a short-latency myogenic response recorded over the sternocleidomastoid muscle (SCM) in response to saccular stimulation. The aim of this study was to make recordings in patients with brainstem and cerebellar strokes to see how lesions involving vestibular nuclei or the vestibulo-cerebellar connections affect the potentials.

Method: 20 patients with brainstem and cerebellar strokes were included in the study. Patients were seated on an armchair and the reference electrode was placed on the upper third of sternum and the ground electrode on the middle of the forehead. To record the surface EMG activity, an active electrode was placed on the upper half of the SCM ipsilateral to the stimulated ear. The latencies of peaks p13 and n23 and peak-to-peak amplitude of p13-n23 were measured and compared with the potentials recorded from 50 healthy controls.

Results: cVEMPS were recorded in all healthy controls and in 17 patients from both SCM muscles. p13, n23 latencies and p13-n23
amplitude recordings of these patients were not different from the healthy controls. In a patient with cerebellar stroke the potential from the ipsilateral SCM was absent. In two other patients (one with cerebellar and the other with lateral medullary infarction) contralesional responses showed latency and amplitude abnormalities.

**Discussion:** Normal responses recorded in most patients with vestibular nuclear or vestibulo-cerebellar lesions or contralesional abnormal responses cast doubt on the known pathways involved in the generation of the cVEMPs and necessitate further studies to understand the anatomical connections.

**Early recurrent ischaemic stroke (ERIS) — under recognised cause of early neurological deterioration (END) in stroke patients undergoing thrombolysis**

N. Keshavan, A. Asokanathan, L. Sekaran. *Luton & Dunstable Hospital NHS Trust, UK; Geriatric/Stroke, Luton & Dunstable Hospital NHS Trust, Luton, UK*

**Introduction:** ERIS is a rare cause of END associated with intravenous thrombolysis. We present a case with ischaemic stroke with sudden neurological deterioration resulting in a new vascular territorial infarction during thrombolysis.

**Case:** A 67 year old gentleman with left-sided hemiplegia and dysarthria. Risk factors included atrial fibrillation and hypertension. NIHSS score was 16. CT scan revealed a right Middle Cerebral Artery (MCA) hyperdense sign. Just after the completion of thrombolysis, GCS dropped from 13 to 3 and NIHSS rose from 16 to 25. An urgent CT scan revealed a new left MCA hyperdense sign. MRI head showed extensive infarction encompassing both MCA, the left anterior and posterior cerebral artery territories and left pons. ECHO did not show thrombus in the heart. Intensive care treatment was withdrawn and patient subsequently died.

**Discussion:** The pathophysiological mechanism of ERIS is thought to be related to destabilisation of thrombus by tPA and a consequent release of emboli from a more proximal vascular location towards the brain. The incidence and prognosis of ERIS documented in the literature is poor. The incidence ranges from 0.2% to 1.0%. An evaluation of risk is impossible in the absence of clear characterisation, implying a need for larger scale multicentre data. In future, if we evaluate the risk, endovascular treatment can be utilised in treating ERIS in high risk cases.

**Conclusion:** Our case suggests AF is a risk factor for developing ERIS. Increased awareness and risk evaluation of ERIS would allow clinicians to consider endovascular treatment in future.

**Distribution of the corticobulbar tract in the internal capsule**

J.H. Kim. *Department of Neurology, Dementia Center, Ilsan Hospital, National Health Insurance Corporation, Koyang-Shi, Republic of Korea*

**Background and objectives:** It is generally thought that the corticobulbar tract descends through the genu of the internal capsule (IC). There have been several reports that genu lesions cause bulbar symptoms such as facial palsies, dysarthria, and dysphagia. However, the precise location of the corticobulbar tract in the IC remains controversial. The purpose of our study is to assess whether the corticobulbar tract passes through the IC genu.

**Methods:** We reviewed 26 patients with selective IC infarction and located the sites related to bulbar symptoms. In addition, using diffusion tensor imaging, we reconstructed tracts passing through the IC in ten subjects without cerebral infarction.

**Results:** Patients with genu infarction, which extended to more than half of the posterior limb of the IC, showed bulbar symptoms. However, patients with genu infarction, which was limited to the genu, did not have bulbar symptoms. In contrast, patients with lesions limited to the posterior limb may show bulbar symptoms. According to statistical maps of the region of interest, the lesions related to bulbar symptoms were localized to areas that were beyond the midpoint of the posterior limb of the IC. In diffusion tensor imaging of subjects without cerebral infarctions, the corticobulbar and corticospinal tracts did not pass through the IC genu.

**Conclusion:** Our data provide evidence that the corticobulbar tract does not pass through the IC genu. The proposed location of the corticobulbar tract in the level of the IC lies beyond the midpoint of the posterior limb.

Acute ischemic stroke, classification in terms of ethiopathogenesis, correlation between neuroradiological, clinical and prognostic findings
A. Gülte,1 G. Uncu1, H. Şirin2, S. Çiftçi4, A. Sağdıgyu Kocaman1,2, M.C. Cullu5,1,2, 1Neurology, Ege University Faculty of Medicine, Izmir, Turkey; 2Neurology, Acibadem Maslak Hospital, Istanbul, Turkey; 3Radiology, Ege University Faculty of Medicine, Izmir, Turkey

Background: Determination of ‘core’ which is defined as centre of ischemia, in other words tissue around the irreversible one and with the early diagnosis and emergent therapy that can be saved, causes an evident regression in mortality and morbidity because of the stroke. Besides the diagnosis, determining reperfusion signs at the perfusion imaging is useful to clarify the prognosis of stroke subtypes during the monitoring patients with acute stroke. Causative Classification of Stroke is a standardized and reliable program which is organized by Harvard University. Everybody can reach this program by internet.

Objective: Our purposes were interpreting the correlations between DWI/PWI MRI mismatch methods and ethiological factors, an effect of this correlation on clinical findings and prognosis.

Material and methods: Totally, 30 patients with acute ischemic stroke were involved in the study. Cranial MRI imaging DWI/PWI MRI mismatch methods and clinical measurements that were determined by NIHSS and Glasgow outcome scale were performed three times at first 24 h, at 48 h and at discharge. CCS forms were filled with whole clinical and laboratory findings. rCBV, rCBF, and rTTP mapping were done with perfusion MRI.

Results: End of the study deficit areas on rCBV map was found to be effective on prognosis of patients. rTTP maps were used in the calculation penumbra. Also we detected that more meaningful prognostic results may be obtained with rCBV maps.

Conclusion: Early diagnosis and treatment of the disease affect the patient’s quality of life significantly. Perfusion studies can be useable to appropriate patient selection eligible for thrombolytic therapy.

ICT-supported CVD prevention through phone-based automated lifestyle coaching
D.W. Droste2, D. Vittore1, L. Spassova1, N. Rösch1, 1Department of Neurology, Centre Hospitalier de Luxembourg, Luxembourg; 2SANTEC, Public Research Centre Henri Tudor, Luxembourg, Luxembourg

The development and maintenance of a healthy lifestyle (smoking cessation, healthy nutrition, moderate physical exercises etc.) is a major objective concerning the primary and secondary prevention of CVD. CAPSYS is a computer-based lifestyle coaching system, which aims at supporting CVD patients in performing appropriate behavior changes in order to minimize their individual risk factors. Patients can access CAPSYS by dialing a local-rate telephone number and answer to a set of previously known questions concerning their current nutrition, physical activity, blood pressure, smoking etc. In an interactive voice response approach, questions are issued by the system in natural language using a text-to-speech module, and the patient can provide the required values using the phone keypad (DTMF touchtone). Based on the gathered values for each patient, the system automatically generates personalized verbal feedback at runtime and presents it to the patient during the phone dialog. Depending on the individual development of the patient’s risk factors, the system feedback can contain advice for improvement, praise for healthy behavior and motivation to pursue a certain goal.

The automated feedback is generated based on rules derived from the guidelines of the Luxembourg Conseil Scientifique for prevention of cerebro-cardiovascular diseases and obesity. CAPSYS has been developed by researchers from the Public Research Centre Henri Tudor in Luxembourg in collaboration with neurologists from the Centre Hospitalier de Luxembourg (CHL). Currently, the user acceptance and efficacy of the system is being evaluated in a six-month randomized controlled study with eligible participants recruited at CHL’s neurology department.

Epidemiology of stroke in a teaching hospital in subsaharan africa: 3 years prospective study in douala, cameroon
Y.N. Mapoure1, B.C. Tchaleu1, H.B. Mbatchou Nghane1, G.N. Mouunjoupo2, A.Y. Mefire2, G. Behiya3, A.K. Njannshi2, H.N. Luma4, A.S. Mouelle5, 1Clinical Sciences, Faculty of Medicine and Pharmaceutical Sciences, Cameroon; 2Douala General Hospital, Cameroon; 3Clinical Sciences, University of Douala, Douala, Cameroon; 4Intensive Care Unit, Faculty of Medicine and Pharmaceutical Sciences, University of Douala, Douala, Cameroon; 5Neurology, Faculty of Medicine and Biomedical Sciences, University of Yaoundé I, Yaoundé, Cameroon; 6Internal Medicine, Douala General Hospital, Douala, Cameroon

Background: Stroke is the leading cause of hospitalization in neurology but epidemiological data for this condition are scarce in Cameroon.

Objective: Describe the epidemiology of stroke in a tertiary hospital in Cameroon.

Patients and methods: We carried out a prospective study from 1st January 2010 to 31st December 2012 at the Douala General Hospital in 2 sites: the neurological unit (NU) and the intensive care unit (ICU). All patients admitted for confirmed stroke were included consecutively. Socio-demographic, clinical and paraclinical data were collected.

Results: 318 patients presented with stroke (252 in the NU and 66 in the ICU) with a mean age of 58.84 ± 13.04 years; 38.1 were female. The major risk factor before stroke were high blood pressure (69.6%), alcohol consumption (28%), diabetes mellitus (20.4%), tobacco (16%), heart disease including atrial fibrillation (11.3%), dyslipidemia (8.5%), HIV infection and sleep apnea constituting each 3.1%. The mean delay for consultation was 27.19 ± 97.52 h. 53.8% had an ischemic and 46.2% a hemorrhagic stroke. The mean duration of hospitalization was 10.56 ± 23 days with a global mortality rate of 26.4% (13% in the NU).

Septic conditions were the leading cause of death.

Conclusion: Fighting vascular risk factors by informing and screening the population should be emphasized in our context in order to reduce the burden of stroke.

Metabolic burden and intracranial atherosclerotic disease in an asymptomatic population
B.-S. Kim1, H.-S. Jung1, Y.H. Choi1, 1Department of Neurology, Samsung Medical Center, Sungkyunkwan University School of Medicine, Republic of Korea; 2Center for Cohort Studies, Total Healthcare Center,
Background: To date, few data are available with respect to intracranial atherosclerotic disease (ICAD) in general population. This study examined whether metabolic abnormalities, metabolic syndrome (MetS) and non-alcoholic fatty liver disease (NAFLD), are surrogate markers for intracranial atherosclerotic disease (ICAD) among apparently healthy population.

Methods: Over 3 years, study data were collected on subjects who underwent a comprehensive health check-up. The presence of ICAD was ascertained based on the findings of brain MRA, and the diagnosis of NAFLD was made by liver ultrasound work-up. Finally, 6146 subjects without a previous stroke history (mean age, 54.7 ± 8.9 years; male, 70.5%) were enrolled in this study.

Results: The prevalences of MetS, NAFLD, and ICAD were 46.4% (n = 2853), 23.8% (n = 1460), and 4.6% (n = 282), respectively. After the adjustment for atherosclerosis risk factors, NAFLD (OR: 1.89, 95% CI: 1.45–2.46) and MetS (OR: 1.50, 95% CI: 1.14–1.96) were independently associated with increased risk of ICAD. In addition, the number of individual components of metabolic syndrome was associated with the risk of ICAD in a dose-response manner.

Conclusions: The present study suggested that the detection of NAFLD and metabolic syndrome in an asymptomatic population was independently associated with the increased risk for ICAD; however, further prospective studies would be needed to confirm our findings.

doi:10.1016/j.jns.2013.07.991
correlation with the BMI, but without establishing one with the IMT. 34% of the stroke patients were smokers, whereas 27.1% of their relatives smoked; the relative risk of stroke for relatives was over 2 times higher for smokers than for non-smokers. Although in both groups the value of the IMT was high (0.91–0.97 mm), there was no statistical significance \( (p > 0.05) \). IMT was correlated to almost all the other parameters measured.

**Conclusion:** In our study the IMT was correlated with atherosclerosis and obesity markers, but had no statistical significant value as an independent risk factor for cerebrovascular disease in first degree relatives of stroke patients.

**Objective:** The role of statins for aneurysmal subarachnoid hemorrhage remains confusing. The relevance of different end points was evaluated to discuss the role of statins.

**Methods:** Systematic literature retrieval was carried out to obtain studies of randomized controlled trials researching on statins for aneurysmal subarachnoid hemorrhage before March 2013. Data extraction and quality evaluation of studies were performed by 2 investigators. A meta-analysis was performed by RevMan 5.2.3.

**Results:** 7 RCTs with 347 patients which met the inclusion criteria were included in the meta-analysis. The results showed statins did not delay the time to vasospasm or delayed ischemic neurological deficit from ictus, or shorten duration of vasospasm in clinical practice, but reduced 22% vasospasm on transcranial Doppler \( (RR = 0.60; 95\% CI 0.42 to 0.86, P = 0.005) \), 26% delayed ischemic neurological deficit \( (RR = 0.48; 95\% CI 0.32 to 0.70, P = 0.0002) \), and 10% mortality in hospital \( (RR 0.54; 95\% CI 0.32 to 0.91) \) compared to the placebo group.

**Conclusion:** It might be a choice that acute statins treatment is for aneurysmal subarachnoid hemorrhage, but the role was limited. Further large scale, well-designed RCTs on this topic are still needed.

**Obstructive sleep apnea and ischemic stroke**

N. Chtaou\(^a\), O. Messouaka\(^b\), F. Belahsen\(^b\). \(^a\)University Hospital of Fez, Morocco; \(^b\)Hassan II University Hospital, Fez, Morocco

**Background:** The obstructive sleep apnea syndrome (OSAS) is a chronic respiratory disorder which is at present a real public health problem because of its cardiac and vascular side effects.

**Objective:** The purpose of the study is to detect OSAS in patients with ischemic stroke to optimize secondary prevention.

**Patients and methods:** This is a prospective study of 50 patients suffering from ischemic stroke admitted to the Neuro-vascular unit of the University Hospital Hassan II of Fez in whom nocturnal oximetry was performed in search of OSAS, polysomnography is supplemented by the following if nocturnal oximetry appears abnormal. The exclusion criteria of the study were: disorders of consciousness, oxygen saturation of less than 95%, and obstructive lung disease.

**Results:** The average age was 60.6 years, the sex ratio (M/F): 1.38. In 50 patients recruited 13 patients (26%) had abnormal nocturnal oximetry. Polysomnography was applied systematically in 13 patients. The review has been performed in 8 patients and OSAS was confirmed in 6 patients and the syndrome of mixed sleep apnea (obstructive and central) in 2 patients. In 13 patients, snoring was found in 46% of cases, hypertension in 46% and diabetes in 30.7%.

**Conclusions:** Screening for obstructive sleep apnea syndrome appears an important issue in the treatment of ischemic stroke to reduce the morbidity associated with ischemic stroke.

**Eicosapentaenoic acid prevents cerebral vasospasm after aneurysmal subarachnoid hemorrhage: A meta-analysis**

B.F. Zhang, J.N. Song, H.C. Zhai, X.H. Luo, L.X. Bai, T.Q. Huang, X.D. Ma. Department of Neurosurgery, First Affiliated Hospital of Medical College, Xi’an Jiaotong University, Xi’an, China

**Background:** In recent years, studies have shown that eicosapentaenoic acid has multiple effects: including reduced platelet aggregation, plaque stabilization, vasodilation and anti-inflammation, could reduce the recurrence of stroke. Studies in vitro have shown that eicosapentaenoic acid inhibited the SPC-Rho-kinase pathway, without affecting the calcium dependent vascular smooth muscle contraction. In vivo model of cerebral vasospasm also found that eicosapentaenoic acid could be used for adjuvant therapy preventing cerebral vasospasm after aneurysmal subarachnoid hemorrhage.

**Objective:** To systematically evaluate the curative effectiveness and safety of eicosapentaenoic acid preventing cerebral vasospasm after aneurysmal subarachnoid hemorrhage.

**Studies and methods:** Systematic literature retrieval was carried out to obtain studies of randomized controlled trials preventing cerebral vasospasm after aneurysmal subarachnoid hemorrhage with eicosapentaenoic acid before January 2013. Study selection, data collection and methodological quality assessment were performed by two individual reviewers. A meta-analysis was performed by RevMan 5.2.3 software.

**Results:** 3 studies and 307 patients were included totally. Meta-analysis showed that eicosapentaenoic acid decreased symptomatic cerebral vasospasm \( (RR = 0.46,95\% CI (0.29,0.72), P = 0.0006) \), cerebral infarction was caused by vasospasm \( (RR = 0.27,95\% CI (0.14,0.51), P < 0.0001) \), but did not improve the modified Rankin Scale \( (RR = 1.15,95\% CI (0.98,1.33), P = 0.08) \). Few gastrointestinal adverse effect has been reported.

**Conclusion:** Eicosapentaenoic acid is safe and reliable to be used for the prevention of aneurysmal cerebral vasospasm after subarachnoid hemorrhage. However, further studies are needed to confine the long-term clinical outcomes.

Level of von willebrand factor in patients with carotid artery stenosis
S. Migunova\textsuperscript{1}, I. Urvantseva\textsuperscript{1}, L. Salamatina\textsuperscript{1}, V. Shirokov\textsuperscript{2}, E. Bakhtereva\textsuperscript{3}, \textsuperscript{1}District Cardiologic Dispensary, Center of Diagnostics and Cardiovascular Surgery, Surgut, Russia; \textsuperscript{2}Yekaterinburg Medical Research Center for Prophylaxis and Health Protection of Industrial Workers of Rospotrebnadzor, Yekaterinburg, Russia

According to the results of numerous studies, von Willebrand factor (vWF) is one of the markers of endothelial dysfunction in stenosis of the carotid arteries. An objective of the study is to explore vWFu patients with stenosis of the carotid artery.

Target groups and techniques: The group included 83 people with carotid stenosis. The average age of 59.07 (±6.62). In two groups of patients: I — stenosis <50\% (n = 70, 34 men, 36 women), II — stenosis >50\% (N = 13, 6 males, 7 females). Not stable plaques identified in 75.7\% (n = 53) in the first and 100\% (n = 13) of the second groups.

Results: vWF first group with unstable plaque was significantly higher than those with stable plaque (P = 0.004). Significant differences were found in men (p = 0.024) and women (p < 0.05). When comparing groups I and II with the unstable plaque, significant differences were detected (p = 0.065).

Conclusions: The comparative study has indicated relationship between the vWF level and the structure of plaques in patients with occlusive lesions of the carotid arteries as well as absence of the relationship between the level of vWF and extent of the carotid arteries stenosis.

Comparison of risk factors between ischaemic stroke and haemorrhagic stroke
L.Y. Hor\textsuperscript{1}, W.L. Khor\textsuperscript{1}, C.S.T. Lim\textsuperscript{1}, A.C.H. Lau\textsuperscript{1}, Y.K. Chia\textsuperscript{1}, T.T. Lim\textsuperscript{1}, G.B. Eow\textsuperscript{1}, P.E.S. Easaw\textsuperscript{1}, M.H. Rajia\textsuperscript{1}, \textsuperscript{1}Department of Neurology, Penang General Hospital, Penang, Malaysia; \textsuperscript{2}Department of Medicine, Aberdeen Royal Infirmary, Aberdeen, UK; \textsuperscript{3}Department of Medicine, Penang Medical College, Penang, Malaysia; \textsuperscript{4}Department of Neurology, Kuala Lumpur General Hospital, Kuala Lumpur, Malaysia

Background: Post hoc analysis of SPARCIL trial showed that low LDL was associated with haemorrhagic stroke. Different meta-analyses also revealed conflicting results as to whether cigarette smoking favours ischaemic or haemorrhagic stroke.

Objective: To study the demography and risk factors of our stroke patients; to compare any difference in risk factors between ischaemic and haemorrhagic stroke; and to study whether low LDL favours haemorrhagic stroke.

Patients and methods: All patients with a diagnosis of stroke admitted to the Neurology Ward, Penang General Hospital in the past year were included. Data was collected from the stroke registry, and telephone interviews were conducted to fill in missing data.

Results: Of the 335 stroke patients being admitted, 83.3% had ischaemic stroke (mean age 64.5 years, male 60\%), and 16.7% had haemorrhagic stroke (mean age 64.7 years, male 57\%). The top three risk factors were: hypertension (32\%), high LDL (21\%), and diabetes mellitus (17\%). The presence of diabetes mellitus was shown to favour ischaemic stroke (p < 0.05). Hypertension, high LDL, cigarette smoking, atrial fibrillation, prior stroke/TIA, alcohol intake, ischaemic heart disease, and valvular heart disease were common risk factors for both ischaemic and haemorrhagic stroke.

Conclusion: In our study, diabetes mellitus was shown to favour ischaemic stroke. On the contrary, LDL level and cigarette smoking were not shown to favour either type of stroke. Further large-sample study may be needed to clarify this relationship.

Ursoniu\textsuperscript{e}, \textsuperscript{a}Nephrology, ‘Victor Babes’ University of Medicine and Pharmacy, County Emergency Hospital, Romania; \textsuperscript{b}Diabetes and Metabolic Diseases, ‘Victor Babes’
University of Medicine and Pharmacy, Romania; ‘Neurology, Victor Babes’ University of Medicine and Pharmacy, County Emergency Hospital, Romania; ‘National Institute for Research and Development of Electrochemistry and Condensed Matter, Timisoara, Romania; ‘Institute for Life Sciences, Western University ‘Vasile Goldiș’, Arad, Romania; ‘Nephrology, Victor Babes’ University of Medicine and Pharmacy, Timisoara, Romania; ‘Clinical Laboratory, Immunology, Victor Babes’ University of Medicine and Pharmacy, Timisoara, Romania; ‘Public Health Medicine, Victor Babes’ University of Medicine and Pharmacy, Timisoara, Romania

Introduction: The aim of study was to clarify if advanced glycation end-products (AGEs) may explain the endothelial variability in microvascular territories, (kidney, brain) and exert toxic effects upon the proximal tubule (PT) in patients with type 2 diabetes mellitus (DM).

Methods: A total of 70 patients with type 2 DM and 11 gender- and age-matched healthy subjects were assessed concerning urine albumin: creatinine ratio (UACR), urinary alpha2-microglobulin, urinary neutrophil gelatinase-associated lipocalin (NGAL), plasma and urinary AGEs, plasma asymmetric dimethyl-arginine (ADMA), and serum cystatin C. Fully automated chip-Nano electrospray ionization in conjunction with high-capacity ion trap multispray mass spectrometry was utilised to characterize the urinary proteomic profile; extra- and transcranial Doppler and the breath-holding test for the assessment of cerebrovascular reactivity were performed.

Results: The cerebral haemodynamic indices were correlated with plasma ADMA, plasma AGEs, inflammation, DM duration, GFR, and cystatin C. Urinary glycated peptide fragments were identified, in normo-(m/z ratio 700–900 Da) and microalbuminuric patients (m/z ratio 1000–1200 Da). Urinary alpha2-microglobulin and urinary NGAL were correlated with urinary AGEs ($R^2 = 0.586$; $P < 0.001$; $R^2 = 0.415$; $P < 0.001$), UACR ($R^2 = 0.292$; $P < 0.001$; $R^2 = 0.116$; $P < 0.002$), GFR ($R^2 = 0.172$; $P < 0.001$; $R^2 = 0.135$; $P < 0.001$), cystatin C ($R^2 = 0.146$; $P < 0.001$; $R^2 = 0.129$; $P < 0.001$), but not with ADMA.

Conclusion: In normalalbuminuric type 2 DM patients, AGE-induced endothelial dysfunction plays a putative role in the brain vasculature. AGEs are toxic for the PT, but spare the glomerular endothelium. The proteomic pattern of urinary glycated peptides and PT dysfunction are the key factors which could make the difference between normo- and microalbuminuric patients.

Knowledge and attitudes towards stroke among workers in three university hospitals in Egypt

S. El-Mouslya, H. Hamdyb, A. Abdel-Monemc, A.M. Abdelalimc

Neurology, Fayoum University, Fayoum, Egypt; Neurology, Ain Shams University, Egypt; Neurology, Cairo University, Cairo, Egypt; Public Health, Fayoum University, Fayoum, Egypt; Paediatrics, Fayoum University, Fayoum, Egypt; Neurosurgery, Ain Shams University, Cairo, Egypt

Background: The rising global burden of stroke is more pronounced in the less developed world, including Egypt.

Objective: To evaluate the level of knowledge and attitudes towards stroke among workers affiliated to hospitals in Egypt.

Material and methods: This is a hospital-based cross-sectional observational study of workers affiliated to three university hospitals in Egypt using convenience sampling over 3 months. They were classified into clinical (Health care staff and pre-clinical medical students) and non-clinical workers (e.g. Administrative & sanitary staff). A structured self-administered questionnaire of knowledge and attitudes towards stroke was developed.

Results: Of 468 questionnaires administered, 396 were completed. Most respondents have heard of stroke before (98.4%). The most commonly identified risk factors of stroke were hypertension, stress, smoking and high cholesterol levels. Age and lack of exercise were among the least recognized. There were no differences between clinical and non-clinical workers in knowledge about the risk factors of stroke expect for unhealthy diet ($p = 0.007$) and obesity ($p < 0.001$). Clinical workers were more likely to identify the symptoms of stroke. Non-clinical workers were more likely to go to hospital ($p < 0.001$).

Conclusion: Knowledge of stroke among workers in the three studied university hospitals is poor. There is a discrepancy in level of knowledge and attitude towards stroke between clinical and non-clinical workers. This addresses the need for public stroke education programs to improve public awareness of stroke in Egypt.

Serum levels of YKL-40 in acute arterial ischemic stroke patients, and its relationship to infarct volume
A. Kirbas1, S. Kirbas2, M.C. Cure3, A. Tufekci3. 1Department of Biochemistry, Faculty of Medicine, Recep Tayyip Erdogan University, Rize, Turkey; 2Department of Nutrition, Faculty of Medicine, Recep Tayyip Erdogan University, Rize, Turkey

Background: The aim of this study was to investigate the levels of YKL-40 in serum from patients with acute arterial ischemic stroke (aIS), and its relationship to infarct volume.

Patients and methods: A total of 90 subjects, including 50 patients with aIS, (28 males, 22 females, at 42–72 years of age) and 40 controls (21 male, 19 female) were enrolled in our study. Trials of Org 10172 in Acute Stroke Treatment (TOAST) was used for etiologic classification. Serum YKL-40 was measured by ELISA. Acute cerebral infarction was defined as an area of high signal intensity on the diffusion weighted images. Infarction volume was calculated by multiplying the manually contoured hypertensive region by the slice thickness plus the intersection gap with the aid of Scion image software.

Results: Serum YKL-40 levels of aIS patients were significantly higher than in healthy controls. Serum YKL-40 levels were 227.28 ± 78.23 ng/ml in aIS patients and 74.78 ± 13.94 ng/ml in controls (p < 0.001). There were significantly positive correlations between serum YKL-40 levels and infarct volume in patients with aIS (r = 0.931, p < 0.001). Serum YKL-40 levels were especially elevated in patients with large artery (carotid) atherosclerosis according to TOAST.

Conclusions: Our study showed that YKL-40 is higher in aIS patients. In our opinion, the relationship between the serum YKL-40 level and cerebral infarction volume may represent a new opportunity for the possible utility of serum YKL-40 as an inflammatory marker for ischemic stroke.

Acute cerebrovascular accidents and sudden weather changes: Any association?
K. Spandel, M. Arkuszewski. Department of Neurology, Medical University of Silesia in Katowice, Katowice, Poland

Introduction: It is suggested that changes of climate, weather or seasons are the risk factors of the acute cerebrovascular accidents (CVA). We hypothesized, that independently of the seasonal atmospheric changes, abrupt weather changes may influence the incidence of CVA. In this study we analyzed the association between sudden changes of atmospheric pressure and air temperature with the incidence of CVA.

Material and methods: In 607 consecutive patients (mean age 69.7 years, 56% women) admitted to our Stroke Unit in the year 2010 we analyzed the association of the time of onset of CVA (ischemic stroke 70.0%, hemorrhagic stroke 7.3%, transient ischemic attack 21.9%, subarachnoid hemorrhage 0.8%) with abrupt changes of atmospheric pressure and air temperature measured in half-hour intervals before admission (17,479 recordings).

Results: With the use of logistic regression we observed significant increase of the incidence of CVA after decrease of air temperature of at least 8 °C during 19 h (p < 0.001; OR = 2.72; 95%CI 2.13–3.47), or after decrease of atmospheric pressure of at least 8 hPa during 7 h (p = 0.012; OR = 2.95; 95%CI 1.42–6.14). However, respective regression models allowed for interpretation of only 1.0% and 0.1% in the variability of the incidence of CVA. The incidence of CVA was not associated with the seasons (chi-square p = 0.439).

Conclusions: After sudden drops of atmospheric pressure or air temperature the incidence of acute cerebrovascular accidents rises independently of seasonal weather changes. Although the statistical models are significant, this association appears to be very subtle or incidental and therefore probably clinically not important.

CD34+ /CXCR4+/CD45- stem cells and cerebrovascular risk factors in acute stroke patients
A. Gciska-Grymajlo1, W.M. Nyka1, M. Zielinski2, T. Bandurski3. 1Department of Neurology, Medical University in Gdansk, Gdansk, Poland; 2Department of Clinical Immunology and Transplantology, Medical University in Gdansk, Gdansk, Poland; 3Department of Informatics and Statistics, Medical University in Gdansk, Gdansk, Poland

Background: Endogenous non-hematopoietic stem cells seem to play a protective role in acute ischemic stroke.

Objective: We hypothesized that:
– levels and dynamic changes of CD34+CD45−, CD34+CXCR4+CD45− and CXCR4+CD45− stem cells correlate positively with neurological and functional status of acute stroke patients;
– certain comorbidities may correlate with lower levels of the abovementioned cells and negatively influence their dynamics.

Patients and methods: Venous peripheral blood was sampled and assessed by flow cytometry on days 1, 2, 4, and 6 after acute stroke onset in 34 patients. Parallel to blood sampling and after 3 and 6 months patients were assessed with the National Institute of Health Stroke Scale, Barthel Index, Scandinavian Stroke Scale, and modified Rankin Scale.

Results: Higher initial levels of all 3 subgroups of cells correlated with better neurological or functional status on admission. Higher increase in CD34+CD45− and CD34+CXCR4+CD45− stem cells and lower increase in CXCR4+CD45− stem cells during the 6 days following stroke correlated positively with initially more severe stroke. Diabetes in anamnesis correlated with initially lower levels of CD34+CXCR4+CD45− and CXCR4+CD45− cells. Hypertension correlated with initially lower levels of CD34+CD45− cells. Diabetes and hypercholesterolemia correlated with higher increase or smaller decrease of all 3 subgroups of cells.

Conclusions: The lower initial levels and the subsequent increase in the levels of the chosen subgroups of stem cells seem to indicate more severe neurological/functional state of the stroke patients. Diabetes, hypertension and hypercholesterolemia seem to negatively influence the initial levels of the cells and/or augment their dynamics.

Pharmacogenomic assessment of clopidogrel — A step toward personalized medicine for patients with ischemic stroke
D. Maslarov4, D. Drenska2, O. Micova4, L. Todorova2, M. Vlaskovska4. 4Neurology, 1st MHAT, Sofia, Bulgaria; 2Multiprofile Clinic, University Hospital Lozenetz, Bulgaria; 3Bulgarian Drug Agency, Bulgaria;
So frequently used antiplatelet agents and anticoagulants that potentiate genetic variations in drug metabolism in regard to the most causes of cerebral infarction are: large artery atherosclerosis, small vessel disease and cardioembolism. Furthermore, there are several genetic variations in drug metabolism in regard to the most frequently used antiplatelet agents and anticoagulants that potentially underlie variability in drug efficacy and adverse drug reactions.

**Objective:** This study discusses investigation, outcomes and the clinical effectiveness of clopidogrel administration for secondary stroke prevention in Bulgarian patients with cerebral infarction based on an assessment of “clopidogrel resistance”.

**Patients and methods:** Participants included 214 patients (104 male and 110 females, range 41–89 years) with ischemic stroke. They were assigned to receive 75 mg of clopidogrel daily despite regular medical therapy. Assessment of individual pharmacological response to antiplatelet therapy was performed on 24 cases by platelet function tests, including multiple electrode aggregometry (MEA).

**Results:** Among the 28 subjects evaluated by laboratory tests, only 3 showed a resistance to clopidogrel. During the clinical follow-up of a period of 5–8 months, the prevalence of consecutive cerebrovascular events was greater in 6 patients who underwent tests, and none of them were resistant to clopidogrel. Our study presents confirmatory results with respect to efficiency and safety of clopidogrel administration for secondary stroke prophylaxis. In fact, only 4% of Bulgarians are not responding to clopidogrel treatment.

**Conclusion:** Antiplatelet drug clopidogrel is the main point for secondary stroke prevention with or without assessment of platelet function testing. We recommend an individualized approach for each patient with cerebrovascular disease.

Results: All patients presented different degrees of arousal, consciousness, and other neurological and behavioral symptoms. The extent of structural brain damage and brain response in fMRI was found to be variable in spread.

Conclusion: The relevant differences between LIS and LIPS lie on the variety of additional pontine lesions in LIPS and in symptoms caused by these lesions: Frequently occurring features in LIPS include hypomnusia, frontal release signs, thalamic posturing of hand and/or feet. Rarely an akinetic mutism may occur.

Extra pontine brain lesions may occur in mesencephalic, thalamic and cerebellar brain structures, as well as occipital, temporal brain regions, depending on varieties of the vertebro-basilar artery blood supplying system. Due to the heterogeneity of the data collected, a new diagnostic category should be implemented in clinical practice.

Early stroke predictors in hypertensive obesity men aged 60–69:
Pulse feeling and therapy
S.S. Yuldashev. Rehabilitation Department, 'Kibray' Clinical Sanatorium, Tashkent, Uzbekistan

Background: Hypertension is the major risk factor for stroke. Aim: Research of early predictive value of pulse feeling in hypertension, complicated stroke.

Methods: Pulse was palpated in 12 positions in the points Cun, Guan, and Chi. ECG and computed tomography were investigated. Valuation of the pulse was made taking into account the gender, age, season, and given region. Data of rhythm, heart rate frequency, filling, tension, depth, length, hardness, form, width, and smoothness of pulse were determined. Pulse was investigated to the healthy with systolic and diastolic blood pressure less than 140/90 mm Hg respectively, in comparable 27 patients with II (basal Gr1) and in 36 patients also with II (control Gr2) degree of hypertension (WHO classification) survivors of stroke. Patients had BMI 30.2–34.6 kg/m^2.

Results: The healthy had balanced pulse. The patients a long time before stroke had the pulse disbalance, which was correlated with the level of blood pressure. Frequent and sudden weather changes (magnetic storm, the changeability of barometric pressure, relative humidity, air temperature), and stresses enhanced the disbalance of pulse among non-treated by acupuncture Gr2, that correlated with the increase of cases' frequency and the hardness of stroke. The patients treated by acupuncture and other therapy methods, in Gr1 had the best prognosis.

Conclusion: Pulse feeling early predicts stroke. Correct acupuncture using stress free needles based on the everyday results of PF normalizes the pathological pulse, in complex with the antihypertensive, neuro-protective treatment reduces the risk of stroke, improves prognosis and the life quality.

Sensitivity of the color trails test (CTT) in stroke and lacunar infarction
K. Konstantopoulos¹, T. Doskas⁵, C. Stylianou⁵, K. Spenigos⁵.
¹Speech and Language Therapy, European University Cyprus, Nicosia, Cyprus; ²Neurology, Navy Hospital of Athens, Greece; ³Neurology, Eginition Hospital, University of Athens, Athens, Greece

Background: The color trails test (CTT) is a culture free neuropsychological test to measure sequencing, visual scanning, and speed of mental processing abilities. No clinical data are available about the utility of this test in the Greek population.

Objective: To provide clinical data on the sensitivity of the CTT in 2 groups of patients (6 month post stroke and lacunar infarction) and 2 groups of pair matched (in age) controls.

Patients and methods: Twenty-four patients exhibiting ischaemic stroke (IS) and 14 patients exhibiting lacunar infarction (LI) were compared to 38 controls. All patients were seen in the Neurology department of the Athens Navy Hospital and the Eginition Hospital of Athens between December 2011 and December 2012.

Results: The mean age for the IS group was 64.75 years (SD = 12.79) and the mean age for the LI group was 66.74 years (SD = 10.06). The Mann–Whitney statistical tests were used to find differences between the groups. Significant differences were found between the IS group and the controls (CTT1 U = 132.500, p = 0.001, CTT2 U = 126.000, p = 0.001), and the LI group and the controls (CTT1 U = 66.500, p = 0.150; CTT2 U = 48.500, p = 0.021).

Conclusion: The CTT can be a useful tool to measure the speed of mental processing in stroke and lacunar infarction. Further research is needed to prove its clinical utility in larger samples.

The clinical significance of the intraoperative ultrasound research during carotid endarterectomy
R. Medvedev, G.K. Kuntcevich, E. Gemdjian, S. Scrylev. 1
1Department of Reanimation and Intensive Therapy, Research Center of Neurology of the Russian Academy of Medical Sciences, Russia;
2Ultrasonic Investigations Laboratory, Russia; 3Biostatistics, National Research Center for Hematology, Russia; 4Vascular Surgery Department, Research Center of Neurology of the Russian Academy of Medical Sciences, Moscow, Russia; 5Radial Diagnostics Department, Research Center of Neurology of the Russian Academy of Medical Sciences, Moscow, Russia; 6Neurological Department, Research Center of Neurology of the Russian Academy of Medical Sciences, Moscow, Russia

Objective: To appraise the possibility of intraoperative blood flow monitoring of artery ophthalmic (AO) and middle cerebral arteries (MCA) during the carotid endarterectomy.

Material and methods: The research included 67 patients with stenosis of ICA at the age of 43 to 73 (the median of age is 57). The volume of research included clinical data, intraoperative blood flow monitoring in AO and MCA, and results of DWI of brain made 24 h after the operation.

Results: Monitoring blood flow in the AO was carried out with 40 (60%) patients and with 27 in MCA (40%). With low sensitivity and hence with low prognostic value in registering material emboli during the AO blood flow monitoring, the further analysis was based on the data received during the blood flow monitoring in MCA. The combination of same signs such as material emboli with 12% of patients and gaseous signals during 5 and 16 gaseous showers with 8% of patients made it possible to determine the sensitivity of the method in revealing of acute ischemic lesions in 65% of cases. The prognostic significance of positive results made up 95%.

Conclusions: The intraoperative ultrasound control of the blood flow made it possible to prognosticate the development of acute ischemic lesions in brain.

Hypertension rates and mortality in spontaneous intracerebral hemorrhage and ischemic cerebrovascular disease
H.L. Gul, O. Karada, S.K. Gul, S. Firtuna. 1Department of Neurology, Kartal Education and Research Hospital, Istanbul, Turkey;
2Department of Neurology, Erzinca Military Hospital, Erzincan, Turkey;
3Department of Radiation Oncology, Kartal Education and Research Hospital, Istanbul, Turkey; 4Department of Cardiology, Erzinca Military Hospital, Erzincan, Turkey

Introduction: In the prevention of spontaneous intracerebral hemorrhage (ICH) and ischemic cerebrovascular disease (ICVD), treatment against risk factors takes an important role. Hypertension (HT) is one of the most important independent modifiable risk factor in ICH and ICVD development. In this study, it was aimed to underline the importance of hypertension as a risk factor of cerebrovascular disease.

Methods: 133 patients (69 male, 64 female with a mean age of 65.9) diagnosed as ICH and 137 patients (56 male, 81 female with a mean age of 69.7) diagnosed as ICVD were included to our study. Hypertension rates of both groups were noted and after one year of follow up, mortality rates were recorded.

Results: 115 patients had a history of hypertension in ICH group (86.4%) and 102 patients had a history of hypertension (74.4%) in ICVD group. There is a relation between hypertension and development of ICH and ICVD. One year of mortality is 49.6% (66 patients) for ICH group and 42.3% (58 patients) for ICVD group.

Conclusion: As the number of risk factors like hypertension increases, the risk of development of ICH and ICVD increases. Treatment of HT decreases the incidence of both ICH and ICVD. It was shown that maintaining blood pressure within normal limits reduces mortality and morbidity significantly.

Are stable patients on warfarin treatment actually stable?
D. Necioglu Orken, L. Gundogdu-Celebi, E. Turgut, S. Mumcu. Neurology, Sisli Etfal Education and Research Hospital, Istanbul, Turkey

Anticoagulant agents, especially warfarin, are widely used for the prevention of cardioembolic infection related to atrial fibrillation (AF) but it is limited by inherent problems. New anticoagulant agents are expected to revolutionize the field of stroke prevention in AF. But the question of which patients should use these new agents is not yet answered. The aim of this study is to determine the ratio of anticoagulated patients with warfarin who are inside the target therapeutic range at any given time.

Material and methods: Among 204 patients who had ischemic cerebrovascular disease, treated with warfarin and being followed-up in the Cerebrovascular Diseases outpatient clinic, 131 who had AF were included to this study. The INR in their last visit is evaluated whether it was in therapeutic range or not.

Results: The mean age (±SD) of patients was 73.9 ± 9.6 years, and 65 of patients (49.6%) were females. INR of 80 patients (61%) was inside, while INR of 51 patients (39%) was outside of therapeutic range. INR of 25 patients (49%) was below and 26 (51%) patients were above the therapeutic range.

Discussion: Despite regular monitoring of INR, 39% of our patients on warfarin treatment are outside of therapeutic range at any given time. In spite of careful dose adjustment, the INR is frequently outside the target therapeutic range. This uncontrollable situation increases the risk of thromboembolism and bleeding. New anticoagulant agents might be used in preference to warfarin in most cases.

Assessment of functional outcome and quality of life after aneurysmal subarachnoid hemorrhage
I. Gabrielyan, A. Zakaryan, H. Manvelyan. 1Department of Neurology, Yerevan State Medical University, Yerevan, Armenia; 2Department of Neurosurgery, Yerevan State Medical University, Yerevan, Armenia

Background: Subarachnoid hemorrhage from a ruptured intracranial aneurysm (aSAH) accounts for approximately 5% of all strokes, occurs at relatively young age and has poor prognosis of survival, despite improvements in medical care. Survivals often have disability with reduced quality of life (QoL).

Objective: The aim of the study is to assess the level of disability and QoL to unveil any association between functional outcome and QoL.
Methods: The study is a cross-sectional survey of 50 patients with surgically treated aSAH. Functional outcome was evaluated by the modified Rankin Scale (mRS), Barthel index (BI) and QoL was measured with SF-36 after discharging from hospital, during one month period after hemorrhage.

Results: Mean age of patients was 46.7 year, 31 male and 19 female. By the mRS 38 (76%) patients were independent (mRS < 4), 3 (6%) were assisted independent with BI >60 for 40 patients (80%). The mean BI was 84.56 (±SD 26.2). Scores of almost all domains of SF-36 were higher than one-half of total score of 100 with close correlation between the subscales. The mean scores for PH and MH were 46.2 ± 12.0 and 46.3 ± 10.5 respectively. Statistically significant correlation was established between physical and mental components of SF-36, BI and mRS scores showing the reduced QoL associated with the more severe disability (p ≤ 0.05).

Conclusion: There are certain correlations between the level of disability and the QoL: patients with neurological deficit are more prone to suffer from low QoL, so the treatment of aSAH must aim to lesser neurological deficit.

Cerebral amyloid angiopathy-related leukoencephalopathy: A case of successful steroid treatment for neurological deficit and white matter lesions

T. Murakami, A. Hoshii, S. Nakatani-Enomoto, M. Ichikawa, K. Tasaki, A. Kakita, Y. Toyoshima, R. Oegura, K. Saito, H. Takahashi, Y. Ugawa. Neurology, Fukushima Medical University, Fukushima, Japan; Neurosurgery, Fukushima Medical University, Fukushima, Japan; Pathology, Fukushima Medical University, Fukushima, Japan; Pathology, Niigata University, Niigata, Japan

Background: Cerebral amyloid angiopathy (CAA)-related leukoencephalopathy (LE) is a relatively rare cerebrovascular disease in which amyloid β-protein (Aβ) is deposited on the vessel walls in the cerebrum. However, pathophysiology of Aβ in the CAA-related LE has not been understood completely.

Objective: We report a case of CAA-related LE whose neurological symptoms were improved by steroid therapy. In this case, the brain biopsy samples showed glial activations around the Aβ-deposit vessels with absence of acute inflammatory component.

Patients and methods: A 76-year-old woman developed subacute cognitive decline, consciousness impairment and right hemiparesis. Magnetic resonance images (MRI) showed prominent edema in the left-hemispheric dominant white matters and multiple cerebral microbleeds.

Results: Pathological studies of biopsied brain specimen disclosed hyaline-like materials on the vessel walls that were positive for Congo red and were dichroic under the polarized light, indicating amyloid hyaline-like materials on the vessel walls. Numerous reactive astrocytes and upregulation of microglia were observed in the brain parenchyma around the affected vessels. There was no apparent inflammatory cell infiltration or granuloma formation. Repeated high-dose methylprednisolone pulse therapy improved consciousness, cognitive function, and resolved MRI lesions.

Conclusion: The CAA-related LE is considered to be produced by microbleeds and microinfarcts induced by Aβ deposition on the vessel walls. The steroid therapy efficacy in the present case suggests that the activated glial response plays additional role in pathophysiology of the CAA-related LE.

age and had at least one predisposing condition for thromboembolism other than lumbar puncture. Five were young women in postpartum state.

**Conclusion:** Lumbar puncture may trigger CVT especially in patients with congenital or acquired thrombophilia such as pregnancy. We draw attention to the importance of neurological reevaluation of patients with persistent and progressive headache following lumbar puncture. Since missed diagnosis could result in mortality and serious morbidity, prevention strategies should be carried out for patients undergoing lumbar puncture, with known prothrombotic conditions.

**Predictive factors of mannitol induced acute renal insufficiency**  
I.S. Choo, J.Y. Chung, M.Y. Kim. Neurology, Chosun University College of Medicine, Gwangju, Republic of Korea

**Background and objective:** Mannitol is commonly used to treat cerebral edema. Acute renal insufficiency (ARI) is known as one of the mannitol’s most common side effects. Although concerns about renal insufficiency are a major limiting factor in mannitol use, it is very little known about mannitol induced ARI. The goal of this study is to determine predicting factors of ARI.

**Methods:** We retrospectively reviewed the medical records of all ischemic stroke patients treated with mannitol due to brain edema from 2010 to 2012 in Chosun University Hospital. From among 125 patients, 25 patients received mannitol below 3 days were excluded and 100 patients were selected. We identified demographic factor, medical history, NIHSS, baseline renal function, exposure to nephrotoxic or nephrophilic drugs, and laboratory data. An ARI was defined as an increase in the creatine level of >0.5 mg/dl if the base-line value is <2 mg/dl or an increase >1 mg/dl if the base-line value is >2 mg/dl.

**Results:** The 14 patients (14%) were diagnosed as ARI. From mannitol use to ARI development, median hospital days are 5. Glucose level before use of mannitol and peak osmolarity during mannitol treatment were associated with ARI. In logistic regression analysis with suspected factors independent predictive factors of mannitol induced ARI were glucose level before use of mannitol and peak osmolarity.

**Conclusion:** Our study presented in 14% of mannitol induced ARI. Strict glucose control before mannitol treatment may be able to reduce the rate of ARI occurrence.

**In-hospital fatality in stroke patients in relation to risk factors and clinical presentation at Hadhramout: Analysis of 1072 cases**  
R.M. Bamekhlah, H.S. Al Ghazali, N.S. Musaian. Internal Medicine, College of Medicine Hadhramout University, Mukalla City, Yemen

**Background:** Stroke is the third leading cause of death, and a cause of long-term disability among survivors.

**Objectives:** To identify the frequency of in-hospital deaths among stroke patients admitted in Ibnseena Teaching Hospital, Mukalla, Hadhramout, Republic of Yemen.

**Patients and methods:** A retrospective cross-sectional study of stroke patients admitted at Mukalla, Hadhramout in 1/2009–12/2011. Data were collected in a questionnaire from patients’ files.

**Results:** There were 1072 stroke cases; ischemic stroke were 78.5% and hemorrhagic 21.5%. Males were 56.5% and females 43.5%. In-hospital deaths were higher in old (36.5%) than in middle-aged and young (23.8% and 25.9% respectively), non-significantly higher in females (35.2%) than in males (31.4%), highly significantly higher in hemorrhagic Stroke (50.6%) than ischemic type (28.2%). Hypertension, diabetes, smoking, previous attacks and family history of stroke significantly increased in-hospital deaths. Deaths among patients without risk (22.2%) with one risk factor (25%) and with ≥2 risk factors (34.6%). Death in late hospitalization (>24 h from onset) was significantly higher (43.4%) than in early hospitalization (within 24 h from onset) (29%). Death in comatose cases was significantly higher (67.5%) than fully (21.8%) or disturbed conscious (31.2%).

**Conclusions:** In-hospital death was more common in elderly, in females, in hemorrhagic stroke, and in patients with hypertension, death in comatose cases was significantly higher (67.5%) than fully (21.8%) or disturbed conscious (31.2%).

**Immune thrombopenic purpura (ITP) elicited by childhood vaccination and antiphospholipid syndrome (APS) manifested as cerebral venous thrombosis: Coincidence or no?**  
C. Plastiras, E. Zafeiropoulou, E. Kontogeorgi, D. Karakalos. Neurological, Evangelismos General Hospital, Athinai, Greece

APS is defined by: the occurrence of at least one clinical feature: vascular event or pregnancy morbidity and the presence of at least one type of an antiphospholipid antibody (APA) on two separate occasions 12 weeks apart. Cerebral venous thrombosis (CVT) is an uncommon manifestation of APS. ITP is an autoimmune disease defined by low platelet count due to antiphaselet antibodies. A 21 year old female was admitted due to headache, vomiting and tinnitus, beginning 15 days ago. She had a history of ITP, after MMR vaccination and antiphospholipid syndrome (APS) manifested as cerebral venous thrombosis: Coincidence or no?

**Conclusions:** In the case, in the absence of prospective studies with a more prolonged follow-up. Yet, we would like to suggest that more attention should be devoted to episodes of ITP in early childhood, as they may be connected with hypercoagulable states, like APS, in young adults.

Relapsing polychondritis (RPC) is a chronic inflammatory disease associated with an autoimmune disorder in cartilaginous tissue, eyes, lymph nodes, blood vessels, and central nervous system. A minority of patients with RPC develop neurological involvement (3%). A 43-year-old right handed woman acutely developed a left hemiparesis. A noncontrast CT scan revealed a right MCA infarct. During the previous three years she had history of peripheral vascular disease (deep vein thrombosis), posterior uveitis, two episodes of auricular chondritis and an episode of polyarthritis of her small peripheral joints. The blood count showed 3,100,000 red cells and 634,000 platelets per cubic millimeter. Serum electrolytes, creatinine, glucose, coagulation tests, liver functional tests, lactocidohydrogenase, and creatine kinase were normal. C-reactive protein (CRP) (119 mg/dL) and the erythrocyte sedimentation rate (ESR) (88 mm/h) were elevated. Laboratory data associated with collagen disease were all within the normal range. Echocardiography showed a mild mitral valve prolapsus and regurgitation suggesting the heart involvement.

Ischemic stroke with RPC is a rare condition which has been related to vasculitis of the CNS. The diagnosis is challenging because of its rarity and the diversity of clinical presentations. Early manifestations often showed a mild mitral valve prolapsus and regurgitation suggesting the heart involvement.

Ischemic stroke due to RPC is a rare condition which has been related to vasculitis of the CNS. The diagnosis is challenging because of its rarity and the diversity of clinical presentations. Early manifestations often remain unrecognized for prolonged periods. As a result, the diagnosis is frequently obtained only after the emergence of classic features such as auricular inflammation or other features of cartilage destruction.

D/D genotype together with homozygous MTHFR A1298C polymorphism may be a risk factor in the etiology of cerebral infarction.

doi:10.1016/j.jns.2013.07.1024
brain MSCT was normal, while MSCT cranial angiography showed occlusion of left middle cerebral artery. Patient had mamectomy due to breast carcinoma 2.5 month earlier, received chemotherapy 2 days prior the stroke and was on every day anti-estrogen therapy for 2 months. After 3.5 h of stroke onset, patient received 300 mg of aspirin, 30 mg enoxaparin iv, abcinimab 10 mg iv, and t-PA 0.9 mk/kg/60 min iv. After 15 min of t-PA initiation, platelet function (multiplate method) showed suboptimal inhibition of platelet aggregation, so she received additional 10 mg of abcinimab, with confirmed optimal inhibition of platelets. DSA was performed after thrombolysis, normal blood flow was registered in the left middle cerebral artery. A 24 h control brain MSCT excluded brain hemorrhage and brain MRI 3 days later showed minor infarction. Patient completely recovered within 7 days. 

Conclusion: In young stroke patients with severe neurological impairment and known hypercoagulable state, combined antithrombotic medications, with intense platelet function monitoring, should be considered to facilitate thrombolysis and prevent early re-thrombosis.

APOE polymorphisms and ischemic stroke in a Greek population

Background: Apolipoprotein E (ApoE) is a plasma protein exhibiting three common isoforms (E2, E3, E4). Its involvement in lipoprotein metabolism may have an impact on stroke occurrence. As results in literature are inconclusive further studies are needed to elucidate its role.

Objective: To study the role of ApoE isoforms and its interplay with environmental risk factors in patients with first ischemic stroke occurrence in Greek population.

Patients and methods: 329 patients with first ever ischemic stroke were included in our study. Strokes of cardioembolic origin and patients with autoimmune or prothrombotic syndromes were excluded. A control group of 361 subjects without stroke history was also included in our study. Risk factors (hyperlipidemia, hypertension, diabetes mellitus and smoking) were assessed. ApoE alleles were determined in all subjects participating in the study.

Results: Genotype ε3/ε3 was found to have a protective role against stroke occurrence compared to other genotypes (OR = 0.574, CI: 0.480–0.946) especially in female patient subgroup. In multivariate analysis after adjustment for age, BMI, hypertension, dyslipidemia, diabetes mellitus and smoking, the role of genotype was limited and outweighed by risk factors in both genders. No association between ApoE alleles and BMI, cholesterol, triglycerides or HDL plasma levels was noted.

Conclusions: Our study supported a protective role of ε3/ε3 genotype, especially in female patients. However, risk factors such as age, BMI, hypertension, dyslipidemia, diabetes mellitus and smoking have strong impact on stroke occurrence and outweigh the protective role of ε3/ε3 genotype.

The underlying problem in stroke; the public waffles in darkness

Introduction: There exists much uncertainty amongst members of the general public as to the actual site of the problem in a stroke.

Objectives: This study aims to evaluate patient’s understanding of which organ has suffered insult in the case of stroke.

Methodology: Volunteers, recruited according to a probability quota sample, underwent a structured interview detailing demographics, first aid training and basic facts about stroke. Individual chi-squared tests were performed to relate knowledge to expected influences.

Results: 500 individuals (47% male, n = 233) were interviewed, of whom 34% (n = 169) had previously attended a formal training in first aid. 59% of subjects correctly indicated that it is the brain that has sustained damage in the case of a stroke; with a significant improvement noted amongst those who had previously attended training (68% vs 54%, p < 0.01). 25% of people questioned identified the problem to be in the limbs or face, and 10% in the heart. 90% of interviewees (n = 452) indicated the need to seek urgent medical attention even in the case transient symptomatology suggestive of stroke; whilst 98% (n = 488) correctly identified hospital as the appropriate first port of call.

Conclusions: A significant proportion of the general public has a poor understanding of the nature of stroke; first aid training results in a significant increase in prevalence of this insight. There is almost universal appreciation of the urgency and seriousness of a “stroke”, rendering the onus on prompt recognition.

after discharge showed total recanalization of the affected sinus. Complete recovery of facial palsy occurred concomitant with recanalization of the transverse sinus.

**Conclusions:** Patients with MTHFR and factor V Leiden mutations may rarely lead to transverse venous thrombosis. The pathophysiology of peripheral facial palsy is unknown in CVT and most likely represents a pressure related situation and generally resolves with decreasing of the elevated intracranial pressure.

**Internal carotid transfer of autologous bone-marrow mononuclear cells for the treatment of severe stroke in patient with thrombotic thrombocytopenic purpura**

**Background:** Stem cell therapy has potential regeneration capacity in patients with severe stroke.

**Objective:** To establish safety and potential efficacy of regenerative capacity of autologous bone-marrow derived stem cells in patient with severe stroke and thrombotic thrombocytopenic purpura (TTP).

**Patient and methods:** A 44-year female with known diagnosis of TTP, during relapse of the disease (thrombocytopenia 75 x 10^9/L) and patient had significant improvement of neurological deficit 6 months after procedure.

**Conclusions:** Internal carotid transfer of autologous bone-marrow MNC in patient with severe acute ischemic stroke and TTP was safe and patient had significant improvement of neurological deficit 6 months after procedure.

**Vertebral artery dissections an under diagnosed stroke**

M.H. Thekkumpurath, N. Ravi, T. Thekkumpurath, A. Kumar, B. Kiran. 

**Background:** Dissections even though theoretically considered being a cause of young stroke practically not included in the differential diagnosis of stroke quite often. Most of the reported data on dissections prove that dissections are one of the commonest causes of stroke in the young and account for up to 2.5% all strokes and 60–75% of these are said to be a carotid artery. Analyzing our data at EMS Hospital we found that vertebral artery dissections are very common and they account 60–70% all dissections.

**Material and method:** First thousand cases of cerebral DSA at the Department of Interventional Neurology, EMS Hospital were included in the retrospective study.

**Discussion:** When analyzed we found that dissections are common at our population also and account up to 3% strokes of this 65% of them were at vertebral artery. Majority of them were without a recognizable injury. Most of them on young people but can occur at any age, most of them improve on supportive treatment and if fluctuating or deteriorating on treatment they need revascularization. Once suspected a cerebral DSA is a must for most of the patients for confirmation of the diagnosis and planning the treatment.

**Conclusions:**
- Dissections are not uncommon at our population
- They are one of the commonest causes of stroke in young adults
- In the population studied vertebral artery dissection (70%) is common than the carotid artery dissection
- Most of the dissection occurs without a recognizable trauma.

**A retrospective study of 100 cases of carotid artery stenting at a non teaching interventional neurology department**

**Background:** Carotid artery stenting (CAS) has been considered as a revascularization method with high morbidity and mortality and is considered as a second option after carotid endarterectomy (CEA) till recently. Now with refinement in techniques and technological advances made it superior to CEA. In our experience CAS is a very safe procedure and the complications are much less than the reported one and safer than the CEA. In this background we wish to publish our experience in doing last 100 cases of CAS.

**Aim:** Aim of the study is to compare the results and complications of the first 100 cases of CAS with the reported data on CAS & CEA.

**Materials and methods:** All the 100 cases of CAS done at EMS Hospital were included and compared with the reported data.

**Results:** In our study CAS is found to be a very safe procedure with a mortality of 1% (due to reperfusion bleeding), morbidity was also less and includes reperfusion bleeding with clinical worsening of 1%, local puncture site hematoma of 2%, and local pseudoaneurysm of 1%. No clinically significant embolic strokes were detected. Minor fluctuations in pulse and BP were seen during carotid bulb manipulations and would improve with symptomatic treatment.

**Conclusions:**
1. CAS is a safe procedure with a mortality of 1% and a serious morbidity of 1%
2. CAS can be done much safer than previously reported
3. Clinically significant embolic strokes are very uncommon
4. In stenosis of more than 95% in elderly with long duration of illness reperfusion bleeding is more common than embolic stroke.

Sudden-onset of hemichorea with hypomania
M.M. Pinto a, R. Miguel a, S. Calado a,b, M.V. Baptista a,b, *Neurology, Hospital Egas Moniz (Centro Hospitalar de Lisboa Ocidental), Portugal; bCEDOC, Faculdade de Ciências Médicas, Universidade Nova de Lisboa, Lisbon, Portugal

Introduction: The key role of thalamic and subthalamic nuclei in motor control through the basal ganglia thalamocortical circuit is well recognized. It is known that the thalamus is a central structure in the processing of impulses, mood and emotional behavior. The involvement of the subthalamic nucleus is however less clear. Focal lesions in these areas caused by strokes, tumors or metabolic diseases may disturb these functions.

Case report: We report the case of a 59-year-old hypertensive female, with no previous history of neurological or psychiatric dysfunction, who was admitted with sudden-onset left involuntary movements. Neurological examination was normal except for choreiform movements involving the left face, trunk and arm. There was also an acute-onset of inappropriate behaviors and mild elevation of mood characterized by disinhibition, increased energy and incessant verbal flow, with strong impulses to talk to strangers and ridiculing other patients, fulfilling ICD-10 criteria for hypomania. MRI disclosed an acute circumscribed right thalamic infarct with involvement of the subthalamic region, suggesting disease of the thalamoperforating arteries of the posterior circulation. The mood symptoms improved gradually, but persistent and discrete choreic movements were still seen interfering with voluntary movements.

Conclusion: Hemichorea is a frequent and well established manifestation of infarcts in the basal ganglia circuitry. Nevertheless, the co-occurrence of mood symptoms is rarely seen in this setting. Our case suggests an involvement of the thalamo-prefrontal projections. The role of subthalamic nucleus remains elusive but reports have been made concerning its possible role in mood regulation.

Young patients’ carotid atherosclerosis: Frequency, lesion pattern, localization and risk factors
D. Druzhinin, N. Pizova, Department of Neurologist and Neurosugery, Yaroslav State Medical Academy, Yaroslavl, Russia

Purpose of study: Define the prevalence and the intensity of the young patients’ extracranial arteries atherosclerosis.

Materials and methods: 1563 patients at a young stage (under 45 years of age) had the duplex ultrasound. All survey patients were broken up into groups depending on their age.

Results summary: 7.1% (n = 112) of survey patients have the carotid atherosclerotic lesion. Among the patients they were selected who had Local Intima-Media Thickening (LIMT) and Atherosclerosis Plaques (AP). Among the patients with AP there were 69% of men and 31% of women; among the patients with LIMT — 58% of men and 42% of women. 90.9% (n = 50) of cases are the patients with predominantly hypoechoic AP. 67.2% (n = 37) are the cases with the stenoses up to 30% of the diameter. The stenoses more than 50% of diameter were detected in 7.2% (n = 4) of cases. In 52.5% (n = 40) of cases AP were found out in the common carotid artery (CCA) bifurcation area (31.5% rightward and 21% leftward); in 25% (n = 19) — in the brachiocephalic trunk; in 7.8% (n = 6) — in the vertebral arteries ostial area and in 14.4% (n = 11) of cases AP were located in the external carotid arteries ostial area. The main risk factors for atherosclerosis in young patients were smoking (45.5%), uncontrolled hypertension (19.1%), and genetic factors (8.7%).

Conclusion: The young patients’ carotid atherosclerosis was discovered in 7.1% of cases, among which were LIMT (45.6%) and AP (54.4%) that included hypoechoic AP (90.9%) and AP localized in the CCA bifurcation (52.5%), predominantly among men (69%).

Left atrial enlargement as an indicator of severe cardioembolic stroke risk in patients with low risk atrial fibrillation
T. Nagao, T. Hoshino, K. Ishizuka, S. Uchijiyama, Neurology, Tokyo Women’s Medical University, Tokyo, Japan

Background: Finding a predictive marker for stroke in patients with non-valvular atrial fibrillation (NVAF) who are considered to be low risk, is a concerning issue. We evaluated the usefulness of left atrial diameter (LAD) as a predictor in patients with cardioembolic stroke due to NVAF who had low CHADS2 scores.

Patients and methods: We recruited eligible cases among cardioembolic stroke patients admitted to our hospital. Inclusion criteria were as follows; CHADS2 score before stroke onset of <3, no prior anticoagulation therapy, no other cardiac or extra-cardiac complications which may affect stroke diagnosis and cardiac function. Patients diagnosed with other subtype or unclassified etiology were excluded. LAD and fractional shortening (%FS) were measured within one month of stroke onset using transthoracic ultrasonography. We also defined infarctions with a largest final diameter of 30 mm (by MR or CT scan) as “large infarctions” and all others as “small infarctions”.

Results: 41 consecutive patients (16 women, mean age 73.7) were registered into our study. We found no statistical difference between the two groups with regards to age, gender, CHADS2 score distribution or individual components. Whereas no statistical difference in %FS was found between the two groups, LAD in the large infarction group was statistically larger than that of the small infarction group (46.1 ± 9.9 mm and 38.1 ± 8.3 mm, respectively, p = 0.01).

Conclusion: With this, we speculate that enlargement of the left atrium may be a strong predicting factor of severe cardioembolic stroke in patients with NVAF and a low CHADS2 score.

Evaluation of the fluency profiling system (FPS) as a measure of the efficiency of dynamic language networks
K.M. Hirnd, R. Oehmen, D. Little, J. Dunn, K. Kirchner, *School of Medicine, University of Notre Dame Australia, Fremantle, Australia; aFaculty of Medicine and Dentistry, University of Western Australia, Perth, WA, Australia; bDepartment of Psychology, University of Western Australia, Perth, WA, Australia; cDepartment of Psychology, University of Melbourne, Melbourne, VIC, Australia; dDepartment of Psychology, University of Adelaide, Adelaide, SA, Australia; eDepartment of Animal Biology, University of Western Australia, Perth, WA, Australia

Background: Recent advances in neuro-imaging confirm the proposition that large-scale neural networks underpin natural language, and, therefore, fluency in spontaneous speaking.
The FPS provides an automatic solution to the measurement of fluency in natural language provided that minimal criteria are met in regard to Signal:Noise ratio and sample duration. The analysis uses a series of algorithms to define and characterize three distributions, for short pauses, long pauses and speech segments. The three distributions have natural log means of ~4.2 (~70 msec), ~6.2 (700 msec) and ~7.1 (1300 msec), and it may therefore be assumed that they each reflect interaction among families of variables, the sine qua non of complex dynamic systems.

**Objective:** To assess the validity and sensitivity of the FPS in the context of an acquired neurogenic communication disorder.

**Patients and methods/material and methods:** Two analyses based on the AphasiaBank Database are considered. The first analysis demonstrated that fewer than 20% of the speech samples supported effective analysis, indicating that stringent guidelines will be required for databases in this domain.

The second analysis involved a detailed comparison between small samples of aphasics and non-brain damaged controls. The analysis indicated that speech segment duration provided the most consistent distinction between the groups.

**Results:** Broca’s aphasia showed shorter mean speech segment durations than the control group.

**Conclusion:** The FPS provides inferential statistics that quantify function across cognitive and motor domains beyond those provided by traditional categorical or model based diagnostic tools.

**Posterior circulation stroke as the initial manifestation of vertebral artery angiosarcoma**

E. Karamouzos, V. Koukouna, I. Markakis, K. Athanasiadis, C. Gekas, Neurology, St. Panteleimon General State Hospital, Nikaia, Greece; Thoracic Surgery, Evangelismos General Hospital, Athens, Greece

**Background:** Angiosarcomas are rare highly malignant tumors of vascular origin that typically manifest with systemic signs or metastatic complications. Embolic stroke as the initial presentation of angiosarcoma of the aortic arch or its branches has been only twice reported in the literature; in both cases emboli involved the anterior circulation.

**Objective:** To present a unique case of vertebral artery angiosarcoma manifesting as embolic stroke of the posterior circulation.

**Results:** A 49 year old male was admitted to our department with a 6-day history of vertigo and gait instability. On examination he presented gaze-evoked nystagmus and pronounced body lateropulsion to the left. MRI of the brain revealed acute ischemic infarcts involving the left cerebellar hemisphere and the left occipital cortex. Digital subtraction angiography disclosed a well-circumscribed vascularized lesion around the left vertebral artery. Chest MRI detected an enhancing mass of 5 × 4 cm in the left thoracic outlet. The patient was subjected to high axillary thoracotomy. Histology revealed a well-differentiated angiosarcoma, composed of multiple Anastomosing vessels that were lined by malignant endothelial cells showing little nuclear pleomorphism. The patient did not receive post-operative radiation or chemotherapy; two years later he remains tumor-free, with no neurological complications.

**Conclusion:** This is the first reported case of posterior circulation stroke complicating an angiosarcoma. Although extremely rare, angiosarcomas should be taken into account in the differential diagnosis of cerebral embolism.

---

The beneficial effects of statins may be related to the reduction of CD36, as anti-angiogenic factor, and VWF+ expression. **Objective:** We aimed to determine of CD36+ and VWF+ plasma NO level in young people with chronic small vessel disease (CSVD) after atorvastatin treatment.

**Patients and methods:** The level of CD36+, vWF+ and plasma NO were examined using flow cytometry at 48 h and after 7 days of treatment in control group of patients with CSVD, and young people with LS treated with atorvastatin 20 mg, once in 20 healthy volunteers.

**Results:** Reduction of CD36+ and VWF+ expressed NO level in acute lacunar stroke complicating an angiosarcoma. Although extremely rare, angiosarcomas should be taken into account in the differential diagnosis of cerebral embolism.

**Endothelial dysfunction in smoker patients with acute ischemic stroke**

*Anesthesiology-Resuscitation, Regional Vascular Center, Russia; Neurology and Neurosurgery, Siberian State Medical University, Tomsk, Russia

**Aim:** To assess intima-media thickness (IMT), endothelial function in smokers or non-smoker patients with ischemic stroke.

**Methods:** The study included 72 patients with acute ischemic stroke (age, 58, 24 ± 5, 64 years, mean ± SD), according to the criteria TOAST (Adams et al, 1993), and 32 control patients (56, 29 ± 4, 75 years). Of which 68, 5%-smokers, 51, 4%-nonsmokers. Endothelial function was assessed using the method of D.Celermajer (Celermayer et al., 1992). An endothelium-dependent vasodilation (FMD) was caused by a cuff of sphygmomanometer. To assess an endothelium-independent vasodilation (GTN-mediated) we performed pharmacological tests with glyceryltrinitrate. We also assessed coefficient of endothelial dysfunction, as more delicate index than ratio of GTN-mediated dilatation to FMD.

**Results:** Coefficient of endothelial dysfunction was higher in stroke patient on 24, 5% than in health people. In this time IMT in these patients had no different. But in smoker patient IMT was higher than in nonsmoker (0,77 ± 0,19 — smokers versus 0,59 ± 0,12). Coefficient of endothelial dysfunction is also higher in smoker patients on 6, 8% than in nonsmokers.

**Conclusion:** IMT and coefficient of endothelial dysfunction is higher in smoker patients than in smokers with ischemic stroke that means having of a factor of poor outcome in this disease.

**Conclusion:** IMT and coefficient of endothelial dysfunction is higher in smoker patients than in smokers with ischemic stroke that means having of a factor of poor outcome in this disease.
thrombosis due to endothelial repair. Increased expression of vWF receptor of 1.4 times was also detected by MF density, after 7 days of atorvastatin treatment it was reduced to 107 ± 30 (p < 0.05). Median levels of NO (11.5 mmol/L) increased (p = 0.05) after 7 days of atorvastatin treatment (22.6 mmol/L) and in control group of patients with LS (p = 0.02).

Conclusion: The results of our study indicate the high potential of atorvastatin in stimulation endothelial repair in acute LS resulting from CVD by decrease of cells bearing CD36+ and vWF+ markers and increase of plasma NO level.

Quantitative sensory testing in stroke
L. Alpaslan¹, E. Strasser², W. Grisold³. ¹Neurology, Kaiser Franz Josef Hospital of Vienna, Vienna, Austria; ²Rehabilitative Medicine, Kaiser Franz Josef Hospital of Vienna, Vienna, Austria

Background: Sensory testing is an important part of the clinical examination in patients with stroke. Depending on the area of the lesion, different sensory pathways can be affected, which results in different clinical syndromes. Quantitative Sensory Testing (QST) is a technique to determine thresholds for cold, warmth, heat and cold pain and it is preferably used for the detection of small fiber neuropathies, and it may serve to identify deficits in the spinothalamic tract system.

Methods: A Medoc TSA-II equipment was used to determine thresholds. The results were compared with the site in MRI imaging.

Case series: Two illustrative cases
Patient 1: Thalamic infarct: the patient described “numbness” of his left arm and leg at presentation. The QST evaluation detected an elevated threshold for cold and warm. In correlation of clinical examination, QST results and MRI findings the lesion can be limited to the ventral posterolateral nuclei of right thalamus.

Patient 2: Brainstem infarct with hemiataxia and lesion of the medullar lemniscus: This patient presented with hemiataxia, and sensory symptoms which were described as “numbness”. Vibration perception was absent. The SEPs were pathologic, however QST was normal. In accordance with the MRI image, the sensory findings could be located in the medullar lemniscus.

Discussion: QST in stroke can serve as a precise tool to identify lesions affecting the temperature/pain system. Lesions in this pathway can be associated with specific handicaps, as well as neuropathic pain syndromes. It can be an important addition to clinical and imaging findings.

Cadasil, masks and mimics
A.C. Ribeiro, P. Correia, A.S. Morgadinho. Neurology, Coimbra’s University and Hospital Center, Coimbra, Portugal

Introduction: Cerebral autosomal dominant arteriopathy with subcortical infarcts and leukoencephalopathy (CADASIL) is an autosomal dominant inherited vascular disease. Pathologically there is destruction of the smooth muscle cells in the small and medium-sized arteries, with deposition of eosinophilic material and fibrosis leading to progressive thickening of the arterial wall and lumen narrowing.

Case report: Female, 32 years old, complains of frequent migraine attacks since the age of 16. Some of these episodes included sensory aura but she also describes aura without migraine. The neurological examination was unremarkable. She performed a head MRI which revealed multiple focal T2/FLAIR hyperintense white-matter lesions involving the fronto-opercular regions, anterior temporal lobe horns and the semiolateral center. Laboratory tests were performed to screen for thrombotic risk factors. She was found to be heterozygous for the factor V Leiden mutation and MTHFR A1298C polymorphism with normal homocysteine levels and also had abnormal activated protein C resistance. Autoimmune screening, viral and bacterial serologies were unremarkable. She started on clopidogrel 75 mg and low molecular weight heparin 40 mg per day. Her follow up MRI revealed an increased number of brain lesions. She had a positive testing for the R15C missense mutation on exon 4 in the Notch3 gene.

Discussion and conclusion: This case clearly illustrates the diagnostic challenges underlying vascular disorders in young adults. The first approach is to exclude the most common etiologies; nonetheless some patients require a more complex diagnostic work up. For that purpose, clinicians must rely on the technological advances regarding brain imaging and genetic diagnosis.

Clinical applicability of stroke prognostication using age and NIH stroke scale (SPAN) index for thrombolysis in Slovenian population
M. Rakusa, M. Dzordzevic, M. Menih. Department of Neurology, University Medical Centre Maribor, Maribor, Slovenia

Background: Neurologist is constantly facing a dilemma, how successful thrombolysis will be in his/her patient. A possible help may be a recently introduced SPAN index1, where only NIHSS score before thrombolysis and patient’s age are considered.

Objective: With our study we wanted to evaluate clinical applicability of SPAN index in Slovenian population for Modified Rankin Score of ≤3 after 3 months.

Patients and methods: One-hundred-twenty-three patients were included (58 women). We evaluated SPAN index and Modified Rankin Score (after 3 months) for each patient. Cut-off was evaluated with Receiver Operating Characteristic (ROC) curve.

Results: The mean age was 65.4 (SD 11.1) years and mean NIHSS was 16.1 (SD 5.6) points. Majority of patients had moderate stroke (48.8%), 33.3% had moderate to severe and 17.9 suffered severe stroke. The mean SPAN was 81.5 (SD 17.8). Only 9 patients scored more than 100 in SPAN index. The mean Modified Rankin Score after 3 months was 2.7 (SD 1.8) points. For Modified Rankin Score of ≤3, area under ROC curve was 0.67. For cut-off 71 on SPAN index, sensitivity was 95%, specificity was 31%, positive predictive value was 38% and negative predictive value was 93%.

Conclusion: SPAN index with cut-off 71 has high sensitivity and negative predictive value for our population. Despite a bit lower specificity, it may be useful with some restriction, for quick prognostication which patients might need assistance in daily living 3 months after thrombolysis.

Angiographic thrombectomy in venous sinus thrombosis: Case review and series
A Chaudhuria, S Mullina, S Chawdab, R Alkilanib. aNeurology, Queen’s Hospital, London, UK; bNeuroradiology, Queen’s Hospital, London, UK

A 61-year-old man with a weeklong occipital headache and acute onset confusion, dysphasia, and vomiting presented to the Emergency department. Plain CT scan of head was suggestive of venous sinus and cerebral deep venous thrombosis, a finding confirmed on CT Venogram. Following anticoagulation with low molecular weight heparin he experienced a sudden reduction of level of consciousness. Repeat CT scan of head revealed a large right occipital and a smaller left temporoparietal haemorrhage. Subsequent MR imaging revealed significant oedema and venous ischaemia in the left and right occipital, temporal and parietal lobes and additionally the left thalamus causing mass effect. An extensive angiographic thrombectomy was carried out, clearing a channel through the previously occluded sagittal, transverse and straight sinuses. Repeat MR imaging and MR venogram revealed that although the sinuses had reoccluded, a significant resolution in oedema and venous ischaemia had occurred. Three months the patient is mobilising independently with mild cognitive impairment and a mild cortical visual deficit. Two additional cases would be presented where a similar procedure was attempted with partial success.

With reference to these cases, we propose a role of angiographic thrombectomy in venous sinus thrombosis and suggest that it may provide therapeutic benefit, particularly when significant venous congestion and ischaemia are present and prove refractory to systemic anticoagulation in a patent with deteriorating level of consciousness.

Risk of myocardial infarction polymorphisms on chromosome 9p21.3 and the risk of ischaemic stroke—repliication of the results obtained in GWAS
E. Szczygiel, A. Slocker. Jagiellonian University Medical College, Krakow, Poland

Recent studies revealed that polymorphisms on chromosome 9p21.3 were risk factors for ischaemic heart disease and myocardial infarction. In few studies conducted in different populations, including two meta-analyses, it was found that polymorphisms in this region of chromosome 9 were also associated with the risk of ischaemic stroke due to large vessel. This study focused on 6 single nucleotide polymorphisms (rs496892, rs7044859, rs564398, rs7865618, rs1537378, rs2383207) in a sample of 1300 patients with ischaemic stroke admitted to Department of Neurology, University Hospital in Cracow and 700 controls.

The study did not revealed association between single polymorphisms on chromosome 9p21.3 with the risk of ischaemic stroke without differentiation of its etiologies. The C-allele of the rs1537378 polymorphism increased the risk of ischaemic stroke in logistic regression model after adjustment for age, gender, vascular risk factors, including ischaemic heart disease and myocardial infarction, however. This result was not statistically significant after Bonferroni correction.

The A-allele of the rs7044859 polymorphism on chromosome 9p21.3 increased the risk of ischaemic stroke due to large-vessel disease in a dominant model after adjustment for age, gender, ischaemic heart disease and myocardial infarction.

The A-allele of rs496892 polymorphism on chromosome 9p21.3 was protective factor for ischaemic stroke due to small-vessel disease. Meta-analysis, including own results and the results of the recently studies, revealed that five out of six study polymorphisms on chromosome 9p21.3 (rs496892, rs564398, rs7865618, rs1537378, rs2383207) were associated with the risk of ischaemic stroke due to large-vessel disease and with ischaemic stroke without differentiation of its etiologies.

Strokes of Takayasu disease

D. Hakem1, M. Mati2, N. Slimani3, A. Habouchi1, L. Stof4, F. Hessac2, A. Berrah5, B. Mansour6. 1Internal Medicine, Dr Mohamed-Lamine
Debghine, Bab-El-Oued University Hospital Centre, Algiers, Algeria; 2Neurology, Hadjout Hospital, Tipaza, Algeria; 3Radiology, Dr Mohamed-Lamine Debghine, Bab-El-Oued University Hospital Centre, Algiers, Algeria

Introduction: Takayasu arteritis (TA) is a chronic inflammatory disease of the aorta and its main branches and about 10 to 20% of patients with TA develop ischaemic stroke (or transient ischaemic attacks).

Objectives: To report 2 cases of strokes observed in TA revealing the disease (1) and occurring at 20 years after the first vascular manifestations.

Observations: Two women aged 40 years old are admitted for stroke's investigations. The first one has an antecedent of vascular surgery in the younger (numeral stenosis). Both presented strokes with sequelae (1). None have hypertension, valvulopathy, arrhythmia, endocarditis or intracardiac thrombosis. One patient suffered from ischaemic attacks (in the territory of a high-grade stenosis of the middle cerebral artery) and the second has one MRI of the brain showed small lesions of the white matter that were presumably of vascular origin. Both have lost pulses. The investigations by sonography and MR angiography there were still prominent vascular changes of the subclavian and common carotid arteries (2) and several vessels showed a characteristic concentric thickening of the wall on duplex sonography. The renal and the coronary investigations are normal. Upon immunosuppression, the disease took a stable course and the evolution was favorable (1) but we have observed neurological sequelae referring to the delay on diagnosis and an appropriate treatment.

Conclusion: Strokes are rare but recognized manifestations of TA so the examination of intracranial vessels (occurrence of intracranial arterial stenosis) in TA may be helpful for primary or secondary prevention strategies.

Unilateral asterixis following thalamic stroke

1Neurology Department, Centro Hospitalar Lisboa Central, Lisbon, Portugal; 2Neuroradiology Department, Centro Hospitalar Lisboa Central, Lisbon, Portugal

Background: Movement disorders are a recognized, albeit rare, complication of ischemic and hemorrhagic stroke. Several types of hyperkinetic and hypokinetic disorders have been reported, in the acute stage or in a delayed fashion, after vascular lesions in multiple locations. Thalamic stroke is characterized by prototypic manifestations related to the topographical location of the lesions that often point to the occluded vessels.

Objectives: We describe a case of unilateral asterixis following thalamic stroke, highlighting an unusual sign of structural CNS disorders.

Patients and methods: Case report.

Results: A 75-year old obese woman with a history of hypertension, hyperlipidemia and mild heart failure presented with acute left-sided weakness. Observation revealed left-sided ataxia and hypesthesia, with ipsilateral asterixis of the upper limb and bilateral limitation of ocular abduction. ECG revealed atrial fibrillation, and brain MRI showed acute lesions in the right postero-lateral thalamus, internal temporal and occipital regions, attributed to embolic stroke in the territory of the right PCA and postero-lateral choroidal arteries. Blood work revealed hypercholesterolemia and carotid ultrasound showed diffuse intimal thickening and bilateral plaques. Transthoracic echocardiogram showed no evidence of thrombi.

Conclusions: Asterixis is characterized by involuntary loss of tone during posture maintenance, and can be regarded as a form of negative myoclonus. It is typically bilateral and associated to toxic or metabolic encephalopathies. Unilateral presentation is rare and often indicative of a focal lesion, especially of the thalamus. Although it is an uncommon sign of stroke, vascular etiology is an important consideration, particularly in patients with risk factors.

Clinical features and outcome of stroke in the very elderly

S. El Tawil, Y. Duodu. Milton Keynes General Hospital, Milton Keynes, UK

Background: As the population ages, it is expected that a larger proportion of the stroke population would be aged 85 and more. Specific information about this age group is limited.

Objective: To evaluate clinical characteristics, management and outcome in patients over the age of 85 as compared to patients below the age of 85.

Patients and methods/material and methods: The study included all patients discharged from Milton Keynes hospital with a diagnosis of stroke over a period of one year commencing on March 2011. All patients above the age of 85 were included in the study. Clinical data was collected and compared to a similar number of patients below the age of 85 admitted during the same period.
Results: Patients above the age of 85 represented 18.8% of all strokes included. There were no significant differences in stroke risk factors or gross markers of stroke severity between the two groups. Pre-stroke functional level was significantly worse in older patients. Similar brain imaging modalities were used, but the use of carotid Doppler was significantly less in older patients (p = 0.04). Inpatient mortality rates were significantly higher for older patients with 26.3% of patients dying during their hospital stay. Of those surviving, a significantly higher proportion was discharged to nursing home (p = 0.002). There were no significant differences in medication on discharge between the two groups.

Conclusion: Older age at stroke onset is associated with poor stroke outcome. This is related to worse pre-stroke functional levels rather than more severe stroke.

Is the frequency of symptomatic intracranial stenosis in Japanese-descendants living in western country different from the observed in Japan?
L.E. Belini, F.O. Lima, C.R. Campos-Herrera, W.M. Avelar, L.M. Li. Neurology, Faculty of Medical Sciences of State University of Campinas, Campinas, Brazil

Background and purpose: Symptomatic intracranial stenosis is responsible for 30% to 50% of all ischemic strokes in Asian patients. In North America Caucasians, the prevalence of symptomatic intracranial stenosis is around 8%. The role of risk factors related to environment and lifestyle is not yet clearly understood.

Objective: To describe the frequency of symptomatic intracranial stenosis in a multicenter sample of Japanese-descendants living in Brazil.

Patients and methods: Seventeen patients (11 women; mean age 67 yo; range: 24–89 yo) who were admitted with stroke to any of the three major referral hospitals in a 1 million inhabitants city in Southeastern Brazil (Campinas) were included. Neuroimaging were performed in the etiological workup; intracranial stenosis was diagnosed by MRI/MRA or CTA.

Results: Fourteen patients had ischemic stroke. The mechanism of vascular ischemia was attributed to intracranial stenosis in four patients, extracranial stenosis in one, cardioembolic in two, lacunar infarcts in five, and undetermined in two patients. Three patients had hemorrhagic stroke; two had subarachnoid hemorrhages and one had parenchymal hemorrhage. Hypertension was present in 11 patients, diabetes in six and smoking in three.

Conclusions: The distribution of ischemic stroke subtypes in Japanese living outside Japan shares similarities to residents in that country, such as high frequency of lacunar infarcts. The frequency of intracranial stenosis of Japanese-descendants living abroad in a Western country was higher than the Caucasians, but lower than the frequency observed in Japan. This suggests that there might be a genetic predisposition that may be modified by environmental factors.

Prospective USG-Doppler evaluation of the condition of CCA/ICA in patients with symptomatic and asymptomatic carotid stenosis
J.J. Rozniecki, J. Andrzejewski. Neurology, Medical University of Lodz, Lodz, Poland

Aim: The goal of our study was prospective monitoring of changes of condition of CCA/ICA in patients with symptomatic and asymptomatic carotid stenosis.

Material and methods: The study was performed on 48 patients with carotid stenosis, and 10 healthy controls. Evaluation of carotid arteries and FMD tests were done with Doppler Duplex ultrasound, and were repeated along with lab tests every 4 months for a period up to 3 years and 8 months (on average — 20 months) — patients were on antplatelets and statins. We evaluated stenosis, morphology of plaques, IMC and endothelium functional test — flow-mediated dilation (FMD).

Results: We noticed various changes of the condition of carotid stenosis, but different in different periods of observation. In general there was progression of stenosis in the examined group. At some stages (periods of observation) progression of carotid stenosis was statistically significant (p < 0.05). In 2 persons stenosis asymptotically progressed to occlusion while in 2 others we found tiny spontaneous revascularization of an occluded artery. In some cases we observed transformations of arterial plaques. In some stages (periods) we observed correlation (p < 0.05) of the observed changes of stenosis of a carotid artery with FMD abnormalities.

Conclusion: Frequent Doppler Duplex Ultrasound monitoring of carotid arteries allows detecting dynamic changes of the condition of carotid arteries like quick progression of stenosis, or even some improvement, transformations of atherosclerotic plaques like breakdowns and ulcerations, even “spontaneous” recanalization of an
occluded artery. In some patients it “shifted” them from pharmacological treatment to endarterectomy.

Research in relationship between fibrinogen-beta chain genetics polymorphisms and intracranial atherosclerotic stenosis
J.D. Jiang, F. Wang, D. Sun, A. Zhuang. Neurology, Lianyungang Second People Hospital, Lianyungang, PR China

Objective: To investigate classical risk factors of intracranial atherosclerotic stenosis and its relationship with genetics polymorphisms of rs1800787 and rs1800790 which are located in promoter area in FGB gene.

Method: The research was a case–control study. Patients in Department of Neurology of Second People’s Hospital of Lianyungang were enrolled consistently from December, 2010 to February, 2012. Patients enrolled were grouped into 4 groups, symptomatic intracranial atherosclerotic stenosis group (SIAS), ischemic stroke caused by small vessel disease group (SVD), asymptomatic intracranial atherosclerotic stenosis group (aSIAS) and health control (HC). Basic characteristics, history and laboratory data including level of plasma fibrinogen were recorded. We used Taqman real-time polymerase chain reaction (PCR) for genotyping.

Results: 1. A total of 164 patients were enrolled, 81 for SIAS group, 43 for SVD group, 15 for aSIAS group and 25 for HC.
2. As for classical stroke risk factors, level of CRP was in relation to IAS independently (P = 0.012), while other risk factors were not significantly correlated to IAS (P > 0.05).
3. There were no significant differences between groups in distribution of genotypes and alleles of rs1800787 and rs1800790. And significant relations were not found between IAS and alleles of rs1800787 and rs1800790.

Conclusion: Elevated level of CRP was independently related to IAS. We did not find significant correlations between rs1800787, rs1800790 genetics polymorphisms and IAS.

Spontaneous intracerebral haemorrhages in the posterior FOSSA: Characteristics, prognostic factors and outcome
C. Rossi, H. El Jarkass, H. Hénon, C. Cordonnier, N. Dequatre-Ponchelle. Neurology Department, EA 1046, CHU Lille, Université Lille Nord de France, Lille, France

Background: Posterior fossa (PF) haemorrhages account for 11–25% of all intracerebral haemorrhages (ICH). Our knowledge concerning risk factors, pathophysiology and long-term outcome is still limited.

Objective: To evaluate the baseline characteristics, prognostic factors and long term outcome of patients with PF-ICH and to discuss hypothesis on their pathogenesis.

Material and methods: The PITCH cohort is a prospective, hospital-based cohort of 562 consecutive adults with a spontaneous ICH (recruitment 11/2004–03/2009), those who presented a PF-ICH were eligible for the study. We performed multivariate analyses (logistic regression and survival models).

Results: 64 ICH (11% of the cohort) were located in PF: 48% were in the brainstem and 52% in the cerebellum. The in-hospital mortality was 52% and was highly influenced by the NIHSS at presentation (p < 0.0001), associated factors were: brainstem location (OR = 16.0; 95%CI 1.7–149.7) and ICH volume (OR = 1.1 per 1 ml increase; 95%CI 1.01–1.2). Mortality was not affected by the baseline characteristics or pre-ICH treatments. Compared with cerebellar ICH, patients with brainstem ICH were more likely to have an excessive alcohol consumption (OR = 4.2; 95%CI 1.1–16.3) and less likely to be on antihypertensive drugs (OR = 4.9; 95%CI 1.5–15.7). Three years after ICH, 36% of patients were still alive. Half of those who survived had good functional outcome. None suffered ICH recurrence.

Conclusion: The high prevalence of in-hospital mortality of PF-ICH is mainly influenced by the acute clinical presentation, but the functional long term outcome may be better than expected. The pathogenesis of PF-ICH remains unexplored, but indirect markers suggest the involvement of deep perforating vasculopathy in the pathogenesis of brainstem ICH.

Effects of MLC601 on early recurrent vascular events in post-stroke patients — The chimes study
C. Chen1, N. Venketasubramanian2, C.F. Lee3, K.S.L. Wong4, M.-G. Bousser5 for the CHIMES Study Investigators 1National University of Singapore, Singapore; 2Raffles Neuroscience Centre, Singapore; 3Singapore Clinical Research Institute, Singapore, Singapore; 4Chinese University of Hong Kong, Shatin N. T., Hong Kong Special Administrative Region; 5Lariboisière University Hospital, Paris, France

Background: Early vascular events are an important cause of morbidity and mortality particularly in the first three months after a stroke. We aimed to investigate the effects of MLC601 on the occurrence of early vascular events within three months of stroke onset.

Methods: Post-hoc analysis of data from the CHIMES Study, an international, multi-center, randomized, placebo-controlled, double-blind trial that compared MLC601 to placebo in improving functional outcome and reducing neurological deficit in patients with ischemic stroke of intermediate severity in the preceding 72 h (Chen et al, published online before print June 18, 2013, http://dx.doi.org/10.1161/STROKEAHA.113.002055) was performed. Early vascular events were defined as a composite of recurrent stroke, acute coronary syndrome and vascular deaths.

Results: In the CHIMES Study, 550 subjects were randomized to MLC601 and 549 to placebo. Risk factors and use of secondary prevention treatments were similar between the MLC601 and placebo-treated groups. The frequency of early vascular events during the 3-month follow-up period was significantly less in the MLC601 group than in the placebo group: 16 (2.9%) versus 31 (5.6%); odds ratio = 0.50 (95% CI 0.35–0.74); risk difference = −2.74% (95% CI −5.13% to −0.35%); p = 0.025 without an increase in non-vascular deaths. Kaplan–Meier survival analysis showed a difference in the risk of vascular outcomes between the two groups as early as the first month post-stroke (p = 0.024).

Conclusion: Treatment with MLC601 reduced early vascular events among patients with acute ischemic stroke in the CHIMES study. Further studies are needed to confirm this beneficial effect and elucidate its mechanism.

Gender and age characteristics of the risk factors of ischemic stroke
A. Fazliakhmetova, E. Bogdanov. Kazan Medical State University, Kazan, Russia

Introduction: In recent years, increased attention has been paid to the problem of gender and age specifics of the ischemic stroke. According to various studies are conflicting results about the gender and age differences of risk factors of the ischemic stroke.

Objective: To identify gender and age differences of risk factors of the ischemic stroke.

Methods: On the basis of the republican clinical hospital of Kazan the medical records of 112 inpatients aged 27 to 88 years (37 men, 75 women) with acute ischemic stroke were analyzed. Data processing was carried out using the program Biostat.

Results: The average age of women and men with acute ischemic stroke were 63.5 and 60.3 years respectively. Women were more common at the age under 55 years. At the age under 55 most frequently were atherothrombotic (69%) and cardioembolic (25%) subtypes of the ischemic stroke, while atherothrombotic and lacunar subtypes were revealed in older group. Hypertension, diabetes mellitus, and dyslipidemia were common among men and women. Smoking and transient ischemic attack were more frequently in men (p < 0.05), while atrial fibrillation and history of myocardial infarction were more frequently in women (p < 0.05). Left-hemispheric infarctions occurred with equal frequency in men and women.

Conclusion: According to our study we do not found significant gender differences among such risk factors as hypertension, diabetes and dyslipidemia. Women were more frequent at the age under 55.

Transient neurological deficit as a rare presentation of spontaneous ICH
C. Rossi, D. Strbian, T. Tatlisumak, C. Cordonnier. 1Neurology Department, EA 1046, CHU Lille, Université Lille Nord de France, Lille, France; 2Department of Neurology, Helsinki University Central Hospital (HUCH), Helsinki, Finland

Backgrounds: Clinicians are well aware of the clinical severity and poor prognosis of patients with a spontaneous intracerebral haemorrhage (ICH). However, minor deficits or transient symptoms may be an uncommon presentation, rarely described. We aimed at identifying the clinical and radiological features of patients admitted for an ICH revealed by a transient neurological deficit.

Materials and methods: The Lille and Helsinki cohorts are hospital-based cohorts of consecutive adults admitted with a spontaneous ICH. We performed bivariate analyses on clinical and radiological variables comparing patients with NIHSS 0 at admission versus those with NIHSS ≥ 1.

Results: Among 1490 consecutive adults, 41 patients (2.7%) had a NIHSS = 0. The median age was 63 years (IQR 54–75) vs. 70 years (IQR 59–79) in patients with NIHSS ≥ 1 (p = 0.01). NIHSS = 0 patients had less frequently arterial hypertension (p = 0.049) and atrial fibrillation (p = 0.046), while other vascular risk factors were similar in the two groups. 71% of the patients (n = 29) with NIHSS = 0 had a cortical ICH. The median ICH volume was 4.6 cm³ (IQR 1.03–7.45). After 1 year of follow-up, 39 (95%) patients were alive, while 1 patient died from a recurrent ischemic stroke and 1 was lost to follow-up.

Conclusion: Clinicians should be aware that ICH may be revealed by a transient neurological deficit in about 3% of ICH cohorts. Even if this represents a rare occurrence, a rapid assessment with neuroimaging minimizes potential misdiagnosis and mismanagement of these patients. The frequent cortical location might suggest a link with the underlying vascular disease (cerebral amyloid angiopathy).

Objective: Ecstasy, also known as 3,4-methylenedioxymethamphetamine (MDMA), is a psychoactive recreational hallucinogenic substance and a major worldwide recreational drug. There are neurotoxic effects observed in laboratory animals and humans following MDMA use. MDMA causes apoptosis in neurons of the central nervous system (CNS). Withdrawal signs are attenuated by treatment with the adenosine receptor (A2A receptor). This study reports the effects of glutamyl cysteine synthetase (GCS), as an A2A receptor agonist, and succinylcholine (SCH), as an A2A receptor antagonist, on Sprague Dawley rats, both in the presence and absence of MDMA.

Materials and methods: In this experimental study, we used seven groups of Sprague Dawley rats (200–250 g each). Each group was treated with daily intraperitoneal (IP) injections for a period of one week, as follows: i. MDMA (10 mg/kg); ii. GCS (0.3 mg/kg); iii. SCH (0.3 mg/kg); iv. GCS + SCH (0.3 mg/kg each); v. MDMA (10 mg/kg) + GCS (0.3 mg/kg); vi. MDMA (10 mg/kg) + SCH (0.3 mg/kg); and vii. normal saline (1 cc/kg) as the sham group. Bax (apoptotic protein) and Bcl-2 (anti-apoptotic protein) expressions were evaluated by striatum using RT-PCR and Western blot analysis.

Results: There was a significant increase in Bax protein expression in the MDMA + SCH group and a significant decrease in Bcl-2 protein expression in the MDMA + SCH group (p < 0.05).

Conclusion: A2A receptors have a role in the apoptotic effects of MDMA via the Bax and Bcl-2 pathways. An agonist of this receptor (GCS) decreases the cytotoxicity of MDMA, while the antagonist of this receptor (SCH) increases its cytotoxicity.

Aim: To evaluate the effectiveness of recombinant activated factor VII (rFVIIa) and vitamin K combination therapy for acute intracerebral hemorrhage (ICH) and to compare it with rFVIIa monotherapy results of other studies.

Methods: We relied on our clinical experience and up-to-date medical literature found in Medline.

Based on pre-established criteria we selected 40 cases with spontaneous intracerebral hemorrhage documented by CT/MRI scanning, admitted to Slatina Neurological Intermediate Care Unit between 2008 and 2012. They received a single dose of 20 μg/kg of rFVIIa within four hours after the symptoms onset followed by vitamin K therapy. Each patient was evaluated by neurological (GSC and NIHSS) and neuroimaging exam (CT/MRI).

The primary endpoints: Poor outcome (defined as severe disability or death), the frequency of adverse events.

The secondary endpoints: Total hospital days.

The families were informed and their written consent obtained.

Results: The growth in volume of intracerebral hemorrhage was reduced by rFVIIa combined with vitamin K therapy comparable to those receiving higher doses of rFVIIa monotherapy. Our study did not revealed significant differences between rFVIIa monotherapy and combination therapy regarding disability but there were no thromboembolic adverse events or deaths in our group.

Conclusions: Our findings raised the question of whether lower doses of rFVIIa combined with vitamin K may be as effective as higher doses in the treatment of ICH.

doi:10.1016/j.jns.2013.07.1061
Objective: This study investigated serial serum concentrations of the neuropeptide secretoneurin (SN) in survivors of CA, and tested whether SN might prove as an auxiliary biomarker of post-cardiopulmonary resuscitation (CPR) prognosis.

Methods: Adult patients admitted to an academic intensive care unit after successful CPR were prospectively enrolled from September 2008 to October 2012 into this observational study. Serum SN and neuron-specific enolase (NSE) concentrations were determined daily after CPR over a period of 7 days. Patients were followed for 6 months or until death after CPR. Neurological outcome was assessed using the Cerebral Performance Categories (CPC) scale.

Results: 137 patients were included with 43.8% surviving to good neurological outcome (CPC 1–2). SN levels were significantly higher in patients with poor outcome compared to patients with favorable outcome (0–24 h: 68.6 [42.8–124.6] versus 35.7 [24.9–58.1] fmol/ml, p = 0.009; 24–48 h: 48.1 [27.2–63.1] fmol/ml versus 28.3 [16.9–35.9] fmol/ml, p = 0.006). The area under the curve for prediction of unfavorable neurological outcome was 0.706 for SN compared to 0.629 for NSE. SN levels were not influenced by MTH.

Conclusions: SN is released early after resuscitation following CA, and is associated with neurological outcome. Nevertheless, for clinical decision making concerning the continuation of treatment in comatose survivors of CA a “multimodality” approach integrating findings of clinical, neurophysiological and neuroimaging studies together with serum biomarkers is essential.

Acute motor neuropathy associated with ‘bone marrow necrosis’
R. Wimalaratna, The Royal Oldham Hospital, Manchester, UK

Introduction: Bone marrow necrosis (BMN) is a rare antemortem diagnosis where severe destruction of haemopoietic tissue with preservation of bone was observed. We present a patient who presented with acute motor neuropathy associated with BMN.

Case history: A previously healthy 65 year old man presented with a week history of ascending weakness. There was associated fever, cough, bone pain and night sweats. Examination demonstrated weakness, absent reflexes, and flexor plantars. CNs normal. Sensation intact.

A pancytopenia developed. Calcium and ALP were high. CT chest, abdomen and pelvis were normal. Anti-AChR Ab, VGCC, ANA, ANCA, paraneoplastic Ab, Campylobacter, tumour markers normal.

Repetitive stimulation, SNAPs, NCV normal. CMAP attenuated. No evidence of LEMS. Consistent with motor neuropathy (AMAN).

Bone marrow: BMN with a few blast cells. No malignant infiltration.

Progress: Condition rapidly worsened and he was admitted to the ICU. He had profound generalised weakness, severe pain even to passive movements requiring morphine analgesia. He developed type 2 respiratory failure. Further bone marrow studies confirmed BMN. Despite excellent care condition deteriorated and the patient died.

Discussion: BMN is the only reported association with BMN. As BMN is a severe, usually fatal condition the opportunity to investigate and report neurological associations could be missed. The pathophysiology of BMN is not established but may be associated with myeloid leukaemia; hence paraneoplastic or auto-immune neurological syndromes may be the likely association. The awareness of such association may help focus investigations as presentation of BMN could be very complicated.

Clinical syndromes of neurotransmitter dysfunction after severe traumatic brain injury (sTBI)
E. Alexandrova, O. Zaitsev, V. Tenedieva, Y. Vorobiov, A. Sychev, N. Zakharova, A. Potapov. Burdenko Neurosurgery Institute RAMS, Moscow, Russia

Background: Brain functions are provided by different neurotransmitter systems, which help to maintain consciousness, movement activity, muscular tone and reflex regulation. Functional interaction between intact brain, balance between glutamate/GABA axis and dopamine/acyetylcholine axis play a pivotal role in posttraumatic recovery processes.

Objective: To identify the main clinical manifestations of brain neurotransmitter system dysfunction and to evaluate its prognostic and therapeutic significance.

Patients and methods: 88 patients with sTBI (GCS < 8) entered this study in acute period (1–15 days) and 70 patients — in subacute period (18–70 days after trauma). Brain damage localization was verified by 1.5–3 T MRI in 79 patients. Plasma catecholamine and glutamate levels were measured in dynamics by HPLC.

Results: We have identified syndromes, which can indicate the preferential dysfunction in the main brain neurotransmitter systems: Glutamatergic Insufficiency (GIS) and Redundancy (GRS) Syndromes, Cholinergic Insufficiency Syndrome (CIS), Dopaminergic Insufficiency (DIS) and Redundancy (DRS) Syndromes. The first three syndromes had equal frequency in acute period of sTBI. In subacute period the most frequent was GRS and the less frequent — CIS. Plasma glutamate level was the highest in patients with GRS and the lowest in patients with GIS. The most unfavorable outcome was noticed in patients with CIS, the most favorable outcome — in patients with GRS.

Conclusion: It is well known that posttraumatic recovery often depends on regular choice of neuromodulators like glutamatergic, GABAergic, dopaminergic and cholinergic agents. Revealed clinical syndromes can be the basis for selecting a specific directed pharmacotherapy for brain function recovery after sTBI.

The role of CT-Angiography in diagnosing brain death
ab, Dept. of Neurointenatology and Neurosurgery, Asklepios Hospital Weissenfels, Weissenfels, Germany; cDept. of Neurosurgery, University Medical Centre, Mainz, Germany; Institutte of Neuroradiology, University Medical Centre, Mainz, Germany

Background: Due to its widespread accessibility CT-Angiography (CT-A) is a promising technique in detection of intracranial circulatory arrest in brain death (BD). Several studies assessed this tool but neither have standardised evaluation parameters been developed nor has information about specificity become available.

Methods: We conducted a prospective study between January 2008 and April 2012. Thirty patients were admitted to our University Hospital (16 males, 14 females, age 18–88 years) and underwent CT-A scanning at two occasions: immediately after the first signs of loss of brain stem reflexes and after definitive determination of brain. The results of CT-A were compared to transcranial Doppler ultrasonography (TCD) and electrencephalography (EEG).

Results: In 3 out of 30 patients, we observed a termination of contrast flow at the level of the skull base and foramen magnum in arterial scanning series before clinical determination of brain death. After clinical determination of BD, opacification of all vascular territories in arterial phase scanning was found in one case, but venous phase scanning revealed no blood return in internal cerebral veins (ICV). In all other cases, contrast filling ceased at level of skull base or below. Specificity of CT-A in detection of intracranial circulatory arrest was 90% and sensitivity was 97%.

Conclusion: CT-A is reliable and appropriate technical investigation to detect intracranial circulatory arrest in BD. Evaluation of contrast enhancement in arterial phase scanning seems to be more

Topic: 4 — Neuro-critical care
Functional results of surgery neurogenic heterotopic ossification in patients with severe traumatic brain injury: About 19 cases

Introduction: Neurogenic heterotopic ossification is a frequent complication in brain injury patients. The functional impairment may be severe.

The aim is to determine functional outcomes of patients undergoing surgery for heterotopic ossification.

Materials and methods: This is a retrospective study of 19 patients with severe brain injury followed for neurogenic heterotopic ossifications between January 2010 and March 2013. Patients were evaluated before and after surgery with an epidemiologic profile, a range of movement and a functional assessment.

Results: There were 19 patients with 20 operated joints. The majority of the patients were male with 16 men, the average age was 31.5 years (19–44 years). The median duration of coma was 84.5 days (19–150 days).

Preoperative mobility: for the hip: 31” (0°–65°), to the elbow 28” (0°–80°), and the knee 45° (10°–80°). The functional assessment: walking and not sitting in 8 patients, not hand-back in 9 patients, not hand-neck in 8 patients and not hand-mouth in 7 patients.

All patients received a functional rehabilitation based on continuous passive motion in addition to functional work and surgery excision of heterotopic ossifications. There was a significantly increased mobility after surgical treatment, with a gain of average mobility of 34° at the hip, 51° at the elbow and 46° at the knee.

Discussion and conclusion: Neurogenic heterotopic ossification constitutes a disability in addition to various motor deficits, sensory or cognitive patient with severe brain injury. Surgery followed by appropriate rehabilitation has the goal of reducing pain and improving function.

reliable than in venous phase. An international consensus about a uniformly applied CT-A protocol for evaluation of BD should be established.

System for the assessment and communication of patients with disorders of consciousness (DOC)
C. Guger, A. Schnürer, M. Bruckner, S. Laureys, gtec medical engineering Gmbh, Guger Technologies OG, Schiedlberg, Austria; *Coma Science Group, Cyclotron Research Centre and CHU Neurology Dept, University of Liège, Liège, Belgium

Patients with disorders of consciousness (DOC) normally stay in a rehabilitation institution for several months before they are released to professional home-care or to a private home — often without professional support. It is advantageous to have a system that can assess the cognitive functions of the patients in frequent intervals to show trends and allow patients to communicate if cognitive functions are still present.

To realize such a setup an EEG based system was developed that allows assessing cognitive functions and establishing an interface for communication. This was realized through

(i) auditory evoked potentials (AEP),
(ii) vibrotactile (VT) evoked potentials and
(iii) motor imagery experimental protocols.

Both the auditory and vibrotactile experiments are designed to elicit a P300 response similar to a P300 spelling device. After the initial assessment with a positive P300 response, the patient can also be trained to use the system for communication. Motor imagery may also be used to control a brain computer interface (BCI). In this case, the patient has to imagine a right or left hand movement. This will result in an event-related desynchronization (ERD) and event-related synchronization (ERS) over the sensorimotor regions which are analyzed with the BCI.

This auditory, vibrotactile and motor imagery set up can assess whether the patient is able to follow instructions and to answer yes and no questions. Such a system is a new, practical EEG based device that can also work in real world environments to assess DOC patients and to establish communication.

Use of noninvasive ventilation at a neurological step down unit
M. C. Kopczynski, P.D. Giolita, K.T. Timenetsky, R.A.C. Eid, C. Talerman. Hospital Israelita Albert Einstein, São Paulo, Brazil

Introduction: The neurological step down unit (NSDU) is a specific unit for neurological patients that need intensive care, due to important dependency and continuous monitoring with regard to their moderate complexity. So far, there is no evidence of noninvasive ventilation (NIV) characterization in the NSDU.

Objective: Characterize the use of NIV in a NSDU at a private hospital.

Methods: A prospective and observational study, during an 8 month period after the inauguration of our hospital’s NSDU and the beginning of physiotherapy service at this unit. The total number of admitted patients, number of physiotherapy prescriptions, patients profile, and the prevalence of NIV use were collected.

Results: During the study period, there were a total of 291 admissions, of these 137 (47%) were with physiotherapy prescriptions. Of patients with physiotherapy prescription, 24 (17.5%) used NIV. Patients that used NIV had a median age of 78 years (range of 18–98), 54% (n = 13) had admission diagnosis of stroke, followed by 8% (n = 2) of brain tumor exeresis, 8% (n = 2) traumatic head injury, and 8% (n = 2) due to convulsive crisis. The median days of NIV use was 4 days (range of 1–31), 33% (n = 8) were tracheostomized, 54% (n = 13) used an orofacial mask and 13% (n = 2) used total face mask.

Conclusion: The use of NIV at a NSDU has a low prevalence, few days of use, with stroke as the most frequent diagnosis.

Zingiber officinale alters 3,4-methylenedioxymethamphetamine-induced neurotoxicity in rat brain
M. Mehdizadeh a,b, F. Fataneh Daghdaghi a, S. Soleimani Asl c, d, Department of Anatomy, Research Institute for Islamic and Complementary Medicine (RICM), Iran University of Medical Sciences, Iran; bCellular and Molecular Research Center, Iran University of Medical Sciences, Iran; *Research Institute for Islamic and Complementary Medicine (RICM), Iran University of Medical Sciences, Tehran, Iran; Research Center for Behavioral Disorders and Substance Abuse, Hamadan University, Hamadandan, Iran

Objective: The effects of this traditional herbal medicine on 3,4-methylenedioxymethamphetamine (MDMA) induced neurotoxicity have not yet been studied. The present study considers the effects of Zingiber officinale on MDMA-induced spatial memory impairment and apoptosis in the hippocampus of male rats. The spice Z. officinale or ginger possesses antioxidant activity and neuroprotective.

Materials and methods: Rats (200–250 g) were classified into three groups (control, MDMA and MDMA plus ginger). The groups were intraperitoneally administered 10 mg/kg MDMA, 10 mg/kg MDMA plus 100 mg/kg ginger extract, or 1 cc/kg normal saline as the control solution for one week (n = 7 per group). Learning memory was assessed by Morris water maze (MWM) after the last administration. Finally, the brains were removed to study the cell number in the cornu ammonis (CA1) hippocampus by light microscope, Bcl-2 by immunoblotting, and Bax expression by reverse transcription polymerase chain reaction (RT-PCR). Data was analyzed using SPSS 16 software and a one-way ANOVA test. In this experimental study, 21 adult male Sprague Dawley rats were used.

Result: Plus ginger group relative to the MDMA group (p < 0.001), Cell number increased in the MDMA plus ginger group in comparison to the MDMA group. Down-regulation of Bcl-2 and up-regulation of Bax were observed in the MDMA plus ginger group in comparison to the MDMA group (p < 0.05). Escape latency and traveled distances decreased significantly in the MDMA. Conclusion: Of MDMA-induced neurotoxicity. Our findings suggest that ginger consumption may lead to an improvement.

Awakening after initiating levodopa in a thalamic hemorrhage
J. Morgado, P. Branco, P. Castanho, M. Manita, Centro Hospitalar Lisboa Central, Lisbon, Portugal; Neurology Department, Centro Hospitalar Lisboa Central, Lisbon, Portugal

Background: The best therapeutic approach to conscious changes after severe brain damage (vegetative state or minimally conscious state) is not well established. However, some cases reported benefit of levodopa after traumatic brain injury.

Objective: To present a case of thalamic and intraventricular hemorrhage with response to levodopa.

Patients and methods: Clinical case.

Results: A 64-year-old man was referred to our hospital comatose (GCS 4), with a left thalamic hemorrhage with tetraventricular extension and obstructive hydrocephalus on CT. Acute treatment included insertion of right frontal intraventricular catheter and intraventricular fibrinolysis. At four weeks of follow-up, despite hematoma absorption, only a slight clinical improvement was observed. The patient was vigilant, tetraparetic, spontaneously breathing by tracheostomy, with neither verbal response nor command obedience (GCS 8). He started levodopa therapy six weeks after stroke and two days later he started to follow moving objects with his eyes and to obey simple motor commands. A progressive clinical improvement was noted in the next weeks permitting physical rehabilitation. At ten weeks of follow-up, the last one, the patient could express verbally simple words, answer to simple questions and do more complex motor tasks with a grade 3 motor strength (GCS 13).

Conclusion: This case presented a temporal relationship between levodopa use and improvement of consciousness state in a patient with a severe thalamic hemorrhage, although this association may be equivocal.

Phenytoin serum concentrations and factors affected after traumatic brain injury
J.-K. Kanjanaasilp, K. Srisaeng, Faculty of Pharmacy, Mahasarakham University, Maha Sarakham, Thailand

Background: Phenytoin is an effective drug used for decreasing the risk of early post-traumatic seizures in patients with traumatic brain injury.

Objective: This study investigates phenytoin level and factors affecting seizure control in patients with traumatic brain injury.

Patients and methods: 122 patients with traumatic brain injury data were collected from Supprasithiprasong Hospital, Thailand, between May 2012 and January 2013. Phenytoin serum concentrations were measured in days 3–7 after initiation. Two regimes of phenytoin had been taken; 100 mg q 8 h or 300 mg q 24 h with or without loading dose.

Results: 64 patients had total phenytoin concentrations in subtherapeutic level (52.5%), 52 patients had phenytoin level in therapeutic range (42.6%) and 6 patients had phenytoin level in toxic level (4.9%). Eleven patients (9.0%) did not control seizures during the first 7 days. Five of them (45.5%) had phenytoin concentration in subtherapeutic level, 5 patients (45.5%) had phenytoin concentrations in therapeutic range and 1 patient (9.1%) had phenytoin concentration in toxic level. Fever has correlation with phenytoin level (P = 0.001). Serum albumin concentration, severity of brain injury, and GCS score were not correlated with phenytoin level (P > 0.05).

Conclusion: More than half of the patients who were taking phenytoin for prophylaxis of seizures in patients with traumatic brain injury had phenytoin in subtherapeutic level. Phenytoin dosage should be adjusted appropriately to effective control seizure.

Temperature modulates the neuronal response in the thalamus and the cortex in rats
C. Chen, A. Maybhate, H. Cal, X. Jia, Biomedical Engineering, Johns Hopkins University, Baltimore, MD, USA; Intensive Care Unit, Sir Run Run Shaw Hospital, Zhejiang University, Hangzhou, China; Biomedical Engineering, Physical Medicine & Rehabilitation, Anesthesiology & Critical Care Medicine, Johns Hopkins University, Baltimore, MD, USA

Temperature fluctuations significantly impact clinical outcome after neurologic injuries. Although therapeutic hypothermia is used during cardiopulmonary bypass, and after hypoxic ischemia or stroke, the neuroprotective mechanisms underlying the temperature changes have not been fully elucidated. We electrophysiologically evaluated uninjured rat brains in response to mild hypothermia (32–34 °C) and mild hyperthermia (38.5–39.5 °C) by external systemic cooling/warming in rats (N = 6 each). For each rat, the EEG, and the neural spikes from the somatosensory cortex (CX) and the ventral posterolateral nucleus of the thalamus (TH) were continuously recorded after stabilization of temperature: normothermia at baseline (36.5–37.5 °C), hypothermia or hyperthermia, and normothermia after temperature modulation. The burst suppression ratio (BSR) in EEG, cortical and thalamic spike signals was computed using a custom algorithm. BSR significantly increased during hypothermia compared with baseline (EEG: 73 ± 3%/30 ± 12%, P = 0.001; CX: 79 ± 3%/31 ± 11%, P = 0.011; TH: 63 ± 7%/13 ± 5%, P = 0.003). Under hypothermia, there was a marked decrease from baseline in the firing rate of spontaneous spike activity in the cortex (16.3 ± 4.8/7.4 ± 1.8 spike/s, P = 0.017) and in the thalamus (3.3 ± 1.1/1.5 ± 0.4 spike/s, P = 0.046). With peripheral nerve stimulation to evoke brain activity, the spike amplitude significantly decreased with hypothermia in cortical (94.2 ± 9.2/61.4 ± 3.0 μV, P = 0.014) and
thalamic (97.1 ± 8.0/72.0 ± 5.6 μV, P = 0.001) neurons, with a prolonged response latency (CX: 9.3 ± 0.5/14.4 ± 1.2, TH: 4.8 ± 0.2/6.3 ± 0.4 ms, both P < 0.01). The increased BSR, reduced firing rate and spike amplitude, and prolonged response latency indicated that hypothermia suppressed the metabolism in the cortex and the thalamus, which might be one of the main mechanisms underlying neuroprotective benefits of hypothermia.

EEG pattern of alpha activity and survival in comatose patients
M. Khaburzania1, G. Chakhvad2, M. Beridze3, L. Shanidze3
1Critical Care Unit, Railway Hospital, Georgia; 2Neurology, Tbilisi State Medical University, Tbilisi, Georgia

Purpose: To identify the factors determining survival in alpha coma.

Patients and methods: Totally 21 patients in comatose state with alpha frequency patterns have been investigated. Patients were grouped as traumatic brain injury (7 cases—1st gr.), basal ganglia hemorrhage (4 cases—2nd gr.), brainstem stroke (5 cases—3rd gr.), and diffuse hypoxic encephalopathy due to cardiac arrest (5 cases—4th gr.). Patients were rated by Glasgow Coma Scale (GCS). Spontaneous breathing, pupil reactions and gag reflexes were investigated. Brain lesion was assessed on conventional MRT (1.5 T). Brain electrophysiology was assessed by a 19 channel EEG apparatus. Non-parametric statistics was performed by SPSS—11.0.

Results: In the 1st group 5 patients revealed high amplitude non-reactive alpha frequency predominantly in fronto-temporal dimensions, while 2 patients showed reactive alpha frequency predominantly in parieto—occipital dimensions. In the 2nd group 3 patients showed high amplitude non-reactive alpha frequency in frontal regions and 2 patients revealed reactive EEG in dorsal parietal and temporal regions. In the 3rd group all patients showed non-reactive alpha frequency in fronto—temporal regions. The 4th group found 2 cases of reactive EEG in parieto—occipital region and 3 patients—non-reactive EEG in the same region. Three patients from the 3rd group and two patients from the 4th group were on artificial breathing. From all groups only 3 patients survived from coma. EEG patterns, brain damage location and size as well as brainstem reflex activity were entered in the logistic regression toward the outcome.

Conclusion: Apparently, in alpha coma the reactive EEG in parieto—occipital dimensions leads to more favorable prognosis.

Topic: 4 — Neuro-critical care  
Effects of prehospital neurologist assessment on appropriate delivery to neurology facilities: The stroke emergency mobile (STEMO) project  
Objective: Neurological diagnosis is challenging in prehospital emergency medicine. Neurological symptoms vary widely and may be similar in different diseases. Pre-hospital decisions are important to deliver patients to hospitals with specialists’ expertise when required. We aimed to evaluate whether appropriate delivery of patients with neurological diseases can be increased by neurologists who are directly engaged in prehospital care in the STEMO project in Berlin/Germany.  
Patients and methods: STEMO is a specialized ambulance equipped with a CT-scanner plus point-of-care laboratory and staffed with a neurologist trained in emergency medicine. The effects of the STEMO implementation were evaluated in a prospective study comparing weeks with and without STEMO-availability. STEMO was deployed when the dispatchers suspected an acute stroke during emergency calls. Discharge diagnosis and destination were collected from hospitals to which patients were delivered.  
Results: At the time of preliminary analysis, discharge documentation was available in 6012 patients (3117 in STEMO and 2895 in control weeks). 50% of all diagnoses were cerebrovascular, 22% were non-cerebrovascular but neurological and 28% were non-neurological. Patients with cerebrovascular respectively neurological (including cerebrovascular) diagnoses were less frequently delivered to hospitals without Stroke-Unit or without Neurology department when STEMO was deployed (6 versus 12%, p < 0.01 and 4 versus 6% respectively, p = 0.02).  
Conclusion: Emergency assessment by a STEMO neurologist enhances the chances to be admitted to appropriate in-hospital care. Outcomes will be presented at the WCN.

Association of the Shank3 gene mutations coupled with the 22q13.3 deletion syndrome  
V. Balachandar, S. Sureshkumar, M. Arun, K. Sankar, B. Balamurukrishnan, K. Sasikala. Human Genetics Laboratory, School of Life Sciences, Bharathiar University, Coimbatore, India  
Background: Phelan–McDermid syndrome results from simple 22q13 deletions, ring chromosomes and unbalanced translocations. The gene responsible for the core neurological features is SHANK3, which is found to be mutated in patients with autism spectrum disorders and intellectual disability. The aim of the present study was to detect the chromosomal alterations and SHANK3 mutations in Phelan–McDermid syndrome patients in Coimbatore region.  
Methods: In the present study among 468 patients observed, only 8 patients were selected based on the clinical features, behavioural habits and standard questionnaire. The work was carried out in accordance with the ethical standards laid down in the 1964 Declaration of Helsinki. Commercially available FISH probes and PCR-SSCP techniques were used to detect chromosomal alterations and the mutations of SHANK3 gene in patients.  
Results: In our study, 22q13.3 deletion was observed in 5 patients and 2 patients had deletions of unbalanced translocation and one patient was mosaic for the 22q13.3 deletion with 85% of the cells showing deletion. Moreover 4 patients with nonsense de novo SHANK3 mutation was detected and these results imply the mental status is related to sporadic occurrence of SHANK3 gene complex multiple deletions.  
Conclusion: Our findings conclude that 22q13.3 deletions may be a more frequent cause for the present study, and the SHANK3 gene is involved in the Phelan–McDermid syndrome. Furthermore, our study supports haploinsufficiency of the gene SHANK3, which codes for a structural protein of the postsynaptic density, as a major causative factor in the neurological symptoms of 22q13.3 deletion syndrome.

Computational EEG analysis for critically ill patients based on the standardized terminology of the ACNS  
F. Fürbaß, J.J. Halford, J. Herta, J. Koren, H. Perko, M. Schnabel, M. Weinkopf, T. Kluge, A. Gruber, C. Baumgartner, M.M. Hartmann, Safety & Security Department, AIT Austrian Institute of Technology GmbH, Vienna, Austria; Department of Neurosciences, Medical University of South Carolina, Charleston, SC, USA; Department of Neurosurgery, Medical University of Vienna, Vienna, Austria; Neurological Department Rosenhügel, General Hospital Hietzing, Vienna, Austria  
Continuous EEG monitoring is an important tool to recognize clinically invisible deteriorations in critically ill patients. However, manually reviewing continuous EEG recordings requires substantial resources, which are often limited in intensive care units.  
A computational algorithm for automatic analysis and trend of continuous EEG recordings from critically ill patients is being developed. Main Terms and most important Major Modifiers of the ACNS’ standardized critical care EEG terminology are automatically determined and represented graphically, allowing reading of trends in the neurological state of patients.  
Continuous EEG recordings from 65 patients from ICUs in three different clinics are used for algorithm development. Artifacts are removed using the PureEEG algorithm. Then EEGs are split into segments representing normal waves, discharges, or spikes. Localization and morphology of these segments are assessed, and finally the segments are reassembled into groups representing rhythmic activity, periodic discharges or spike-and-wave patterns (Main Term II). The localization of these patterns is determined (Main Term I) and finally frequency and amplitudes are determined.  
In a visual analysis of results from the first algorithm version all patterns covered by Main Term II could be detected successfully. Results for localization, frequency and amplitude have been checked on a sample basis and were correct in most cases.  
First results are very promising, but a quantitative performance analysis will be important, although methodologically demanding. We see a huge potential benefit from our algorithm analyzing EEGs from ICUs. Resources could be substantially saved, allowing for extended coverage of EEG monitoring in critically ill patients.

A rare presentation of brain abscess and ventriculitis caused by Klebsiella pneumonia

W.T. Yoon, Neurology, Kangbuk Samsung Hospital, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea

Background: Klebsiella pneumonia is a Gram-negative, non-motile, encapsulated, lactose fermenting, rod shaped bacterium. This is a pathogen that causes opportunistic infections, mainly in immune compromised patients. Typical manifestations of Klebsiella infections are pyogenic liver abscess, meningitis, septicemia, pneumonia and endophthalmitis. In contrast, K. pneumonia is an uncommon pathogen of bacterial meningoencephalitis.

Objective: Our aim is to report a case of a rare presentation of brain abscess and ventriculitis caused by K. pneumonia.

Patient and results: A 50-year-old female Korean was sent to our hospital three hours after acute onset of confusion. Her past medical history was depressive disorder. She had marked nuchal rigidity. The cerebrospinal fluid (CSF) was yellowish with pleocytosis (350/mm³; N/L = 96%), increased protein (536 mg/dl), and a low glucose level (7 mg/dl). Brain abscess and ventriculitis was found in the lateral ventricles on brain MRI. Culture of CSF was isolated K. pneumonia. She was treated with intravenous Carbapenem, Ampicillin, Vancomycin and 3rd Cephalosporin for two months and clinical symptom was fully recovered.

Conclusions: In our case, ventriculitis with periventricular inflammation and necrosis, and multiple brain abscesses were manifestations of Klebsiella meningoencephalitis. To our knowledge, this is the first case report of Klebsiella meningoencephalitis with brain abscess and ventriculitis in immunocompetent patient. As like this case, if there are brain abscess and ventriculitis in meningoencephalitis, it should be considered diagnosis of Klebsiella meningoencephalitis.

Valproate-induced hyperammonemic encephalopathy with triphasic waves: A case report

B. Nazliel, I. Yıldırım Capraz, H.Z. Batır Çaglayan, C. Irkek, M. Mutluçan. Neurology, Gazi University Faculty of Medicine, Ankara, Turkey

Introduction: Sodium valproate (VPA) is an effective antiepileptic drug used in neurology as well as in psychiatry. It is also associated with a hyperammonemic encephalopathy, when used in combination with other drugs.

Case report: We herein present a case of valproate-induced encephalopathy (VHE) in an epileptic patient who had subtherapeutic levels of valproate with subclinical hyperammonemia accompanied by triphasic waves on electroencephalography (EEG). We believe the hyperammonemia became clinically evident following diphenylhydantoin (DPH) loading.

Discussion: Hyperammonemia without clinical or laboratory evidence of hepatotoxicity is an important idiosyncratic side effect of VPA treatment. Clinical manifestations of VHE as well as EEG findings and hyperammonemia tend to normalize rapidly when VPA therapy is discontinued.

Vitamin D deficiency in neurointensive care: A retrospective observational study

T. Urbanic Purkart, P. Zajic, C. Schnedl, A. Holl, F. Fazekas, T. Pieber, K. Amrein. 1Neurology, Division of Endocrinology and Metabolism, Medical University of Graz, Graz, Austria; 2Internal Medicine, Division of Endocrinology and Metabolism, Medical University of Graz, Graz, Austria

Background: To date, vitamin D deficiency is frequently encountered in the general population. Critically ill patients have been found to be particularly susceptible to this condition and a poor vitamin D status is associated with higher morbidity and mortality. The prevalence of vitamin D status in neurointensive care is unknown.

Methods: In this retrospective analysis, we included 164 patients with available 25(OH)D serum levels hospitalized at the 8-bed neurointensive care unit (NICU) of the tertiary care center at the Medical University of Graz between 2008 and 2010.

Results: Patients were 61 ± 16 years old and mean SAPS2 was 25 ± 12 points. The main admission diagnoses included intracranial bleeding and stroke. Mean serum 25(OH)D level was 22.9 ± 12.3 ng/ml. Normal 25(OH)D levels (>30 ng/ml) were found in only 21.3% of all patients. 43.9% were vitamin D deficient (<20 ng/ml), while 34.8% were considered vitamin D insufficient (>20 and <30 ng/ml) by current definitions. 20.7% even had 25(OH)D levels below 12 ng/ml. All-cause hospital mortality was 10.4%. In patients with vitamin D deficiency, hospital mortality was significantly higher (15.3%, \( \chi^2 \) p = 0.03).

Conclusion: A low 25(OH)D status is common in the NICU and is associated with higher hospital mortality. Future studies are needed to investigate if critically ill patients may benefit from vitamin D treatment.

Spontaneous spinal epidural hematoma after abrupt sneeze with prompt recovery of severe paraparesis without surgical treatment

L. Stetkarczyk, L. Jelinkova, V. Janik, T. Peisker. 1Neurology, Third Faculty of Medicine, Charles University, Hospital Kralovske Vinohrady, Prague, Czech Republic; 2Radioiology, Third Faculty of Medicine, Charles University, Hospital Kralovske Vinohrady, Prague, Czech Republic

Background: Spontaneous spinal epidural hematoma (SSEH) is a rare neurological condition which can lead to acute spinal cord compression. Objectives: Symptoms of SSEH include sharp back pain and progression of muscle weakness. The diagnosis has to be done very quickly using magnetic resonance imaging (MRI). There is an indication for urgent surgical decompression, however, conservative therapy is supposed to be feasible in selective patients with early recovery. A relevant review of SSEH literature is included.

Methods: We present a 64-year-old female with history of hypertension and low dose of aspirin (100 mg daily) who had experienced severe low thoracic and back pain accompanied by severe paraparesis and urinary retention after abrupt sneeze.

Results: MRI revealed a posterior thoracic epidural hematoma extending from T6 to T11 vertebral level with spinal cord compression. Decompression was recommended but she refused surgery. Complete neurological recovery was observed within 24 h after SSEH onset. MRI one month later showed total absorption of hematoma.
Conclusion: Surgical decompression is still the main treatment option of SSEH, however, a conservative therapeutic approach with careful observation may be considered as a treatment of choice in some cases where surgery is refused (high risk or other reasons) and neurologic recovery is early and sustained.

Population pharmacokinetics of phenytoin in patients with traumatic brain injury
K. Srisaeng, Mahasarakarm Univ., Mahasarakarm, Thailand

Background: Phenytoin is commonly used to treat and prevent seizure after neurotrauma. However, many physiological changes occur in the neurotrauma patient, which alter the pharmacokinetics of drugs.

Objective: This prospective study investigated the population pharmacokinetics and the related factors that affect to pharmacokinetics of intravenous phenytoin in neurotrauma patients.

Patients and method: Patient data were collected from routine clinical visits between May 2012 and January 2013 at the neurotrauma wards of Sunpratiprasong Hospital, a hospital in the northeast of Thailand. Data from 122 patients aged between 12 and 79 years old were obtained in this study. Times of sampling were days 3–7 after starting with phenytoin, and about 3 serum samples/patients were taken. A 1-compartment model with nonlinear pharmacokinetics was fitted to the log-transformed concentration data using nonlinear mixed effect model (NONMEM). Gender, age, height, ABW, IBW, regimen, alcohol drinking, smoking, severity of head injury, depressed skull fracture, brain hematoma/hematoma, brain edema, brain contusion, midline shift, trauma organ involvement, brain surgery, fever, albumin level, LFT, and loading dose phenytoin before starting continuous regimen were 20 factors that were studied for the effect to pharmacokinetics of intravenous phenytoin in neurotrauma patients.

Results: The parameters of the pharmacokinetics base model were Km = 4.47 mg/L, Vmax = 21.2 mg/kg/day, and volume of distribution = 43.4 L. These finding actual body weight had affected on Km, fever had affected on Vmax, and regimen had affected on volume of distribution.

Conclusion: This study proposed population pharmacokinetics of phenytoin in patients with traumatic brain injury for appropriate dose adjustment.

Early Robot-Assisted Therapy in Patients with Stroke in Neurointensive Care Unit
M. Piradov, P. Prokazova, J. Ryabinikina, E. Gnedovskaya. Research Center of Neurology, Russian Academy of Medical Sciences, Moscow, Russia

Background: Pulmonary embolism (PE) increases risk of unfavorable outcome and mortality in stroke.

Objective: To evaluate the impact of robot-assisted therapy in stroke patients on neurological outcome and rate of venous thromboembolism.

 Patients and methods: This case–control study included 66 neuroICU patients (49 males, 17 females, median age 59.3) within 7 days from onset of ischemic and hemorrhagic stroke. We used NIHSS and GCS scores and assessed the rate of deep vein thrombosis (DVT) revealed with ultrasound scanning, the rate of PE and mortality from admission to Day 21.

Results: Patients were equally divided into two homogenous groups — Intervention and Control to receive standard stroke therapy plus daily robot-assisted arm and leg therapy (MOTOmed letto 2) in Intervention group. Groups had similar stroke severity on admission (GCS: Me = 13 [LQ-10, UQ-15] vs. Me = 14 [LQ-10, UQ-15], p = 0.11; NIHSS: Me = 20 [LQ-16, UQ-29] vs. Me = 18 [LQ-15, UQ-27], p = 0.5) in Intervention and Control group, respectively). There was no significant difference in neurological outcome on Day 21 (GCS: Me = 15[LQ-14, UQ-15] vs. Me = 15[LQ-15, UQ-15], p = 0.12; NIHSS: Me = 11[LQ-8, UQ-25] vs. Me = 15 [LQ-10, UQ-19], p = 0.4) in Intervention and Control group, respectively). In the rate of DVT and mortality on Day 21 (58% vs. 45%, p = 0.147; 39% vs 12%, p = 0.058, respectively). Rate of PE on Day 21 were higher in the Control vs. Intervention group (39% vs. 9%, p = 0.029).

Conclusion: Early robot-assisted therapy in severe stroke patients was associated with significant reduction of PE rate on Day 21, but did not influence neurological outcome and DVT rate.

Amyloid-ß in CSF predict neurological status and mortality after severe traumatic brain injury: Results of a pilot study
S. Mondelloa,b, A. Bukić, J. Randallc, G. Prounchecd, D. Hanzold, D. Wilsond, D. Italianoe, F. Tomaselloa, A. Jerominf, aNeuroscience, University of Messina, Messina, Italy; cClinical, Banyan Biomarkers, Inc., Alachua, FL, USA; dNeurosurgery, University of Pecs, Pecs, Hungary; eQuanterix Corporation, Lexington, MA, USA; fUniversity of Messina, Messina, Italy; fNextGen Sciences Dx, Gainesville, FL, USA

Objective: To assess amyloid-ß1-42 (Ab42) concentrations and time-course in CSF and in plasma of patients with severe traumatic brain injury (TBI) and their relationship to injury characteristics, neurological status and clinical outcome.

Patients and methods: Twelve patients with severe TBI [Glasgow Coma Scale (GCS) ≤ 8] and 13 controls were included this pilot study. Paired CSF and plasma samples were taken from each TBI patient at admission and daily up to 7 days and Ab42 levels assessed by ultrasensitive digital ELISA. Data collected included demographic and clinical variables and survival 6 months post-injury.

Results: CSF Ab42 levels were significantly lower in TBI patients acutely after injury as compared to controls (median 105.9 vs. 537.6 pg/ml, p < 0.0001) with lower levels in patients who died than in those who were alive. Conversely, plasma Ab42 levels were significantly increased in TBI as compared to controls (median 17.02 vs. 7.289 pg/ml, p < 0.0001) with higher levels in patients who survived. A trend analysis using the Jonckheere-Terpstra test showed that both CSF and plasma Ab42 levels strongly correlated with mortality (P < 0.0001). CSF and plasma Ab42 concentrations within the first 24 h after injury did not correlate with TBI characteristics. A positive correlation between changes in CSF Ab42 concentrations and neurological status was identified, with Ab42 levels increasing as neurological status improved and decreasing when neurological status deteriorated.

Conclusion: These results suggest that determination of Ab42 may be valuable to obtain prognostic information in patients with severe TBI as well as for monitoring the response of the brain to injury.

Small-world characteristics of EEG patterns in post-anoxic encephalopathy
M. BeudelA, M.C. Cloostermansb, J.H. BoersmaA, M.J.A.M. van Puttenb,c, ANeurology, University Medical Center Groningen, Groningen, The Netherlands; bDepartment of Clinical Neurophysiology, MIRA Institute for Biomedical Technology and Technical Medicine, University of Twente, The Netherlands; cNeurology/Clinical Neurophysiology, Medisch Spectrum Twente, Enschede, The Netherlands

Background: Post-anoxic encephalopathy (PAE) has a varying outcome from death to good recovery. At present, it is possible to predict bad outcome using somatosensory evoked potentials in only a minority of the patients at an early stage. Network architecture, as can be quantified with continuous electroencephalography (cEEG) may serve as a candidate measure for predicting neurological outcome.

Objective: Using cEEG monitoring to detect the integrity of neural network architecture in PAE patients.

Material and methods: 19-Channel cEEG data was obtained from 56 PAE patients. Adjacency matrices of shared frequencies between 1 and 25 Hz of the EEG channels were obtained using Fourier transformations. Number of network nodes and connections, clustering coefficient (C), average path length (L) and small-world index (SWI) were derived. Outcome was quantified by the best Cerebral Performance Category (CPC)-score.

Results: Compared to non-survivors, survivors showed significantly more nodes and connections. L was significantly higher and C and SWI were significantly lower in the survivor group relative to the non-survivor group. The combination of number of nodes, connections, C and L showed the most significant difference and between survivors and non-survivors. At a specificity of 100% a sensitivity of 31% was present for predicting non-survival using this combination.

Conclusion: Our data shows that non-survivors have insufficient distribution and differentiation of neural activity for regaining normal brain function. These network differences, already present during hypothermia, might be used as an early prognostic marker. The predictive values, although already superior to current practice parameters, need to be further determined.

Aneurysmal subarachnoid hemorrhage in stroke unit

Purpose: The aim of this study was to assess the features of meningeal syndrome (MS) in subarachnoid hemorrhage (SAH) patients depending on location of the cerebral aneurysm.

Materials and methods: We retrospectively analyzed clinical data from stroke unit of 25 SAH patients in age from 33 to 59 years old between January 2011 and March 2013. The relationship between symptoms severity, intracranial aneurysm location (by CT and angiography data) and Hunt–Hess scale grade was assessed.

Results: Aneurysm rupture as the cause of SAH was found in 71% of patients, in 29% the cause was unknown. The anterior communicant artery location of ruptured intracranial aneurism was found in 31%, internal carotid artery — 16%, anterior and middle cerebral arteries — 12% of each. Hunt–Hess scale scores were: 0 in 4%, 1 in 28%, 2 in 36%, 3 and 4 in 16% of each. The development of MS on the 1st day was found in 44%. MS time of developing was unknown in 66% of the patients due to later recourse in hospital. Nuchal rigidity was found in 96%. Symmetrical Kernig’s sign was detected in 96%. Asymmetry of Kernig’s sign and Brudzinski’s sign was not found in all patients.

Conclusions: The location of ruptured aneurysm in most cases was detected in anterior communicant artery. Meningeal syndrome severity was not depended of aneurism location. Mortality was in 20% of the patients due to cerebral edema and brainstem dislocation, 12% had subarachnoid hemorrhage rebleeding. 48% of all patients underwent cerebral aneurysm clipping.

Early prognostic biomarkers in Guillain–Barre syndrome
M.A. Piradov, A.A. Khoroshun, A.A. Shabalina, M.V. Kostyreva. Research Center of Neurology, Russian Academy of Medical Sciences, Moscow, Russia

Background: The clinical manifestations of Guillain–Barre syndrome (GBS) vary from mild neurologic deficiency up to tetraplegia with respiratory failure. The early correct prognosis of the clinical course might be helpful for the well-timed diagnostic of the life threatening disturbances.

Objective: To determine the prognostic value of biomarker neurofilament heavy chains (NFH), glial fibrillary acidic protein (GFAP) and tau heavy chains (hTau) in the clinical course of GBS.

Patients and methods: 35 patients, who fulfilled the diagnostic criteria of GBS, were included. The serum and cerebrospinal fluid (CSF) were collected before the beginning of therapy. CSF and serum NFH, GFAP and hTau levels were measured using a standard ELISA with analyst being blinded to all other data. All patients were divided into groups depending on symptoms of interest (respiratory failure, duration of ventilation, dysphagia) and their serum and CSF concentrations of biomarkers were compared. The statistic analysis was carried out using the Statistica 7.0, MedCalc 12.1.4.0.

Results: We determine the serum level of the NFH > 0.144 ng/mL which could predict the respiratory failure (AUC 0.804, p < 0.0001) and the serum level NFH > 0.094 ng/mL indicating the development of dysphagia (AUC 0.773, p = 0.001). We found the correlation between the duration of ventilation and serum (R = 0.825 p = 0.003) and CSF (R = 0.820 p = 0.007) GFAP levels. We also estimated prognostic hTau and GFAP levels in relation to prolonged ventilation.

Conclusion: Serum levels of NFH, GFAP and hTau can be prognostic markers in the clinical course of GBS.

The experience of creating a mobile neurodiagnostic unit in a megalopolis (Moscow)
1Moscow State University of Medicine and Dentistry, Russia; 2City Hospital #11, Russia; 3Russian State Medical University, Russia; 4City Hospital #13, Moscow, Russia

Background: An important factor in working out a comatose patient treatment plan is express neurophysiologic evaluation and assessment of the cerebral blood flow. It is evident that all the tests should be performed bedside and have high sensitivity and specificity.

Objective: To evaluate the performance of mobile neurodiagnostic unit in a megalopolis.

Material and methods: The special Mobile Neurodiagnostic Unit (MNU) was created in 1995. It is staffed with neurologists who can perform neurophysiology and neurosonology tests (EEG, TCD, EVP, duplex scan). The MNU, equipped with portable ultrasound scanner and encephalograph with EVP tool, works around the clock.

The MNU specialists go to Moscow hospitals to perform clinical examination and evaluate EEG, EVP and cerebral blood flow status for deep coma patients (GCS < 5). In case of suspected brain death (BD), the MNU experts take part in clinical consultations and perform ancillary tests.

Results: 4000 critically ill patients have been examined by experts of the MNU since 1995. Most patients suffered from stroke/SAH (68%), or TBI (28%), 3% and 1%, respectively, accounted for tumor and secondary brain damage. BD was confirmed more than 600 times. Since 1995, the average annual rate of BD diagnostics performed by the MNU has increased from 15 to 73 cases per year.

Conclusion: In a large megalopolis area, a highly professional mobile group able to make neurophysiological and cerebral blood flow assessment can improve the quality of neurocritical care without additional material costs, and increase the accuracy of BD diagnostics by using different confirmation tests.

Isolated hypoglossal nerve palsy: A harbinger of serious underlying disease
J.H. Park, J.Y. Kim. Department of Neurology, Sanggye Paik Hospital, Inje University College of Medicine, Seoul, Republic of Korea

Hypoglossal nerve palsy is not an uncommon finding in neurological diseases. Vascular, inflammatory, traumatic or space-occupying lesions
can affect hypoglossal nerve anywhere in its course from the nucleus in the caudal medulla, through the intracranial extramedullary portion of the nerve and hypoglossal canal, and finally into its extracranial termination.

**Case 1**: A 72-year-old woman was referred to the neurology department due to a sudden onset dysarthria. She had right breast cancer in 2003 and underwent mastectomy, radiotherapy and adjuvant chemotherapy for regional metastasis. On neurological examination, her tongue was atrophy and deviated to the left side. The ocular fundi and other cranial nerves were normal. There were no long tract signs or signs of meningeal irritation. Brain MRI showed a subtle enhancing lesion involving the left occipital condyle with the destruction of the petrous apex and clivus.

**Case 2**: A 54-year-old woman with a history of headache for 2 months was admitted due to a sudden onset dysarthria. Her headache was located in the left temporal area and refractory to the medical treatment. Neurological examination showed atrophy with deviation of the tongue to the left. Otherwise were noncontributory. Brain MRI revealed an enhancing lesion involving the occipital condyle and clivus. The biopsy of regional enlarged lymph node showed the poorly differentiated metastatic squamous cell carcinoma.

**Conclusion**: We report two cases of isolated hypoglossal nerve palsy. Isolated hypoglossal nerve palsy is a rare finding but paralysis of this nerve may be the first sign of a serious underlying disease.

**Clomethiazole-induced hepatotoxicity as example of successful treatment with cooperation between clinical pharmacist and physician**

**M. Štuhc**

Clinical Pharmacy, Psychiatric Hospital Ormoz, Ormoz, Slovenia

**Background**: Clomethiazole is being structurally related to thiamine and has been predominantly used for management of agitation, alcohol delirium and withdrawal and in rare cases for restlessness. There is little reported in literature regarding acute clomethiazole-induced hepatotoxicity.

**Objective**: A case of acute hepatotoxicity that occurred in a 71 year-old male patient with psycho-organic delirium who began clomethiazole therapy is described.

**Patient and methods**: A case report. The diagnostic and treatment procedures were reviewed. Clinical pharmacist was also introduced.

**Results**: Laboratory tests excluded other causes of acute liver injury. Liver enzymes returned to normal within one week of clomethiazole discontinuation. From the ratio S-AST/S-ALT it is possible to conclude that hepatocytes damage already occurred and recovered soon after clomethiazole discontinuation. To control symptoms of delirium rapid switching from clomethiazole to zuclopenthixol was advised by clinical pharmacist, therefore zuclopenthixol in small doses could be used in patient with clomethiazole hepatotoxicity.

**Conclusion**: Clomethiazole should be included among the causes of drug-induced hepatotoxicity. Open communication between the physician and clinical pharmacist on the patient’s pharmacotherapy is necessary to achieve optimal clinical outcomes.

**Predictors of functional outcome of patients with Guillain-Barré syndrome in intensive care unit**

S.-B. Kwon¹, H.-J. Park², S.-S. Hong³, Y.-K. Minn⁴, S. Jung⁴, S.-H. Hwang⁵, K.-H. Kwon⁶

¹Neurology, Hallym University College of Medicine, Republic of Korea; ²Radiology, Soonchunhyang University College of Medicine, Seoul Hospital, Seoul, Republic of Korea

**Background**: Approximately one third of patients with GBS need to be admitted to the ICU because of respiratory failure. They are at risk for systemic complications with substantial morbidity and consequent mortality. There were only limited data about the morbidity of ICU GBS patients and its impact on functional outcome.

**Objective**: To analyze predictors for the functional outcome in consecutive GBS patients admitted to ICU.

**Methods**: Consecutive adult (≥ 15 years old) GBS patients admitted to the ICU during 11-year period from Jan 2000 through Dec 2010 were included. Using mRS (modified Rankin Scale) at 6 months, we divided and analyzed patients into favorable (mRS 0–2) and unfavorable (mRS 3–6) outcome groups.

**Results**: Of 43 patients, there were significant differences in age (P = 0.007), ICU stay (P = 0.01), intubation (P = 0.003), mechanical ventilation (P = 0.0001), tracheostomy (P = 0.014), comorbid conditions such as congestive heart failure (P = 0.013), complications such as acute renal failure (P = 0.034), normal liver function test (P = 0.017), cardiac complication (P = 0.026), pneumonia (P = 0.014), and sepsis (P = 0.026), a high score in the TISS-28 (P = 0.0001), and a high APACHE II score (P = 0.007) between favorable (25; 58.1%) and unfavorable outcome (18; 41.9%) groups. The mortality rate was 11.6% (n = 5). Main causes of mortality were sepsis and cardiogenic shock. In multivariable logistic regression analysis, TISS-28 (OR 2.55, 95% CI 1.06–6.10, P = 0.036) was independent predictor of unfavorable outcome.

**Conclusion**: The predictors for functional outcomes such as TISS-28 in GBS patients admitted to the ICU could help identify correctable factors, optimize medical treatment, and guide discussions of prognosis.

**Minocycline cannot protect neurons against bilirubin-induced hyperexcitation in the ventral cochlear nucleus**

C. Li, S. Yin. Department of Otorhinolaryngology, Affiliated Sixth People’s Hospital of Shanghai Jiaotong University, Shanghai, China

Excitotoxicity has been suggested to play an important role in many central nervous system diseases, particularly in bilirubin encephalopathy. Minocycline treatment has been proposed to be one of the most promising potential therapies for excitotoxicity-induced neurological disorders. However, some key questions, such as the electrophysiological effect of minocycline on neuronal excitability and hyperexcitation in pathological conditions, require clarification. In this study, using patch-clamp techniques, we showed that bilirubin increased the frequency of both spontaneous excitatory postsynaptic currents (sEPSCs) and neuronal firing in isolated ventral cochlear nucleus (VCN) neurons at postnatal days 11–14 (P11–14) in rats but it did not affect the amplitude of sEPSCs or glutamate-activated (Icau) currents. However, minocycline had no effect on sEPSC frequency or Icau amplitude. Furthermore, minocycline pretreatment did not abolish bilirubin-induced sEPSC potentiation or neuron firing. These data...
suggest that minocycline does not affect excitatory synaptic transmission or hyperexcitation induced by bilirubin in VCN neurons. From these results, we propose that the neuroprotective efficacy of minocycline, if it can protect neurons against neurotoxicity induced by substances like bilirubin, is mediated by either an alternative mechanism or downstream events post neuronal hyperexcitation. Certainly, additional investigation of the neuroprotective effects of minocycline is required before embarking on further clinical trials.

A new percutaneous model of subarachnoid haemorrhage in rats
F. Murillo-Cabezasa, J. Egea-Guerreroa, E. Gordillo-Escobarb,
M. Moreno-Valladaresb, M. Munoz-Sánchezb. aCritical Care,
Sevilla, Spain; bVirgen del Rocio University Hospital, Sevilla, Spain

Objective: Describe the results obtained with a new percutaneous, intracisternal model of subarachnoid haemorrhage (SAH) in Wistar rats by a single injection of non-heparinised, autologous blood.

Methods: Once anaesthetized the rat was fixed prone in a stereotaxic frame. After identifying the projection of the occiptal bone, the needle of the stereotaxic frame aspirated towards the foramen magnum until it punctured through the atlanto-occipital membrane and obtained cerebrospinal fluid. Autologous blood (100 μl) was withdrawn from the tail and injected intracisternally. This procedure was repeated in the sham group, injecting 100 μl of isotonic saline. On the fifth day post-intervention, the rats were anaesthetized and the brain was exposed. After a lethal injection of ketamine the brain was explanted and fixed in paraformaldehyde. Gross and microscopic inspection of the slices revealed the existence or non-existence of pathological findings.

Results: A total of 26 rats were operated on (13 in the SAH group/13 in the sham group). The average time between obtaining the blood and the start of the intracisternal injection was 10 (±1.2) seconds. The mortality rate was 16.12%. Intra- and extraparenchymal ischemic–haemorrhagic lesions were found in three animals (23.07%) — all from the SAH group — with ischemic neuronal cell injury detected in two of the three.

Conclusions: The new rodent model of SAH is easy to perform, with low mortality, minimally invasive, which makes it interesting for future studies on vasospasm-related delayed SAH complications.

**Addenbrooke's Cognitive Examination standardized verbal fluency scores for differential diagnosis of AD and FTLD**

A.J. Larner. *Cognitive Function Clinic, Walton Centre for Neurology and Neurosurgery, Liverpool, UK*

**Background:** The Addenbrooke’s Cognitive Examination (ACE) is a commonly used cognitive screening instrument for the diagnosis of dementia.

**Objective:** To examine the differential impairment of ACE Standardized Verbal Fluency (SVF) scores for category fluency (CF) and letter fluency (LF) and measure their diagnostic utility for the differentiation of Alzheimer’s disease (AD) and frontotemporal lobar degenerations (FTLD).

**Patients and methods:** ACE was administered to consecutive new outpatients attending a Cognitive Function Clinic.

**Results:** Of 285 patients administered ACE, final diagnoses included 114 AD patients and 16 FTLD patients. Examining scaled ACE SVF scores, LF < CF was found to have modest sensitivity (0.66) but poor specificity (0.44) for the diagnosis of AD. LF < CF was found to have excellent specificity (0.86) but poor sensitivity (0.25) for the diagnosis of FTLD. These figures were compared unfavourably with the ACE VLOM ratio for the same differential diagnosis: VLOM of > 3.2 for diagnosis of AD had sensitivity of 0.76 and specificity of 0.76; VLOM ratio of < 2.2 for diagnosis of FTLD had sensitivity of 0.31 and specificity of 0.90. The comparison of area under the receiver operating characteristic curves also favoured VLOM over SVF scores (0.80 vs 0.56).

**Conclusion:** Although verbal fluency has been described as the “ESR of cognition” and VF tasks are very sensitive in detecting dementia, ACE SVF scores showed no diagnostic advantage over VLOM ratios for the differential diagnosis of AD and FTLD in this patient cohort.

**Age-associated changes of rat brain glutamate synthetase in rat brain Astroglial cells**

M. Mesripour. *Medical Biochemistry, Islamic Azad University, Khorasgan Branch, Isfahan, Iran*

Glutamate (Glu) is known as an excitatory amino acid neurotransmitter which interacts with Glu receptors for basal excitatory synaptic transmission. Excessive levels of extracellular Glu in the brain are excitotoxic and could lead to neurotransmitter imbalance, neuronal death and several neurodegenerative processes. Astroglial cells remove extracellular Glu and convert glutamate by astroglial-specific glutamine synthetase (GS) enzyme. Several line of evidence indicated that aging induces many disturbances in the regulation of astroglial glutamate metabolism. Because age-related changes in the metabolism of DNA could lead to alter the brain protein synthesis, in this study the rate of DNA strand breaks, cytoskeletal glial fibrillary acidic protein (GFAP) and GS contents in astroglial cells isolated from rat brain were investigated. Three and 30-month-old Wistar rats were used. Astroglial cells were purified and morphological characteristics of the cells were confirmed and the rate of DNA strand breaks, GFAP and GS contents of the cell preparations were determined. The rate of DNA strand breaks was higher in cell preparation from aged rats, whereas the levels of GS on a protein basis were relatively lower in old animals as compared to that of young rats. However, GEAP content of the cells does not show a

The correlation between cognitive impairment and depression in patients on maintenance dialysis
S. Jung^a, Y.-K. Lee^b, S.-B. Kwon^a, S.Y. Son^b, S.R. Choi^b, S.-H. Hwang^a, J.-W. Noh^b. ^aDepartment of Neurology, Hallym University College of Medicine, Seoul, Republic of Korea; ^bDepartment of Internal Medicine, Hallym Kidney Research Institute, Hallym University College of Medicine, Seoul, Republic of Korea

Patients with chronic kidney disease frequently show cognitive dysfunction. The association of depression and cognitive function is not well known in dialysis patients. We evaluated cognitive impairment, depression and their relationship between methods of dialysis, hemodialysis (HD) and peritoneal dialysis (PD). Fifty-six dialysis patients were recruited and their clinical and laboratory data were collected. The Korean version of Mini-Mental State Exam (K-MMSE) was applied to screen cognitive function of patients and the Korean version of Beck Depression Inventory (K-BDI) was used for detecting depression. The average age of participants was 54.2 ± 10.2 years and 29 (51.8%) were female. The average dialysis vintage was 4.2 ± 3.8 years. PD group showed significantly higher K-MMSE score (27.8 ± 2.9 vs. 26.1 ± 3.1, p = 0.010) and lower K-BDI score (12.0 ± 8.4 vs. 20.2 ± 10.4, p = 0.003) compared with HD group. The percentage of depression was higher in HD group (51.7% vs. 18.5%). There was a negative correlation between cognitive function and depression in both groups. Depression and education level were the independent predictors for cognitive impairment in multivariate analysis. The cognitive impairment was closely correlated with depression. It is important to detect cognitive impairment and depression early in dialysis patient with simple bedside screening tools.

Dementia, delirium and aggressive behaviour (AB) among hospitalised elderly
A.N. Withanage^a, S. Wass^a, A. Foy^a,c, ^aDepartment of Geriatrics, Hunter New England Health, New Lambton Heights, Newcastle, NSW, Australia; ^bDepartment of Geriatrics, Hunter New England Health, Newcastle, NSW, Australia; ^cDepartment of Medicine, Calvary Mater Newcastle, Newcastle, NSW, Australia; ^dUniversity of Newcastle, Newcastle, NSW, Australia

Background: Aggressive behaviour (AB) is common among hospitalised patients. Most available literature is focused on younger patients. We investigated the association of dementia and delirium with AB in the inpatient setting among a cohort of elderly subjects and the outcome of their index admission.

Method: We carried out a retrospective, observational study between January 2010 and January 2012 using a standardized electronic reporting system in a tertiary acute hospital in sub urban Australia.

Results: 145 episodes of AB among elderly (N = 93) accounting for 23.0% of all reported AB were identified. (4.9/1000 admissions, age 81.9 ± 6.3 years, male 61.5%). Delirium (92.3%) and dementia (60.4%) were strongly associated. Antipsychotics (66.6%), Benzodiazepines (9.6%) and a combination of the two (12.9%) were commonly used to manage AB. 20% had to be physically restrained. In hospital mortality rate was 10.3%, better than most reported rates for delirium. Residential care placement (39%) and the mean length of stay (15.5 ± 11.2 days) were comparable to reported outcomes of delirium.

Conclusions: AB in elderly inpatients is strongly associated with delirium and dementia. Frequently reported associations among younger patients are not common in the elderly counterparts. There is a window of opportunity to act when the majority of these patients demonstrate milder AB prior to its escalation. Elderly hospitalized patients demonstrating AB have unfavourable outcomes but our institution had lower hospital mortality compared to most reported outcomes of delirium. The frequency of residential care placement and length of stay was comparable to reported outcomes of delirium.

Dietary patterns and risk of dementia in an elderly Japanese population: The hisayama study
M. Ozawa^ab, T. Ninomiya^ab, T. Ohara^ab, Y. Doi^ab, K. Uchida^a, T. Shirota^a, K. Yonemoto^a, T. Kitazono^a, Y. Kiyohara^c, The Hisayama Study Group. ^aDepartment of Environmental Medicine, Kyushu University, Fukuoka, Japan; ^bDepartment of Medicine and Clinical Science, Kyushu University, Fukuoka, Japan; ^cDepartment of Neuropsychiatry, Graduate School of Medical Sciences, Kyushu University, Japan; ^dHealth Promotion, School of Health and Nutrition Sciences, Nakamura-Gakuen University, Fukuoka, Japan; ^eBiostatistics Center, Kurume University, Fukuoka, Japan

Background: There are no previous reports that assessed the association between dietary patterns and the risk of dementia in Asian populations.

Objective: We investigated dietary patterns and their potential association with the risk of incident dementia in a general Japanese population.

Methods: A total of 1006 community-dwelling Japanese subjects without dementia, aged 60–79, were followed up for 15 years (median). The reduced rank regression procedure was used to efficiently determine their dietary patterns. The estimated risk conferred by a particular dietary pattern on the development of dementia was computed using a Cox proportional hazards model.

Results: Seven dietary patterns were extracted, of which dietary pattern 1 was correlated with high intakes of soybeans and soybean products, vegetables, algae, and milk and dairy products, and low intake of rice. During the follow-up, 271 subjects developed all-cause dementia. Among them, 144 had Alzheimer’s disease (AD) and 88 had vascular dementia (VaD). After adjusting for potential confounders, the risks for the development of all-cause dementia, AD and VaD, were reduced by 0.66 (95% CI 0.46–0.95), 0.65 (95% CI 0.40–1.06), and 0.45 (95% CI 0.22–0.91) among subjects in the highest quartile of score for dietary pattern 1 as compared to those in the lowest quartile.

Conclusion: Our findings suggest that higher adherence to a dietary pattern was characterized by a high intake of soybeans and soybean products, vegetables, algae, and milk and dairy products, and a low intake of rice is associated with a reduced risk of dementia in the general Japanese population.

Neurocognitive impairment (NCI) in HIV-1 infected adults in Sub-Saharan Africa: A systematic review and meta-analysis
A. Ibrahim1, A.G. Habib2, A.M. Yakasai1, L.F. Owolabi3, Z.G. Habib1, M. Gudaji4, K.M. Karaye1, D.A. Ibrahim1; 1Medicine, Bayero University Kano, Kano, Nigeria; 2Medicine, Aminu Kano Teaching Hospital, Nigeria; 3Neuropsychiatry, Bayero University Kano, Kano, Nigeria

Background: In SSA estimates of HIV related neurocognitive impairment (NCI) and the effect of ART on it have varied. A study was conducted to obtain the prevalence, burden and impact of ART on NCI.

Materials and methods: We searched Medline and other databases for relevant English language publications up to June 2012. Prospective studies in adults from SSA reporting HIV status, utilization of ART and presence of NCI using the IHDS were selected. Study quality was assessed using standard criteria. Meta-analysis used random-effects model to derive estimates and meta-regression was done to assess the effects of age, gender, education and CD4 cell counts on NCI. Publication bias and sensitivity analyses were conducted.

Results: 16 studies from 7 countries in SSA were included. The frequency of NCI pre-ART was 42.37% (95% CI = 32.18–52.56%) and 30.39% (95% CI = 13.17–47.61%) among those on ART for ≥6 months.

We found no significant associations between age, gender, CD4 cell counts and years of education with NCI. The patients on ART were less likely to have NCI compared to HIV infected pre-ART patients with OR of 0.36 (95% CI = 0.19–0.69). In longitudinal studies with same patients followed before and ≥6 months after ART, the OR of NCI after ART compared to pre-ART was 0.23 (95% CI = 0.14–0.37). The combined burden of NCI among pre-ART and on-ART patients was estimated at 8,121,910 (95% CI = 5,772,140–10,471,680).

Conclusions: HIV strongly predisposes to NCI leading to a huge burden in SSA. Scale-up of ART can substantially reduce NCI in the region.

The effect of an APOE polymorphism on cognitive function depends on age
S.-K. Jeong1, M.-H. Shin2 Namwon Study
1Neurology, Chonbuk National University, Jeonju, Republic of Korea; 2Preventive Medicine, Chonnam National University, Gwangju, Republic of Korea

Objectives: APOE E4 polymorphism is a genetic susceptibility marker of Alzheimer’s disease. However, it remains controversial whether this polymorphism is related to cognitive function in general population. We aimed to evaluate a cross-sectional association between the APOE E4 genotype and cognitive function, and whether this association may differ by age.

Methods: Cognitive function was assessed using the Korean version of modified Mini-Mental State Examination (K-mMMSE) in 10,371 Koreans aged 45 to 74 yrs in Namwon City. According to the APOE E4 status, all participants were classified as non-carriers, heterozygotes, or homozygotes. Participants were also categorized by age; 45–54, 55–64, and 65–74 years. Cognitive impairment was defined as scoring below the 25th percentile according to age, sex, and education. Multiple linear and logistic regression models were used to evaluate the association between APOE genotypes and cognition.

Results: The frequency of APOE genotypes in the study population was 0.4, 10.1, 1.1, 72.9, 14.7 and 0.8% for E2E2, E2E3, E2E4, E3E3, E3E4, and E4E4, respectively. Compared to the APOE E4 non-carriers, the heterozygotes and homozygotes showed 1.3% and 7.3% lower K-mMMSE scores at 65–74 yrs and 0.8% and 4.6% higher scores at 45–55 yrs, respectively. The E4 homozygotes had a higher risk for cognitive impairment (OR = 2.38, 95% CI = 1.13–4.98) at 65–74 yrs compared to the non-carriers, but showed lower risk (0.19, 0.03–1.48) at 45–54 yrs.

Conclusions: The present study demonstrates that the effect of APOE E4 on cognitive function depends on age, with positive correlation until late adulthood and negative correlation in the elderly.

A randomized placebo-controlled trial of quetiapine for the treatment of behavioral and psychological symptom of dementia in Alzheimer’s disease patients
C.-S. Shin, Neurology, Seogwang General Hospital, Gwangju, Republic of Korea

Objectives: This randomized, double-blind, placebo-controlled trial examined the efficacy and safety of quetiapine in the treatment of
aggression, agitation, and psychosis in elderly nursing-home patients with dementia.

**Methods:** We conducted a 12-week, rater-blinded, randomised study of 80 outpatients (72–85 years) with behavioral and psychological symptom of dementia (BPSD) (assessed by NPI baseline score), who received low dose quetiapine (12.5–50 mg/day). Primary efficacy measures were: Neuropsychiatric Inventory (NPI); secondary efficacy measures: Clinical Global Impression (CGI), Cohen–Mansfield Agitation Inventory (CMAI), and Mini-Mental State Examination (MMSE). Safety evaluations included the incidence of extrapyramidal symptoms (EPS) and adverse events (AEs).

**Results:** Seventy-six of 80 patients were evaluable for efficacy (80 were evaluated for safety), while 4 patients discontinued (4 lost to follow-up). Seventy-six patients received quetiapine (mean dose 29 mg/day). NPI scores decreased significantly from baseline to week 12 (P < 0.05 vs. baseline). Most patients (72.5%) experienced clinical improvement (CGI-Improvement scores); quetiapine reduced agitation (CMAI scores); and there was no cognitive impairment (MMSE scores). There were no significant EPS. There were no cerebrovascular AEs or deaths. Most iatrogenic cognitive impairment (ICI) can be explained and can be attributed to polypharmacy in elderly, drug interactions, and altered pharmacokinetics.

**Conclusions:** Treatment with low-dose (mean dose 29 mg/day) quetiapine resulted in significant improvement in aggression, agitation, and psychosis associated with dementia and it was generally well tolerated (including no cognitive impairment) in the treatment of BPSD in elderly patients.

Iatrogenic cognitive impairment in elderly patient in Russia

S. Duma, Research Institute of Internal Medicine SB RAMS, Novosibirsk, Russia

**Introduction:** Most iatrogenic cognitive impairment (ICI) can be explained and can be attributed to polypharmacy in elderly, drug interactions, and altered pharmacokinetics.

**Objective:** To evaluate iatrogenic effects of drugs in elderly patients.

**Material and Methods:** The treatment of 180 patients aged >65 years who sought medical care in FSBI of Internal Medicine with complaints of cognitive impairment (CI) with the diagnosis of ICI in 2011–2012 was analyzed. All patients who received at least 6–8 drugs per day prescribed by the doctor about the current somatic pathology during long-term period (more than 2 month) were included in the analysis.

**Results:** It was found that the most adverse effects on cognitive function caused by benzodiazepine derivatives were use to improve sleep and sedation — in 34%, the same effect for the neuroleptic group with 4.1%. Antidepressants and antiepileptic drugs which were used in order to reduce pain caused CI in 12.6% of cases. Clinical picture was almost identical to Alzheimer’s disease and after cessation of treatment CI persisted for 2–3 months. There was a growth of CI in patients receiving drugs for internal, ophthalmic and neurological disease (CHD, diabetes, constipation, glaucoma, ulcers, Parkinsonism, vertigo, others) even with minimal anticholinergic activity — in 49.3% of patients. An effect similar to the action of atropine was typical for prednisolone, digoxin, nifedipine, and diprydamole in few cases.

**Conclusions:** Our findings show that mental confusion was the most frequent symptom of CI. The decrease in the severity of CI after withdrawal of the drug indicates CI. General practitioners should consider the possible iatrogenic effects in the treatment of elderly patients.

Subjective memory complaints: Is family history of dementia a risk factor?

A.J. Larner, Cognitive Function Clinic, Walton Centre for Neurology and Neurosurgery, Liverpool, UK

**Background:** Ascertaining family history of dementia is a routine part of cognitive assessment.

**Objective:** To measure the frequency of cognitive impairment (dementia or mild cognitive impairment) in patients with or without a positive family history of dementia.

**Patients and methods:** Family history of dementia was ascertained in consecutive new outpatients attending a Cognitive Function Clinic.

**Results:** Of 139 patients, 43 reported a positive family history of dementia but only four satisfied criteria for autosomal dominant disease (3 or more affected family members in at least two generations). Of 63 patients with dementia or MCI, 14 (22.2%) had a positive family history, all familial disease (at least one first degree family relative affected). Of 76 patients with subjective memory complaints (neither dementia nor MCI), 29 (38.2%) had a positive family history (either autosomal dominant disease or familial disease). Risk ratio for subjective memory complaint patients having a positive family history of dementia was 1.72 (95% confidence interval = 1.00–2.96). The null hypothesis that the proportion of patients with a positive family history of dementia was the same in cognitively impaired and non-impaired groups was not rejected, although a trend was observed (x² = 3.41, df = 1; 0.1 > p > 0.05).

**Conclusion:** Positive family history of dementia may be one stimulus for patients concerned about memory, leading to consultation and onward referral of individuals with subjective memory impairment. These individuals may be sensitized to the symptoms of memory impairment, including memory lapses, by their family history.

Effects of gender on two clinical signs (attended alone and head turning) of use in the diagnosis of cognitive complaints

**Background:** Previous studies have shown that the attended alone sign is very sensitive for the absence of cognitive impairment, whilst the head turning sign is very specific for the presence of cognitive impairment.

**Objective:** To report the effect of gender on the attended alone sign and the head turning sign in diagnosis of cognitive complaints.

**Patients and methods:** Data from studies of consecutive new outpatients attending a Cognitive Function Clinic were analysed by patient gender.

**Results:** In a study of the attended alone sign in 726 consecutive patients (M:F = 383:343), the null hypothesis that the proportion of patients attending alone did not differ significantly by gender was not rejected (x² = 0.02, df = 1, p > 0.1). Diagnostic accuracy data by gender showed similar sensitivity and specificity in males (0.91 and 0.49) and females (0.96 and 0.40). In a study of the head turning sign in 246 consecutive patients who attended with an informant (M:F = 123:123), the null hypothesis that the proportion of patients with the head turning sign did not differ significantly by gender was not rejected although a trend was observed (x² = 3.26, df = 1, 0.1 > p > 0.05). Looking at the diagnostic accuracy data by gender, test sensitivity and specificity were better in females (0.72, 0.98) than in males (0.58, 0.91).
Conclusion: In prospective observational studies, gender does not seem to influence the attended alone sign. The head turning sign may possibly be of greater diagnostic utility in female patients.

Analysis of polymorphism in Brain-derived neurotrophic factor gene in sporadic Alzheimer’s disease in Han Chinese
X. Shu-Wen, G. Guangsheng, L. Dongfeng, Y. Ruihan, F. Fangfang, X. Hao. Department of Neurology of Guangdong General Hospital, Guangdong Academy of Medical Sciences, Guangdong Geriatrics Institute, Guangdong Neuroscience Institute Guangzhou, Guangzhou, China

Objective: To investigate the association between the C270T polymorphism of the Brain-derived neurotrophic factor (BDNF) gene and sporadic Alzheimer’s disease (SAD) in Han Chinese.

Methods: The polymerase chain reaction-restriction fragment length polymorphism (PCR-RELP) was used to detect BDNF genotypes of 55 SAD patients and 80 controls.

Results: Gender or age had no significant difference in SAD and control group ($x^2 = 0.072$, $p = 0.789$; $t = 1.494$, $p = 0.137$, respectively). The genotype distribution for the control group was not significantly deviated from the Hardy–Weinberg equilibrium ($x^2 = 0.167$, $p = 0.682$), and the frequency distributions of the two groups’ genotype and allele were not significantly different ($x^2 = 0.219$, $p = 0.640$; $x^2 = 0.211$, $p = 0.646$, respectively).

Conclusion: There is no association between the C270T polymorphism of BDNF gene and SAD in Han Chinese.

Behavioural Assessment of the Dysexecutive Syndrome (BADS) on the context of normal and pathological aging
M. Paixãoa, B. Peixotoa, bPsychology and Health Research Unit (UnIvPsa-CESPU), Gandra, Portugal; bSciences, Instituto Superior de Ciências da Saúde-Norte (CESPU), Gandra, Portugal

Several authors advocate the need to assess executive functioning (EF) as a robust determinant of the functional status of the subject and as a potential marker of dementia. However there are few available instruments that allow the assessment of different components of the EF in the context of aging, both normal and pathological. The present work aimed to determine the psychometric properties of the Behavioural Assessment of the Dysexecutive Syndrome (BADS) in the context of aging in a Portuguese sample.

Our sample comprised 33 subjects with more than 65 years divided in two groups: Control Group ($n = 22$), made of cognitively intact subjects; Dementia Group ($n = 11$), composed of patients with probable diagnosis of Alzheimer’s disease (NINCDS-ARDA Criteria). We have applied the BADS, the Dementia Rating Scale and the Geriatric Depression Scale to both groups. The BADS revealed good levels of acceptance, internal consistency, discriminative and criterion validity. These results favor the use of this instrument in the context of aging and dementia. It may be very useful in monitoring EF and in the detection of dementia.

Objective: We aim to investigate the effects of ginkgolide B (GKB) and velvet antler polypeptide (VAP) on the generation and differentiation of cholinergic progenitors.

Methods: Telencephalon cells were cultured. GKB, VAP and the combination of them were added into the culture medium. Cell culture was terminated on day 4, and then the SP kit (Boster, China) was used to mark the ChAT and BrdU positive cells. The data of these positive cells were analyzed among groups.

Results: Compared to the control group, the neurospheres of experimental group were bigger and the neurites were longer and stronger. More cells migrated from neurospheres. Most cells of ChAT positive distributed on the edge of neurospheres; only a small amount scattered among the neurospheres. The number of ChAT positive neurons in experimental group was higher than that in the control group, especially the GKB and VAP combined group. The VAP group had the most BrdU positive cells.

Conclusion: GKB and VAP, especially when used together, could facilitate the generation and differentiation of cholinergic progenitors efficiently.

Antidepressant treatment improves estrogen levels and cognitive function in postmenopausal anxiety/depression patients
B.R. Zhou. GuangZhou Medical College, GuangZhou, China

Rationale and objectives: The current study investigated the role of antidepressant treatment on the level of sex hormones and cognitive function in post-menopausal anxiety/depression patients.

Methods: A total of 82 post-menopausal patients who were diagnosed with anxiety/depression disorder and were not receiving hormonal replacement therapy participated in a prospective, 6-month, open-label naturalistic study. Patients were divided into an antidepressant treatment group (44 cases) and a non-antidepressant treatment (control) group (38 cases). We collected demographic data and tested cognitive function in post-menopausal anxiety/depression patients.

Results:
1) The E2 level at six-months post-treatment was significantly increased, conversely, FSH and LH levels were significantly decreased, in the antidepressant treatment group compared with pre-therapy or the control group (P < 0.01).
2) HARS-14 and CHDS scores decreased significantly more, MoCA scores significantly improved in the antidepressant treatment group than in the pre-therapy or the control group (P < 0.01).
3) E2 levels were strongly correlated with MoCA and CHDS or HARDs-14 scores at pre- and post-therapy in the antidepressant treatment group. E2 levels maintained a significant association with improvement in CHDS at post-therapy, even we controlled for age, severity of depression, and MoCA scores, (R 0.35, P 0.038).

Conclusions: The antidepressant Paroxetine improved cognitive function in postmenopausal anxiety–depression patients, possibly by increasing endogenous estrogen discharge or delaying degeneration of the gonads.

‘Lexical’ alexia in a Chinese semantic dementia patient
S.K.S. Ting, S. Hameed. Neurology, National Neuroscience Institute, Singapore, Singapore

Semantic dementia (SD) is characterized by losing the ability to understand the meaning of words and losing semantic knowledge. Reading disorder or surface dyslexia or ‘regularization’ error is typically described in English speaking patients. However, to date little is known about the reading disorder in Chinese semantic dementia patients. We describe a case of a Chinese SD patient who completely lost the ability to read Chinese characters even with common low stroke high frequency words. This suggests that Chinese character reading is likely mainly reliant on visual ventral pathway (orthography), in keeping with temporal lobe atrophy seen in SD, rather than phonological pathway.

Effects of green tea consumption on cognitive dysfunction: An exploratory clinical study
Graduate School of Pharmaceutical Sciences, University of Shizuoka, Shizuoka, Japan; White Cross Nursing Home, Higashimurayama, Japan; Central Research Institute, ITO EN Ltd., Shizuoka, Japan

Background: In rapidly aging societies worldwide, the number of patients with disorders marked by cognitive dysfunction, such as Alzheimer’s disease, is gradually increasing; however, thus far, no fundamental curative therapy has been established. Green tea, whose major constituents are catechins and theanine, is known to have various health benefits for humans. However, the effects of green tea consumption on cognitive dysfunction remain to be clinically verified.

Objective: To conduct a clinical study to investigate the effects of green tea consumption on cognitive dysfunction.

Patients and methods: Twelve elderly nursing home residents (2 men, 10 women; mean age, 88 years) with cognitive dysfunction (Mini Mental State Examination [MMSE] score: <28) were recruited. Written informed consent was obtained from the patients and caregivers. The patients were asked to consume green tea powder (2 g/day containing 227 mg of catechins and 37 mg of theanine; manufactured by ITO EN Ltd., Tokyo) for 3 months. Cognitive function was assessed by performing MMSE, and serum lipid levels were measured.

Results: The MMSE scores (mean ± S.D.) significantly improved after the intervention (before intervention, 15.3 ± 7.7; after intervention, 17.0 ± 8.2; p = 0.025), especially for the category recent memory. Regarding serum lipid levels, low-density lipoprotein (LDL)-cholesterol levels remained unaltered, but triglyceride levels decreased significantly (before intervention, 124 ± 80 mg/dL; after intervention, 103 ± 57 mg/dL; p = 0.041).

Conclusion: These results suggest that green tea consumption may be effective in improving cognitive function, and additional confirmatory long-term controlled studies are needed.

Fast and slow conversion to Alzheimer’s disease in mild cognitive impairment: Role of cerebrospinal fluid biomarkers
M. Tondelli, A. Chiari, M.A. Molinari, R. Bedini, G. Bonifacio, T. Trenti, P. Nichelli. Neuroscience Department, University of Modena and Reggio Emilia, Modena, Italy; Clinical Pathology-Toxicology, Ospedale Civile S. Agostino-Entense, Modena, Italy

Introduction: It is well known that CSF biomarkers help discriminating preclinical AD from age-associated memory impairment and other forms of dementia. Little is known about the ability of these biomarkers to predict speed of progression to AD in MCI patients.

Objective: To examine whether demographic, neuropsychological and CSF parameters at the preclinical stage of AD can be used to discriminate between slow and rapid converters to AD in patients with MCI.

Materials and methods: A group of 71 MCI patients was recruited from our Memory Clinic according to clinical criteria. We investigated baseline CSF and neuropsychological biomarker patterns between groups of MCI patients stratified by later diagnoses of conversion to AD or other dementia. In addition, MCI patients who converted to AD (cMCI) were classified in slow and rapid converters (< 18 months).

Results: cMCI show at baseline lower Aβ1–42 as compared to patients who remained stable MCI or who developed other dementia. The subgroup analysis between slow and rapid converters confirmed the role of Aβ1–42 to discriminate between the 2 groups: rapid converters showed already at baseline lower Aβ1–42 levels as compared to slow converters. Survival analysis confirmed that cMCI patients with lower value of CSF Aβ1–42 at baseline had significantly shortest median dementia-free survival.

Conclusion: Our results suggest that Aβ1–42 may be related to speed of conversion to AD in MCI patients and it could be useful in the stratification of cMCI population to support patients’ workup in clinical setting.

Music therapy using flash song therapy for outpatients with juvenile Alzheimer’s disease
M. Nakamura, M. Iizuka. Neuroscience, Kyoto Medical Center, Kyoto, Japan; Brain Nerve Center, Kyoto Medical Center, Kyoto, Japan

Background: Music therapy is applied to dementia as a non-pharmacological treatment; there is some evidence of its beneficial effects. However, most reported studies have been focused on patients in nursing homes.

Objective: To examine the effects of music therapy using Flash Song Therapy for dementia patients at home and visiting our hospital.

Patients and methods: Eight patients with juvenile Alzheimer’s disease (MMSE 0–23, average 10.5) were included in this study; their cognitive functions, behavioral and psychological symptoms of dementia (BPSD), ADL, QOL and caregiver burden were evaluated before and after 8 and 16 private sessions. We used Flash Song Therapy, a method of music therapy that we developed. In this method, patients sing their favorite songs, usually more than twenty, one after another. Just when the first verse of one song ends, the introduction of the next song begins; the quick changes of songs and rhythms stimulate their brains and bodies and fill them with pleasure and satisfaction.
Results: The scores of BPSD and QOL improved significantly after the sessions, and some patients showed improvements in cognitive function. The tempo of gait tended to increase after each session. Some families and caregivers reported that the patients became calmer, joyful and able to speak about themselves confidently, among others.

Conclusion: Music therapy using Flash Song Therapy could be one clinical approach for outpatients with dementia.

Utility of neuropsychological tests in the diagnosis of amnestic mild cognitive impairment and Alzheimer’s disease or other forms of dementia
S. Gjici\textsuperscript{a}, D. Naço\textsuperscript{b}, E. Shehu\textsuperscript{c}, M. Rakacolli\textsuperscript{d}, J. Krupa\textsuperscript{a}, \textsuperscript{a}Neurology, University of Medicine, Service of Neurology, Albania; \textsuperscript{b}Neurology, Specialistic Polyclinic, Tirana, Albania; \textsuperscript{c}Neurology, Specialistic Polyclinic, Durres, Albania

Aim: To show objective cognitive decline and estimate the severity of dementia and to determine whether dementia severity and the atrophy predict subsequent cognitive deficiency in dementia.

Background: The identification of variables that accurately predict progressive cognitive decline in dementia has important clinical implications and is essential to apply potential treatments. Amnestic mild cognitive impairment patients form a heterogeneous population that constitutes a higher risk for dementia development.

Methods: We recruited 5 AD patients and 3 amnestic mild cognitive impairment (aMCI) patients. Magnetic resonance imaging (MRI) was applied to all subjects for evaluating the atrophy. We applied a neuropsychological test battery including Wechsler memory scale (WMS), verbal fluency, verbal learning, dual similarities, clock drawing test, Benton face recognition, Hooper visual organisation test, visual memory test, visual learning and MMSE.

Results: 5 AD patients confessed cognitive problems with the worst cognitive score on memory test (encoding, recall, retrieval) and impaired visuospatial skill (Benton Facial Recognition) related with medial temporal or posterior cortical lobe atrophy. The 3 amnestic mild cognitive impairment patients confessed cognitive problems on executive dysfunction (and lesser on memory impairment) and severe visuospatial and visuo-constructive disabilities and psychomotor slowing.

Conclusion: AD patients presented progressive episodic memory impairment and impaired visuospatial skills (progressive cortical visual and visuospatial impairments if posterior cortical atrophy was present). aMCI patients may develop AD, but also other forms of dementia. Clinical correlates of cognitive disorders must be frequent in dementia.

Cognitive function in patients with arterial hypertension and cerebrovascular complications of Uzbek people
N.U. Mahkamova, Cerebrovascular Disease, Republikan Specialized Centre of Cardiology, Tashkent, Uzbekistan

Objective: To study the state of cognitive function in patients with arterial hypertension (AH) and chronic cerebrovascular events (CCVEs).

Material and methods: 50 patients of both sexes were examined aged from 33 years to 73 years. Cognitive disorders were detected using some scales: MMSE and a battery of tests of frontal dysfunction — BTFD. All the patients were divided as follows: the first group — patients with hypertensive encephalopathy; the second group — patients with ET 2, the third group — patients with ET-3, and the fourth group — patients with GE effects of stroke.

Results: Thus, 85.7% patients of the first group were with normal cognitive function according to BTFD. Patients with mild cognitive impairment were 14.3%. In the second group the frequency of occurrence of false violations and symptoms of mild dementia according to BTFD were the same with similar data obtained in the study on an MMSE scale. Moderate cognitive disorders are almost 2 times less likely (21.8% vs. 35.8% p < 0.05).

In the third group consisting of patients with mild cognitive impairment according to BTFD was 70.8%. The lowest percentage included patients with dementia of mild severity (4.2% vs. 20.8%, p < 0.03).

Involvement of the cholinergic basal forebrain nuclei in spinocerebellar ataxia type 2 (SCA2)
U. Rüh\textsuperscript{a}, K. Farrant\textsuperscript{a}, K. Seidel\textsuperscript{b}, E. Brunit\textsuperscript{c}, H. Heinsen\textsuperscript{d}, K. Bürk\textsuperscript{d}, B. Meleghi\textsuperscript{e}, G. Auburger\textsuperscript{f}, W. den Dunnen\textsuperscript{g}, H.-W. Korf\textsuperscript{h}, \textsuperscript{a}Dr. Senckenberg Chronomendical Institute, J.W. Goethe University, Frankfurt/Main, Germany; \{b}Department of Neurology, University Medical Center Groningen, Groningen, The Netherlands; \textsuperscript{c}Morphological Brain Research Unit, Julius Maximilians University, Würzburg, Germany; \textsuperscript{d}Department of Neurology, Philipps-University of Marburg, Marburg, Germany; \textsuperscript{e}Department of Medical Genetics, University of Pecs, Pecs, Hungary; \textsuperscript{f}Department of Neurology, J.W. Goethe University, Frankfurt/Main, Germany; \textsuperscript{g}Department of Pathology and Medical Biology, University Medical Centre of Groningen, Groningen, The Netherlands

Background: Spinocerebellar ataxia type 2 (SCA2) is a polyglutamine disease associated clinically with attention deficits, impairments of verbal memory, frontal-executive and visuospatial functions, as well as global cognitive decline. The possible morphological correlates of these cognitive deficits are unclear.

Objective: To analyze the neuropathological state of the cholinergic basal forebrain nuclei (i.e. medial septal nucleus, MS; nuclei of the vertical and horizontal limbs of the diagonal band of Broca, DBV, DBH; basal nucleus of Meynert; BNM) in SCA2 patients which are believed to be crucial for several aspects of normal cognition.

Patients and methods: Pigment–Nissl stained and AT8 tau-immunostained serial thick sections through the cholinergic basal forebrain nuclei of clinically diagnosed and genetically confirmed SCA2 patients and control individuals were analyzed.

Results: These analyses revealed a severe and consistent neuronal loss in all of the cholinergic basal forebrain nuclei (MS: 72%; DBV: 74%; DBH: 72%; BNM: 86%) of the SCA2 patients studied. Damage to the basal forebrain nuclei was associated with everyday relevant cognitive deficits only in our SCA2 patient with an advanced Alzheimer’s (AD)-related tau pathology.

Conclusions: The findings of the present study (1) indicate that the mutation and pathological process of SCA2 play a causative role for the severe degeneration of the cholinergic basal forebrain nuclei and (2) suggest that degeneration of the cholinergic basal forebrain nuclei per se is not sufficient to cause profound and global dementia detrimental to everyday practice and activities of daily living.
In the fourth group consisted of patients characterized by differences in the absence of dementia, detection of dementia is 20% according to the MMSE and BTDF scales. That the results of both tests in 80% of patients had mild cognitive impairment.

Conclusion: The degree of cognitive impairment depends on the degree and duration of hypertension.

Background: A nationwide surveillance system for human prion diseases (PrDs) was established in April 1999 (Nozaki et al.).

Objective: To describe the features of epidemiology, clinical manifestations and CSF biomarkers of human PrDs in Japan.

Patients and methods: Information on clinical, neuropathological, and molecular genetic data of patients suspected as having PrDs was analyzed by the Committee, from April 1999 to September 2012.

Results: We have obtained the information of 3664 patients. A total of 1894 cases (51.7%) of PrDs were identified, including 1452 cases of sporadic CJD (sCJD) (76.7%), 270 cases of genetic CJD (14.3%), 79 cases of GSS (4.2%), 4 cases of FFI (0.2%), 81 cases of dura mater graft-associated CJD (dCJD) (4.3%), and 1 case of variant CJD (vCJD) (0.1%). The overall annual incidence rate was 1.01 cases per million person-years. Genetic analysis was performed in 1375 patients, and revealed that 351 cases had a mutation in PRNP gene. The most frequent mutation was 151 cases of V180I mutation (43.0%), followed by 70 cases of P102L, 52 cases of M232R, 49 cases of E200K, 6 cases of P105L, 5 cases of D178N, and 3 cases of V180I + M232R. Autopsy was performed in 17% of the total 1458 patients. Of the total 144 dCJD cases in Japan, 81 cases appeared in this surveillance system. Only one case of vCJD was identified in 2005.

Conclusion: Human prion diseases in Japan were characterized by frequent occurrence of dCJD and relatively larger amount of patients with uncommon genetic prion diseases.

Brain volumetry and emotional processing in demented patients

G.-R. Beatriz, F.G. Ana, V. Clarissa, G.-F. Daniel, G.-P. Pablo, P. Gonzalez, H.-T. Juan Antonio, C.-G. Carmen, E. Heiner. 1Basic Psychology, Universidad de Educación a Distancia, Spain; 2Neurology, Hospital Universitario La Paz, Spain; 3Fundacion Investigación Biomédica, Hospital Universitario La Paz, Spain; 4Universidad Rey Juan Carlos, Spain; 5Universidad Rey Juan Carlos Juan Carlos, Spain; 6Universidad de Educación a Distancia, Madrid, Spain; 7Julius Maximilliam University, Würzburg, Germany

Background: Emotional deficits and cerebral atrophy are both features of Alzheimer’s disease (AD). Behavioral studies have provided evidence that AD patients have deficits in the recognition of emotional expressions, especially when the processing is concurrent with another task.

Objective: We examined the relationship between brain atrophy and deficits in the identification of emotional expressions under two attentional conditions: simple and double task (DT) performance.

Patients and methods: 40 subjects (27 healthy subjects, mean age = 71.70 ± 4.23 and 13 AD patients, mean age = 75.92 ± 6.64 years) had to identify 24 facial expressions enacting the six basic emotions under two conditions: identification task and the atrophy of cortical structures correlates with both conditions (frontal lobe and parietal lobe).

Conclusion: The present findings represent a contribution to our understanding of emotional processing in demented patients. Specifically, we demonstrate how brain atrophy characteristic of AD patients affects the ability to identify emotional faces as a function of attentional demands.

The mini mental state examination could be helpful for thromboembolic risk stratification in atrial fibrillation?

N. Diaconu. Institute of Cardiology, Chisinau, Moldova

Aims: To determine whether atrial fibrillation (AF) in stroke-free patients is associated with impaired cognition and to determine the correlation between thromboembolic risk and the cognitive impairment.
Methods: 218 patients with AF, free of stroke, were consecutively examined. All cases underwent physical and instrumental examinations. To investigate the cognitive status subjects underwent the Mini Mental State Examination.

Results: The subjects (218) (mean 70.1 ± 0.65 years; 59% W) were stratified according to ECG features into 3 groups: (I) those with de novo AF (n = 6; 28%); (II) those with paroxysmal AF (n = 40; 18.4%), and (III) those with chronic AF (n = 172; 78.9%). Cognitive status was found to be significantly different in the 3 groups: group I — 28.1 ± 1.9; group II — 25.9 ± 2.9; and group III — 24.9 ± 2.9 (p < 0.01). Thromboembolic risk (according to CHA2DS2-VASc) was similar between groups (3.1 ± 0.6 in gr.II vs. 2.9 ± 0.8 in gr.I and 1.9 ± 0.2 in gr.I, p = 0.05). There was a significant association between thromboembolic risk and the presence of cognitive disturbances (MMSE < 26) (8.7% low risk, 21.4% moderate risk, and 48% high risk, p < 0.05). Brain CT scan has shown multiple cerebral ischemic areas in 52% of patients with cognitive disturbances. Among 56 patients with CHA2DS2-VASc score = 1, twelve of them (21.4%) have had MMSE — 26 with lacunar or ischemic changes in 25%.

Conclusions: Cognitive dysfunction is common in patients with chronic atrial fibrillation. The MMSE, in addition to CHA2DS2-VASc, could help to identify patients with atrial fibrillation who need oral anticoagulation and those who need extra efforts to maintain effective optimal anticoagulation.

Diabetes exacerbates Alzheimer's disease induced brain pathology. Possible neuroprotective effects of Cerebrolysin

H.S. Sharmaa, R.J. Cascellib, D.F. Muresanuc, M.A. Smithd, R. Patnaikf, H. Moesslera, A. Sharma. 1Surgical Sciences, Anesthesiology & Intensive Care Medicine, Uppsala University Hospital, Uppsala, Sweden; 2Pathology, University of Maryland, Baltimore, MD, USA; 3Clinical Neurosciences, Medicine & Pharmacy Cluj-Napoca, Cluj-Napoca, Romania; 4Pathology, Case Western Reserve University Medical School, Cleveland, OH, USA; 5National Institute of Technology, School of Biomedical Engineering, Banaras Hindu University, Varanasi, India; 6Ever Neuro Pharma, Oberburgau, Austria

Diabetes mellitus is a devastating disease that affects central nervous system (CNS) function causing brain pathology. Recent studies indicate that Alzheimer's Disease (AD) may reflect brain diabetes and may have a strong link with the disease as predisposing factor. However, the details of a possible link between diabetes and AD are still not well known. Previous works from our laboratory showed that diabetes exacerbates brain pathology following heat stroke and traumatic brain or spinal cord injuries. Thus, there is a possibility that diabetes may also aggravate AD induced brain pathology. This hypothesis was examined in our lab using a rat model of AD using amyloid-beta protein (AbP) infusion in normal or diabetic rats. Our observations show that AbP infusion exacerbates brain pathology in diabetic rats as compared to normal control group. This indicates that diabetes has the capacity to enhance AD pathology. Interestingly, concomitant infusion of Cerebrolysin, a small peptide fragments is able to thwart AbP induced AD pathology in low doses (2.5 to 5 ml/kg, i.v.) in normal rats. However, in diabetic animals high doses of the drug (10 ml/kg) or nanowired delivery of the compound (5 ml/kg) is needed to achieve effective neuroprotection. These observations suggest that diabetes play a major role in AD pathology and modulate therapeutic efficiency of drug therapy.

Background: Disorders of higher mental functions of vascular diseases of cerebrum and dynamics under influence of treatment

S. Perminova, MSH ‘OO Gazprom Transgaz Kazan’, Kazan State Medical Academy, Kazan, Russia

Objective: To study the specialties of disorders of higher mental functions of patients with cerebrovascular disease.

Patients and methods: 121 patients (26.4% men and 73.6% women) with an average age 63.6 ± 8.8 and with cerebrovascular disease were studied. Neuropsychological examination was made in all spheres of higher mental activity. After treatment, examination of dynamic condition of higher mental function was made.

Results: Disorders memory 88.4% of patients, attention 83.5%, somatosensory gnosiss 81.9%, intellect 66.9%, auditory gnosiss 59.5%, dynamic praxiss 52.9%, speech 50.4%, optic gnosiss 44.6%, counting 11.6%, writing 10.7%, and reading 8.3%. After treatment: disorder memory 40.5% of patients, attention 31.4%, somatosensory gnosiss 18.2%, intellect 26.4%, auditory gnosiss 13.2%, dynamic praxiss 9.9%, speech 17.4%, optic gnosiss 18.3, counting 5.0%, writing 6.6%, and reading 4.1%. Most changes: memory 88.4%, attention 83.5%, somatosensory gnosiss 81.9, and intellect 66.9%. Least changes: counting 11.6%, writing 10.7%, and reading 8.3%. Spheres of higher mental activity which had considerable improvements: after treatment — somatosensory gnosis: before treatment 81.8% after treatment 18.2%; auditory gnosis: before treatment 59.5%, after treatment 13.2%; and dynamic praxis: before treatment 52.9%, after treatment 9.9%.

Conclusion: For diagnostics of higher mental disorders of vascular diseases of cerebrum, the study of memory, attention, somatosensory gnosis and intellect is necessary. All spheres of high mental activities can be treated. Best results are possible in somatosensory gnosis, auditory gnosis and dynamic praxis.

doi:10.1016/j.jns.2013.07.1132
according to their cognitive development, at two years of obtaining the sample.

**Material and methods:** Between 2008 and 2010, 67 subjects without cognitive or behavioral disorders were included as a control group in a study of CSF-AD-BMK. In most cases, neuropsychological assessment was performed both at baseline and at follow-up two years later. CSF was obtained at the inclusion and analyzed by INNOTEST reagents, measuring Aβ1–42, total-tau and P-tau181P protein levels, as well as T-tau/Aβ1–42 and P-tau181P/Aβ1–42 ratios.

**Results:** Two years after inclusion, 28 subjects were not able to be checked. Among the 39 remaining, 29 were cognitively stable and 11 showed a GDS score greater than 2. When compared both groups, we found significant differences in Aβ1–42 protein level (820 vs 1359 pg/ml, p < 0.003), in the T-tau/Aβ1–42 ratio (0.40 vs 0.19, p < 0.009) and in the P-tau181P/Aβ1–42 ratio (0.09 vs 0.04, p < 0.003).

**Conclusion:** In a group initially asymptomatic, CSF-BMK-AD seems able to discriminate between subjects depending on their cognitive evolution at the two years follow-up. Our results are consistent with the decrease of CSF Aβ1–42 protein levels, as the first finding in preclinical AD.

**Serum levels of albumin–amyloid beta complexes are useful for monitoring of the progression of Alzheimer’s disease**

K. Yamamoto, H. Shimada, S. Ataka, T. Miki. Department of Geriatric Medicine and Neurology, Osaka City University Graduate School of Medicine, Osaka, Japan

**Objective:** Decreased amyloid β (Aβ) clearance from brain to blood may play a key role in the development of Alzheimer’s disease (AD). Aβ is normally bound to and transported by albumin in blood, thus possibly maintaining a constant concentration of free Aβ in blood. We therefore hypothesized that decreased serum levels of albumin–Aβ complexes may be associated with decreased Aβ accumulation in the brain.

**Methods:** We performed a cross-sectional investigation of the association between serum levels of albumin–Aβ complexes (SLAAC) and AD prevalence.

**Results:** The mean SLAAC was significantly lower in the AD group than in the control group. Decreased SLAAC was correlated with decreased CSF levels of Aβ42 and elevated CSF p-tau (r = 0.38, P = 0.0221; r = −0.43, P = 0.0090, respectively), findings that have been shown to be associated with AD progression.

**Conclusions:** This novel method may be very useful for monitoring of the progression of AD.

**Suicide in dementia**

W.-D. Möller, G. Brandt, J. Wohler, P. Kropp.  
**HG-Creutzfeldt-Institute, University of Kiel, Kiel, Germany; Institute of Applied Neurobiology, University of Heidelberg, Heidelberg, Germany; Institute of Medical Psychology and Medical Sociology, University of Rostock, Rostock, Germany

**Objectives:** Suicide occurs more often in elderly and its risk is increasing with age. Suicide rates in men are three times higher compared with women. The reasons for suicide are predominantly mental or physical illness. Especially mood disorders and the assumption to suffer from degenerative dementia are risk factors. The aim of our study is to determine risk factors of suicide in our memory-ambulance.

**Methods:** We examined n = 1000 patients in our memory-ambulance between 2002 and 2012. All patients suffered from dementia (vascular dementia or dementia of Alzheimer’s type). Testing by Mini-mental-status test (Folstein, 1990) revealed mild, or moderate dementia.

**Results:** In our sample, only one patient (0.1%) suffering from moderate dementia of Alzheimer’s type took his own life by suicide. We did not find any increased risk of suicide in our sample of n = 1000 patients suffering from dementia. We suppose that regular care and continuous consultations may prevent patients to execute suicide.

**Background:** Activation or blockage of serotonin receptors can induce alterations in learning and memory. The physiologic role of serotonin in different models of learning and memory processes is not clearly understood.

**Objective:** In this study the role of endogenous brain serotonin on acquisition, consolidation and retrieval steps of passive avoidance learning and memory was investigated.

**Material and methods:** In this study, in the case groups, fluoxetine was administrated either orally before training (group 1) or retention (group 2), or by intraperitoneal injection after training of passive avoidance learning and memory tasks (group3), while the control groups only received saline without fluoxetine. The data were analyzed by Student t test for parametrical data, and Mann–Whitney test for nonparametrical data.

**Results:** The number of learning trials for acquisition in the group receiving fluoxetine before training was more than control group. There were no significant differences in the step trough latency to the dark compartment and the time spent in the dark compartment between groups that received fluoxetine or saline after training (consolidation),or the groups receiving oral fluoxetine or saline before performance during the retention test.

**Conclusion:** It is concluded that, in the passive avoidance learning and memory task, potentiating serotonin function in the synapses could decrease acquisition (P < 0.05), but cause no significant effect on consolidation and retrieval (P = 0.3).

Impact of homocysteine on cognitive disorders in hypothyroidism
A. Zharykava\textsuperscript{a}, V. Ponomarev\textsuperscript{b}, \textsuperscript{a}The Republican Research Centre for Radiation Medicine and Human Ecology, Gomel, Belarus; \textsuperscript{b}Department of Neurology and Neurosurgery, Belarusian Medical Academy of Postgraduate Education, Minsk, Belarus

Background: Hypothyroidism morbidity in the Republic of Belarus comprises 55.3 per 100 thousand people. In the decompensation stage 64\% of patients with hypothyroidism have cognitive disorders with varying intensity (M.E. Begin et al.). Their formation mechanism is connected with the metabolic disorders.

Objective: To determine the impact of homocysteine on the formation of cognitive disorders.

Patients and methods: The amount of examined patients with clinical hypothyroidism from 2010 to 2012 comprises 80 people (male — 5 people, female — 75), the average age was 50.5 (40.5–57.0) years.

There has been assessed neurological status, the results of neuropsychological testing and serum homocysteine levels by immunofluorescent analysis on the unit «Architect I-2000 SR» company «Abbott» with the help of panel firm «DRG International Inc» (USA).

Results: There have been three subgroups identified:

1) with mild cognitive disorders — 41 people (62.5\%), whose homocysteine level was 13.4 (11.0–16.9) μmol/L;
2) with medium cognitive disorders — 9 people (11.2\%) with homocysteine level 16.8 (13.5–18.8) μmol/L;
3) control group of 30 people (37.5\%) — without cognitive disorders with homocysteine level — 12.8 (10.6–15.6) μmol/L.

The comparative analysis of the homocysteine level in different age groups has revealed statistically significant differences only in patients with hypothyroidism with cognitive disorders between the ages of 41 to 50 years (U = 23.0; p = 0.044).

Conclusion: Mild cognitive disorders are an early presentation of hypothyroidism. Hyperhomocysteinemia affects the formation of cognitive disorders in hypothyroidism in patients older than 40 years.

doi:10.1016/j.jns.2013.07.1138
genetic analyses, as well as investigation of clinical features, including biomarkers, will increase our understanding of sCJD. We investigated the clinical course and cerebral cortical pathology of 38 MM1-type Japanese sCJD cases. The first purpose of this study was to propose cerebral cortical pathological staging of sCJD by using hematoxylin and eosin (H–E staining). The second purpose was to investigate the relationship between clinical findings and cerebral cortical pathology. In the present sCJD series, we observed varying degrees of widespread cerebral neocortical involvement, and severity tended to be associated with total disease duration. On the basis of our present pathologic findings, we re-propose a cortical pathologic staging scheme classified into 6 stages as follows:

- spongiform change (Stage 1),
- hypertrophic astrogliosis (Stage 2),
- tissue rarefaction (Stage 3),
- neuron loss (Stage 4),
- status spongiosus (Stage 5), and
- large cavity formation (Stage 6).

This staging can be used more simply as follows: Stages 1 and 2 regarded as mild, Stages 3 and 4 considered moderate, and Stages 5 and 6 regarded as severe involvement. Statistical analysis revealed a positive correlation between the average neocortical pathologic stage and total disease duration and a negative correlation coefficient between the average neocortical pathologic stage and brain weight.

Convenience sample versus epidemiological sample for the study of mild cognitive impairment and Alzheimer’s disease — Fewer differences than expected

A. Mothakunnela, D. Amesb, H. Brodatyc, M. de vel Pulumob, K.A. Ellisd, K. Kangd, N. Kochane, L. Macaulayf, P. Maruffg, S. Rainey Smitha, S. Reppermunda, P. Sachdeva, G. Savageh, J. Trollorh Sydney Memory and Ageing Study and AIBL Study. aUniversity of NSW, Sydney, NSW, Australia; bNational Ageing Research Institute, Australia; cPsychiatry, University of Melbourne, Australia; dCSIRO, Australia; eCogstate Ltd., Melbourne, VIC, Australia; fEdith Cowan University, Perth, WA, Australia; ghMacquarie University, Sydney, NSW, Australia

Background: The characteristics of cognitively healthy subjects and subjects diagnosed with Mild Cognitive Impairment (MCI) from the epidemiologically derived Sydney Memory and Ageing Study (MAS) sample were compared with those of the convenience sample used for the Australian imaging, Biomarkers and Lifestyle (AIBL) study of ageing, in order to better understand relationships between selection methods and sample characteristics when studying MCI and risk factors for the future development of cognitive decline, MCI and Alzheimer’s disease among healthy subjects.

Methods: Cognitive variables were harmonised and identical MCI criteria were applied.

Results: Cognitively healthy AIBL subjects were demographically advantaged but not different in cognitive function to cognitively healthy MAS subjects. For MCI subjects from both studies there were negligible cognitive or demographic differences when diagnostic criteria were applied identically to subjects from both studies.

Conclusion: Results from convenience samples may be more generalisable than expected.

Value of dehydroepiandrosterone sulfate determination in the diagnosis of early forms of Alzheimer’s disease

D. Tolibov1, G. Rakhibibaev2. 1Neurology, Tashkent Medical Academy, Uzbekistan; 2Neurology, Tashkent Institute for Postgraduate Medical Education, Tashkent, Uzbekistan

Purpose: Establishing the relationship with cognitive performance level of DHEA-S with early form of Alzheimer’s disease (AD).

Material and methods: The study included 30 patients (12 men and 18 women), aged 65 (average age 61.3 ± 5.7 years) from the presence of cognitive impairment, and 5 healthy individuals. Research was conducted by ELISA with the definition of the level of DHEA-S before and after the oxidation catalyst Fe2+.

Results and discussion: Clinic of AD in patients of the main group was characterized by the presence of organic neurological deficits and a progressive decline in cognitive function. Neuropsychological research on the MMSE results suggest cognitive functions: 21.8 ± 4.05 in the group of patients with asthma and 28.1 ± 0.8 in healthy individuals. Oxidation of serum leads to a sharp increase in DHEA levels in the control group (up to 5.2 ± 0.5; after 7.1 ± 0.5), whereas in the serum of patients with AD, improvement wasn’t observed or was negligible (up to 2.1 ± 0.5; after 2.3 ± 0.3).

Conclusions: Determining the level of DHEA and the reaction of Fe2+ may be taken as one of the biochemical markers of diagnosis of early forms of AD, which can be recommended for screening diagnosis of early forms of AD.

Clinicopathological study of dementia in a consecutive autopsy series of 83 patients

K. Mori1, M. Ito2, M. Mimuro3, Y. Iwasaki4, M. Yoshida5. 1Neurology, Oyama Memorial Spa Hospital, Yokkaichi, Japan; 2Institute for Medical Science of Aging, Aichi Medical University, Nagakute, Japan

Background and objective: The prevalence of dementia has been increasing lately. Here, we retrospectively assessed the difference in clinical diagnosis and pathological diagnosis of dementia.

Patients and methods: From a consecutive autopsy series of 83 patients at Oyama Memorial Spa Hospital, Japan, we reviewed 58 patients (25 men, 33 women; age at autopsy, 79.7 years) who had been clinically diagnosed with dementia. All cases were examined postmortem at the Institute for Medical Science of Aging, Aichi Medical University, Japan.

Results: Clinical diagnoses were Parkinson’s disease/dementia with Lewy bodies (DLB; n = 15), Alzheimer’s disease (AD; n = 13), prion disease (n = 11), vascular dementia (VD; n = 6), progressive supranuclear palsy (PSP; n = 4), frontotemporal dementia (FTD; n = 2), Huntington disease (HD; n = 2), mixed type dementia (AD–VD; n = 2), corticobasal degeneration (CBD) + normal pressure hydrocephalus (NPH) (n = 1), multiple sclerosis (MS; n = 1), and Korsakoff’s syndrome (n = 1).

Pathological diagnoses were DLB (n = 14), prion disease (n = 11), AD (n = 6), VD (n = 6), argyrophilic grain disease (AGD; n = 4), PSP (n = 4), CBD (n = 3), frontotemporal lobar degeneration (FTLD; n = 2), HD (n = 2), superficial siderosis (n = 2), DLB + AD + NPH (n = 1), amyloid angiopathy (AA; n = 1), MS (n = 1), and senile dementia of the NFT type (SD-NFT; n = 1). Besides the pathology of

Different cognitive profiles between Parkinson's and Alzheimer's diseases screened by Montreal cognitive assessment. A multicenter study of Keio PD database
K. Ohta‡, T. Osada, Y. Shinohara, K. Takahashi§, J. Gotoh, K. Yamaguchi†, M. Seki†, Y. Nihei†, S. Iwasawa†, N. Suzuki†, Keio Parkinsons Disease Database. †Department of Neurology, Tachikawa Hospital, Japan; §Department of Neurology, Tokyo Metropolitan Neurological Hospital, Tokyo, Japan; ‡Department of Neurology, Saiseikai Yokohama-City Eastern Hospital, Yokohama, Japan; †Department of Neurology, Ichinomiya Nishi Hospital, Ichinomiya, Japan; †Department of Neurology, Keio University School of Medicine, Tokyo, Japan; †Department of Preventive Medicine and Public Health, Keio University School of Medicine, Tokyo, Japan

Objectives: To demonstrate the difference in cognitive impairment between PD and AD, evaluated by Montreal Cognitive Assessment (MoCA) which is recommended as screening cognitive impairments of PD.

Methods: We registered PD and AD patients at 13 participating hospitals, and measured their cognitive functions employing Japanese versions of MoCA and MMSE.

Results: The subjects were 304 PD patients (age 70.6 ± 8.3, H&Y 2.7 ± 0.7, mean ± SD) and 97 AD patients (age 78.4 ± 5.9). The PD patients were grouped into tertiles according to MoCA score; the high (24–30 points, n = 108), middle (19–23, 98) and low (5–18, 82) score groups. The AD patients were grouped likewise; the high (17–24, 35), middle (12–16, 31) and low (3–11, 31) score groups. By comparing the AD patients of high score group with the MoCA score- and age -matched PD patients, the subscores of trail making test (26% in AD vs. 51% in PD, mean) and orientation (76% vs. 95%) were lower in AD, and the average concentration of OxyHb in the normal subjects increased in the left lateral frontal channels in Test 1, the bilateral frontal to parietal channels in Test 2 and the left posterior frontal to parietal channels in Test 3. In the AD patients, the average OxyHb concentration decreased significantly in these channels in all tests.

Conclusions: Measuring the concentration of OxyHb using NIRS is useful for making a diagnosis of mild AD.

Neuropsychological and cognitive profile of retired Filipino boxers

Introduction: Boxing has been a popular sport in the country, more so in the past few years, with a Filipino boxer dominating the global professional boxing scene. In light of its fame, the risk factors of actual and potential chronic injury among Filipino boxers should be investigated. It has been known that repetitive brain trauma associated with boxing may produce progressive neurological deterioration and is associated with memory disturbances, behavioral and personality changes.

Objectives: This study aimed to describe the neuropsychological and cognitive impairment among retired Filipino boxers and its possible risk factors.

Methods: This is a descriptive study on the cognitive and behavioral profile of retired Filipino boxers using standard screening examinations such as the Neuropsychiatric Index, Symptoms Suggestive of Cognitive Impairment, Hospital Anxiety Depression Scale and Montreal Cognitive Assessment Scale.

Results and discussion: An increase in times knocked showed a possible relationship with a low MoCA score. However, the test being in English, language barrier is therefore a big factor. SSCI and HADS showed a relationship with the increased rate of being knocked out and with longer years since retirement. Development of cognitive impairment, and neuropsychologic and neuropsychiatric features is therefore strongly supported by an increased rate of being knocked out and a longer time after retirement, chronic traumatic encephalopathy being a potential consequence of repetitive brain trauma.

Conclusion: An increased rate of being knocked out therefore increases the risk of developing cognitive impairment, neuropsychologic and
neuropsychiatric features. Moreover, symptoms are manifested after longer retirement years.

Neuropathological study in dementia-free centenarians
T. Iwase, M. Yoshida, Y. Hashizume. *Nagoya City Koseiin Medical
Welfare Center, Nagoya, Japan; *Aichi Medical University, Nagakute,
Japan; *Fukushima Hospital, Toyohashi, Japan

Background: There are centenarians who are free of dementia despite the presence of high Alzheimer’s disease pathology. 

Objective: To assess the prevalence of “dementia-free” among centenarians, and to ascertain presence of dementia-related neuropathological changes in dementia-free centenarians. 

Material and methods: Centenarians were evaluated with MMSE or Hasegawa dementia scale. The autopsied brains from thirteen dementia-free centenarians were studied with standard hematoxylin–eosin, Klüver–Barrera and Gallyas–Braak stainings, and immunostainings for α–synuclein, phosphorylated tau, amyloid-β (Aβ1–42) and TDP-43. CERAD criteria of neuritic amyloid plaques, Braak and Braak staging of neurofibrillary tangles and Saito’s staging of argyrophilic grains were used to assess the brains.

Results: Thirteen of 46 (28%) centenarians were cognitively intact. The average brain weight of dementia-free centenarians (1096.5 g) was heavier than that of 46 centenarians (1035 g). While they were clinically dementia-free, they were diagnosed neuropathologically as Lewy body disease (5 cases), argyrophilic grain disease (3 cases), senile dementia of the neurofibrillary tangle type (3 cases), and Binswanger’s disease (2 cases). Although none of the cases was diagnosed as Alzheimer’s disease, substantial amount of senile plaques (CERAD B) and neurofibrillary tangles (Braak IV) were observed. Only 4 cases with subtle age-related changes were diagnosed as “normal-aged”.

Conclusion: Many dementia-free centenarians had neuropathological evidence of dementia. These results may indicate that dementia-free centenarians seem to have resistance to developing dementia despite the presence of subtle pathology of dementia.

The pathogenic mechanisms induced by amyloid beta in neural stem cells

Objectives: Many studies of biochemical and animal studies support the concept that amyloid beta (Aβ42) plays a central role in the development of Alzheimer’s disease (AD). Although a lot of efforts have been focused on the pathogenic mechanisms of Aβ, it is unresolved how Aβ accumulates in the central nervous system and subsequently initiates the disease of cells. In this study, we investigated the clue of the pathogenic mechanisms of Aβ by proteomics and antibody microarray. 

Material and methods: To evaluate the effect of Aβ on neural stem cells, we treated primary cultured cortical neural stem cells with several doses of Aβ for 72h. We detected several factors that may be associated with Aβ treatment by proteomics and antibody microarray. An MTT assay and BrdU cell proliferation assay were performed. And, western blotting for the evaluation of effect on intracellular signaling proteins was achieved.

Results: Various viability tests showed that Aβ decreased neural stem cell viability and cell proliferation in a concentration-dependent manner. After Aβ treatment, it significantly decreased lactate dehydrogenase B (LDHB), high-mobility group box 1 (HMGBox1), survival signals, including phosphorylated Akt, and glycogen synthase kinase-3β. Aβ also increased Heat Shock Protein (HSP70), Electron-transferring Flavoprotein (ETF), and death signals, such as phosphorylated tau (pThr231) and activated caspase-3.

Conclusion: These results suggest that several factors which we found by proteomics and antibody microarray could be the clues of Aβ pathogenesis. Further studies should be conducted, with a focus on these factors.

Calcium-sensing receptor antagonist (calcilytic) NPS2143 prevents amyloid-beta(42) secretion in postnatal human neurons
A. Chiarini, J.F. Whitfield, B. Chakravarthy, R. Pacchiana, U. Armato, F. Dal Prà, *Scienze della Vita e della Riproduzione, University of Verona, Verona, Italy; †Molecular Signaling Group, Institute for Biological Sciences National Research Council of Canada, Ottawa, ON, Canada

Objectives: We investigated whether calcium-sensing receptor (CaSR) signaling plays any role in fibrillar (f)Aβ42–35 and soluble (s)Aβ42–35-elicited effects on Aβ42 and Aβ40 secretion by HCN-1A neurons.

Methods: Human cortical HCN-1A neurons were treated with fAB42 or sAB42, plus/minus the CaSR allosteric antagonist NPS2143. The intracellular accumulation and secretion of Aβ42 and Aβ40 were analyzed via ELISA and immunofluorescence microscopy.

Results: In the HCN-1A neurons, fAB42 and sAB42 stimulate Aβ42 production and secretion through a CaSR-mediated control of Aβ42 accumulation and release. A CaSR antagonist, the “calcilytic” NPS2143, significantly prevented fAB42 and sAB42-stimulated HCN-1A neurons from secreting an excess of Aβ42. Instead the intracellular distribution and secreted amounts of Aβ40 were not changed by an exposure of HCN-1A neurons to fAB42 or sAB42. NPS2143 preserved the viability of the fAB42 and sAB42-exposed HCN-1A neurons, whereas in its absence the Aβs induce the death of about 25% of the neurons within 72 h.

Conclusions: These data suggest that after stimulation with f- or s-AB42 the Aβ42 is the main species released from HCN-1A neurons. By negatively modulating Ab/CasR signaling NPS2143 prevents the surplus release of Aβ42 induced by f- or s-AB42 and exerts a protective effect on the survival of Ab-treated neurons. Furthermore they suggest that a CaSR inhibitor like NPS2143 blocking by a feed-forward mechanism of Aβ self-induction might be a novel therapeutic drug for Alzheimer’s disease.

MRI classification of idiopathic normal pressure hydrocephalus and its prediction of shunt effectiveness
M. Ishikawa. Normal Pressure Hydrocephalus Center, Rakuwakai Otowa Hospital, Kyoto, Japan
**Background:** With the rapid aging of Japanese society, medical care of the idiopathic normal pressure hydrocephalus (iNPH) becomes an important issue. We reported the clinical significance of disproportionately enlarged subarachnoid-space hydrocephalus (DESH) on diagnosis of iNPH in our multicenter prospective cohort study. DESH findings fulfill three criteria of tight high convexity, enlarged sylvian fissure and ventriculomegaly (Evans index > 0.3). However, we noted some patients in which these criteria were equivocal.

**Purpose:** To make clear which MRI findings are favorable for prediction of shunt effectiveness, we classified the MRI findings of our iNPH patients into DESH, incomplete DESH and non-DESH. Incomplete DESH consisted of findings fulfilling two criteria with one equivocal criterion.

**Methods:** The present study included 83 patients [54 males and 29 females] aged 66–87 years [mean 77 years] in our hospital during the recent four years. All of them were treated with ventriculo-peritoneal surgery. Improvement was assessed at discharge.

**Results:** Among the eighty-three patients, DESH was noted in 55 patients, incomplete DESH in 24 patients and non-DESH in 4 patients. Patients with DESH showed improvement in 74.5%, incomplete DESH in 58.3% and non-DESH in 33.3%. Among patients with incomplete DESH, patients with ambiguity on tight high convexity showed improvement in 27.2%, while patients with tight high convexity showed improvement in 84.6%. In the patients with tight high convexity showed high predictability of shunt effectiveness.

**Conclusion:** iNPH patients can be divided into three types of DESH, incomplete DESH and non-DESH. DESH and incomplete DESH with tight high convexity showed high predictability of shunt effectiveness.

**Conclusion:**

**References:**

- Evans index: 0.3
- Tight high convexity: 27.2%
- Enlarged sylvian fissure: 84.6%

**The targets in Alzheimer’s disease are A\(\beta\) oligomers: Count them for diagnosis and destroy them for therapy**

D. Willbold. ICS-6: Structural Biochemistry, Forschungszentrum Jülich, Jülich, Germany; Institut für Physikalische Biologie, Heinrich-Heine-Universität Düsseldorf, Düsseldorf, Germany

Alzheimer’s disease (AD) is a progressive neurodegenerative disorder. Several lines of evidence suggest a central role of amyloid-(\(\beta\)) peptide (A\(\beta\)) in the pathogenesis of AD. More than A\(\beta\) fibrils, small soluble and prion-like A\(\beta\) oligomers are suspected to be the major toxic species responsible for disease development and progression. Therefore, these oligomers should be our major target for therapy and used as the most direct biomarker for diagnosis and therapy monitoring.

**Diagnosis:** The A\(\beta\) oligomer count in CSF of AD-affected and healthy persons as determined by our new ultra-sensitive surface-based fluorescence intensity distribution analysis (sFIDA) assay revealed a surprisingly clear distinction between both groups. All samples of the control group showed homogeneously low numbers of A\(\beta\) oligomers, while the samples of the AD group exhibited significantly higher levels of A\(\beta\) oligomers with high variability. The A\(\beta\) oligomer levels clearly correlated with the patients’ mini-mental state examination (MMSE) scores [Wang-Dietrich et al., J Alzheimers Dis. 34, 985–994 (2013)].

**Therapy:** We present our newest in vitro and in vivo results on \(\alpha\)-enantiomeric peptide derivatives that specifically address A\(\beta\) oligomers and convert them into non-amyloidogenic, non-fibrilar and non-toxic species without increasing the concentration of monomeric A\(\beta\). We show that next to plaque load and inflammation reduction, oral application of the peptide improved cognitive performance of AD transgenic mice. Cognitive improvement was even observed upon treatment of very old mice [Funke et al., ACS Chem. Neurosci. 1, 639–648 (2010); van Groen et al., J Alzheimers Dis. 34, 609–620 (2013)].

**Vascular dementia risk factors: The role of diabetes and hypertension among younger-old and older-old patients**

T. Zandi. Psychology, SUNY Plattsburgh, Plattsburgh, NY, USA

**Objective:** The main objectives of this project were:

1. To identify the role of diabetes hypertension as a predictor of vascular dementia among the young-old and older-old patients.
2. To identify the co-morbid psychological disorders and determine their contributing role in presentations of dementia symptom.

**Participants and methods:** 350 individual ages 55 and older participated in this study; the subjects were the clients of a local large primary care practice. The participants’ medical file was evaluated in order to obtain information as to their vascular risk factors. The risk factors were mainly based on the present diagnosis of HTN, high cholesterol and diabetes. Several cognitive screening data were obtained from the patients.

**Results:** The most prevalent risk factors that were identified in this group of participants were hypertension, and then high cholesterol and finally diabetes. Age was highly correlated with these risk factors as well. The group that was at the highest risk with the three risk indicators of hypertension, high cholesterol and diabetes was the older age group. The group with long term hypertension (more than 10 years) also showed a great deal of cognitive impairment.

**Effect of montelukast and its interaction with the protective effect of rofecoxib, caffeic acid in kainic acid induced cognitive dysfunction**

A. Kumar, A. Prakash, D. Pahwa. Neuropharmacology, UIPS, Panjab University, Chandigarh, India

**Introduction:** Potential role of antioxidant and COX-2 inhibitors has also been well reported against memory impairment in different experimental models.

**Objective:** The present study aims to explore the potential role of montelukast (a cysteinyi leukotriene inhibitor) in concert with rofecoxib (COX-2 inhibitor) and caffeic acid (a 5-LOX inhibitor and potent antioxidant) against kainic acid induced cognitive dysfunction in rat.

**Materials and methods:** In the experimental protocol, kainic acid (0.4 \(\mu\)g /2 \(\mu\)l ACSF) was given intrahippocampally (CA3 region). Memory performance along with the locomotor activity was measured on the days 10–14 and 1, 7 and 14 respectively. The brains were isolated on the 14th day; oxidative stress parameters and mitochondrial enzyme complexes were then estimated.

**Results:** Montelukast (0.5 and 1 mg/kg), rofecoxib (5 and 10 mg/kg) and caffeic acid (5 and 10 mg/kg) showed significant improvement in memory performance as compared to that in control (kainic acid treated). Further, two weeks of the drug treatments reversed all the biochemical indices and showed favourable mitochondrial protection. Combination treatments of montelukast with rofecoxib or caffeic acid showed significant synergism of their protective effect which was significant as compared to their effect per se.

**Conclusion:** Thus the present study is unique in that it shows the positive modulation of cysteinyi leukotriene receptor inhibition on COX and LOX pathways in the control of existing neuroinflammation.

**doi:** 10.1016/j.jns.2013.07.1151
Conclusions: Preventing the vascular risk factors is essential for either delaying or preventing symptoms of dementia. In the U.S. we need to manage the underlying causes of the risk factors in order to be able to prevent dementia disorders. The current practice of symptomatic treatment of the vascular risk factors does not necessarily prevent development of dementia related disorders.

Methods: We examined 417 subjects (mean age 83 (+8.1) years, 59% females) of the prospective registry on dementia in Austria (PRODEM), an ongoing longitudinal multi-center cohort study, conducted in 12 Austrian memory clinics. We analyzed differences in the cognitive profile between male and female AD patients on the CERAD-Plus test battery.

Results: We found gender related differences in the neuropsychological domains of verbal learning, delayed recall, recognition and intrusion errors; the women tended to perform worse than men. There were no significant differences between the two groups in constructional praxis. Analyzing the effect of gender in the possible AD and the probable AD groups, we found gender differences in the probable AD group only in verbal learning performance. Controlling for stage and duration of dementia and the level of education there was still a significant effect of gender on verbal episodic memory.

Conclusion: There is an interaction between gender and cognitive function, most notable in verbal episodic memory; female patients with AD performed worse on verbal episodic memory than men. This indicates that the gender specificities of neuropsychological functions should be given careful consideration in clinical diagnosis of dementia.

Agraphia in posterior cortical atrophy

Introduction: The Posterior Cortical Atrophy (PCA) is a neurodegenerative syndrome that is characterized by progressive decline in visuospatial, visuo-perceptual, literacy and praxis skills. We report two cases of PCA with severe writing disorders.

Case 1: A 60-year-old man, right-handed, had progressive visual disorders. The neuropsychological examination shows: apperceptive agnosia, visuo-spatial disorders, apraxia, alexia and agraphia, realizing Gerstmann’s syndrome and an incomplete Balint’s syndrome. The agraphia was of spatial type. Cerebral MRI showed parieto-occipital atrophy predominating on the left hemisphere.

Case 2: A 51-year-old man, right-handed, had progressive visuospatial and gestural disorders. The neuropsychological examination shows: left visual hemi-neglect, neglect alexia and severe apraxia affecting hands, feet and the trunk; agraphia was of apraxic type. Cerebral MRI showed bilateral parietal atrophy predominating on the right hemisphere.

Comments: We report two cases of PCA with different cognitive and neuroradiological presentations (Aharon-Peretz et al, 1999). An occipital form with viso-perceptive disturbances and writing disorders of the spatial type, and a parietal type with predominant apraxic disorders with a writing disorders of the apraxic type. And a parietal form with predominating apraxic disorders, in this form writing disorders is of apraxic type.

Gender specific differences in cognitive profiles of patients with Alzheimer dementia. Results of the prospective dementia registry Austria (PRODEM-Austria)
G. Pusswald, J. Lehrner, P. Dal-Bianco, T. Benke, J. Marksteiner, G. Ransmayr, R. Schmidt, PRODEM (Austria); "Neurology, Austria"; "Medical University of Vienna, Vienna, Austria; "Medical University of Innsbruck, Innsbruck, Austria; "General Hospital of Hall in T, Hall, Austria; "General Hospital of Linz, Linz, Austria; "Medical University Graz, Graz, Austria"

Goals: Gender differences have been well documented for healthy individuals in several cognitive tasks. Recent investigations suggested that gender may be an important modifying factor in the development and progression of Alzheimer’s disease (AD). Here we examined gender-specific differences in the pattern of cognitive dysfunction of patients with mild to moderate AD.

White matter change and cognitive function are related to APOE status
M.S. Oh, Y.-K. Jang, K.-H. Yu, B.-C. Lee. "Hallym University Sacred Heart Hospital, Anyang, Republic of Korea"
Background and objectives: The aim of our study was to examine whether the presence of cerebral white matter change (WMC) associated with the performance in various cognitive domains. Additionally, we investigated whether apolipoprotein E (APOE) genotype influenced the association between WMC and cognitive function.

Method: We subjected 230 persons who visited our memory clinic. All subjects underwent MMSE and comprehensive neuropsychological tests to evaluate the following cognitive domains: attention, language, visuospatial function, verbal memory, visual memory, and executive function. The presence and severity of WMC was rated using a Fazekas scale and categorized into three groups. Multiple linear regression models were conducted to explore the association of WMC with cognitive domains after adjustments for age, sex, and education. We also performed analyses stratified according to APOE genotype.

Results: Two hundred fourteen participants (93.0%) had WMC. 75.6% had a Fazekas total score ranging from 1 to 4 and 40 (17.4%) were in the severe WMC group. Severe WMC group was older than no WMC group. Hypertension, atrial fibrillation, and prior stroke history were frequently shown in the severe WMC group. Higher Fazekas score was shown to lower Z score in MMSE and worse performance on attention, language, visuospatial function, and verbal memory. Sixty two (27.0%) had APOE ε4 allele. After stratifying according to APOE genotype, we found that severe WMC was associated with MMSE, attention, language, visuospatial function in APOE ε4 non-carriers, while no association between WMC and cognitive function in APOE ε4 carriers.

Conclusion: The present study showed the association of WMC with cognitive dysfunction. Especially, WMC implicated the performance in multiple cognitive domain in the APOE ε4 non-carrier group.

Using cognitive qEEG to characterize disease severity in the prospective dementia registry Austria (PRODEM)

H. Garn, M. Waser, T. Benke, P. Dal-Bianco, G. Ransmayr, M. Deistler, D. Grossegger, R. Schmidt, AIT Austrian Institute of Technology GmbH, Vienna, Austria; Department of Neurology, Medical University of Innsbruck, Innsbruck, Austria; Department of Neurology, Medical University of Innsbruck, Innsbruck, Austria; Institute for Mathematical Methods in Economics, Vienna University of Technology, Austria; Dr. Grossegger & Drbal GmbH, Vienna, Austria; Department of Neurology, Medical University of Graz, Graz, Austria

Quantitative EEG (qEEG) changes in Alzheimer’s disease (AD) include frequency slowing, altered synchrony and reduced complexity. So far, qEEG alterations have been used to distinguish AD or prodromal AD from controls. The current study validated these qEEG metrics by assessing their relationship with cognitive functioning in patients with probable AD. Moreover, we defined an overall qEEG metric by independent component analysis. We studied 103 AD cases from the multi-centric study PRODEM-Austria. Their mean age was 73.1 years and mean dementia duration was 27 months. All patients underwent EEG recording in resting and cognitively active state. EEG analysis included automated artifact removal, manual selection of artifact-free epochs for qEEG assessments and calculation of six different markers in the domains frequency, synchrony and complexity. Quadratic regressions were calculated to determine the magnitude of variance of MMSE scores that was explained by each EEG metric and by the combination factor. Analyses were adjusted for age, sex, duration of dementia, and educational level. Relative theta power during face encoding explained 38% of the variance of MMSE scores, followed by relative alpha and beta1 power which explained 35% and 32%, respectively. No single measure of synchrony or complexity explained more than 30% of MMSE variance. With 28% variance explanation the combination factor was also inferior to frequency measures. Our data indicate theta power measured during face encoding to be most closely related to AD severity. Its role as a qEEG marker to predict AD progression needs to be further determined in longitudinal studies.
cognitive dysfunction. We further explored the association between aCLs and cognition and evaluated the relationship between aCL titres and brain magnetic resonance imaging (MRI) findings in a large cohort of community-dwelling individuals.

**Methods:** The study cohort was drawn from the Austrian Stroke Prevention Study (ASPS). A total of 1895 subjects had a complete risk factor assessment and measurement of aCL titres in serum. Participants were classified as aCL positive if either the IgG or IgM aCL titres were elevated (IgG > 21 U/ml, IgM > 12 U/ml). All subjects were also categorized based on the quartile distribution of IgG and IgM isotype titres. All underwent cognitive testing by the Mini Mental State Examination (MMSE) and a random sample of 947 participants also underwent brain MRI.

**Results:** aCL positive participants performed worse on the MMSE. IgG but not IgM isotype titres related to worse performance on the MMSE. There existed no significant association with vascular brain abnormalities including white matter lesions, lacunes and atrophy.

**Conclusions:** These data support the view that in normal elderly persons increasing IgG aCL titres relate to global cognitive dysfunction. It is unlikely that structural brain lesions are responsible for this finding.

Are practice effects an important confounder of longitudinal studies of HIV-associated neurocognitive disorders?

A.-C. Meyer a,b, K. Robertson c, E.A. Bukusi d, G.L. Birbeck e, C.R. Cohen f, P. Oyaro g, R.W. Price h, aNeurology, SFGH/University of California, San Francisco, CA, USA; bFamily AIDS Care and Education Services, Kenya Medical Research Institute, Nairobi, Kenya; cNeurology, University of North Carolina, Chapel Hill, NC, USA; dNeurology, Michigan State University, East Lansing, MI, USA; eObstetrics and Gynecology, University of California, San Francisco, CA, USA

**Background:** The diagnosis of HIV-associated neurocognitive disorders (HAND) is based on neuropsychological testing. Scores on neuropsychological tests tend to improve with repeated administrations—the practice effect. Longitudinal studies of HAND may be confounded by the practice effect. We determined the magnitude of the practice effect among HIV-uninfected individuals in Kenya.

**Methods:** A comprehensive battery of seventeen neuropsychological tests designed to diagnose HAND was administered to 100 HIV-uninfected individuals in 2009. We traced these individuals, performed HIV-antibody testing, and re-administered the neuropsychological tests. Raw scores were converted to Z-scores, and practice effect was assessed using the Reliable Change Index (standardized Z-score difference ≥ 1.64).

**Results:** Of 100 individuals initially studied, we located 69 of whom 47 participated. The median interval between testing was 98 weeks [Range: 83–130]. Mean age was 30 years, 26% were female, 26% had less than primary school education, and 24% had more than secondary school education. One individual was found to be HIV-infected and was excluded. Overall, practice effects ranged from −0.29 to 0.75 and, among the 33 individuals without neurologic or psychiatric co-morbidities, ranged from −0.26 to 0.72. Practice effects were significantly different from the null for Color Trails, Grooved Pegboard and WAIS-3 Digit Symbol. Between 3 and 9% of HIV-uninfected individuals had clinically significant improvements or declines.

**Conclusions:** Practice effects may be an important confounder of longitudinal studies. Further research in larger and more representative populations in sub-Saharan Africa is essential.

Aerobic physical activity stabilizes cognitive status in patients with dementia

M. Seijro-Martinez a, J.M. Cancela b, C. Ayan a, S. Varela b, aNeurology, Xestion Integrada Pontevedra-Hospital do Salnes, Spain; bFacultad de Ciencias de la Educación y el Deporte, Universidad de Vigo, Pontevedra, Spain

**Background:** Only symptomatic medical therapy with limited efficacy is presently available for dementia. There is insufficient evidence to date regarding the benefits of physical activity in patients with dementia and its impact on the rate of cognitive decline.

**Objective:** To evaluate the effect of aerobic physical exercise on the cognitive status in patients with dementia.

**Patients and methods:** 312 residents with dementia in long-term care facilities were included. The MEC scale (Mini-Examen-Cognoscitivo; cutoff score for dementia: 24/35), the Spanish-validated version of the MMSE, stratified individuals into two groups according to severity: mild (MEC 19–24; n = 48) and moderate–severe (MEC ≥ 19; n = 264). Individuals were randomly allocated to two groups: control-care group and treatment group consisting of a 15-month supervised-training program of daily moderate aerobic physical activity (recumbent bicycle-rate-heart-rate-integrated system). Cognitive status was measured by the change from baseline-to-final (15 months) in the total score on MEC, Neuropsychiatric Inventory (NPI) and Fuld Object Memory Evaluation (FOME). T-student and 2-way ANOVA statistics were applied.

**Results:** The mean work load/week was 106.67 min. In the control-care group (n = 208) the baseline/final scores (mean ± sd) worsened significantly (p < 0.05 for all values): Mild (MEC: 22.00 ± 1.55/20.36 ± 1.33; NPI: 5.38 ± 2.65/8.10 ± 6.95; FOME: 14.00 ± 13.04/11.50 ± 9.09). Moderate–severe (MEC:11.43 ± 2.85/14.08 ± 3.03; NPI: 14.30 ± 15.56/19.74 ± 15.46; FOME:8.46 ± 10.23/5.52 ± 2.01). Treatment group (n = 104) scores remained stable: Mild: MEC: 22.00 ± 1.59/22.66 ± 0.98 (ns); NPI: 5.63 ± 6.32/5.01 ± 4.49 (ns); FOME: 13.50 ± 12.67/18.00 ± 11.31 (p < 0.05). Moderate–severe: MEC: 11.75 ± 3.03/11.62 ± 2.84 (ns); NPI: 12.24 ± 10.10/10.78 ± 6.29 (p < 0.05); FOME: 4.36 ± 8.59/6.34 ± 5.09 (ns).

**Conclusions:** Moderate aerobic physical activity showed benefit in stabilizing the cognitive status in patients with dementia.

**Background:** Disease State Index and its graphical counterpart Disease State Fingerprint form a novel tool that combines data from different
Objective: The tool was applied to classify FTD cases in comparison with AD and control cases.

Methods: The study cohort contains 40 FTD cases, 59 AD cases and 21 controls. The Disease State Index combined data from a wide battery of neuropsychological tests, volumetric MRI and single photon emission computed tomography (SPECT) parameters, cerebrospinal fluid biomarkers and the APOE genotype.

Results: We applied DSI for classifying patients between FTD, AD and controls groups. The data showed that FTD patients could be differentiated with a high accuracy, sensitivity and specificity from controls (0.97, 0.95, 1.00) and AD (0.82, 0.80, 0.83), and AD patients could also be differentiated with a high accuracy from controls (0.96, 0.95, 1.00). Additionally we present one example FTD case compared with controls, AD and FTD population data.

Conclusion: The results suggest that combining data from several sources (neuropsychological tests, MRI, SPECT, APOE and cerebrospinal fluid markers) with the Disease State Index can help differentiate normal status from disease and also FTD from AD. This study also suggests the implementation of SPECT and a full-scale battery of neuropsychological studies, which may help particularly in the differential diagnosis between AD and FTD.

Variation in risk factors of dementia among four elderly groups of hospitalized patients
B.A. Husaini, V. Cain, R. Levine, M. Moonis. Center for Prevention Research, Tennessee State University, USA; Preventive Medicine, Meharry Medical College, Nashville, TN, USA; Neurology, University of Massachusetts, Boston, MA, USA

Objective: To examine variation in risk factors that contribute to dementia among four elderly cohorts by race and gender.

Background: We examined the 2008 Tennessee Hospital Discharged database for vascular factors that play a role in both stroke and dementia. Risk factor for dementia was examined for black and white patients aged 65+.

Methods: Four race-gender groups of patients — white males (WM), black males (BM), white females (WF), and black females (BF) were compared for prevalence of dementia and stroke. A logistic model predicted dementia in each group separately and used several vascular factors affecting dementia directly or indirectly through stroke.

Results: 3.6% of patients hospitalized in 2008 had dementia and dementia was higher among females than males (3.9% vs. 3.2%, p < 0.001). Further, BM had higher prevalence of dementia than WF (4.2% vs. 3.8%, p < 0.001); similarly BM had more dementia than WM (4.1% vs. 3.1%, p < 0.001). In Logistic regression models, however, different patterns of risk factors were associated with dementia in four groups: among WM & WF, stroke, hypertension, CHF, and diabetes predicted dementia. Among BF & BM, only stroke and diabetes were related to dementia.

Conclusions: Aggressive management of risk factors (hypertension and diabetes) may subsequently reduce stroke and dementia hospitalization.

Diagnostic validity comparison between NIA criteria for CSF Alzheimer’s disease biomarkers and other new criteria
J.A. Monge-Argilés, M.E. Blanco-Cantó, C. García-Pérez. A. García-Escrivá, C. Badia-Picazo, C. Muñoz-Ruiz, J. Sánchez-Pays, R. Gasparini-Berenguer, C. Leiva-Santana. Neurology Department, University General Hospital of Alicante, Alicante, Spain; Neurology Department, Hospital Baix Vinalopó, Elche, Spain; Neurology Department, Clínica Levante, Benidorm, Spain; Neurology Department, Denia Hospital, Denia, Spain; Immunology Laboratory, University General Hospital of Alicante, Alicante, Spain; Preventive Medicine Department, University General Hospital of Alicante, Alicante, Spain

Background: In recent NIA criteria for Alzheimer’s disease (AD) diagnosis, CSF biomarkers (BMK) have been accepted as evidence of pathophysiological process, for research purposes. Nevertheless, using it for diagnosing mild cognitive impairment (MCI) due to AD with high probability, they show a low sensitivity.

Objective: To compare the diagnostic validity of NIA criteria and our own new criteria, that take into account tau/Aβ proteins ratios, because they have showed their ability to predict dementia in preclinical AD.

Material and methods: Between 2008 and 2010, 157 MCI patients were included, after lumbar puncture, for measuring Aβ 1-42, T-tau and P-tau 181 CSF proteins and the ratios T-tau/Aβ 1-42 and P-tau 181/Aβ 1-42 We used NIA and our own criteria for the evaluation of AD CSF BMK results. Using this analysis we consider a high probability of MCI due to AD, when 3 or more variables were abnormal. We calculated the diagnostic validity for every criteria.

Results: After a two year follow-up, 49 MCI patients remained clinically stable, 78 developed AD and 16 developed other dementia. Using NIA criteria and our own criteria, the BMK for AD showed: sensitivity 35% versus 76%; specificity 89% versus 66%; predictive positive value 79% versus 73% and a predictive negative value of 53% versus 69%.

Conclusion: The use of our criteria for AD CSF BMK assessment should be interesting for early detection of AD, because they show a higher sensitivity than NIA criteria.

Discriminability in recognition memory in amnestic mild cognitive impairment and mild Alzheimer’s disease. A preliminary study

Clinical memory tests that included a yes/no recognition format provide scores only for the total number of target items correctly endorsed. However, many patients with cognitive impairment present a strong “yes” response bias in recognition tests, yielding both high hit and false alarm rates because they cannot reject distractor items. The purpose of this study is to assess recognition memory performance in a sample of cognitively normal adults, amnestic mild cognitive impairment (a-MCI) and Alzheimer’s dementia (AD) participants. The sample included 45 a-MCI, 51 AD participants, and 43 controls. Individuals completed the Rey Auditory Verbal Learning Test as part of a larger neuropsychological battery. Yes/no recognition performance was analyzed using signal detection theory. Discrimination indices between targets and distractors (d’ — how effectively the individual could differentiate targets.
from distractors) and response bias (c — tendency to produce more yes or more no responses) were calculated. Yes/no recognition showed significant group differences for d′, F (2) = 83.26, p < .001, and for response bias (c), F (2) = 6.05, p = .003. Both the impaired groups performed more poorly than controls on discrimination indices (p < .001) and response bias (p = .03), but there were no differences between the MCI and dementia groups. Results suggest that the a-MCI and AD groups exhibited significantly poorer recognition discrimination accuracy and a significantly more liberal response bias than the control group. These two recognition memory components can enhance the clinical characterization of an individual’s recognition memory performance.

CSF Alzheimer’s disease biomarker validity for early differential diagnosis of mild cognitive impairment patients
J.A. Monge-Angüésa, M.E. Blanco-Cantób, A. García-Escrivá, C. Badía-Picazo, C. Muñoz-Ruiz, J. Sánchez-Payá, R. Gasparini-Berenguera, C. Leiva-Santana, aNeurology Department, University General Hospital of Alicante, Alicante, Spain; bNeurology Department, Hospital Baix Vinalopó, Elche, Spain; cNeurology Department, Clínica Levante, Benidorm, Spain; dNeurology Department, Denia Hospital, Denia, Spain; eImmunology Laboratory, University General Hospital of Alicante, Alicante, Spain; fPreventive Medicine Department, University General Hospital of Denia, Spain;

Background: The early differential diagnosis between mild cognitive impairment (MCI) patients who will remain stable from those who will develop Alzheimer’s disease (AD) or other dementia remains a critical issue in clinical setting. CSF AD biomarkers (BMK) have been accepted as evidence of pathophysiological process of AD, in recent NIA criteria.

Objective: To calculate the diagnosis validity of CSF AD BMK in our MCI patients, after a two year clinical follow-up.

Material and methods: Between 2008 and 2010, 157 MCI patients were included, after the realization of a lumbar puncture, for measuring Aβ1-42, T-tau and P-tau181 CSF proteins, and the ratios T-tau/Aβ1-42 and P-tau181/Aβ1-42. As cut-offs, we considered 500 pg/ml, 450 pg/ml, 70 pg/ml, 0.5 and 0.07, respectively. Innoest reagents from Inno-techniques were used.

Results: After a two year follow-up, 49 MCI patients remained stable, 78 developed AD and 16 developed other dementia. We excluded in the analysis 14 patients because of death, no data or other diagnosis. When we calculated the variable diagnostic validity for AD, they showed the highest specificities for Aβ1-42 (79%) and P-tau181 (80%) and the highest sensitivities for ratios T-tau/Aβ1-42 and P-tau181/Aβ1-42 (84%).

Conclusion: CSF AD BMK showed a high validity for early diagnosis of AD in MCI patients. Our longitudinal study confirms data from the literature, outlining the value of the ratios tau/Aβ1-42 for this purpose.

Butyrylcholinesterase genotype in Alzheimer patients not treated with rivastigmine
G. Adler, a, N. Baumgart, b, B. Müllerb, aInstitut für Studien zur Psychischen Gesundheit (ISG), Mannheim, Germany, aInstitut für Studien zur Psychischen Gesundheit (ISG), Mannheim, Germany; bNovartis Pharma GmbH, Nürnberg, Germany

In advanced stages of Alzheimer’s disease (AD), butyrylcholinesterase (BuChE) progressively replaces acetylcholinesterase (AChE) in the hydrolysis of acetylcholine. This applies particularly in AD patients with the genetic variant of the BuChE wild-type, which has a higher hydrolysis rate than the frequent BuChE K-variant and is associated with a faster progression of dementia. Rivastigmine is the only commercially available AchE inhibitor, which also inhibits BuChE. Thus it may have advantages over the other AchE inhibitors, particularly in patients with BuChE wild-type.

We determined the proportion of patients with BuChE wild-type in AD patients not treated with rivastigmine. In a multicentric study, the BuChE genotype was examined in AD patients with progressing dementia, who had no antidementive treatment or were under treatment with either donepezil, galantamine or memantine. The study was conducted in 126 AD patients (48 men, 78 women) at ages between 57 and 94 years (mean/SD: 79.2/7.3 years); MMSE score ranged between 4 and 27 (mean/SD: 17.8/5.7). The patients were treated with either donepezil (n = 58), memantine (n = 29) or galantamine (N = 22); 17 patients were not under antidementive medication. The BuChE wild-type was found in 95 (75.4%) of the patients, in 89 (70.6 %) in the heterozygous and in 6 (4.8%) in the homozygous genotype.

We found the BuChE wild-type in 75% of AD patients with progressing dementia, who were not under treatment with the BuChE inhibitor rivastigmine. In these patients, a switch of antidementive medication to rivastigmine or the initiation of rivastigmine treatment seems to be advisable.

Study of vestibular dysfunction in frontotemporal lobar degeneration
K. Nakamagoe, M. Fujimiya, T. Koganezawa, K. Shimizu, N. Fujizuka, A. Tamaoka, *Department of Neurology, Institute of Clinical Medicine, University of Tsukuba, Japan; **Department of Cardiovascular Physiology, Division of Biomedical Science, Faculty of Medicine, University of Tsukuba, Tsukuba, Japan

Background: Vestibular imbalance might be involved in the onset of gait disorders that are frequently noted in patients with frontotemporal lobar degeneration (FTLD).

Objective: In view of this, a caloric test was performed to examine vestibular dysfunction in FTLD patients.

Patients and methods: Electro-vestibulography was performed on 9 FTLD patients (69.8 ± 5.4 years) and 9 healthy volunteers (70.9 ± 6.3 years). An air caloric stimulator was used to provide stimulation for vestibular testing, and the eye movement was recorded before and during the visual suppression (VS) test. The frequency and amplitude (slow phase and fast phase) as well as the mean velocity (slow phase and fast phase) of eye movements were measured as the parameters of induced nystagmus. Then, a statistical analysis was performed to examine the following three factors: stimulation sites (right ear, left ear), stimulation temperatures (24 °C, 46 °C), and the timing of stimulation (before or during the VS test).

Results: No significant difference was detected between any of one of the FTLD patients and the healthy volunteers in the slow-phase velocity of nystagmus before VS test. On the other hand, a significant decrease was noted in VS (%) in the FTLD patients, compared to the healthy volunteers (p < 0.05).

Conclusion: A severe degree of disturbance of visual suppression was noted in FTLD patients. Findings of the present study suggest that FTLD patients might develop vestibular dysfunction related to cerebral lesions, which might be involved in the onset of gait and balance disorders.

Use of pramiracetam in elderly patients with mild cognitive impairment and arterial hypertension
N. Bachinskaya, E. Demchenko, V. Kholin, A. Shulkevich. *Department of Age Physiology and Pathology of Nervous System, D.F. Chebotorev Institute of Gerontology, Kiev, Ukraine

Mild cognitive impairment and arterial hypertension are commonly found states in elderly patients and it is also well known that arterial hypertension is a risk factor for developing vascular or neurodegenerative cognitive impairment. Drugs with nootropic activities potentially can change cognitive status in such patient group.

Aim: To determine possibilities of cognitive state correction in patients with mild cognitive impairment (MCI) and arterial hypertension (AH) by oral intake of pramiracetam (Pramistar). 

Methods and subjects: 25 elderly patients with MCI and AH were examined prior to and following one month of Pramistar treatment, 1200 mg daily. General clinical and neurological examinations, MMSE, WMS-R, FAB, GDS, State–Trait Anxiety Inventory (STAI), qEEG, and cognitive evoked potentials were performed.

Results: The performed treatment has shown positive improvements for the MCI and AH patients in WMS-R subtests: Attention (visual memory span (p < 0.002), digit span (p < 0.002)); short-term memory (logical memory (p < 0.002), verbal paired associates (p < 0.01) and visual reproduction (p < 0.01)) as well as long-term memory (logical memory (p < 0.002) and visual reproduction (p < 0.01)). In FAB subtest, improvements occurred in conceptualization, motor series (programming) and inhibitory control (p < 0.01).

Anxiety (p < 0.03) and depression (p < 0.04) rates were reduced. Reduction in delta rhythm power in multiple leads as well as an increase in beta rhythm power in separate leads (p < 0.05) had taken place. According to cognitive evoked potentials, peak latencies for N2 and P3 significantly reduced while their amplitude values increased.

Conclusion: Pramiracetam (Pramistar) has shown positive effects in elderly patients with MCI and AH.

Co-morbid medical conditions among patients with vascular dementia: A case–control study from a national managed care database
Neurology, Hospital Julio Mendez, Buenos Aires University, Capital Federal, Argentina

Objective: To compare the prevalence of medical co-morbid conditions between patients with vascular dementia (VaD) with a control group without VaD, from the National Managed Care Benchmark Database (HCIS).

Methods: The prevalence of comorbid medical conditions was compared between patients with VaD (defined by ICD-9 codes) and controls using data from the HCIS, a fully de-identified, HIPAA compliant database made up of more than 35 managed care health plans within the US and covering seven census regions. Matched case–control method was used to compare medical comorbidity. Controls were matched to cases by type of health plan and pharmacy benefits on an 18:1 ratio.

Results: Among the 488,091 patients 60 years or older with full year of eligibility, (from January 1st to December 31, 2010), there were 725 patients with VaD, 57.3% of them were women. A concurrent diagnosis of Alzheimer’s disease and/or unspecified dementia was exclusion criteria. In general, VaD patients had more cerebral degeneration (odds ratio (OR) = 21.5, 95% CI = 7.0–66.1); Parkinson’s disease (OR = 13.6, 95% CI = 4.0–46.1); cerebrovascular diseases (OR = 12.6, 95% CI = 5.0–31.7); septicemia (OR = 6.5, 95% CI = 2.7–15.5); hypotension (OR = 4.6, 95% CI = 2.0–1052); atherosclerosis (OR = 4.6, 95% CI = 2.6–8.1); injuries (OR = 4.0, 95% CI = 2.6–6.1); heart failure (OR = 2.8, 95% CI = 1.6–4.7); lung diseases (OR = 2.4, 95% CI = 1.6–3.9); COPD (OR = 1.8, 95% CI = 1.2–2.7); cardiac dysrhythmias (OR = 1.7, 95% CI = 1.1–2.6) and urinary diseases (OR = 1.6, 95% CI = 1.1–2.3) compared to controls.

Conclusions: The present study confirms that medical comorbidities are frequent complications of VaD and physicians should be alerted to their presence in patients with VaD.

Stressful life events and development of Alzheimer’s disease
Neurology, Hospital Julio Mendez, Buenos Aires University, Capital Federal, Argentina

Background: The sporadic nature of AD suggests that aside from biological determinants, environmental factors such as stress play a role in the development of disease. This study aims to analyze the relationship between stressful life events and AD.

Methods: We studied 118 patients with diagnosis of AD. Medium age was 73 years. Meantime elapsed from the initial symptoms was 2.4 years. A control group of 81 healthy individuals was studied. A questionnaire looking for stressful life events in 3 years before diagnosis of AD was performed to patients, caregivers and controls.

Results: In the AD group, 85 patients (72%) presented a history of significant stressful life events, 2.1 years (SD 1.4 years) before the onset of symptoms. The most common findings in the AD group were: couple death (24 cases), child death (15 cases), history of assault (21 cases), history of car accident (11 cases). Other stressful situations were marked financial problems, bereavement, retirement, adaptive changes due to migrations and diagnosis of severe somatic disease in the family. In the control group, only 21 individuals (26%) recognized similar previous stress factors.

Conclusions: We observed an association between stressful life events preceding the onset of dementia in a high percentage of our patients. Stress could trigger the degenerative process in AD and growing evidences suggest a dysfunction in neuroendocrine and immune system. According to our results, we can establish a relationship between several stressful life events and the onset of dementia. It is an observational finding and does not imply direct causality.

Cognitive decline progression prevention in patients with cerebrovascular diseases
M. Khodjaeva, G. Rakhimbaeva. Tashkent Medical Academy, Tashkent, Uzbekistan

Vascular disease of the brain is generally accompanied by focal neurological symptoms along with the development of cognitive memory impairment, that in place may lead to severe degree of dementia. The purpose of this study is to evaluate therapeutic and preventive effects of Alzepil (donepezil) on cognitive impairment in mild multi-infarct dementia in patients with arterial hypertension (AH) and cerebral atherosclerosis (CA).

Material and methods: 32 patients were divided into two groups comparable in all studied parameters. They were all prescribed Alzepil 5 mg/daily for the period of 28 days.

Results: Significant improvement in memory (p = 0.01), abstract thinking and reaction time was observed in patients treated with Alzepil, as evidenced by the improvements in EEG. Therapeutic and preventive effects on cognitive disorders in patients with AH and CA were evaluated. Comparison of scores on MMSE and Khachin scales, showed statistically significant improvement for all clinical symptom severity in patients on Alzepil. Meanwhile, in the placebo group, only partial positive trend was observed.

Conclusion: The investigations indicate that, after repeated treatments by Alzepil with 6 month intervals, patients with mild cognitive impairment amid AH and CA, show a steady improvement of the subjective status of patients. In addition, persistent increase in the memory function of attention, abstract and practical thinking were observed. Results of the study suggest that a course of Alzepil (donepezil) treatment in patients with early forms of vascular dementia provides regression of cognitive impairment, and has a stabilizing effect on the overall process, preventing its progression.

Selective bilateral thalamic necrosis following carbon monoxide poisoning: Case report

J. Abdelhedi, I. Bouchhima, E. Turki, M. Damak, A. Boukhriss, M.J. Miladi, I. Fki, C. Mhiri. Department of Neurology, CHU Habib Bourguiba, Sfax, Tunisia

Introduction: Carbon monoxide (CO) poisoning is common and probably underdiagnosed. Delayed neuropsychological sequelae (DNS) commonly occur after recovery. On magnetic resonance imaging (MRI), the most common site of abnormality is the globus pallidus. The thalamus can be affected also but in association. To our knowledge, selective lesion of thalami on MRI has not been described.

Case report: We describe the case of a patient presenting with memory dysfunction, disorientation and apathy. He had no cardiovascular risk factors. Mini Mental State Examination estimated to 21/30. The interrogation revealed a CO poisoning 15 days ago. The lesions of the thalami were hypo-intense T1, hyperintense T2 and FLAIR with restricted diffusion.

Discussion: The most frequent symptoms of DNS after CO poisoning include delirium, amnesia and cognitive dysfunction. In our case, the dementia was secondary to bilateral thalamic necrosis. The selective thalamic involvement following CO exposure is rare. CO in particular has a propensity to affect the globus pallidus. The whole basal ganglia can be affected, or the putamen, caudate nucleus, and thalamus may be involved in isolation. Abnormalities of the brain following CO poisoning are shown with greater sensitivity by MRI. Necrosis of the basal ganglia is seen, typically showing low T1 and high T2 signals, but could be observed with high signal on T1 and T2 suggesting haemorrhage, often with restricted diffusion.

Conclusion: Our report suggests that selective thalamic involvement is rare but may occur after CO poisoning.

Aphasic syndrome in dementia with Lewy bodies (DLB): Is language impairment one of the features of DLB?

T. Fukui, K. Okita, M. Uchiyama, H. Kasai, R. Kinno. Neurology, Internal Medicine, Showa University Northern Yokohama Hospital, Yokohama, Japan

Background: Logopenic aphasia has recently been suggested in DLB.

Purpose: To discuss language impairment in DLB.

Patient 1: An 83-year old man started to stumble on words, use non-words and has difficulty in understanding for a year. Subsequently, he showed confusion with fluctuations, delusions and shuffling gait. Initial evaluations revealed logopenic plus jargon aphasia. Brain atrophy and hypoperfusion were accentuated at the left temporo-parietal regions on MRI and SPECT. Phosphorylated (P-) tau and beta-amyloid 42 (Aβ42) in CSF suggested concomitant Alzheimer's (AD) pathology.

Patient 2: A 90-year old women presented reduced verbal output, phonological errors, impaired comprehension and shuffling gait for two months. Initial assessment revealed logopenic aphasia. Atrophy and hypoperfusion were detected at the left temporo-parietal areas. MIBG scintigraphy was slightly decreased. P-tau and Aβ42 in CSF suggested AD pathology.

Patient 3: A 67-year old woman presented amnesia and mis-identification syndrome for a year. At presentation, she showed mild cognitive decline without linguistic problems. Abnormal MIBG scintigraphy suggested DLB. SPECT showed that bilateral frontoparietal uptake decreases. Two years after the onset, the patient developed progressive apraxia of speech.

Conclusion: Clinical DLB may present logopenic aphasia and rarely apraxia of speech. Co-pathology of AD may be associated.

Neurotechnology for early-stage diagnosis and treatment of Alzheimer's disease

J.W. Leszek, J. Zhang, Psychiatry, Wrocław Medical University, Wrocław, Poland; Chemical and Biochemical Engineering, University of Western Ontario, ON, Canada

Dementia of Alzheimer’s type (AD) is a loss of brain function that occurs with certain diseases. It affects memory, thinking and behavior. Scientists believe that changes in the brain may begin 10–20 years before symptoms appear and AD is diagnosed. The need to diagnose the devastating disease at an early stage is critical to manage and treat AD. Unfortunately, the lack of validated biomarkers limits the possibility of the earlier stages of AD. Recent advancements of nanotechnology and nanomaterials in biodetection/bioanalysis may provide an alternative excellent method to help researcher identify the biomarkers for the disease. The advantages of nanomaterials stem from nanostructures’ high surface to volume ratio which enables multi-bioreceptors to bind on the surface of transducer at nano-scale. The nanoparticles as DNA carriers enable million-fold improvements over ELISA sensitivity. Recently, the gold nanoparticles were used to detect the amyloid beta-derived diffusible ligands (ADDL). The finding was made possible by combining ADDL-specific monoclonal antibodies. According to our opinion it is very important to develop multifunctional nanomaterials which are able to deliver genomic sequences and act as a sensor to recognize the targeted biomarkers. Such proposed multifunctional system will lead to a multifunctional bioassay for early-stage diagnosis of AD.

A flash on contemporary society

P.F. Fiori, G. De Chiara, E. Pace, L.M. Giannetti, A. Monaco. "Neurology, S. Ottone Frangipane ex Civil Hospital - II University of Naples, Ariano Irpino (AV), Italy; "Paediatrics, S. Ottone Frangipane ex Civil Hospital - II University of Naples, Ariano Irpino (AV), Italy; "Intensive Care - Anesthesiology, S. Ottone Frangipane ex Civil Hospital - II University of Naples, Ariano Irpino (AV), Italy; "Infantile Neuropsychiatry - Social Service, S. Ottone Frangipane ex Civil Hospital - II University of Naples, Ariano Irpino (AV), Italy"

Excessive preoccupation, denial, neglect or even exhibition of flaws in appearance are expressions of a dysfunctional body image (Fiori P, Giannetti LM, 20). This may prelude the appearance of behavioral and cognitive dysfunction (Fiori P et al., Rankin KP et al., 2003).
Although the borderline is wider than frank pathological manifestations, the subtle pervasive features of such condition may have individual and social consequences.

The aim of our observational and interventional study is early identification and treatment of such condition. The diagnosis is performed by neuropsychological examination on subjects under the age of 65 years. Preliminary results of our study show:

- A high directiveness, peculiar of males, as well as a high transcendence, predominantly present in females, may not be positive factors concerning self realization, relational competence, social integration and development, compatible with environmental resources and worldwide shared strategy.

- Comorbidity of a dysfunctional body image with addiction, eating disorders, psychoses, epilepsy, cognitive deterioration, vascular diseases.

- Misdiagnosis, scarce compliance, especially in the case of unstable socio-economic conditions, lack of educational programs and political leadership.

Body image is the cornerstone of our fitness. Its dynamic steadiness depends on genetic factors, modality of attachment, emotional and affective experiences, personality (temperament and character), behavioral repertoire, cognitive development, environmental, cultural and social factors. Although it is modified by life events, aging and diseases, the response to such challenge is different and depends on cognitive reserve, which has to be preserved and transmitted to new generations.

Clinical implications of hippocampal vulnerability patterns in tauopathies

I. Milenkovic1, T. Petrov2, G.G. Kovacs3, 1Institute of Neurology, Medical University of Vienna, Vienna, Austria; 2Automatic Control Laboratory, Department of Information Technology and Electrical Engineering, Swiss Federal Institute of Technology, Zurich, Switzerland

Background: Deposits of phosphorylated tau in the hippocampus is a hallmark of several neurodegenerative diseases (NDD), which show different, but partially overlapping cognitive symptoms. The hippocampus has several subregions involved in different aspects of cognition.

Objectives: The aim of the study was to evaluate vulnerability patterns of tau pathology in the hippocampus in different NDDs.

Methods: We investigated tau-AT8 immunoreactivity in the neouril, neurons, astrocytes and oligodendrocytes in 24 hippocampal subregions in individuals above 75 years, including Alzheimer-related pathology with different Braak and Braak stages (AD; total 40 cases), argyrophilic grain disease (9 cases), progressive supranuclear palsy (7 cases), corticobasal degeneration (CBD, 7 cases), Pick’s disease (8 cases), globular glial tauopathies (5 cases) and astroglialopathies of the elderly (12 cases). Using mathematical modelling, we analysed the constellation of the AT8-immunoreactivity for every disease.

Results: Our model demonstrates specific constellations of tau pathology in the hippocampus. There are regional and cellular differences: Tau-immunopositive oligodendrocytes in stratum oriens of the hippocampus is highly indicative for the CBD; Tau-immunoreactivity in the dentate gyrus (DG) granular cells is suggestive of a non-AD disorder; and, the DG was highly vulnerable in tau-astroglialopathy of elderly.

Conclusions:
1) Distribution of hippocampal tau immunoreactivity can predict the neuropathological diagnosis;
2) These observations have implications for the spreading of disease;
3) Neuropsychological examinations evaluating distinct functions related to hippocampal structures might be useful in the clinical practice to distinguish these disorders.

Supported by the European Commission’s 7th Framework Programme “DEVELAGE”.

Argentina-ADNI: Preliminary report on CSF biomarkers

M.J. Russo1, G. Sevlever2, S. Vázquez3, D. Gustafson4, E. Surace5, J. Campos6, M.E. Martín6, H. Martineto6, F. Ventricie6, S. Guijoana6, R.F. Allegri7, 1Fleni, Buenos Aires, Argentina; 2SUNY Downstate Medical Center, New York, NY, USA

Argentina has launched the first South American ADNI, (Arg-ADNI) effort to acquire data comparable to those gathered throughout other WW-ADNI centers. It is important to share data across the international research community, to evaluate whether clinical, neuroimaging, genetic and molecular characteristics in aging Argentines are similar to those observed in other global ADNI sites. The purpose of this abstract is to describe baseline profiles of 62 (9 controls, 37 mild cognitive impairment (MCI), and 16 Alzheimer’s disease (AD)) Arg-ADNI participants.

Compared to individuals with AD, controls and MCI subjects evidenced higher MMSE and Categorical Verbal Fluency scores. MCI and AD cases scored lower than controls on delay and recognition trial RAVLT. APOE ε4 allele possession was prevalent among 33% (n = 7) MCI and 33% (n = 4) AD patients. Levels of CSF biomarkers corresponding to an AD profile including Aβ1-42, T-tau and P-tau, Aβ1-42/P-tau ratio and AD profile were not different between MCI and AD subgroups. Based on CSF biomarkers, 25% (n = 7) MCI patients showed biomarkers of neurodegeneration without positive markers of amyloid accumulation.

After one year of recruitment efforts, this is the first Arg-ADNI report. Arg-ADNI is a growing sample with ongoing recruitment of MCI and AD patients and controls. Follow-up of this important sample, particularly related to CSF and brain biomarkers, will allow better characterization of AD in Argentina, and perhaps point to unique environmental factors influencing brain health in South America. Clinical and biochemical follow up of MCI patients with neurodegenerative profiles and without amyloid accumulation may provide important insights.

Intranasal delivery of curcumin-donepezil nanoemulsion for brain targeting in Alzheimer’s disease

S. Sood1, K. Jain, K. Gowthamarajan. 1Department of Pharmaceutics, J.S.S. College of Pharmacy, Udhagamandalam, India

Objectives: The objective of the present work was the development of curcumin-donepezil nanoemulsions for delivery to brain by intranasal route. The combination therapy was based on cholinergic replacement hypothesis in combination with anti-amyloid and anti-inflammatory approach for better management of Alzheimer’s disease via intranasal route for better brain targeting.
Methods: Nanoemulsions were prepared using aqueous titration technique using components selected based on solubility studies. They were characterized for various physicochemical parameters like globule size, zeta potential, refractive index, transmittance and ex vivo diffusion studies using sheep nasal mucosa. Pharmacokinetic studies of developed formulations were carried out in Wistar rats by intranasal and intravenous administration. The in vivo studies of developed nanoemulsions were carried out in streptozotocin induced Alzheimer’s model. Various behavioural parameters like radial arm maze, elevated plus maze and one trial passive avoidance test were carried out. Biochemical parameters like acetylcholinesterase activity, glutathione, SOD were estimated.

Results: The developed nanoemulsions had particle size less than 50 nm suitable for intranasal delivery. In vivo pharmacokinetic studies revealed that higher drug concentration was achieved in brain via intranasal route compared to intravenous route and clearance was slower. Behavioural tasks showed improved memory and learning in group treated with nanoemulsions compared to pure drugs. Acetylcholine levels were significantly improved in brain of nanoemulsion treated group. Oxidative stress was much lower in animals treated with combination therapy.

Conclusions: The intranasal strategy of delivering acetylcholinesterase inhibitor with a neuroprotective and anti-amyloid drug is a promising strategy for the management of Alzheimer’s disease.

Psychological impact of young onset dementia in Singapore
A. Lee, X. Lin, N. Kandiah. National Neuroscience Institute, Singapore, Singapore

Background: Young onset dementia (YOD) carries significant psychological burdens for patients and their caregivers. Previous Asian studies have focused on the geriatric age-group. This is the first study to examine the psychosocial impact of YOD in Singapore.

Objectives: The aim of the study was to investigate the psychosocial effects and perceived needs of YOD patients and their caregivers in Singapore.

Methods: A random sample of YOD patients (age ≤65 years old) attending a memory clinic in a tertiary setting was identified. Diagnosis of dementia had been made by a cognition neurologist.

2 independent physicians conducted phone interviews with patients and caregivers. A questionnaire on psychological impact and perceived needs was used. Case-notes were reviewed for demographic data.

Results: 12 patients (5 AD; 5 FTD; 1 VaD; 1 Hashimoto’s) and 10 caregivers were interviewed. Patients’ mean age was 59 (51–64); mean MMSE 18 (9–27). Caregivers comprised spouses (8) and children (2). Emotional responses could be staged into pre-diagnosis, diagnosis, post-diagnosis and future. Caregivers verbalised frustration from the pre-diagnosis period. A few expressed relief at receiving diagnoses that explained patients’ behavioural changes. Others experienced helplessness from loss of a functional family member. Prognostication to prepare for care needs and legal matters was found difficult. Associated perceived needs could be further classified into resource-related, rehabilitation, medical and psychological needs. At least 5 identified a lack of age-specific psychoeducation interventions and community services.

Conclusion: YOD patients and their caregivers experience significant emotional upheavals. Healthcare providers need to acknowledge and address this psychological impact. Further nationwide studies are underway.

Cerebrospinal fluid biomarkers in Chinese Alzheimer’s disease patients
L.-W. Chu a,b, Y.-F. Shea a, L. Zhou a, b, Department of Medicine, The University of Hong Kong, Hong Kong, Hong Kong; bAlzheimer’s Disease Research Network, The University of Hong Kong, Hong Kong

Background: Previous cross-sectional studies have shown that Alzheimer’s disease (AD) patients have lower circulating leptin levels than non-demented older adults. There is a paucity of data on the risk of leptin and subsequent AD development in older adults with mild cognitive impairment.

Objective: The aim of the study was to investigate the relationship of the serum leptin level to subsequent risk of progression to AD among Chinese older adults with amnestic MCI (aMCI).

Patients and methods:
Design: One-year prospective cohorts study:
Setting: Ambulatory setting.
Subjects: Chinese older adults, aged 55 to 93 years old, with aMCI by the Petersen’s criteria.

Measurements: Baseline demographic, clinical factors, and serum leptin level. All subjects were followed for one year. AD was diagnosed by the NINCDS-ADRDA criteria for probable AD.

Results: 131 Chinese older adults with aMCI were recruited and followed up for one year. 13.7% (n = 18) of them progressed to Alzheimer’s disease by the end of one year. Older adults who progressed to AD had significantly a lower mean serum leptin level than that of stable MCI subjects (mean ± SD leptin levels = 5.18 ± 7.40 versus 9.72 ± 8.04 ug/L, respectively).

Conclusion: In Chinese older adults with amnestic MCI, having a low baseline serum leptin level predicts an increased risk of progression to Alzheimer’s disease.

oligomer levels (> 1.98 pmol/L) were more common in AD than non-AD patients (35.7% versus 0%; p = 0.021, Chi-square statistics). In ROC curve analyses, the area-under-curve (AUC) of CSF levels of A\(_{\beta}\) 42, tau, p-tau181, A\(_{\beta}\) 42/ tau and A\(_{\beta}\) 42/ p-tau ratios ranged from 0.777 to 0.929. For the diagnosis of AD, the ratio of A\(_{\beta}\)42/ tau had high sensitivity and specificity of 86% and 88%, respectively. The A\(_{\beta}\)42/ p-tau ratio was the most specific for the diagnosis of AD (100% specificity), while retaining a good sensitivity of 79%.

Conclusion: In conclusion, the A\(_{\beta}\)42/tau and A\(_{\beta}\)42/p-tau ratios were sensitive and specific diagnostic biomarkers of AD in our Chinese population.

Actions to stop driving in different types of dementia: Data on 8850 patients from the Swedish dementia quality registry (SveDem)

D. Religa\(^a\), S.-M. Ferestenhejda, H. Eriksson\(^a\), S. Fishan\(^a\), B. Farahmand\(^a\), C. Lundberg\(^a\), K. Johansson\(^a\), M. Eriksdotter\(^a\).\(^a\) Department of Neurobiology, Care Sciences and Society, Karolinska Institute, Stockholm, Sweden; \(^b\)Mossakowski Medical Research Centre, Polish Academy of Sciences, Warszawa, Poland; \(^c\)Geriatric Clinic, Handangeriatriken, Haninge, Sweden; \(^d\)Psychology Clinic, Karolinska University Hospital, Stockholm, Sweden; \(^e\)Geriatric Clinic, Karolinska University Hospital, Stockholm, Sweden

Background: Executive functions impairment, visuospatial dysfunction, behavioural disturbances and problems with orientation affect fitness to drive in dementia patients. We investigate if the reporting of driving unfitness by physicians differs with different dementia diagnoses.

Patients and methods: Totally, 8850 patients from SveDem were included. The registry holds information on 8 different dementia diagnoses (ICD-10). The primary outcome was agreement with patient to quit driving or report the patient to the driving license authority with a recommendation of license suspension. Variables such as age, gender and type of dementia were considered in the model.

Results: The mean age was 76.6 (8.0) years with a majority (55.1%) of males. An agreement with the physician not to drive was obtained in 80% of cases. In 705 (8.7%) cases the patients were reported to the Swedish Transport Agency. The highest and lowest rates of reporting were recorded in frontotemporal dementia (FTD) (23.3%) and dementia with Lewy bodies (DLB) (4.9%), respectively. After controlling for age, MMSE score (w = 0.002) and gender (w = 0.001), FTD [P = 0.015], DLB (P = 0.004) and Parkinson’s disease with dementia (PDD) (P = 0.014) were significantly associated with driving license suspension.

Conclusion: SveDem data demonstrated that for the majority of dementia patients an agreement with the physician not to drive was reached. In less than 9% the driving license was reported to authorities. Of those, the majority of patients suffered from FTD. The loss of disease awareness in these patients may contribute to difficulties in reaching an agreement not to drive resulting in suspension of the driving license.

Correlation between epileptiform activity and cerebrospinal fluid biomarkers in Alzheimer's disease

M. Albanese\(^a\), D. Ferrazzoli\(^a\), A. Martorana\(^a\), A. Romigi\(^a\), F. Izzii\(^a\), F. Sica\(^a\), C. Liguori\(^a\), G. Sancesario\(^a\), G.M. Sancesario\(^a\), M.G. Marciani\(^a\), N.B. Mercuri\(^a\), F. Placidi\(^a\). \(^a\)Department of Neurosciences, University of Rome 'Tor Vergata', Italy; \(^b\)Department of Clinical Biochemistry and Molecular Biology, University of Rome 'Tor Vergata', Italy; \(^c\)Santa Lucia Foundation, Rome, Italy

Background: Alzheimer’s disease (AD) is associated with an increased incidence of unprovoked seizures. Epileptiform activity in AD has long been recognized as a secondary process resulting from advanced stages of neurodegeneration and aging-related cofactors; actually some evidence suggests that seizures may contribute to cognitive decline in AD.

Objective: The aim of the study was to investigate the relationship between the qualitative electroencephalographic pattern and cerebrospinal fluid biomarkers (CSF) in AD patients.

Methods: 141 outpatients with AD underwent a neuropsychological examination, conventional EEG recording and lumbar puncture for assessing tau protein, phosphorylated-tau protein (p-tau) and Ab\(_{\beta}\)42 amyloid protein values. According to a visual qualitative EEG analysis, all participants were assigned to the following categories: Type 1: normal; Type 2: slow; Type 3: epileptiform.

Results: 37 patients showed the type 1 EEG pattern, 59 the type 2 and 45 the type 3. Statistical analysis indicated that patients with epileptiform EEG pattern have p-tau and tau/Ab\(_{\beta}\)42 ratio values significantly higher than patients showing type 1 EEG pattern. This finding was independent from age, estimated disease duration and MMSE values of each EEG group. A correlation between the progressive reduction of MMSE, and respectively, the increase of both tau and p-tau values, and the decrease of Ab\(_{\beta}\)42 was also found: patients with type 3 epileptiform EEG pattern showed a significant correlation between the reduction of Ab\(_{\beta}\)42 and the decrease of MMSE.

Conclusions: Our findings support the hypothesis that aberrant excitatory neural activity may represent a primary upstream mechanism in the genesis of cognitive decline. Therefore, qualitative EEG analysis integrated with CSF biomarkers may be a valid tool to define prognosis of AD and possible therapeutic implications.

Conclusions: After controlling for duration of the disease, the use of neuroleptics is found to influence the appearance of extrapyramidal symptoms in patients with Alzheimer’s disease. Patients who presented extrapyramidal symptoms at initial examination appeared to deteriorate faster, mainly cognitively, but also functionally.

Rationale and study design of a MRS study to explore the effects of Souvenaid on brain metabolites in Alzheimer's disease
A. Rijpmaa,b, O. Meulenbroekab, M. van der Graafc,d, M.M. Lansberge, R.L. Wieggerse, A. Heerschapc, M.G.M. Olde Rikkertab, R. Sijbenab, aDepartment of Geriatric Medicine, Radboud University Nijmegen Medical Centre, The Netherlands; bAlzheimer Centre Nijmegen, Radboud University Nijmegen Medical Centre, The Netherlands; cDepartment of Radiology, Radboud University Nijmegen Medical Centre, Nijmegen, The Netherlands; dDepartment of Paediatrics, Radboud University Nijmegen Medical Centre, Nijmegen, The Netherlands; eNutricia Advanced Medical Nutrition, Danone Research, Centre for Specialised Nutrition, Wageningen, The Netherlands

Background: Synaptic dysfunction is a major contributing factor to the development of cognitive impairment in individuals with Alzheimer’s disease (AD). Synapses consist of neuronal membranes largely composed of phospholipids. The formation of neuronal membranes is controlled by nutritional precursors and cofactors that are obtained from the circulation. The medical food Souvenaid®, containing the specific nutrient combination Fortasyn® Connect (FC)1, has been formulated to support synapse formation and function in patients with AD by promoting phospholipid and membrane formation. It has been demonstrated that Souvenaid improves memory in mild AD patients.

Objective: The main objective of the present Magnetic Resonance Spectroscopy (MRS) study is to investigate to what extent Souvenaid affects brain phospholipid metabolism.

Patients and methods: A total of 30 drug-naïve patients with mild AD (MMSE ≥ 20) will be enrolled in this double-blind randomised controlled study (NTR3346) to receive either Souvenaid (containing FC) or an iso-caloric control product (without FC) for a 4-week period. At baseline and after 4 weeks, participants will undergo phosphorus (31P)-MRS measurements to study phospholipid turnover. Additional proton (1H)-MRS measurements will be conducted to assess neural integrity. Main outcome parameters are brain levels of the phosphomonoesters phosphocholine and phosphatidylcholine, and of the phosphodiester glycerophosphocholine and glycerophosphoethanolamine.

Results: The enrollment for the study started in October 2012. Currently, fifteen patients have been randomised.

Conclusion: The effects of Souvenaid on brain phospholipid metabolism are investigated using 31P-MRS. Furthermore, 1H-MRS measurements will provide additional information on its effects on neural integrity.

Souvenaid and Fortasyn are registered trademarks of N.V. Nutricia.

Socioeconomic burden of young onset dementia in Singapore — A pilot study

Background: The socioeconomic cost of dementia is significant for patients, caregivers and society. Few studies have examined the impact of young onset dementia (YOD) in Asia, and none in Singapore.

Objectives: To determine the socioeconomic impact of YOD in Singapore.
Methods: A random sample of YOD patients (age ≤ 65 years old) attending a memory clinic in a tertiary setting was identified. Diagnosis of dementia had been made by a cognition neurologist. 2 independent physicians conducted phone interviews with patients and their caregivers on separate occasions using a set of questionnaire on financial burden. Case–notes were reviewed for patients’ demographics and medical history.

Results: 12 patients (5 Alzheimer’s dementia; 5 fronto-temporal dementia; 1 vascular dementia; 1 Hashimoto’s-associated dementia) and 10 caregivers were interviewed. Mean age of patients was 59 (51–64); mean MMSE 18 (9–27). 7 patients reported premature loss of employment with average loss of employment of 4.6 years. This resulted in an estimated average monthly income loss of SGD$2992 ($0.1–6.5 k/month). Caregivers reported varying degrees of indirect income loss including reductions of working hours. Most were unable to quantify exact

In vivo visualization of tau pathology in Alzheimer's disease patients by [11C]PBB3-PET
S. Hiranoab, H. Shimadaa, M. Higuchia, Y. Ikoma, H. Shinotohc, S. Furukawaa,b, S. Moriguchi, Y. Eguchia, T. Nogami, T. Nagashimaa, M. Suzuki, K. Takahata, T. Sasaki, F. Kodaka, H. Fujiiwara, Y. Kimura, M. Yamada, M. Maruyama, H. Takano, M.-R. Zhang, S. Kuwabara, H. Ito, T. Suhara. aMolecular Imaging Center, National Institute of Radiological Sciences, Chiba University, Japan; bDepartment of Neurology, Graduate School of Medicine, Chiba University, Japan; cNeurology Chiba, Chiba, Japan

Background: Neuroimaging results of brain amyloid beta by PET have provided many novel insights in the pathomechanisms of Alzheimer's disease (AD). Tau is another pivotal protein associated with neural dysfunction in AD, and in vivo tau estimation would be an important biomarker for AD research. We have developed a novel PET radioligand [11C]PBB3, which shows high affinity and selectivity for tau deposits.

Objectives: To investigate the spatial characteristics of [11C]PBB3 and PET in human with both normal and impaired cognition.

Patients and methods: Participants were patients with AD and age-matched healthy controls (HCs). [11C]PBB3 was intravenously injected and dynamic scans were acquired over a 70 min. Standardized uptake value ratio (SUVR) image was created by the cerebellar cortex as reference region, and visually assessed in each subject. Additionally, cerebral amyloid deposition was estimated with amyloid-binding agent, [11C]PIB and SUVR images were created from 50–70 min post-injection PET scan.

Results: All HCs were [11C]PIB-negative, and all AD patients were [11C]PIB-positive. SUVR images of [11C]PBB3-PET demonstrated high accumulation of [11C]PBB3 in the medial temporal cortex of all AD patients, in contrast with relatively low [11C]PIB binding in the same region. Distribution of [11C]PBB3 binding observed in AD patients extended to the limbic system and subsequently to the neocortex as a function of the disease severity.

Conclusions: The [11C]PBB3 binding region in AD patients is in accord with the prior neuropathological findings and was distinct from [11C]PIB binding region. Therefore, we conclude that [11C]PBB3-PET can effectively visualize human brain tau deposition in vivo.

Conclusions: The [11C]PBB3 binding region in AD patients is in accord with the prior neuropathological findings and was distinct from [11C]PIB binding region. Therefore, we conclude that [11C]PBB3-PET can effectively visualize human brain tau deposition in vivo.

income loss; 1 reported a monthly loss of SGD$4000 resulting from a job change.

Direct monthly medical cost averaged SGD$480 (medication $142; medical consultations $85; out-of-pocket expenses $253). Majority expressed a need for financial aids for medications and care.

**Conclusion:** Patients and caregivers of YOD are burdened with significant direct and indirect costs. Further studies are underway to exact nationwide socioeconomic burden, and rationalize resource allocation for YOD in Singapore.

The etiology of moderate cognitive disorders (MCD) in a working-age population according to epidemiological studies

L.V. Sapryvina, I.A. Belova, S.V. Butrsev, N.V. Belova, D.S. Elistratova, A.G. Koroleva, Neurology, Ulyanovsk State University, Ulyanovsk, Russia; Research Center of Neurology, Russian Academy of Medical Sciences, Moscow, Russia

**Background:** Early diagnosis of pre-dementia contributes to the timely administration of pathogenetic therapy to delay or stop the progression of cognitive functions disorders.

**Objective:** To evaluate the prevalence and etiology of the MCD syndrome in the working-age population of Ulyanovsk.

**Materials and methods:** In the framework of the study the open population of Ulyanovsk in the age of 40–59 years underwent screening. MCD syndrome was determined in accordance to the modified R.Petersen and J.Touchon diagnostic criteria; the etiology of MCD syndrome was defined by anamnesis data, the results of the clinical examination, ultrasonic research of cerebral vessels, and brain MRI.

**Results:** We surveyed 300 people: 86 (15.93%) men, 214 (25.78%) women. MCD syndrome was diagnosed in 71 (23.67%) subjects. In 48 (67.61%) patients the cause of this syndrome were vascular diseases (hypertension, and atherosclerosis), confirmed by ultrasound duplex scanning of brachiophetal arteries. 7 patients (9.66%) had cerebral vascular disorders and diabetic encephalopathy. In 4 (5.63%) cases MCD syndrome was a consequence of vascular diseases and cranioiocerebral injury. 5 patients (7.04%) had a cerebrovascular disease and memory weakness, which was associated with an operation, performed under general anesthesia. There were isolated cases: posttraumatic encephalopathy, paraneoplastic syndrome, diabetic encephalopathy, a combination of vascular causes and myasthenia gravis in remission, a combination of such factors as hypertension and consequences of viral encephalitis.

**Conclusions:** The MCI syndrome was diagnosed in 20% of the working-age (40–59 years) population of Ulyanovsk. The main etiological factors for the development of the syndrome were hypertension and atherosclerosis.

**Application of AD7C-NTP ELISA kit on Alzheimer’s disease diagnosis**

R. Wang, Xuanwu Hospital, Capital Medical University, Beijing, PR China

**Objective:** To develop urine AD7C-NTP diagnostic kit, analyze and evaluate clinical application on AD.

**Methods:** Immunogenicity AD7C-NTP peptide fragments had synthesized by solid-phase methods, then immunized animals and prepared antibodies. After matching screening, mouse antibody as packets antibody, while biotin-labeled rabbit antibody as testing antibody, antibody ELISA titer was 1:8000, and rabbit anti-AD7C-NTP antibody ELISA titer was 1:32,000; WB detected human brain specimens found a single band. In the relative molecular mass of 41,000, the sensitivity of WB detected human brain specimens found a single band. In the relative molecular mass of 41,000, the sensitivity of ELISA methodology was 0.5 μg/L, the linear range was 0–10 μg/L, normal reference value of ≤ 1.5 μg/L, the average recovery rate was 100.2%, approved of CV 3.8%, 4.5%, and inter CV 7.6%, 6.8%. AD group [2.250(0.43–8.62)] μg/L was higher than control group [0.82(0.47–2.77)] μg/L, P < 0.0001]. The positive rates of AD group and control group were 89.3% and 15.3% respectively, the sensitivity was 89.3% and specificity was 84.7%.

**Conclusions:** Using the self-designed synthetic peptide fragment and immunizing animals, preparing AD7C-NTP antibodies successfully, establish an ELISA detective method of urine AD7C-NTP on AD diagnosis. This ELISA diagnostic kit is high precision and sensitive, and can be used as an assistant examination in clinical diagnosis of AD.

**Early-onset dementia (EOD). Demographic and etiologic characteristics of 170 patients**

M. Benabdellil, F. Boutbibe, M. Rahmani, F. Benbelaid, M. Bennani, S. Aïdi, M. El Alaoui Faris, Neurology A and Neuropsychology, Mohamed V University, Rabat, Morocco

The purpose is to investigate demographic profile and etiology distributions of EOD in a prospective memory centre cohort. 401 cases of dementia were diagnosed between January 2000 and May 2011; 170 were EOD, with age onset less than 65 years. Dementia diagnosis was based on complete neurologic and somatic clinical examination, and neuropsychological assessment. All patients had cerebral imaging. Routine laboratory tests were performed in all cases. More analysis was made when a specific etiology was suspected. We used DSM-IV criteria for diagnosis of dementia, NINCDS-ARDA criteria for Alzheimer’s Disease (AD), NINDS-AIREN criteria for Vascular Dementia (VaD), and the usual criteria for diagnosis of Lewy Body and Fronto-Temporal Dementia (FTD), Progressive Supranuclear Palsy and Cortico- Basal Dementia.

EOD represented 42.4% of dementias, with 90 men and 80 females (range, 21 to 64 years). The mechanism of dementia was degenerative in 78 cases, including 61 AD (36% of EOD cases) and 8 FTD, vascular in 33 cases (19.4%) with 8 cases of Sneddon’s Syndrome, infectious in 26 cases (15.3%) with 19 cases of Neuro-Syphilis and 4 cases of Creutzfeldt–Jakob disease, and inflammatory in 11 (including 4 cases of Neuro-Behcet). Other etiologies were found in 16 cases, and the cause was undetermined in 5 cases.

Our study shows a large diversity of etiologies in EOD, that differ in accordance with age onset. Before 50 years, we find essentially infectious and inflammatory diseases. After 50 years, AD and VaD are the most frequent. EOD needs exhaustive investigations for a rapid diagnosis and potential treatment.

Voltage-gated potassium channel antibody encephalopathy mimicking Creutzfeldt–Jakob disease

Introduction: Rapidly Progressive Dementias (RPDs), in which the sporadic Creutzfeldt–Jakob disease (CJD) is the prototype, requires an urgent and extensive workup. Voltage-gated potassium-channel encephalopathy (VGKC-E) is an auto-immune disorder with variable clinical presentations, including a RPD that mimics CJD.

Case report: A 75 year-old female presented with 6 months history of progressive cognitive abnormalities dominated by behavior, orientation and memory dysfunction with unsteady gait. She also presented continuous diarrhea and later developed myoclonic and generalized tonic–clonic seizures. Past medical history was irrelevant. Neurologic examination revealed a complete dysfunction in multiple cognitive domains (orientation, attention, immediate/recent memory, calculus, writing, construction ability, insight/judgment and abstract thinking — MMSE-Score 2/30), apathy, frontal release signs, axial and appendicular rigidity, retropulsion falls and myoclonic jerks involving face and limbs. Laboratory screening showed hyponatremia. Anti-neuronal antibody testing came positive for VGKC-antibody Lgi1 (Leucine-rich-glioma-inactivated-1). CSF analysis revealed mild lymphocytic pleocytosis, mild proteinorquia and negative 14-3-3 protein.

Brain-MRI showed mesencephalic and anterior temporal lobe atrophy. EEG revealed left fronto-temporal slow and paroxystic activity. The patient was treated with high-dose methylprednisolone and intravenous immunoglobulin achieving a favorable recovery (MMSE-Score 22/30, resolution of diarrhea and hyponatremia).

Discussion: RPD remains one of the most challenging neurologic entities. Despite presenting criteria for CJD, the positivity for a VGKC-antibody LGI1 (Leucine-rich-glioma-inactivated-1) requires an urgent and extensive workup. Voltage-gated potassium-channel encephalopathy is an auto-immune disorder with variable clinical presentations, including a RPD that mimics CJD.

Conclusions: Our case shows how important it is to consider RPDs in the differential diagnosis of rapidly progressive dementia and how important it is to perform an urgent workup and treatment in order to prevent the patient from suffering any further complications.

Healthcare professionals judgement of presence or absence of delirium using the 4AT and CAM tools — A survey
S. Dsouza, M.A. Homaida, D. Mizzell, S. Guptha. 309, Medicine for Older People, Peterborough City Hospital, Peterborough, UK

Background: All adult patients with risk factors admitted to hospitals in the UK should be screened for delirium with a focus on preventing delirium (NICE). The diagnosis of delirium should be made by a trained healthcare professional using a validated tool such as confusion assessment method (CAM). The 4 At test (4AT) is a new screening tool for delirium and cognitive impairment and can be administered by any healthcare professional without the need for training. We surveyed the healthcare professionals in our hospital on their judgement of absence/presence of delirium using the short CAM and 4AT tools and sought their preference for wider use in hospital.

Methods: We devised 2 hypothetical patient histories with hypoactive and hyperactive delirium including essential data for application of the tools. We provided healthcare professionals from various sub-specialties without any specific training on delirium these questionnaires along with the 4AT and CAM tools and asked them to judge for the presence or absence of delirium.

Results: 39 healthcare professionals completed the survey. 34 of the 39 questionnaires were completed fully while the remaining 5 were completed partially. Hypoactive delirium was correctly identified by 84% using the 4AT and by 97% using the short CAM. Hyperactive delirium was correctly identified by 78% using the 4AT and by 50% using the short CAM. There was higher preference for 4AT(57%) for wider use as a tool for screening.

Conclusions: Our survey shows that there is need for training of healthcare professionals in the application of tools for screening delirium.

The effect of physiological aging on spatial navigation in a computerized human analog of the Morris Water Maze
L. Gažová1,2, J. Laczó1, I. Mokrišová1,2, K. Sheardova2, J. Hort1,2. 1Department of Neurology, Charles University in Prague and Motol University Hospital, Prague, Czech Republic; 2International Clinical Research Center, St. Anne's University Hospital Brno, Brno, Czech Republic

Objectives: Our recent findings derived from a real-space human analog of the Morris Water Maze (hMWM) suggested that physiological aging without pronounced hippocampal atrophy or vascular changes is associated with mild spatial navigation decline, which is less profound than in Alzheimer’s disease (AD). The aim of this study was to characterize spatial navigation performance and spatial learning in two different periods of the old age with an inexpensive and easy-to-administer computerized hMWM.

Methods: Healthy participants without cognitive deficit on standard neuropsychological testing: 24 young (18–26 years), 24 young-old (60–70 years) and 20 old-old (71–84 years) without vascular changes and pronounced hippocampal atrophy on brain MRI underwent spatial navigation testing in the computerized hMWM, which has the advantage to test separately hippocampus dependent (allocentric) and parietal lobe dependent (egocentric) navigation.

Results: The old-old group was impaired in allocentric navigation compared to the young (p ≤ 0.001) and the young-old (p = 0.007) groups. The young and young-old groups did not differ in allocentric navigation (p = 0.077). There were no differences in egocentric navigation among the groups (p’s ≥ 0.189). The learning effect was present in all groups (p’s < 0.001) with no between-group differences in learning (p ≥ 0.180).

Conclusions: Our results in the computerized hMWM supported our previous findings from the real-space setting that allocentric spatial navigation decline is age dependent unlike the egocentric and is manifested after the age of 70. Spatial learning seems to be preserved in contrary to prodromal AD, which makes this test be a useful screening tool for evaluation of individuals at risk of AD.

Dementia diagnoses in the young are based on inadequate diagnostic evaluations — A nationwide register-based study
C. Roman-Filip, B.B. Andersen, J. Stokholm, T.R. Nielsen, M.B. Jørgensen, G. Waldemar, Memory Disorders Research Group, Danish Dementia Research Centre, Rigshospitalet, Denmark; Psychiatric Centre Copenhagen, Copenhagen University Hospital, Copenhagen, Denmark

Background: The aim of this nationwide register-based study was to evaluate the quality of the diagnostic work-up in young patients registered with a diagnosis of dementia in routine clinical practice.

Methods: Two hundred patients were randomly selected from 891 patients aged <65 years registered with a dementia diagnosis for the first time in 2008. Through medical record review, 3 raters evaluated the completeness of the work-up on which the dementia diagnosis was based, using evidence-based dementia guidelines as reference standards. Data were compared to results from a previous similar study in the elderly Danish population.

Results: In total, 159 medical records were available for review. One third of the patients had been diagnosed with dementia during an acute admission. In total, dementia diagnosis was confirmed by the raters in 48% while 60% of dementia subtypes were confirmed. Thirty percent of the patients did not meet diagnostic criteria for dementia. An acceptable diagnostic work-up of all items was performed in only 19 patients. Most of the patients had been diagnosed with dementia by neurological or psychiatric departments, but supplementary diagnostic tools were only rarely used.

Conclusion: Our findings indicate that the diagnostic work-up of dementia in young patients in the secondary health care sector may not meet the basic standards set by evidence-based clinical guidelines. Consequently, patients may be either over-diagnosed with dementia or denied the treatment and care they need for their specific neurodegenerative disorder. Our findings call for increased competency in diagnosing dementia in young patients in the future.

High density lipoprotein cholesterol in patient conversion with MCI in dementia
L. Prodan, C. Domaniuc, C. Roman-Filip, “County Emergency Hospital, Lucian Blaga University, Sibiu, Romania;” Department of Public Health, Lucian Blaga University, Sibiu, Romania; Department of Neurology, Lucian Blaga University, Sibiu, Romania

Objectives: The aim of this study was to investigate the impact of HDL-cholesterol in conversion to dementia for MCI patients.

Material and methods: We recruited 365 patients in families with medicine cabinets, patients with age of over 65 years, who met the criteria for MCI and evaluated their global cognitive performances at baseline and annual for the next three years. The diagnosis of dementia was established using DSM IV TR criteria.

Results: There were 365 cases of MCI incident, 194 male patients and 171 female patients. The mean conversion rate during follow-up period was 18.9% for Alzheimer’s disease (AD), 11.8% for vascular dementia (VD) and 13.2% for Alzheimer’s disease with cerebrovascular disease (AD with CVD). In our study, the relative risk of conversion of the patients with low HDL-C was 1.67 in dementia, 2.56 in AD, 4.25 in VD and 2.67 in AD with CVD; for the patients with normal HDL-C was 0.41 in dementia, 1.10 in AD, 0.12 in VD and 0.27 in AD with CVD; and for high HDL-C patients was 1.52 in dementia, 1.48 in AD, 2.21 in VD and 2.13 in AD with CVD.

Conclusion: Conversion in dementia was associated, in our study with low HDL-C. The high values of HDL-C associate a low risk of conversion in AD of patients with MCI comparative with conversion in VD and AD with CVD; in patients with unconverted MCI the normal HDL-C is dominant.

Memory aid — Computer based working memory training in elderly with mild cognitive impairment (MCI). A randomized, controlled trial
M. Flak, S.S. Hernes, J. Skranes, G.C. Lohaugen, Memory Aid-MCI Study Group, “Sorlandet Hospital, Arendal, Norway;” Institute of Medicine, University of Trondheim/NTNU, Trondheim, Norway

Objectives: To evaluate safety, tolerability and efficacy of ORM-12741 on cognitive and behavioral symptoms in patients with Alzheimer’s disease: A randomized, double-blind, proof-of-concept study
L.O. Rinne, K. Wesnes, J. Hänninen, M. Murphy, H. Riordan, J. Rourud, ALPO Study Group, Turku PET Centre, Turku, Finland; Turku University Central Hospital, Turku, Finland; Bracket Global, Goring-on-Thames, UK; Orion Pharma, Turku, Finland; World Wide Clinical Trials, King of Prussia, PA, USA

Background: ORM-12741 is a highly potent and selective alpha-2C adrenoceptor (AR) antagonist that has demonstrated efficacy in rodent models suggesting beneficial effects on both cognitive and behavioral symptoms in AD.

Objectives: To evaluate safety, tolerability and efficacy of ORM-12741 as add-on therapy in patients with Alzheimer’s disease (AD).

Methodology: This was a phase IIa, randomized, double-blind, placebo-controlled, parallel-group, multicentre, proof-of-concept study of 100 moderate AD patients (MMSE scores 12 to 21) with behavioral symptoms (Neuropsychiatric Inventory (NPI) score of ≥15). Patients were randomized to two flexible dose levels of either 30 to 60 mg or 100 to 200 mg of ORM-12741 or matching placebo twice daily for 12 weeks as add-on to their stable cholinesterase inhibitor therapy (± memantine). Efficacy was assessed primarily by computerized cognitive tests from the CDR System. The NPI was used to assess behavioral and psychological symptoms.

Results: Statistically significant treatment effects were noted for ORM-12741 on the composite CDR measures Quality of Episodic Memory (p = 0.03) and Quality of Memory (p = 0.013) as well as on NPI Caregiver Distress (p = 0.034) favoring ORM-12741 over the 12 week treatment period with no significant differences between the two dose groups. However, a positive trend was noted for both Quality of Working Memory and NPI total score favoring the low dose group. ORM-12741 was generally well tolerated in the study.

Conclusion: Significant positive effects of ORM-12741 on several composite measures of memory in moderate AD patients as add-on therapy over 12 weeks were observed suggesting further study in longer term trials.

Topic: 5 — Dementia
Suppression of spike frequency by α-synuclein oligomer in neocortical pyramidal neurons
K. Yamamoto, K. Yamakawa, H. Sawada. Clinical Research Center and Dept. of Neurology, Utano National Hospital, Kyoto, Japan

Background: Dementia with Lewy bodies (DLB) is pathologically characterized by the formation of Lewy bodies and neuronal death throughout the brain. α-Synuclein is a major component of Lewy bodies, and is proposed to play a central role in the pathogenesis of DLB. Recent evidence implicates soluble oligomers rather than insoluble fibrils as the toxic species. These data suggest the hypothesis that soluble α-synuclein oligomers could accumulate intracellularly and alter neuronal activities; however it has not been elucidated.

Objective: To investigate the effect of α-synuclein on neuronal excitabilities in neocortical pyramidal cells.

Material and methods: α-Synuclein protein was introduced into pyramidal neurons through whole-cell patch pipettes in mouse frontal cortex slices. The following four kinds of internal solution are applied; α-synuclein (α-SN; 1 μM), dopamine (DA; 10 μM), α-synuclein co-incubated with dopamine at 37 °C for 3 days (α-SN + DA), and vehicle solution.

Results: The application of α-SN + DA reduced spike firing by depolarizing current injection. Neither resting membrane potential, spike width, nor spike afterhyperpolarization had differences between these groups. Western blot analysis revealed that soluble α-synuclein oligomers accumulated intracellularly and altered neuronal activities; however it has not been elucidated.

Conclusion: α-Synuclein oligomers lower spike frequency, which may cause the downregulation of neocortical activities in DLB.

Clinical and genetic aspects of Moroccan patients with Alzheimer’s disease
N. El Kadmiri, B. El Moutawakil, I. Slassi, S. Nadifi. Laboratory of Medical Genetic and Molecular Pathology, University HASSAN II, Faculty of Medicine and Pharmacy, Casablanca, Morocco; Department of Neurology, CHU IBN ROCHD, University HASSAN II, Faculty of Medicine and Pharmacy, Casablanca, Morocco

Background: Alzheimer’s disease (AD) is the most common cause of dementia in the elderly. In Morocco it affects almost 30000 persons (WHO).

In this first study in Morocco we aimed:

• At evaluating the clinical aspects of Moroccan patients with AD.
• At evaluating the genetic contributions of APP exon 16 and exon 17 mutations in familial and sporadic cases.

Patients and methods: 6 families (8 cases) and 17 sporadic cases presenting at neurology department of the CHU IBN ROCHD, Casablanca, Morocco.

• Clinical methods: Cognitive function assessment, brain imaging and laboratory tests.
• Genomic methods: Genomic DNA extracted from blood. PCR and direct sequencing of the APP exons 16 and 17 were done.

Results:
• Clinical results: All patients had cortical atrophy; 48% of the patients that are either sporadic or family forms have a MMSE score of less than 10 and are affected by severe dementia, 28% by a moderately severe dementia and 12% are slightly insane.
• Genetic results: In APP exon 16, 2 novel frameshift mutations were detected in 4 family cases. No mutations in APP exon 16 have been found in 17 sporadic cases. In APP exon 17, in all patients, 5 novel frameshift mutations were identified. Only one novel splicing mutation was detected.

Conclusion: High correlation between imaging and neuropsychological testing. The more the cortical atrophy is prominent, the more the neuropsychological performances are reduced. Moroccan patients with AD have novel frameshift mutations that induced a complete alteration of the amino acid sequence of a protein, which may lead to disease.

Isolated frontotemporal dementia in valosin containing protein gene mutations
A.G. Velon, A. Veiga, A. Costa, J. Pinto-Basto, M.R. Silva. Serviço de Neurologia, Centro Hospitalar de Trás-os-Montes e Alto Douro, Vila Real, Portugal; Serviço de Genética, Instituto de Biologia Molecular e Celular, Porto, Portugal

Background: Frontotemporal dementia with inclusion body myopathy and Paget’s disease of bone is a rare, autosomal dominant disorder caused by mutation in the gene valosin-containing protein (VCP). It seems that only 3% have FTD as an isolated phenotype.

Case report: A 52-year-old woman dedicated housewife progressively lost interest in her child and husband, making dinner and eating
without waiting for them or speaking with them. Family reported other abnormal behaviors: she started going to funerals of people she didn’t know, trying to look at the dead’s face; she entered every bathroom that she saw to wash her hands. Her family noticed speech problems in finding names and after 2 years her speech became incomprehensible. She developed swallowing problems and urinary incontinence. 10 years later she was referred to our hospital. Past personal and family histories were irrelevant. Examination revealed a profoundly apathetic and later she was referred to our hospital. Past personal and family histories were irrelevant. Examination revealed a profoundly apathetic and

Discussion: This is the first Portuguese VCP mutation with a detailed clinical examination.

Fluidity changes in the forebrain membranes isolated from mice bearing experimental Alzheimer’s disease

N. Gerasimov, A. Goloshchapov, E. Burlakova, Emanuel Institute of Biochemical Physics, Russian Academy of Sciences, Moscow, Russia

Background: Membrane structure may play a mean role in the development of dementia. Therefore, it was important to determine membrane fluidity alterations for the development of AD-like pathology. 

Objectives: In this work changes in fluidity of membranes isolated from the microsomal and synaptosomal fractions obtained from forebrain of mice bearing experimental Alzheimer’s disease induced with olfactory bulbectomy and developed by I. Nesterova et al. [1] were studied. 

Materials and methods: Membrane microviscosity was measured by electron paramagnetic resonance (ESR) with 2,2,6,6-tetramethyl-1,2,3,4-tetrahydro-carboline-3-oxyl as near-proteinic probes. Rotational diffusion correlation time, characterizing membrane components microviscosity, was calculated from the obtained spectra of the ESR.

Results and conclusions: We found out staged changes of forebrain cell membranes fluidity, accompanying AD. These alterations correlate with the stages of «clinical» indicator changes. The main disturbance of the fluidity took place in membranes of near-protein regions. The obtained results testify the lipid peroxidation regulation system failures. Thus, the membrane structure plays an important role in the development of AD, and, taking into account these structural changes, one can better understand the course of dementia, and significantly improve the treatment of AD.

Microtubule-associated tau protein serum level in patients with different neurodegenerative diseases

1Outpatient Clinic and Laboratory of Neuroimmunology and Biochemistry, State Institute of Neurology, Psychiatry and Narcology, NAMSU, Ukraine; 2Department of Biochemistry, Kharkiv National Medical University, Kharkiv, Ukraine; 3Department of Pathophysiology and Pathological Anatomy, Kharkiv National Medical University, Kharkiv, Ukraine; 4Nuffield Department of Clinical Neurosciences, John Radcliffe Hospital, Oxford University, Oxford, UK

Microtubule-associated axonally-derived phosphoprotein tau is essentially involved into neurotoxic degenerative mechanisms: aggregation of its specific sets into filamentous inclusions is a common feature of intraneuronal and glial fibrillary lesions in numerous neurodegenerative disorders: Alzheimer’s disease and Tauopathies. Tau-associated genes, proteins and Tau-phosphorylation were also abnormal in some forms of multiple sclerosis (MS). The aim was to compare tau level in patients with temporal lobe epilepsy (TLE), relapsing remitting MS (RRMS) and amytrophic lateral sclerosis (ALS).

Method: Patients with drug-resistant long-standing TLE (n = 49; 20–41 years), RRMS (n = 38; 27–46), ALS (n = 5; 43–58) and controls (n = 16; 25–35) were investigated. Tau was measured by immunofluorescent method using monoclonal anti-mouse antitau-2 antibodies also specific for phospho-Tau. Results were expressed as optical density (OD = Log10F0 /F 1) units of FITC-labelled binding sites.

Results: Serum tau concentration (mean ± SD) under baseline conditions compared to controls was in TLE = 0.38 ± 0.041 vs. controls = 0.04 ± 0.002; RRMS = 1.02 ± 0.085 (P < 0.01; t = 4.69); ALS = 0.58 ± 0.06 (P < 0.01; t = 3.8). TLE that showed average tau levels had long-standing pharmanco-resistant course (mean duration ±SD: 18.5 ± 11.6) with psychiatric complications using old generation antiepileptic drugs where tau might reproduce secondary neurodegeneration process associated with epileptic lesion. RRMS and ALS (mean duration ±SD: 7.5 ± 2.23 and 14.2 ± 8.31, respectively) detected high tau-mediated toxicity associated in RRMS with relapses severity, and in ALS associated with cognitive decline progression as a part of tau-mediated neurodegeneration; eighteen RRMS patients formerly had brain injury (10), meningoencephalitis virus (7) and chicken-fox (1).

Conclusion: Study revealed high level of hyperphosphorylated tau in RRMS and ALS where it plays role in neurodegeneration associated with diseases severity and progression.

Characteristics of Parkinson’s disease dementia in Southern Tunisia

S. Smaoui1, A. Boukhris, M. Damak, E. Turki, I. Bouchhima, M.I. Miladi, I. Feki, C. Mhiri. Neurology, Habib Bourguiba Hospital, Sfax, Tunisia

Objective: To determine the prevalence, characteristics and factors correlated with the occurrence of dementia in patients with Parkinson’s disease (PD) in Southern Tunisia.

Patients and methods: We recruited and examined 102 unrelated Tunisian patients with sporadic and familial PD. The mean age at onset was 64.9 years (range = 40–86) and 57.8% were men. Neuropsychological evaluation was conducted and included the Unified Parkinson

Disease Rate Scale I “UPDRS I,” Mini Mental State Evaluation “MMSE” and Frontal Assessment Battery “FAB”.

Results: Cognitive impairments were reported by 39.2% patients or their families as a symptom of the disease. The frequency of cognitive impairment was variable depending on the scale used. Based on the UPDRS I, cognitive impairments were present in 62.75%; mild to moderate in 55.88% and severe in 6.86%. Global cognitive efficiency was impaired in 36.26% while dysexecutive syndrome was frequent (56.86%) even in some patients showing normal intellect. There was no correlation between cognitive impairments and some clinical and epidemiological features, such as duration of the disease, age at onset, and the nature and dose of the treatment used. The occurrence of cognitive impairment was strongly correlated with the presence of depression (p = 0.001) and an advanced stage of the disease (Hoehn and Yahr > 2.5, p = 0.002).

Conclusion: We conclude that cognitive impairments are often underestimated. MMSE is less insensitive than FAB to detect cognitive impairments due to PD. Depression and severe disability are the main factors that precipitate cognitive decline in PD.

Mirror neurons in Alzheimer's disease
S. Kumar, A. Kumar. Neurology, Valley Institute of Neurology, Mesa, AZ, USA

Mirror neurons are special neurons because they fire both when an action is performed, and when an action is observed. They play a major role in learning, are a key to empathy, and allow social interaction. Is the Mirror Neuron System in Alzheimer’s Patients Dysfunctional? Never being published, the answer to this question could open a door to new possibilities in treating Alzheimer’s disease by changing the approaches of treatment.

The approach was to use EEG testing. There were two groups, the control group and Alzheimer patients. During an EEG test, each participant was shown a video which consisted of a series of simple movements, followed by faces that expressed various emotions. The participants were first asked to just observe the video, and then when the video was replayed, they were asked to perform the activities. 22 Alzheimer patients and 16 control age matched participants were tested. There was no suppression of the mu range brain wave activity in the Alzheimer’s group during observation and performance of the activities. The control group exhibited constant suppression of the mu range brain wave activity. The video was replayed, they were asked to perform the activities.

Cyclophosphamide-responsive cerebral amyloid angiopathy-related inflammation. A case report and review of the literature
Y. Hagiwara, T. Yanagisawa, C. Atsumi, F. Maki, T. Shimizu, Y. Hasegawa. Neurology, St. Marianna University School of Medicine, Kawasaki, Japan

Background: Cerebral amyloid angiopathy related inflammation (CAA-I) is a rare disease, defined by the deposition of amyloid proteins within the leptomeningeal and cortical arteries associated with vasculitis or perivascularitis. The inflammation typically responds well to steroid therapy.

We report a patient with CAA-I who improved with cyclophosphamide but not with steroid therapy.

Objective: A 78-year-old female was presented with progressive cognitive dysfunction and right hemiparesis. Magnetic resonance imaging (MRI) of the brain revealed high intensity area in bilateral frontal lobe on T2-weighted images (T2WI) and fluid-attenuated inversion recovery (FLAIR) showing leukoaraiosis. Brain biopsy was performed, revealed with no significant findings except edematous change. By the initial steroid pulse therapy, the white matter lesion and her symptoms improved moderately. 3 months later, consciousness disturbance and right hemiparesis worsened again, and the white matter lesion expanded on MRI. Steroid pulse therapy was performed again, but her condition got worse gradually and became akinetic mutism. T2* on MRI showed microbleeding, and analysis of the APOE genotype showed ε4/ε4. She was diagnosed as CAA-I and two periods of cyclophosphamide pulse therapy were performed. After the first cyclophosphamide pulse therapy the white matter lesion, consciousness disorder, and hemiparesis improved immediately. She was discharged from the hospital fully mobile.

Conclusion: In Japan, although steroid therapy for CAA-I is already known and common, CAA-I which resists steroid therapy should be treated by cyclophosphamide therapy on the early stage of the disease.

Common genetic variants are associated with severity of cognitive decline in Korean Alzheimer’s disease
E.H. Jang1, M.-J. Kim2, J.H. Lee3, S.Y. Kim4, S.J. Chung4. 1Department of Neurology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea; 2Department of Neurology, Bobath Memorial Hospital, Seongnam-si, Republic of Korea; 3Department of Psychiatry, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea

Background and objective: Recent genome-wide association studies reported evidence that some single nucleotide polymorphisms confer genetic risk for Alzheimer’s disease. Whether these risk variants for AD also associated with severity of cognitive functions has not been studied. We aimed to find out correlations between severity of cognitive function and SNPs which were associated with risk of AD.

Methods: We prospectively recruited 211 patients diagnosed as AD from March 2010 to July 2011. They tested detailed neuropsychological evaluation which examined attention, language and related functions, visuospatial functions, verbal and visual memory, frontal and executive functions, K-MMSE, GDS, B-ADL and CDR scale. Percentiles of each neuropsychological test for age- and sex-matched controls in Korea were obtained. 86 SNPs in CR1, BIN1, LRAT, CD2AP, EPHA1, CLU, MS4A, ABCA7, CD33 and APOE genes were previously reported to be associated with AD in GWAS. Multiple regression analyses in additive model were performed using SAS version 9.1.3.

Results: In multiple regression analysis adjusting for age at neuropsychological evaluation, sex, disease duration and education, 4 SNPs were identified with P values of <5.0×10−5: rs11803956 (CR1) in K-MMSE score, rs2075650 (APOE) in percentile of total score in phonemic fluency and percentile of RCFT copy score, and rs3752232 (ABCA7) in RCFT copy score.

Conclusions: We found significant genetic influences on global and specific cognitive domains. These results that risk variants for AD associated with severity of cognitive decline could strengthen the genetic effect for the pathogenensis of AD.

Aβ augments mCa2+ independent mros-mediated shift of lethal transient mitochondrial permeability transition to its permanent mode in narp cybrids
M.-J. Jou. Chang Gung University, Tao-Yuang, Taiwan R.O.C.

Mitochondrial dysfunction is a hallmark of amyloid β-peptide (Aβ)-induced neurodegeneration of Alzheimer’s disease (AD). This study investigated whether mtDNA T8993G mutation-induced complex V inhibition, clinically associated with neurological muscle weakness, ataxia, and retinitis pigmentosa (NARP), is a potential risk factor for AD and the pathologic link for long-term exposure of Aβ-induced mitochondrial toxicity and apoptosis in NARP cybrids. Using noninvasive fluorescence probe-coupled laser scanning imaging microscopy and NARP cybrids harboring 98% mutant genes along with its parental 143B osteosarcoma cells, we demonstrated that Aβ1-42-augmented mitochondrial Ca2+ (mCa2+)-independent mitochondrial reactive oxygen species (mROS) formation for a cardiolipin (CL, a major mitochondrial protective phospholipid)-dependent lethal modulation of the mitochondrial permeability transition (MPT). Aβ1-42 augmented not only the amount but also the propagation rate of mROS induced mROS formation to significantly depolarize mitochondrial membrane potential (ΔΨm) and reduce mCa2+ stress. Aβ1-42-augmented mROS oxidized and depleted CL, thereby enhances mitochondrial fission and movement retardation, which promoted the NARP-augmented lethal transient-MPT (t-MPT) to switch to its irreversible mode of permanent-MPT (p-MPT). Interestingly, melatonin, a multiple mitochondrial protector, markedly reduced Aβ1-42-augmented mROS formation and therefore significantly reduced mROS mediated depolarization of ΔΨm, fission of mitochondria and retardation of mitochondrial movement to stabilize CL and hence the MPT. In the presence of melatonin, Aβ1-42-promoted p-MPT was reversed to a protective t-MPT, which preserved ΔΨm and lowered elevated mCa2+ to sublethal levels for an enhanced mCa2+-dependent O2 consumption. Thus, melatonin may potentially rescue AD patients associated with NARP symptoms.

New aspects in the study of regional forecasting of post-stroke dementia in Uzbek population of Aral Sea region of Uzbekistan
G. Izyumova4, D. Izyumov4. 4Republican Scientific Centre of Emergency Medical Aid, Khorezm Branch, Uzbekistan; 4Khorezm Regional Multifield Medical Centre, Urgench, Uzbekistan

There is a critical ecologically unfavorable situation in the Aral Sea and worsening health outcomes require urgent modern complex of preventive measures.
The purpose — to explore new aspects of regional forecasting of post-stroke dementia.

Material and methods: As part of screening we used standardized methods for detection of post-stroke dementia. All 113 participants were representatives of the Uzbek nationality.

Results: 28 patients suffered an acute ischemic stroke, 17 — hemorrhagic, 41 — transient ischemic attacks, and 27 — with the consequences of stroke. During magnetic resonance tomography (MRT) examination the presence of subcortical lesions of leukoaroesis at white substance of the frontal lobes, nucleus basalis (globus pallidum) was revealed. There are 7 factors that determine the relationship of psychoorganic disorders with comorbid syndromes: F1—is associated with atherosclerosis and hypertension disease; F2-TIA and diabetes; F3—encephalopathy with convulsive syndromes; F4—with the type of cerebrovascular accident; F5—a risk Parkinsonism; F6—ischemic stroke and coronary heart disease; and F7—angiopatic impairments in obesity. Graduation and the numerical values of risk factors were identified After that, according to a formula, the prognostic factors D1 and D2 with biofeedback was determined. During the identification of D2 ≥ D1, it revealed a high risk of subcortical dementia in 78 participants.

Conclusions: The new approach will increase the accuracy in prediction of post-stroke dementia and help to choose adequate therapeutic tactics.

Dual phases of respiration chain defect-augmented mros-mediated mCa2+ stress during oxidative insult in normal and rho 0 rho1 astrocytes
M.-J. Jou. Chang Gung University, Tao-Yuang, Taiwan R.O.C.
Mitochondrial respiratory chain (RC) deficits, resulting in augmented mitochondrial ROS (mROS) generation, underlie pathogenesis of astrocytes. However, mtDNA-depleted cells (rho 0) lacking RC have been reported to be either sensitive or resistant to apoptosis. In this study, we sought to determine the effects of RC-enhanced mitochondrial stress following oxidative insult. Using noninvasive fluorescence probe-coupled laser scanning imaging microscopy, the ability to resist oxidative stress and levels of mROS formation and mitochondrial calcium (mCa²⁺) was compared between two different astrocyte cell lines, control and rho 0, over time upon oxidative stress. Our results showed that the cytoplasmic membrane becomes permeated with YO-PRO-1 dye at 150 and 130 min in RBA-1 and rho 0 astrocytes, respectively. In contrast to RBA-1, 30 min after 20 mM H₂O₂ exposure, rho 0 astrocytes formed marked plasma membrane blebs, lost the ability to retain Mitochr, and showed condensation of nuclei. Importantly, H₂O₂-induced ROS and accompanied mCa²⁺ elevation in control showed higher levels than rho 0 at early time point but vice versa at late time point. Our findings underscore dual phase of RC-defective cells harboring less mitochondrial stress due to low RC activity during short-term oxidative stress but augmented mROS-mediated mCa²⁺ stress during severe oxidative insult.

**Background and purpose:** In addition to cognitive decline, behavioral and psychological symptoms of dementia (BPSD) are of equal importance in the clinical profile of the disease in patient with Alzheimer’s disease (AD). Therefore, in this study, we investigated the relationship between neuroanatomical structure and subtype of BPSD in AD.

**Methods:** Voxel-based morphometry was used to correlate gray matter (GM) derived from T1-weighted MRI images of 57 patients with Alzheimer’s disease and specific neuropsychiatric symptoms and behaviours measured by the Korean version of Neuropsychiatric Inventory.

**Results:** The BPSD of AD are associated with atrophies of specific brain region. Delusion, hallucination, anxiety, euphoria, apathy, disinhibition, irritability, aberrant motor behavior, night time behavior, and appetite change were associated with GM density loss in specific cerebral region, significantly.

**Conclusion:** In this study, we confirm an atrophy of particular cerebral regions correlated with the subtype of BPSD.

**Impacting quality of life and cognition in dementia patients through dance movements: Everyday waltzes**

L. Ng¹, G. Gabrielt², S. Hameed³, A. Liông⁴, S. Ting⁵, ¹Neurology, National Neuroscience Institute (SGH Campus), Singapore; ²Neurology, Singapore General Hospital, Singapore; ³Arts Fission Company, Singapore, Singapore

**Introduction:** Literature has shown that physical health deterioration parallels cognitive decline in dementia patients. However, programs for physical rehabilitation are few and mainly target specific motor skills. Using a creative dance movement program designed for the elderly demented, we hypothesize, firstly that, it will lead to improved physical skills and enhanced perceptions of quality of life, and secondly, it will lead to improvements in objective measures of cognitive skills.

**Method:** 10 subjects participated in the 6-sessions workshop based on inclusion criteria. They were diagnosed with dementia as per DSM IV criteria, had verified objective cognitive impairments, were mobile, and had no other health issues. Outcome measures were the Alzheimer Disease Quality of Life Inventory (ADQoL) and the Neuropsychiatric Inventory (NPI). These inventories were administered before the start of the program and on the day of the last session.

**Results:** In the ADQoL, we found significant difference between pre and post total quality of life score as rated by participants [t(9) = 2.849, p = .019]. There were no significant differences between pre and post ADQoL perceptions by caregivers. In the NPI, caregivers reported a general decrease in the frequency and the severity of inappropriate behaviors following the workshop but with only one significant finding in total frequency and severity scores [t(9) = 3.077, p = .013].

**Conclusion:** Everyday waltzes program helped improve physical skills which in turn led to perceptions of increased quality of life and improved behaviors.

**The ephA4-elicited signaling governs the stability of amyloid precursor protein fragment proteins through a Lyn-mediated pathway**

W.-B. Lai, B.-J. Wang, Y.-F. Liao. Institute of Cellular and Organismic Biology, Academia Sinica, Taipei, Taiwan R.O.C.

Alzheimer’s disease is the most common dementia afflicting the elderly in the modern society. This disease is a result of the neurotoxicity elicited by abnormal amyloid-β (Aβ) protein aggregates. Aβ is generated by the γ-secretase-catalyzed proteolysis of amyloid precursor protein (APP) C-terminal fragment (APP-CFF) that is released by the β-secretase cleavage of APP. Recent evidence suggests γ-secretase’s substrate β-CFF, and its metabolite APP intracellular domain (AICD) could exert harmful effects on cells, suggesting that the proteolytic products of APP, including Aβ, β-CFF, and AICD, could play a pivotal role in neuronal viability. Here, we demonstrated that ligand-activated EphA4 signaling could govern the proteostasis of β-CFF, AICD, and Aβ independent of γ-secretase activity. The inhibition of EphA4 by Dasatinib, a receptor tyrosine kinase inhibitor, effectively suppressed the EphA4-induced accumulation of β-CFF and AICD. This EphA4-elicited accumulation of β-CFF and AICD was mediated by a Lyn-dependent pathway whose activation could in turn phosphorylate EphA4 to constitute a positive feedback in governing the proteostasis of β-CFF and AICD. Furthermore, EphA4 signaling could regulate the ubiquitin-proteasome system to control the proteolysis of β-CFF and AICD. In conclusion, our data delineate an EphA4-Lyn pathway that is essential for the metabolism of APP and its proteolytic derivatives, providing novel pharmacological targets for the development of anti-Aβ therapeutics for AD.

The medical food Souvenaid improves memory performance and preserves functional connectivity in mild Alzheimer’s disease (AD)

P. Schelten1, C.J. Stam1, R. Shah2, D. Bennett1, R.L. Wiegge3, T. Hartmann1, D. H. Soininen, M.C.M. Olde Rikkert4, J.P. Kamphuis5, L. Sibbe6, 1Alzheimer Centre Nijmegen, Radboud University Nijmegen Medical Centre, Nijmegen, The Netherlands; 2Department of Clinical Neurophysiology, VU University Medical Center, Amsterdam, The Netherlands; 3Rush Alzheimer’s Disease Center, Rush University Medical Center, Chicago, IL, USA; 4Nutricia Advanced Medical Nutrition, Danone Research, Centre for Specialised Nutrition, Wageningen, The Netherlands; 5Deutsches Institut für Demenz Prävention (DIDP), Saarland University, Germany; 6Neurodegeneration and Neurobiology, Saarland University, Homborg/Saar, Germany; 7Experimental Neurology, Saarland University, Homborg/Saar, Germany; 8Department of Neurology, University of Eastern Finland, Kuopio University Hospital, Kuopio, Finland; 9Radboud Alzheimer Centre, Radboud University Nijmegen Medical Centre, The Netherlands; 8Department of Geriatric Medicine, Radboud University Nijmegen Medical Centre, Nijmegen, The Netherlands

Objective: Souvenaid®, containing the specific nutrient combination Fortasyn®Connect1, is designed to improve synapse formation and function in patients with Alzheimer’s disease (AD). The efficacy of Souvenaid is investigated in the clinical trial program.

Patients and methods: The program includes: 1)12-week Souvenir I RCT in drug-naïve mild AD patients; 2) 24-week S-Connect RCT in mild-to-moderate AD patients using AD medication; 3) 24-week Souvenir II RCT in drug-naïve mild AD patients; 4) 24-week Souvenir II open-label-extension (OLE) study; 5) 24-month LipiDiDiet RCT in prodromal AD; and 6) Mode of action studies: a) electroencephalography (EEG) and magnetoencephalography outcomes in Souvenir II; b) MRI and CSF measures in LipiDiDiet; c) magnetic resonance spectroscopy and d) FDG-PET.

Results: Souvenirs I and II showed that Souvenaid improved the primary outcome memory performance. The Souvenir II OLE showed a significant continued improvement of the memory outcome throughout 48 weeks. S-Connect did not show an effect on cognition in more moderate AD patients using AD medication. All studies showed that Souvenaid is well-tolerated, with a high compliance (≥85%). Electroencephalography (EEG) measures in Souvenir II assessed neuronal activity and thus indirectly synaptic activity. Significant EEG differences suggest that Souvenaid preserves functional connectivity and brain network organization, supporting the hypothesis of changed synaptic activity.

Conclusion: These results suggest that Souvenaid is most efficacious in early AD and warrant long-term trials in the early AD process.

Developing early functional neuromarkers for abnormal cognitive decline: Multimodal brain imaging approach in MCI

Y. Lerner1, G. Yogev-Seligmann1, T. Hendler2,3, A. Arsh4, N. Giladi2,3, 1Tel Aviv Sourasky Medical Center, Israel; 2Tel Aviv University, Tel Aviv, Israel

Introduction: The capacity to accumulate information over time is crucial to our functioning in an ever-changing world. As individuals age, the ability to store, process, and manipulate information drops. Recently, in young healthy subjects, we showed that brain uses a distributed and hierarchical network of brain areas to process information over time. Here we study information processing under deficient cognitive state – amnestic mild cognitive impairment (a-MCI).

Objectives: One of the most common characteristics of cognitive impairment is difficulty with comprehension. We intended to map, in a-MCI patients, the topographical organization of temporal scales using an ecologically relevant auditory stimulus — a real-life story. In addition, we assumed that studying healthy elders, who are at high-risk for cognitive dysfunctions, will enable to determine neuromarkers of predisposition to disorder. Moreover, since this control group is not symptomatic, results will allow us to discriminate between critical and non-critical differences between patients and controls.

Methods: The fMRI data were analyzed using inter-subject correlation approach. The time-courses within each brain area in patients were estimated against matched controls.

Results: Among healthy elders, we observed widespread sensitivity to the content of the story through PSTG, TIP, supramarginal gyrus, parietal lobule, precuneus, and prefrontal cortex. Among a-MCI patients, remarkably similar response reliability was found at the earliest stages
of processing (along STG up to Wernicke’s area) only. In higher-order areas, reliability of responses dramatically disrupted.

Conclusions: Findings pointed to a possibility that MCI may impact higher-order cortical regions, while regions involved in early processing remain unaffected.

Background: Cerebral Amyloid Angiopathy-related inflammation (CAA-ri) is a rare disease characterized by vasogenic edema and multiple cortical/subcortical microbleeds, sharing several aspects with the recently defined Amyloid-Related Imaging Abnormalities (ARIA) during Alzheimer’s disease (AD) passive immunization therapies.

Objective: We investigated the putative role of anti-Aß autoantibodies as the primary actor of the inflammatory reaction rising in these two conditions.

Methods: By a multicenter case–control study in 80 subjects, using a novel ultra-sensitive technique (patent application pending), we evaluated the anti-Aß autoantibodies concentration in the CSF of CAA-ri, CAA, AD, MS and healthy-control subjects. Levels of circulating Aß1-40, Aß1-42, tau, P-181 tau and APOE4 genotype were also investigated.

Results: We confirmed a direct involvement of anti-Aß autoantibodies during the course of CAA-ri, demonstrating that their concentration is specifically increased during the acute phase and progressively reduced with clinical and radiological remission. Moreover, a strong correlation with the increased mobilization of cAß1-40 and cAß1-42 during the acute phase was shown, followed by their return to control levels and reduced tau and P-181 tau after remission.

Conclusions: Our data strongly support the hypothesis that the pathogenesis of CAA-ri is mediated by a selective autoimmune reaction against cerebro-vascular Aß, directly related to autoantibody concentration and cAß1-42 overloading. Given the similarities between spontaneous ARIA which develops in CAA-ri and that induced through immunization strategies, anti-Aß autoantibodies in the CSF may be proposed as a valid alternative for the diagnosis of CAA-ri and as a novel biomarker to monitor ARIA during the ongoing amyloid-modifying therapies for AD.

Clinical and neuroimaging profile of probable Creutzfeldt Jakob disease; case series of four patients

R. Verma, M. Gupta, R.K. Garg. Neurology, King George Medical University, Lucknow, India

Background: Creutzfeldt Jakob disease is a rare neurodegenerative disorder, a spongiform transmissible encephalopathy characterized by rapidly progressive dementia, myoclonus, ataxia, pyramidal, extrapyramidal and visual abnormalities. It is universally fatal with almost hundred percent mortality. Creutzfeldt-Jakob disease (CJD) is one of the subtypes of prion diseases, classified as hereditary, infectious and sporadic disorders.

Objective: In recent past, the role of diffusion weighted imaging has been established in Sporadic Creutzfeldt Jakob disease due to presence of characteristic findings of cortical ribboning and hyperintense basal ganglia structures. Our objective is to highlight the clinical description and magnetic resonance findings of 4 patients diagnosed as Sporadic Creutzfeldt Jakob disease.

Patients and methods/material and methods: The clinical details and neuroimaging features of four patients diagnosed as Sporadic Creutzfeldt Jakob disease were described, admitted consecutively in tertiary center of North India in span of one year.

Results: Our 3 patients were female and one was male. The age ranged from 42–65 years (mean 55.5 years). Electroencephalography of all patients showed periodic spike and wave complexes. The neuroimaging findings were cortical ribboning of grey mantle and hyperintense signals of basal ganglia structures. All patients succumbed to illness within a year from onset of illness.

Conclusion: Creutzfeldt Jakob disease is an underdiagnosed, fatal neurodegenerative disorder. The awareness of CJD among physicians is essential to differentiate from other causes of treatable dementias. The magnetic resonance imaging should be used as an additive tool for diagnosis of Creutzfeldt Jakob disease.

Cognitive changes in idiopathic normal pressure hydrocephalus

M. Kanai1, K. Ishiguro2, N. Sasakiuchi. 1Neurology, NHO Takasaki General Hospital, Takasaki, Japan; 2Neurosurgery, NHO Takasaki General Hospital, Takasaki, Japan

Background: Idiopathic normal pressure hydrocephalus (iNPH) is a syndrome that is characterized by cognitive decline, gait disturbance and impairment in bladder control (Adam’s triad), and is associated with ventriculomegaly in the absence of elevated cerebrospinal fluid (CSF) pressure.

Objective: Diagnosis can be challenging due to its varied presentation and overlap with other disorders common in the elderly. The neuropsychological characteristics of iNPH have been much debated during recent years. This study investigates the neuropsychological features in patients with iNPH.

Methods: On the basis of Clinical Guidelines for idiopathic Normal Pressure Hydrocephalus, 8 participants were diagnosed with definite INPH. We examined the scores of the Frontal Assessment Battery (FAB), Behavioural Assessment of the Dysexecutive Syndrome (BADS) and the Mini-Mental State Examination (MMSE). Patients with iNPH were assessed before and six months after shunt operation. The cerebral blood flow (CBF) was measured by N-isopropyl-123-I-ido-amphetamine
single photon emission computed tomography, and the perfusion patterns of the cerebral cortex were measured based on three-dimensional stereotactic surface projection (3D-SSP) Z-score images.

**Results:** The score of FAB improved better than that of MMSE. Three patients showed significant improvement in BADS test. These changes were shown to be sensitive to damage to the frontal function. 3D-SSP analyses of SPECT images revealed that regional CBF in prefrontal cortex and Sylvian fissure decreased in patients.

**Conclusions:** Damages of periventricular structures, such as frontal subcortical and cortical areas, are closely connected with impairments of iNPH. We suggest that the frontal dysfunction should be used in the evaluations of iNPH.

**Are the cortical cerebral microbleeds (CMB) present in dementia with Lewy bodies?**

T. Makotrova, A. Arablinskiy, O. Levin. Russian Medical Academy for Post-Graduate Education, Moscow, Russia

**Objective:** To identify the location and number of CMB in dementia with Lewy bodies (DLB) and to estimate the influence CMB on cognitive decline in DLB.

**Patients and methods:** We examined 33 patients with DLB [(mean age 73.5 years, 20 (67%) males) and 51 patients with Alzheimer's disease (AD) with cognitive decline. MRI was performed by 1.5 T MR tomography. CMB were estimated in T2GRE. Patients with DLB (16 (48%)) had hyperintensity in T2 reflecting vascular leukoencephalopathy which was estimated by the Fazekas scale. Neuropsychological testing was carried out by Montreal Cognitive Assessment scale (MoCa), Addenbrooke's Cognitive Examination (ACE-R), Clock Drawing Test, verbal fluency test, and visual memory test (SCT).

**Results:** CMB in DLB were found in 13 (39%) patients. The total number of CMB were 70, 40 (57%) — subcortical. Patients with cortical CMB had less memory score (3 ± 2) by ACE than patients with deep CMB. Deep CMB were found in 10 cases with severe vascular leukoencephalopathy. Most cortical CMB were observed in AD — 340 (96%). Patients with AD and CMB had significantly lower score of ACE-R (less than 3.7) than in DBL (p < 0.01). Significant differences in MoCa had been not detected.

**Conclusion:** We have not found cortical CMB in patients with DLB by MRI 1.5 T. The absence of cortical CMB in patients with DLB might be the additional criteria of diagnosis DLB. This observation allows to propose the presence of cortical CMB in patients with clinically diagnosed DLB to point out to the coexistence DLB with AD.

**The diagnostic utility of 99mTc-HMPAO SPECT imaging in early onset dementia: A retrospective audit from a regional cognitive disorders clinic**

Y.S. Nie, J.M. Yeo, A. Swan, G. Holloway, Z. Khan, S. Pal. Department of Clinical Neurosciences, Western General Hospital, UK; College of Medicine and Veterinary Medicine, University of Edinburgh, UK; Department of Old Age Psychiatry, Royal Edinburgh Hospital, UK; Anne Rowling Regenerative Neurology Clinic, University of Edinburgh, UK; Department of Nuclear Medicine, Western General Hospital, NHS Forth Valley, Larbert, UK

**Background:** Single photon emission computed tomography (SPECT) using the radiopharmaceutical agent $^{99m}$Tc-hexamethypropyleneamine ($^{99m}$Tc-HMPAO) provides whole brain perfusion imaging which is of potential diagnostic utility in the diagnosis of dementia.

**Objective:** A retrospective audit was conducted to determine the utility of HMPAO SPECT in a cohort of patients presenting to a tertiary centre early onset cognitive disorders clinic.

**Patients and methods:** 42 patients (23 males, mean age 59.6 y, range 37–80 y) reviewed over 1 year were studied. All were assessed clinically by a neurologist and a psychiatrist SPECT imaging was interpreted visually by a nuclear medicine specialist. Clinical diagnoses, Addenbrooke's Cognitive Assessment Revised (ACE-R) scores, SPECT, MRI and EEG findings were evaluated.

**Results:** 41 patients fulfilled clinical criteria for a dementia syndrome (mean ACE-R score 69/100). Clinical diagnoses included: Alzheimer's disease n = 21, posterior cortical atrophy n = 4, primary progressive aphasia n = 4, behavioural variant frontotemporal dementia n = 3, epilepsy n = 1, HIV n = 1, mixed dementia n = 2, and unclear aetiology n = 6. 78% of HMPAO SPECT scans (n = 32) that demonstrated regional blood flow abnormalities indicative of a dementia. 51% (n = 21) further differentiated between anterior and posterior dementia syndromes. In comparison, MRI imaging detected abnormalities (vascular change, global/regional atrophy) in 46% (n = 20), and EEG (generalised slowing) in 14%.

**Conclusion:** Evaluation of regional blood flow abnormalities identified by HMPAO SPECT imaging appears a useful adjunct in evaluating patients with early onset cognitive impairment with favourable diagnostic sensitivity compared with other investigations. Quantitative methods of image analysis may enhance sensitivity, further aiding accurate diagnosis in this very challenging cohort.

**A.C.E.S.I.D.E. group: Taking care of those who take care**

L.F. Malimpensa, E. Maina, L. Dosio, G. Mercadante, S. Cabodi, A. Cotroneo. Geriatric, ASL TO 2, Turin, Italy

The A.C.E.S.I.D.E. group aims to provide psychological support to caregivers of patients with dementia. The purposes of the A.C.E.S.I.D.E. group are many: give caregivers a space in which they can think to themselves and deal with issues related to anxiety and mood disorders that may be a consequence of their caring tasks, and to find coping strategies in comparison with professionals and with other people in the same situation. We also want to inform the participants of what it means to be suffering from dementia illustrating the main symptoms and also inform them on key local services that constitute a rich resource. Participants are caregivers of dementia patients. Participation is voluntary, although it still requires continuity. The group consists of a number of participants, from 8 to 12. The meetings are 6 and their frequency is fortnightly. After the first meeting devoted to the project description and presentation of conductors and participants, subsequent meetings are devoted to the illustration of the main concepts related to dementia and the management of anxiety and stress, as well as of mood problems, which may occur in everyday life of the caregiver. In the first part of each meeting, nurses inform participants about local services and how to get more aid and economic assistance. Participants say they are always very satisfied and feel “privileged” to have the opportunity to attend a support
group. Generally there is a decrease in anxiety and activation of better strategies to combat stress.

Cardiovascular autonomic function in frontotemporal dementia, behavioral variant (FTDbv)
W. Struhal, G. Ransmayr. Autonomic Unit, Department for Neurology, General Hospital of the City of Linz (AKH Linz), Linz, Austria

Background: Patients with autonomic failure experience postural dizziness, syncope, and falls. Identifying symptomatic dysautonomia in dementia is of importance to ensure appropriate management and reduce risk of falls.

Objective: The aim of this prospective study is to identify autonomic dysfunction in patients suffering FTDbv.

Methods: Patients were recruited from the Department for Neurology, General Hospital, City of Linz. Clinical autonomic function tests were carried out according to Ewing's battery. Parasympathetic tests included resting heart rate variability, deep breathing (E/I ratio), and Valsalva ratio. Sympathetic function tests included blood pressure regulation on Valsalva, cutaneous cold stimulation, arithmetic exercise and 70° head-up tilt.

Results: History taking was often insufficient and could not replace autonomic testing.

One of 23 recruited patients had to be excluded due to atrial fibrillation. Mean age of 22 FTDbv patients was 66 ± 12 years, female/male: 13/9. In 8 patients (36%) autonomic dysfunction was demonstrated; 8 patients with sympathetic dysfunction of those 6 patients (27%) had manifest orthostatic hypotension (two related to medication). 4 had a parasympathetic dysfunction, in only one patient related to medication (beta blocker).

One patient suffered vasovagal syncope during tilt.

Conclusion: This is to our knowledge the first prospective study to elucidate autonomic dysfunction in FTDbv patients. Autonomic dysfunction is not uncommon and is present in about 1/3 of this cohort. Diligent history taking is of major importance in patients suffering autonomic symptoms; however in FTDbv patients, history taking is insufficient. Autonomic dysfunction may therefore be concealed if patients are not tested employing autonomic function tests.

Depression in dementia: Results from an ongoing dementia registry in Pakistan
F. Rao, M. Siddiqui, A. Ahmed. Neurology, Division of Neurology, Shifa International Hospital, Shifa Tameer-e-Millat University, Islamabad, Pakistan

Background: With increasing life expectancy in Pakistan, dementia is becoming a growing public health concern. Depression is the most frequent psychiatric co-morbidity in dementia.

Objectives: To assess depression in dementia patients and identify the correlation between the Mini Mental State Examination (MMSE) scores and the Beck's Depression Inventory (BDI) scores in a tertiary care hospital in Pakistan.

Methodology: Out of 230 patients enrolled in our dementia registry, 92 were excluded because of MMSE scores ≥26 and 4 due to incomplete data, making the final sample of 134. A BDI score ≥17 was taken as clinical depression. SPSS v.16 was used for final analysis.

Results: Male to female ratio was equal. Mean age was 70.1 ± 9.6 years. 21.7% were uneducated. 73.9% were married. The majority lived with their spouse and children (46.4%) or in joint families (39.1%). Mean MMSE score was 16.5 ± 6.3. 44.7% had moderate, 32.8% mild while 22.3% had severe impairment. Mean BDI score was 12.7 ± 9.2. 29.1% had clinical depression. Out of these patients, 46.2% had moderate, 35.8% borderline and 17.9% severe depression; no case of extreme depression was observed. MMSE and BDI scores were significantly correlated showing that patients with higher MMSE scores had lower BDI scores.

Conclusion: Minority of our dementia patients had depression. This could be due to family support systems available for the majority of these patients. But with deterioration in the MMSE scores, risk of developing clinical depression increases hence dementia patients should have periodic evaluation for depression.

Association between orthostatic hypotension and mild cognitive impairment in the patients with benign prostate hypertrophy
H.-K. Parka, J.-H. Rhaa, S.-B. Koa. aNeurology, Incheon, Republic of Korea; bInha University Hospital, Incheon, Republic of Korea; cNeurology, Seoul National University Hospital, Seoul, Republic of Korea

Background: Some reports suggested that orthostatic hypotension (OH) might be associated with the mild cognitive impairment (MCI). However, the prevalence of OH and MCI in the patient with benign prostate hypertrophy (BPH) has not been clearly demonstrated. We investigated the prevalence of OH and MCI in the patients with BPH and also analyzed the association between OH and MCI.

Methods: From April 2011, we recruited BPH patients who were ≥65 years old, and had taken alpha-blocker more than one year. Patients with previous history of OH, stroke, or dementia were excluded. All patients took the head-up tilt table test and the neuropsychological test.

Result: Until July 2012, 43 patients (age 69.6 ± 7.5 years) were finally enrolled to this study. Among them, 26 subjects (60.5%) had OH. The prevalence of MCI was 41.9% on MMSE and 67.4% on MoCA. There was no difference in the prevalence of MCI between OH group and control (On MMSE, 42.3% vs. 41.2%, P = 0.94; On MOCA, 65.4% vs. 70.6%, P = 0.72). The patients with OH had lower body mass index (BMI) than the control group (23.6 ± 2.6 vs. 27.2 ± 6.8, P = 0.04). In the patients ≥70 years old, MMSE score was associated with BMI (P = 0.041) and systolic blood pressure (P = 0.03).

Conclusions: Prevalence of MCI and OH was high in the patients taking alpha blocker for BPH. OH did not seem to be associated with MCI.

Variety of clinical symptoms of logopenic progressive aphasia in Japanese patients
M. Otsukia, Y. Nakagawab, A. Ogataa, K. Makinoc, T. Fukushimaa, T. Kuwabarac, aGraduate School of Health Sciences, Hokkaido University,
Background: Logopoeic progressive aphasia (LPA) is one of the entities of primary progressive aphasia. It was recently established and is not yet sufficiently evidenced.

Objective: The objective of this study is to elucidate the implication of the symptoms, lesions and prognosis in Japanese patients with LPA.

Patients and methods: We investigated four Japanese patients fulfilling the criteria for diagnosis of LPA (Gorno-Tempini et al. 2011) with detailed neuropsychological examinations, MR images, and 3D-SSP analysis of 123I IMP SPECT imagings (SPECT) for 4 to 7 years from the onset of aphasia.

Results: The patients were divided into two sub-groups: the parietal type and the temporal type. The patient of parietal type manifests prominent phonemic paraphasia, with relatively spared word finding ability, and also showed left parietal focal signs such as acalcula, constructional impairment and so on. The MRI and the SPECT findings showed the main lesion in the left parietal lobe, especially in the supramarginal gyrus. The patients of temporal type developed word finding difficulty with some phonemic paraphasia, word deafness due to the lesion in the posterior part of superior temporal gyrus. They also showed impairment of verbal short-term memory heralded by or concomitant with phonemic impairments. The MRI and the SPECT findings suggested the main lesion in the posterior part of the left temporal lobe.

Conclusion: LPA could be divided into two subtypes: the parietal type and the temporal type, which might be informative to know the prognosis and mechanism of the symptoms of the patients with LPA.

Background and purpose: Idiopathic normal pressure hydrocephalus (iNPH) has long been known as one of the causes of treatable dementia. Cerebrospinal fluid (CSF) shunt surgery is the only therapeutic modality for iNPH. As for the types of shunt surgery, ventriculo-peritoneal shunt (VP shunt) is prevailing and ventriculo-atrial shunt (VA shunt) is almost abandoned. However, VA shunt has many advantages. We have performed 466 VA shunts for normal pressure hydrocephalus since April, 2004. Among these patients, there were 393 patients with iNPH. The purpose of this paper is to show the outcome of VA shunt for iNPH.

Method: The 393 candidates for VA shunt were CSF tap test responders over 50 years old. The outcome was evaluated 3 months after the surgery depending on five categories; Excellent (improvement of modified Rankin Scale or improvement of mini-mental state examination over 3, or cease of urinary incontinence), Good (no improvement of mRS but decreased caregiver's burden or increased patient's activity), Fair (no or very slight improvement), Poor (worsen after VA shunt), or Dead (death within 1 month after VA shunt).

Results: Mean age was 78.1 years old and mean operation time was 36.6 min. There was no shunt infection. The outcome was as follows; Excellent (58.3%), Good (21.6%), Fair (16.5%), Poor (1.8%), Dead (0.5%), and Unknown (0.8%).

Conclusion: Despite the old age of the patients, the mortality rate was quite low and the shunt infection was zero. Our results suggest that VA shunt can be the first choice for iNPH.

Evolution of symptoms and signs over 6-months in subjects with possible dementia by Lewy bodies following DaTSCAN™ SPECT imaging

Z. Walker, A. Thomas, N. Tabet, T. Stevens, E. Moreno, G. Pizzolato, M.J. Moreno-Carretero, M.D. Martinez-Lozano, DaTSCAN DLB Study Group, 1Mental Health Sciences Unit, University College London, London, UK; 2North Essex Partnership NHS Foundation Trust, Epping, Australia; *Institute for Ageing and Health, Newcastle University, Newcastle Upon Tyne, UK; 4Brighton and Sussex Medical School, University of Brighton, Brighton, UK; 5Mental Health Unit, St. Margaret's Hospital, Epping, UK; 6Medical Affairs, GE Healthcare, Madrid, Spain; 7Department of Medical Sciences, University of Trieste, Trieste, Italy; 8Hospital do Meixoeiro, Vigo, Spain; 9Unidad de Demencia, Hospital de la Magdalena, Castellon, Spain

Background: The diagnosis of patients with dementia with Lewy bodies (DLB), can be clinically challenging, particularly with possible-DLB. In clinical practice, generally the diagnosis becomes clearer over time with the progression of symptoms and signs.

Objective: To compare baseline and 6-months follow-up clinical data of a cohort of possible DLB patients collected for a dopamine transporter SPECT imaging study.

Methods: One hundred and eighty seven patients with possible DLB (dementia + one core or one or more suggestive features excluding DaTSCAN™) were randomized to have a DaTSCAN™ or to follow-up clinical care without DaTSCAN™. Diagnosis, DLB features and a comprehensive neuropsychiatric battery (Fluctuation scale, ACE-R, MMSE, NPI, UPDRS-III) were compared at baseline and 6 months.

Results: Overall prevalence of DLB features was similar between the two study groups. At 6-months follow-up diagnostic category changed to non-DLB (26%) or probable DLB (26%). However, changes were more frequent in the DaTSCAN™ than in the control group (71% vs 16% p < 0.0001), particularly in those with abnormal images (87%). Parkinsonism at baseline was more prevalent in probable DLB and was the only feature that evolved at 6-months follow-up (42% to 61%), UPDRS-III changes were in the same direction. There were no differences between the groups with regard to other clinical features at baseline and/or at 6 months.

Conclusion: In subjects with possible DLB the clinical evolution over 6-months without DaTSCAN™ did not impact the diagnosis. The DaTSCAN™ results in combination with other core and suggestive features contributed significantly to the diagnosis.

Topic: 5 — Dementia
In Alzheimer’s disease sleep impairment is correlated with cognitive decline, increased tau and decreased beta-amyloid CSF levels

Background: AD is primarily characterized by cognitive decline, but nocturnal sleep disturbances are also features of the disease and seem to be related to dementia severity.

Objective: To correlate in preclinical AD patients the objective macrostructural sleep parameters with MMSE and CSF biomarkers (tau and phosphorylated-tau proteins, beta-amyloid1–42).

Patients and methods: Thirty-seven unselected patients affected by preclinical AD underwent MMSE, a 24-hour ambulatory polysomnography to evaluate the sleep-wake rhythm, lumbar puncture for the assay of CSF biomarker levels. Patients with sleep-disordered breathing were excluded from the study. The sleep macrostructural analysis was performed according to Rechtshaffen–Kales’ criteria.

Results: In our AD patients, the increment of CSF tau levels correlated:

i) positively with the NREM stage 1 sleep (p < 0.05) and the wakefulness after sleep onset (WASO) (p < 0.01);

ii) negatively with sleep efficiency (SE) (p < 0.01) and REM sleep (p < 0.05). Moreover, the decrement of the CSF beta-amyloid1–42 levels correlated with the decrement of REM sleep (p < 0.05) and the increment of the WASO (p < 0.05).

Finally, MMSE appeared statistically related to: i) the decrease of the SE (p = 0.001); ii) the decrement of the NREM stage 3 sleep (p < 0.01); iii) the reduction of the REM sleep (p < 0.01); and iv) the increment of the WASO (p < 0.001).

Conclusion: In AD patients higher tau and lower beta-amyloid1–42 CSF levels are correlated with the impairment of sleep quality and continuity. Finally, our results suggest that in AD patients the cognitive decline is strictly related to the sleep dysregulation.

Cognitive assessment of adults with Down syndrome
A. Silvestre1, R. Mendes2, R. Bispo3, M.J. Gonçalves4, M.J. Figueira5, P. Breia6. 1Hospital Garcia de Orta EPE, Almada, Portugal; 2ISP — Instituto Universitário, Lisbon, Portugal; 3Cercizimbra, Sesimbra, Portugal

Background: Cognitive deterioration, mood and behavioural changes suggest early dementia and are frequently observed in adults with Down syndrome (DS).

Objective: The aim of this study is to identify early signs of dementia in a Portuguese sample of adults with DS.

Patients and methods: Sixteen patients with DS, 25 to 50 years old, without treatable causes of dementia, were assessed at the beginning of the study (T1) and 12 months later (T2) using the Plymouth Dementia Screening Checklist (PDSC), Global Deterioration Scale (GDS), Mini-Mental State Examination (MMSE) and Dementia Questionnaire for People with Learning Disabilities (DLD). The data were statistically analysed.

Results: Most participants had low MMSE values, with no significant differences between T1 and T2. In T1, 2 individuals punctuated above the cut-off point on PDSC, particularly in memory and behaviour complaints. One individual was in stage 3 of GDS (mild cognitive decline) and had a low performance in cognitive and social domains of DLD. At follow-up, 7 participants had warning signs in PDSC, being memory the most compromised skill. Six of them had cognitive deterioration in GDS and altered long-term memory, behaviour, mood, activity and interest as measured by DLD. MMSE values were significantly related to these domains in T1 and T2.

Conclusion: Behaviour, mood and particularly memory should be assessed in DS when dementia onset is considered. PDSC was a useful instrument to predict dementia, further confirmed by GDS and DLD. MMSE identified cognitive deterioration signs in this sample and showed possible interference of mood and initiative.

Network analysis of intrinsic functional connectivity in the semantic variant of primary progressive aphasia
M. Filippi1,2, A. Falini1, A. Reali3, S. Galantucci1,4, S. Sala5,6, P. Valsasina3, A. Meani7,8, E. Canu7, F. Caso7, S.F. Cappa6, G. Magiati9, M. Franceschi6, A. Falini1, G. Comi10. 1Neuroimaging Research Unit, Institute of Experimental Neurology, Italy; 2Department of Neurology, San Raffaele Scientific Institute, Vita-Salute San Raffaele University, Italy; 3Department of Statistics, University of Milano-Bicocca, Italy; 4Department of Clinical Neurosciences, San Raffaele Scientific Institute, Vita-Salute San Raffaele University, Milan, Italy; 5Department of Neurology, IRCCS Multimedica, Castellanza, Italy; 6Department of Neuroradiology, San Raffaele Scientific Institute, Vita-Salute San Raffaele University, Milan, Italy

Background: The semantic variant (SV) of primary progressive aphasia is associated with focal, asymmetric, temporal lobe degeneration. However, language abilities must arise from the activity of distributed neural networks. Graph theoretical analysis allows examining the topology of complex network systems.

Objective: To examine the integrity of the functional brain connectome in SV.

Methods: Graph theoretical analysis was applied to resting state functional MRI data from 14 SV and 50 matched controls. Functional connectivity between 90 cortical and subcortical brain regions was estimated using bivariate correlation analysis and thresholded to construct a set of undirected graphs.

Results: Functional brain networks in SV did not show loss of small world properties, but were characterized by lower clustering coefficient, global efficiency and nodal degree, longer characteristic path length and higher assortativity compared with controls. SV did not show brain hubs in right superior frontal, inferior orbitofrontal, lingual gyri and cuneus, and in left anterior cingulate cortex and inferior temporal gyrus. Left precentral gyrus, supplementary motor area, bilateral middle frontal gyrus and thalamus were hubs only in SV. SV showed decreased nodal degree in left frontotemporal regions and right parahippocampal and middle occipital gyrus.

Conclusions: SV functional networks are characterized by an imbalanced structure, with a loss of efficiency in information exchange between both close and distant brain areas. Local functional network organization is altered in SV. Focal degeneration of “classic” (temporal) language regions in SV may ultimately manifest in widespread connectivity disturbances elsewhere in the brain.

Inherited prion disease due to 5-octapeptide repeat insertion
K. McKnight1, B. Herron2, J. Turkington1, S. Haffey3, S. Mead4, P. McMonagle1, J. McConville1. 1Neurology, Craigavon Area Hospital, Omagh, Northern Ireland; 2Department of Clinical Neurosciences, University of Edinburgh, Edinburgh, United Kingdom; 3Department of Medicine, University of Cambridge, Cambridge, United Kingdom; 4Department of Molecular Biology, University of Edinburgh, Edinburgh, United Kingdom

Background: Prion diseases can be inherited due to sequence expansions in the PRNP gene, which encode the prion protein PrP. The major pathological hallmark of human prion diseases is the presence of PrPSc with the PrPSc isoform composed of oligomers of PrPSc. The prion protein consists of a Series of 58 amino acids, followed by an octapeptide repeat insertion (5-ORI).

Objective: To characterize the clinical and pathological manifestations of a patient with inherited prion disease due to 5-ORI.

Methods: Neurological examination, magnetic resonance imaging, and histopathological and immunohistochemical analysis of brain tissue.

Results: A 35-year-old woman presented with progressive cognitive decline, syncope, and ataxia. Neuroimaging showed atrophy and hypometabolism of the parietotemporal lobe and posterior cingulate gyrus. Brain biopsy revealed amyloid plaques and neurofibrillary tangles, consistent with the diagnosis of non-PrPSc prion disease. The patient was treated with 5-fluorouracil for 3 months, but her condition deteriorated rapidly and she died 6 months later.

Conclusions: This case highlights the importance of considering inherited prion disease in patients with cognitive decline and ataxia, especially when PrPSc is not detected. Early diagnosis and treatment may improve outcomes.

doi:10.1016/j.jns.2013.07.1239
Background: Prion diseases are fatal neurodegenerative conditions which have sporadic, acquired or inherited aetiologies. All inherited cases have coding mutations in the prion protein gene (PRNP) — either point mutations or octapeptide repeat insertion mutations causing variable numbers of an octapeptide repeat element in the N-terminal repeat region.

Case history: A 56 year-old man was admitted to hospital following a fall. He had had symptoms for a minimum of six years which met standard criteria for the behavioural variant of frontotemporal dementia. There was a sub-acute decline in his condition during the admission and he became bedbound, incontinent and mute with marked myoclonus and limb rigidity. He died four months after admission. There is a family history of dementia.

Results: MRI brain showed generalised cerebral atrophy but no focal abnormality. Lumbar puncture constituents were normal. An initial EEG showed encephalopathy but a repeat had persistent generalised sharp waves at 2 Hz. Genetic testing revealed a five octapeptide insertion in the PRNP gene. Postmortem examination confirmed prion disease.

Conclusion: This case demonstrates that inherited prion disease can present with a long history consistent with frontotemporal dementia. The insertion mutation found in this case is identical to a previously reported case from Northern Ireland who presented with a very different phenotype and almost certainly these two cases are related.

Combining SPECT and EEG analysis for assessment of disorders with amnestic symptoms to enhance accuracy in early diagnostics

Univ. Clinic for Neurology, Paracelsus Private Medical University, Austria; 
Rehabilitation Center of the PV Großgmain, Salzburg, Austria

Objectives: Comparative evaluation of regional brain perfusion measured by HMPAO-SPECT and quantitative Electroencephalography (EEG) analysis of persons with subjective cognitive complaints with (SCC+) and without (SCC−) minimal cognitive dysfunction, with amnestic mild cognitive impairment (aMCI) and such with Alzheimer’s disease (AD).

Methods: A total of 662 patients were investigated because of suspected cognitive dysfunction. After exclusion of patients with other forms of dementia than DAT or relevant accompanying disorders, SPECT and EEG data from 31 SCC−, 50 SCC+, 99 aMCI, and 72 DAT (together 252) were analyzed. Relative cerebral blood flow of 34 anatomical regions was assessed with automated analysis software (BRASS). Besides SPECT, each patient has also undergone EEG, which was neither statistically evaluated on a group level, nor quantitatively assessed or correlated with the SPECT-results.

Results: The database is now completed and the comparative evaluation is ongoing the next 3 months. Therefore results will be demonstrated at the WCN 2013 congress.

Conclusion: The present project aims at assessing the diagnostic validity of new biomarkers by quantifying and combining SPECT- and EEG-data. The implementation of these methods in clinical practice could improve accuracy of early diagnosis in disorders with amnestic symptoms.

1716F APP mutation associated with Alzheimer’s and diffuse Lewy body disease

Department of Neurology, Medical University of Vienna, Vienna, Austria; 
Institute of Neurology, Medical University of Vienna, Vienna, Austria

Background: Neurodegenerative diseases (NDDs) are characterised by progressive loss of neurons and deposition of proteins in the brain. Mutations causing familial Alzheimer’s disease (FAD) have been mainly described in three genes: amyloid precursor protein (APP), presenilin 1 (PSEN1) and presenilin 2 (PSEN2).

Objectives: To present clinical, neuroradiological, neuropathological, and genetic data on a patient with early-onset dementia.

Methods: Clinical follow-up, cranial MRI, neuropathology, including immunohistochemistry for phospho-tau, alpha-synuclein, prion protein, amyloid-beta, and phospho-TDP-43. Genetic analysis of the APP, PSEN1 and 2, and PRNP genes.

Results: A 45-year-old man presented with psychiatric symptoms and later motor symptoms with myoclonus and tetrapsasticity, followed by progressive dementia and terminally an apallic syndrome with epileptic seizures. The clinical course was 10 years. Similar symptoms were reported in the patient’s brother. Neuropathological evaluation revealed neuronal loss predominating in the frontal and temporal cortices, basal ganglia, thalamus, and hippocampus. Tau-pathology comprised neurofibrillary degeneration corresponding to stage VI according to Braak and Braak. Alpha-synuclein-pathology consisting of Lewy-bodies and Lewy-neurites corresponded to Braak stage VI and met the criteria for the neocortical stage of dementia with Lewy bodies. Severe amyloid-b angiopathy and numerous amyloid-b plaques were seen throughout the cerebrum and cerebellum. Genetic analysis revealed an 1716F mutation in the APP gene.

Conclusions: Similarly to sporadic NDDs, early onset dementias with a genetic background may be associated with multiple proteinopathies and complex clinical presentations. This study was performed in the frame of the MWW-early-onset-dementia Consortium and was supported by the European Commission’s 7th Framework Programme “DEVELAGE”.

The role of neuroprotein in schizophrenia pathogenesis

R. Zakharova, A. Boyajyan. Institute of Molecular Biology, Yerevan, Armenia

Background: Schizophrenia (SCZ) is a psychiatric disorder with both altered neurodevelopmental and genetic components. Despite several studies performed, the SCZ etiology is still unclear. Altered blood and mRNA expression levels of brain-derived neurotrophic factor (BDNF), promoting synaptic transmission and neural plasticity, in the brain of SCZ patients and genetic analysis suggest contribution of BDNF to disease pathogenesis.
Objective: To clarify the role of the BDNF in SCZ, protein levels and polymorphism in SCZ-aFFECTED and healthy subjects were evaluated.

Patients and methods: In this study, the BDNF blood levels in chronic patients with paranoid SCZ treated with antipsychotics, antipsychotic-naïve patients, and controls were evaluated by ELISA.

Results: Comparative analysis showed a 1.45-fold decreased BDNF levels in SCZ when compared to controls (p = 2.27E−23). Also, there was a significant difference in levels of BDNF between antipsychotic-naïve patients and controls (p = 8.2E−07), whereas treated patients were not differed from antipsychotic-naïve (p > 0.05). With regard to gender, reduced BDNF levels in females compared to males both in patients (p = 0.0018) and controls (p = 0.019) were found. We compared the BDNF levels with regard to the Val66Met genotypes in SCZ patients and controls based upon our previous data. Relevant intragroup analysis showed increased BDNF levels in 66Met allele carriers when compared to Val/Val both in SCZ (p = 0.0003) and controls (p = 4.22E−05).

Conclusion: To summarize, the results obtained suggest that decreased BDNF levels associate with 66Met allele carriers and might be involved in the pathogenesis of SCZ in Armenian population. All authors declare that they read and are aware of the content of abstract.

Predictors of response to the 13.3 and 9.5 mg/24 h rivastigmine patch: The optimizing transdermal exelon in mild-to-moderate Alzheimer’s disease (optima) study

J. L. Molinuevo1, G. Grossberg1, L. Frölich2, J. Galvin1, T. Krahnke2, C. Strohmaier2, 1Alzheimer’s Disease and other Cognitive Disorders Unit, Neurology Service, ICN Hospital Clinic i Universitari, Barcelona, Spain; 2Department of Neurology and Psychiatry, St Louis University School of Medicine, St Louis, MO, USA; 3Department of Geriatric Psychiatry, Central Institute of Mental Health, Medical Faculty Mannheim, University of Heidelberg, Heidelberg, Germany; 4Center of Excellence on Brain Aging, New York University Langone Medical Center, New York, NY, USA; 5Novartis Pharma AG, Basel, Switzerland

Background: The OPTIMA study (NCT00506415) demonstrated reduced deterioration with 13.3 versus 9.5 mg/24 h rivastigmine patch in patients with Alzheimer’s disease (AD). Treatment response can vary according to patients' individual characteristics. We conducted a responder analysis to identify the proportion of patients demonstrating a treatment response to each dose, and patient characteristics predictive of achieving a response.

Methods: Details of OPTIMA are published (Cummings et al., 2012). Patients meeting pre-specified decline criteria during treatment with 9.5 mg/24 h patch, entered a 48-week, double-blind (DB) phase, and were randomized to 13.3 or 9.5 mg/24 h. ADAS-cog and ADCS-IADL were co-primary endpoints. In this post-hoc analysis, the following criteria for achieving a treatment response at weeks 24 and 48 were applied: ≥4 points' improvement on ADAS-cog, and ≥4 points' improvement on ADAS-cog combined with no decline on ADCS-IADL.

Results: Demographics and baseline scores were comparable between patient groups (13.3 mg/24 h, N = 265; 9.5 mg/24 h, N = 271). At week 24, 25 versus 14% (p = 0.001) of patients receiving 13.3 and 9.5 mg/24 h patch, respectively, demonstrated ≥4 points' improvement on ADAS-cog, and 17 versus 7% (p < 0.001) demonstrated ≥4 points' improvement on ADAS-cog and no decline on ADCS-IADL. Of patients receiving 13.3 and 9.5 mg/24 h patch, respectively, at Week 48, 16% and 10% (p = 0.020) displayed ≥4 points' improvement on ADAS-cog, and 8% versus 4% (p = 0.023) demonstrated ≥4 points' improvement on ADAS-cog and no decline on ADCS-IADL.

Conclusion: Titration of patients with mild-to-moderate AD to the high-dose (13.3 mg/24 h) rivastigmine patch (15 cm²) increases the likelihood of achieving a clinically-meaningful treatment response.

Efficacy and safety of high-dose 13.3 mg/24 h rivastigmine patch in severe Alzheimer’s disease with and without concomitant memantine use

G. Grossberg1, M. Farlow2, X. Meng3, M. Somogyi4, 1Department of Neurology and Psychiatry, St Louis University School of Medicine, St Louis, MO, USA; 2Department of Neurology, Indiana University School of Medicine, Indianapolis, IN, USA; 3Novartis Pharmaceuticals Corporation, East Hanover, NJ, USA

Background: The ACTivities of daily living and cognitionON (ACTION) study demonstrated significant efficacy of 13.3 versus 4.6 mg/24 h rivastigmine patch on SIB and ADCS-ADL-SIV in severe Alzheimer’s disease (AD). 61% of the study population was on concomitant memantine (regardless of dose or duration). Here the effect of concomitant memantine use on efficacy and safety of 13.3 mg/24 h patch was investigated.

Methods: ACTION was a 24-week, randomized, double-blind study in patients with severe AD (MMSE score 3–12). Patients randomized to 13.3 or 4.6 mg/24 h patch were subdivided according to whether they received ≥1 dose of concomitant memantine. Change from baseline at week 24 on SIB and ADCS-ADL-SIV was assessed. Safety evaluations included incidence of adverse events (AEs).

Results: Overall, memantine-treated patients, had a lower MMSE at screening (8.6 +/− 2.91 versus 9.2 +/− 2.88). At week 24, the 13.3 demonstrated significantly greater efficacy than 4.6 mg/24 h patch on SIB and ADCS-ADL-SIV in patients receiving concomitant memantine than in those not receiving memantine (p < 0.05 for all). The incidence of AEs was 71.4% with 13.3 mg/24 h patch and memantine, 79.7% with 13.3 mg/24 h patch without memantine, 74.7% with 4.6 mg/24 h patch with memantine, and 71.1% with 4.6 mg/24 h patch without memantine.

Conclusions: These data suggest benefit of 13.3 mg/24 h patch, regardless of concomitant memantine use, and demonstrate similar safety and tolerability of 13.3 mg/24 h patch in memantine-treated patients and those not receiving memantine.

Anxiety levels increase chronic musculoskeletal pain in Alzheimer’s disease patients

V. Papaliagkas1, M. Tsatali1, D. Damigos2, V. Mavreas3, M. Gouva1, M. Tsolaki1, 1Third Department of Neurology, Aristotle University of Thessaloniki, Thessaloniki, Greece; 2Medical Psychology, Greece; 3University of Ioannina-School of Medicine, Greece; 4Nursing, Higher Technological Educational Institute of Epirus, Ioannina, Greece

Background: Mood disorders in Alzheimer’s Disease (AD) patients result in great difficulties in clinical practice in the assessment of pain and further treatment, therefore they should be early diagnosed and managed.
**Material and methods:** Twenty five AD patients, with anxiety and chronic musculoskeletal pain (experimental group) and thirty one age-matched patients with Alzheimer’s disease and chronic musculoskeletal pain without comorbid mood disorders (control group) were examined. All participants were diagnosed with chronic musculoskeletal pain, according to their medical history and their medications (all of them took non-steroid anti-inflammatory drugs). The neuropsychometric evaluations were performed with the following tools: Geriatric Pain Measure, Patient Health Questionnaire, Pain Assessment in Advanced Dementia, Mini Mental State Examination and Pain Anxiety Symptom Scale.

**Results:** AD patients with comorbid anxiety disorders tend to report increased pain intensity more frequently compared to controls. Scores in fearful thinking and physiological responses scales of PASS were higher in female than male ($p = .014$), whereas scores in the cognitive anxiety scale of PASS have shown a highly significant positive correlation with the years of education ($p < .001$).

**Discussion:** According to the results of the present study, anxiety is a significant component and an important part of pain experience among patients with AD, even if they are not able to verbalize it; thus needs to be taken into consideration by the health professionals for the patient’s management.

**Catechin suppressed LPS-induced neuroinflammation in BV-2, C6 and NG108-15 cells by modulating CCL21 through PI3K-Akt**

M.N.A. Kamarudin, H. Abdul Kadir, N.A. Mohd Raflee. Institute of Biological Sciences, Faculty of Science, University of Malaya, Kuala Lumpur, Malaysia

**Background and objectives:** Excessive microglial and astroglial activation that leads to chronic neuroinflammation plays a vital role in the progression of Alzheimer’s, Parkinson’s and Huntington’s diseases. Catechin or flavan-3-ol is mainly found in tea is reported to be neuroprotective. We investigated the regulation of neuroinflammation of LPS-induced neuroinflammation in BV-2, C6 and SHSY-5Y cells.

**Material and methods:** The expression of NO, ROS, PGE$_2$, TNF-$\alpha$, IL-1$, \beta$, IL-2, IL-6, IFN-$\gamma$, iNOS, COX-2, CCL21 and the molecular pathways involved were determined by Flow cytometry chip beads array (CBA), Western blot and ICC. The protective effects of catechin on neuroinflammation in BV-2, and SH-SY5Y co-cultured model induced with LPS were further evaluated.

**Results:** Catechin downregulated iNOS expression leading to concomitant decreased of NO and ROS released. This was followed by reduction of PGE$_2$ production leading to downregulation of TNF-$\alpha$, IL-1$, \beta$, IL-2, IL-6, IFN-$\gamma$ and COX-2 expression. Catechin downregulated CCL21 and prevented IFN-$\gamma$ and IL-1$\beta$ translocation in BV-2 and SH-SY5Y cells. Withal, Catechin upregulated PI3K-Akt expression, suggesting activation of pAkt might be responsible in mitigation of neuroinflammation.

**Conclusion:** Suppression of CCL21 in BV-2 and C6 activation through PI3K-Akt by catechin conferred protection on SH-SY5Y cells against LPS-induced neuroinflammation. This finding further heightens the specific therapeutic potential of catechin for the treatment of neurodegenerative diseases.

**The impact of neurological condition on driver distraction in a driving simulator experiment: Preliminary findings**

A. Economou$^a$, I. Beratis$^b$, M.H. Kosmidis$^a$, A. Liosidou$^b$, N. Andronas$^b$, J. Papatriantafyllou$^b$, G. Yiannis$^b$, S.G. Papageorgiou$^b$. $^a$Department of Psychology, University of Athens, Greece; $^b$Department of Psychology, ‘Antikon’ University General Hospital, University of Athens, Athens, Greece

**Background:** Age-related neurological disorders may affect driver distraction, and medication may also impair driving. In the early stages, neurological disorders have little impact on daily life yet may significantly impact one’s driving ability. Mild cognitive impairment (MCI), the predementia stage of various dementing disorders, is associated with impaired driving to a small extent (Fritelli et al., 2009) and self-reported road accident involvement is correlated with future diagnosis of dementia (Lafont et al., 2008). It is unknown whether distraction affects the driving ability of neurology patients to the same extent as healthy persons. Because of the ageing population, the need to investigate this question becomes critical.

**Objective:** To present preliminary findings from a recently funded research programme, National Strategic Reference Framework (NSRF 2007-13, O.P. Thales), on the causes and impact of driver distraction in a driving simulator experiment.

**Patients and methods:** At least 90 patients with neurological disorders (MCI, mild Alzheimer’s disease, Parkinson’s disease) will be recruited, and will be compared with at least 60 middle aged and older participants. A neuropsychological battery that measures attention, memory, visual and executive functions, a neurological exam, and a detailed history of medication and sleep difficulties are included.

**Results:** Preliminary findings are presented on the impact of presence/severity of neurological disorder, use of medications, and sleep disorders on driving performance with and without distraction, under different driving conditions.

**Conclusion:** The neurological parameters that predict driving performance under different conditions are summarized and discussed. Preliminary recommendations are presented on criteria for safe driving.

Patient and caregiver adherence and persistence to the rivastigmine patch in a non-interventional clinical study

1University of Ulm, Ulm, Germany; 2Institute of Psychiatry, King’s College London, UK; 3Royal Free London Foundation Hospital Trust, London, UK; 4Novartis Pharma AG, Basel, Switzerland; 5Novartis Pharma GmbH, Nuernberg, Germany

Background: Rivastigmine transdermal patch provides smooth drug delivery and therefore increased tolerance at similar efficacy compared to the oral formulation. An earlier registration study for the patch (IDEAL) with 1059 caregivers demonstrated that more than 70% caregivers prefer rivastigmine transdermal patch to capsules.

Objective: To identify patient and caregiver-related factors associated with adherence, persistence and caregiver satisfaction with rivastigmine patch.

Methods: In this non-interventional trial, adherence and persistence were assessed after three and six months of patch treatment. Relevant factors from literature for persistence and adherence to medication were validated prior to study enrolment.

Results: 127 caregivers answered the questionnaires, 3 months (visit 1) and 110 caregivers after 6 months (visit 2) after first prescription of rivastigmine patch. Mean MMSE score of the patients was 20.8 after 3 months of treatment. Physician ratings for CGI-I scores for efficacy suggested patients as ‘improved’ (66.2%). Caregivers were adherent to patch use at both visit 1 and visit 2 respectively, (‘never’ omitted 74.8%; 78.2% or ‘never’ paused for a while, 73.2%; 74.5%) and agreed with ease of its application. Efficacy was rated from caregivers for visit 1 and visit 2 respectively, as ‘satisfied’ for memory (62.2%; 56.4%), activities (69.3%; 66.4%) and behavior and emotions (65.4%; 64.5%). Valuations of tolerability were deemed as ‘good’ (90.5% and 90%) at visit 1 and visit 2 respectively.

Conclusion: Caregivers achieved reasonably high adherence rates to rivastigmine patch. This may be linked to its good efficacy outcomes and favourable tolerability profile.

Ease of use of rivastigmine patch can help manage medication for caregivers and patients with Alzheimer’s disease

1University of Ulm, Ulm, Germany; 2Institute of Psychiatry, King’s College London, UK; 3Royal Free London Foundation Hospital Trust, London, UK; 4Novartis Pharma AG, Basel, Switzerland; 5Novartis Pharma GmbH, Nuernberg, Germany

Background: Rivastigmine transdermal patch provides smooth drug delivery and better satisfaction to caregivers and patients compared to oral formulation. An earlier study demonstrated that more than 70% caregivers prefer the rivastigmine transdermal patch to the capsule.

Objective: To identify patient and caregiver-related factors associated with adherence, persistence and caregiver satisfaction to rivastigmine patch.

Methods: In this non-interventional, clinical and psychosocial study, caregiver or patient-related factors impacting on rivastigmine patch adherence, persistence and caregivers' satisfaction were assessed through an electronic questionnaire.

Results: Of 202 caregivers, 157 were adherent to patch use at both visit 1 and visit 2 respectively, (‘never’ omitted 74.8%; 78.2% or ‘never’ paused for a while, 73.2%; 74.5%) and agreed with ease of its application. Efficacy was rated from caregivers for visit 1 and visit 2 respectively, as ‘satisfied’ for memory (62.2%; 56.4%), activities (69.3%; 66.4%) and behavior and emotions (65.4%; 64.5%). Valuations of tolerability were deemed as ‘good’ (90.5% and 90%) at visit 1 and visit 2 respectively.

Conclusion: Caregivers achieved reasonably high adherence rates to rivastigmine patch. This may be linked to its good efficacy outcomes and favourable tolerability profile.

Reference

adherence and persistence were assessed after three and six months of treatment. Relevant factors from literature for persistence and adherence on medication were validated prior to study enrollment.

**Results:** 127 caregivers answered the questionnaires at visit 1 (after three months of treatment). Most caregivers were female (70.9%), 50.4% female and 45.7 male patients had caregiver assistance. The mean age of caregivers and patients was 66 and 78 years respectively. A large proportion of patients (72.1%) were living at home and caregiver assistance provided within the family (spouse, 57.4%; daughter, 21.7%). Most of the patients and caregivers had comorbid diseases [heart disease, 33.1%; diabetes, 28.3%], [mobility, 26%; vision, 16.5%]. Patients either ‘preferred’ or ‘highly preferred’ the patch (37%; 26%) compared to liquids (17.3%; 6.3%), or pills (17.3%; 2.4%). Caregivers found patch application convenient and easy (‘easy’ and ‘very easy’ package opening, 89%, ‘easy’ and ‘very easy’ use by patients, 89%).

**Conclusion:** Ease of use of rivastigmine patch improves satisfaction of both caregivers and patients and may help enhance the quality of AD patients’ assistance and management by the caregivers.

**Long-term safety and efficacy of 13.3 mg/24 h rivastigmine patch in severe Alzheimer’s disease: ACTivities of daily living and cognition (ACTION) study**

*Department of Neurology, Indiana University School of Medicine, Indianapolis, IN, USA; Department of Neurology and Psychiatry, St Louis University School of Medicine, St. Louis, MO, USA; Division of Neurology, Nova Southeastern University, Fort Lauderdale, FL, USA; Novartis Pharmaceuticals Corporation, East Hanover, NJ, USA*

**Background:** The 24-week, randomized, double-blind ACTION study demonstrated efficacy of higher-dose 13.3 versus 4.6 mg/24 h rivastigmine patch on cognition and ADL, with comparable safety in severe Alzheimer’s disease (AD). A 24-week, open-label extension assessed long-term safety and efficacy of 13.3 mg/24 h patch.

**Methods:** Completers of the double-blind study (13.3 or 4.6 mg/24 h patch) could continue into the open-label extension (13.3 mg/24 h patch). Incidences of adverse events (AEs), severe AEs (SAEs) and discontinuation due to AEs were reported. Change from baseline on ADCS-ADL-SIV and SIB, and ADCS-CGIC were assessed at week 48.

**Results:** 397 patients entered the open-label extension (197 continued on 13.3 and 199 up-titrated from 4.6 to 13.3 mg/24 h patch). Baseline characteristics were comparable. Similar rates of AEs (58% and 60%), SAEs (16% and 16%) and discontinuation due to AEs (11 and 12%) were reported in 13.3 and 4.6 mg/24 h, resp. Larger mean [SD] changes from double-blind baseline were observed in patients switched from 4.6 to 13.3 mg/24 h patch on ADCS-ADL-SIV (−4.6 [8.73]) and SIB (−7.0 [16.56]), than those who continued on 13.3 mg/24 h (−3.9 [8.00] and −4.7 [16.84], resp.). ADCS-CGIC scores were comparable.

**Conclusions:** There were no clinically relevant differences in safety between patients switched from 4.6 to 13.3 mg/24 h and those who continued on high-dose patch in the extension study. Greater decline was observed in patients switched from 4.6 to 13.3 mg/24 h patch at week 24, compared to those who received 13.3 mg/24 h patch for 48 weeks.

**Cerebrospinal fluid protein and white cell count as potential markers for clinical progression in Alzheimer’s disease**

M. Schijnen; P.B. Danborg; A.H. Simonsen; B.B. Andersen; S.G. Hasselbalch; P. Hagh; Regional Dementia Research Centre, Copenhagen University Hospital, Roskilde, Denmark; Danish Dementia Research Centre, Denmark; Memory Disorder Research Group, Denmark; Neurobiology Research Unit, Copenhagen University Hospital Rigshospitalet, Copenhagen, Denmark

**Background:** Neuroinflammation may have an important role in the pathophysiology and the clinical progression of Alzheimer’s Disease (AD). CSF protein concentration (due to defects in the blood-brain barrier) and white cell count are potential markers of such processes.

**Objective:** To investigate whether an elevated CSF protein concentration or an elevated CSF white cell count at baseline can predict clinical progression from MCI to AD.

**Patients and methods:** Routine CSF parameters (white cell count, protein concentrations, albumin CSF/serum concentrations) as well as CSF-AB42, CSF-Total Tau were retrospectively analyzed in a consecutive cohort referred for cognitive evaluation and diagnosed with MCI.

Clinical progression was assessed by clinical history and cognitive tests (MMSE) administered at baseline and during follow-up.

**Results:** Thirteen MCI subjects (4 females, 9 men) were included (mean age 69.6, range 56 to 80 years), mean MMSE 28, range 26 to 30). Patients had a mean follow-up of 26 months (range 14 to 46 months).

Eleven patients had stable MCI during follow-up, and 2 patients progressed from MCI to AD. In 4 subjects an elevated CSF-protein (above 0.45 g/L) concentration was found, and in two of these the CSF/plasma albumin-coefficient was also increased (above 0.012). One subject had elevated white cell count (above 3).

None of the 2 patients with clinical progression had increased CSF protein concentrations nor elevated white cell count.

**Conclusion:** From these very preliminary data we found no association between CSF protein concentration or white cell count and clinical progression of MCI. Analyses on a larger cohort are on-going.

**Various types of visual agnosia are present in Alzheimer’s disease and mild cognitive impairment**

J Laczó; R. Andre; I. Gažová; I. Mokrišová; K. Viček; M. Vyhnilá; E. Hynčíková; O. Lerch; J. Cerman; L. Pecháčová; K. Sheardová; J. Hört.

“Memory Disorders Clinic, Department of Neurology, 2nd Faculty of Medicine, Charles University in Prague and Motol University Hospital, Prague, Czech Republic; St. Anne’s University Hospital Brno, International Clinical Research Center, Brno, Czech Republic; School of Aging Studies, University of South Florida, Tampa, FL, USA; Department of Neurophysiology of Memory, Institute of Physiology Academy of Sciences of the Czech Republic v.v.i., Prague, Czech Republic

**Background:** Higher visual perception, which includes identification and recognition of faces, facial emotions and famous landmarks, is dependent on the medial temporal lobe structures that are affected early in the course of Alzheimer’s disease (AD). However, examination of higher visual perception in patients with dementia due to AD...
and patients with mild cognitive impairment (MCI) is still neglected in routine clinical practice.

Objectives: To determine whether famous faces identification (FFI), facial emotion recognition (FER), and famous landmarks identification (FLI) are impaired in patients with amnestic (aMCI) and non-amnestic (naMCI) MCI and mild AD.

Patients and methods: A total of 40 patients with aMCI, 27 patients with naMCI, 20 with mild AD and 38 controls were recruited. All subjects underwent standard neurological and neuropsychological evaluations as well as tests of FFI, FER and FLI.

Results: The subjects were similar in age and gender, but AD patients were less educated than other groups (p ≤ 0.016). A one-way analysis of covariance adjusted for education was used. Compared to the control group, AD subjects performed worse on FFI (p = .041), FER (p < .001) and FLI (p = .001), whereas the aMCI and naMCI groups had significantly worse scores only on FLI (p = .049 and p = .022, respectively).

Conclusion: Patients with amnestic and non-amnestic MCI may have impairment of higher visual perception restricted to FLI, while patients with dementia due to AD may have more extensive impairment of higher visual perception. The results suggest that FLI testing may be a useful tool for identification of patients with prodromal AD.

Role of 5-HTTLPR polymorphism in vascular dementia
Clinical Genetics Laboratory, Mental Health Research Centre of Russian Academy of Medical Sciences, Russia; Department of Neurology and Neurosurgery, Russian National Research Medical University, Russia; Molecular Genetics Diagnostic Laboratory, A.N. Sypin State Research Institute of Human Ecology and Environmental Hygiene of Russian Academy of Medical Sciences, Moscow, Russia

Background: Early detection and accurate diagnosis of vascular dementia (VD) are important, as vascular dementia is at least partially preventable. Therefore there is a need to optimize and increase panel of diagnostic criteria for this disease. The 5-HTTLPR genetic variant of the serotonin transporter gene might also serve as a marker of vascular dementia.

Methods: The 5-HTTLPR polymorphism was genotyped in 272 subjects (110 males and 162 females) who fulfilled the diagnostic criteria for vascular dementia. Severity of disease was assessed by MMSE, HADS, clock drawing test and Orgogozo scale.

Results: Positive association was shown for males with SS genotype and early onset of vascular dementia: average age of onset for patients with SS genotype was 57 years, while for LL genotype — 63 years (Test M-W, p = 0.031). SS genotype was also associated with deterioration of cognitive functions: impaired attention (p = 0.043) and high results of clock drawing test (p = 0.039). No statistical difference was found for heterozygotes. For females role of 5-HTTLPR polymorphism was less important. Some differences in severity of speech and language impairment were identified.

Conclusion: Based on this study the 5-HTTLPR polymorphism was shown as prognostic marker of vascular dementia for males. SS haplotype indicates an increased risk of early onset of VD and more severe progression.

Higher plasma concentrations of total carotenoids are associated with slower cognitive decline: Results from the Austrian Stroke Prevention Study
Austrian Stroke Prevention Study
Institute of Molecular Biology and Biochemistry, Centre for Molecular Medicine, Austria; Department of Neurology, Medical University Graz, Austria

Background: Antioxidant properties of micronutrients including vitamins and carotenoids may help to prevent cognitive decline.

Objective: To investigate the cross-sectional relationship between antioxidative micronutrients and cognitive function particularly in the domains of memory, attention—speed, conceptualization, visuopractical skills and global cognitive function (g-factor) in the normal elderly. Additionally we investigate mediation by MRI correlates of brain atrophy and white matter lesions (WML) volume.

Patients and methods: The cohort consisted of 614 healthy participants (mean age = 66 years, 58% females) of the Austrian Stroke Prevention Study. Cognitive function measurements include composite scores of specific domains including memory, conceptualization, visual practical skills and attention—speed and g-factor. All subjects underwent brain MRI with assessment of brain parenchymal fraction (BPF, %) and measurement of WML volume (cm³). Principal component analysis constructed four nutrient plasma antioxidant patterns (NPAPs) from original set of ten antioxidants. Association between NPAPs scores and different cognitive functions was analyzed using multiple linear regressions by adjusting for age, sex, education (Model1) and by additionally adjusting for vascular risk factors such as hypertension, cardiovascular disease, diabetes, smoking, BMI, Apo 4 and HDL (Model2).

Results: We observed only NPAP-1 including β-carotene, canthaxanthin, lycopene, α-carotene, β-carotene positively and significantly associated with conceptualization (Model1: β = .043, p = .05) and g-factor (Model1: β = .068, p = .03) when adjusted for age, sex, and education. The association remained significant when additionally adjusted for vascular risk factors (Model2: conceptualization (β = .054, p = .02), g-factor (β = .068, p = .05)). The effect of NPAP-1 on conceptualization and g-factor is not mediated by WML and brain atrophy.

Conclusion: Our result suggests the protective role of total carotenoids on cognitive function, which may ameliorate age-related cognitive decline.

PGRN and MAPT gene mutations cause of frontotemporal lobar dementia in Polish population
Institute of Molecular Biology and Biochemistry, Centre for Molecular Research Polish Centre Academy of Sciences, Warsaw, Poland; Medical University of Gdansk, Gdansk, Poland

Background: Frontotemporal lobar degeneration, the second most common form of presenile dementia, is clinically, pathologically and
genetically heterogeneous disorder. Up to 40% of FTD patients report family members with FTD supporting the important contribution of genetic factors to these diseases.

**Objective:** The aim of the study was to establish genetic backgrounds and frequencies of mutation causing FTD in the Polish population.

**Patients and methods:** The studied group consisted of 120 FTD patients (mean age of onset 63.6 ± 7.8 years), including 44 familial cases. All PGRN and MAPT exons with flanking intronic regions were sequenced. Analysis of hexanucleotide repeat expansion in C9ORF72 is in progress.

**Results:** We identified six different non-synonymous variants (PGRN: R418X, P439_R440fsX6, R433Q; MAPT: G55R, P301L, S305N). Among them two variants were new ones, three were previously reported as pathogenic mutations, and one variant was already known as non-pathogenic polymorphism. All coding non-synonymous variants were observed in familial FTD cases.

**Conclusion:** Causative mutations in MAPT and PGRN occur approximately in 4% of all FTD cases and in 11% of familial FTD cases in the Polish population. It could be concluded that PGRN and MAPT mutations are infrequent cause of FTD in Polish population. The symptoms of FTD are very variable and similar symptoms can result from mutations in different genes. Moreover the same mutation can present different symptoms in the same family.

**Cognitive decline in older age and metabolic profile in middle age: Is there an association?**

R. Tortelli, V.M.B. Guerra, R. Capozzo, A. Leo, F. Veneziani, M.R. Barulli, M. Tursi, A. Grasso, R. Chiloiro, V. Solfirizzi, G. Miciaglia, G. Logroscino, Basic Medical Sciences, Neurosciences and Sense Organs, University of Bari, Bari, Italy; Laboratory of Epidemiology and Biostatistics, IRCCS ‘S. de Bellis’, Castellana Grotte, Italy; Clinical Neurology and Research, Neurodegenerative Disease Unit, Ente Ospedaliero ‘Pia Fondazione Card G. Panico’, Tricase, Italy; Geriatrics, Center for Aging Brain, Memory Unit, University of Bari, Bari, Italy; Clinical Neurology and Research, Neurodegenerative Disease Unit, University of Bari, Tricase, Italy

**Background:** Cognitive impairment and dementia, either from vascular and degenerative origin, have been associated with metabolic disorders. However, there are no population-based studies comparing cognitive decline (CD) in older age and metabolic profile decades earlier.

**Objective:** To evaluate the association between CD in older age and serum metabolites (glycaemia, total cholesterol, HDL cholesterol, triglycerides, ALT) measured twenty years before.

**Patients and methods:** The MICOL cohort included a random sample of 2472 subjects recruited and examined in 1985–1986 and followed-up over 20 years until 2005–2006. In 2005–2006, 855 subjects of the cohort had ≥ 65 years and their cognitive status was explored using MMSE. Metabolic profile at baseline was compared in subjects with and without CD twenty years later.

**Results:** 797 subjects out of 855 answered MMSE, median score 29 (range 1–30). Six hundred eleven subjects (77%) had a MMSE score > 24 (normal), 127 (16%) between 21 and 24 (mild cognitive decline = MCD), and 59 (7%) < 20 (moderate/severe CD = MCD). ANOVA analysis with Bonferroni correction showed that mean fasting glycaemia at baseline in MCD group (115.8 ± 73.7 mg/dl) was significantly higher than fasting glycaemia in both normal (101.4 ± 20.8) (p = 0.0005) and MCD (99.7 ± 18.2) (p = 0.0009) groups. Total cholesterol, HDL-cholesterol, triglycerides and ALT were not different between groups. Multinomial logistic regression adjusting for age, gender and educational level showed that high fasting glycaemia is associated with an increased risk of MCD.

**Conclusions:** Cognitive decline in older age is associated with high fasting glycaemia, measured up to twenty years before, also controlling for main confounders.

**DPPX-related rapidly progressive dementia**

G.B. Stokin, University Psychiatric Hospital, Ljubljana, Slovenia

In the past, rapidly progressive dementias were thought to be easily distinguished from more common “classical” slowly progressive dementias. More recently, diseases distinguished most commonly as causing “classical” slowly progressive dementias, including Alzheimer’s disease and dementia with Lewy bodies, have been shown to produce also rapidly progressive dementias, while diseases distinguished as causing rapidly progressive dementias have been shown to lead to slowly progressive dementias. This is also the case of paraneoplastic disorders. While in the past these disorders were considered as exclusively related to neoplasias, recent evidence suggests that many, if not the majority of them, represent in fact an autoimmune disorder rather than a paraneoplastic one. Accumulating evidence suggests that many autoimmune rapidly progressive dementias result from aberrant action of autoantibodies erroneously targeting synaptic proteins. Best described are autoimmune rapidly progressive dementias due to aberrant action of autoantibodies against voltage gated potassium channels and against N-methyl-D-aspartate receptor. Last year, rapidly progressive dementia due to aberrant action of autoantibodies against dipeptidyl-peptidase-like protein-6 was first described. This form of rapidly progressive dementia targets a subunit of Kv4.2 potassium channels, which play a role predominantly in regulating post-synaptic somatodendritic signaling. Here we present the first thorough description of clinical characteristics, results of cerebrospinal fluid and imaging analyses as well as neuropathological findings.

**The effect of the neuroprotector NT-1505 on the structural parameters of mice membranes in vivo**

N. Gerasimov, A. Goloshchapov, O. Nevrova, E. Burlakova, Emanuel Institute of Biochemical Physics, Russian Academy of Sciences, Moscow, Russia

**Background:** NT-1505 influence on lipid composition and fluidity of the mice membranes was studied.

**Objective:** Lipid component of membranes plays an important role in the transmission, processing and storage of information in the cell. Activation of lipid peroxidation processes in AD leads to a change in the membranes’ structural organization. Disruptions in the regulation system work of membranes’ cell metabolism allow considering AD as membrane pathology. Cognition enhancer NT-1505 is the most promising substance for AD treatment, which modifies glutamate receptors functioning [1]. It was an apparent interest to study the influence of NT-1505 on the membrane structural state for the
estimation of the possibly favorable or unfavorable side effects during therapy. In this work the effect of neuroprotector NT-1505 on the lipid composition and fluidity of the mice membranes in vivo was studied.

Material and methods: The experiment was carried out on scrub mice. NT-1505 was kindly furnished to us by Bachurin S.O. Membrane microviscosity was measured by electron paramagnetic resonance (ESR) with 2,2,6,6-tetramethyl-4-capryloyl-oxypiperidine-1-oxyl and 5,6-benzo-2,2,6,6-tetramethyl-1,2,3,4-tetrahydro-γ-carboline-3-oxyl probes. Rotational diffusion correlation time calculated from the obtained spectra of the ESR as microviscosity. Lipid composition was determined by mass-spectrometry and TLC methods.

Results and conclusions: Obtained data shows, that NT-1505 reduces microviscosity of the synaptosomal membranes and modifies fluidity of the microsomal membranes. NT-1505 significantly influences lipid composition of the membranes. It was found out that changes in membrane structural state are preferred to be considered during therapy scheme development.

Molecular genetics investigation of SIRT2A gene in frontotemporal lobar dementia
D. Luís\textsuperscript{a,b}, I. Santana\textsuperscript{a,c}, M.J. Santos\textsuperscript{b}, D. Duro\textsuperscript{d}, J. Pratas\textsuperscript{b}, P. Cerveira\textsuperscript{e}, F. Silva\textsuperscript{f}, M. Grazina\textsuperscript{a,b}, \textsuperscript{g}Faculty of Medicine, University of Coimbra, Portugal; \textsuperscript{g}CNC — Center for Neuroscience and Cell Biology, University of Coimbra, Portugal; \textsuperscript{h}CHUC EPE — Neurology Service, Portugal; \textsuperscript{i}Centre of Ophthalmology and Vision Sciences, IBILI — Faculty of Medicine, Coimbra, Portugal

Frontotemporal lobar dementia (FTLD), characterized by neuronal loss in the frontal and/or temporal cortices, includes behavioural variant of frontotemporal dementia (bvFTD), semantic dementia and progressive non-fluent aphasia subtypes. Mutations in the associated genes do not explain the majority of cases and the mechanism underlying the aetiology of FTLD remains unknown. The genes encoding for serotonergic (5-HT) components are good candidates for susceptibility factors, due to their role in human behavior modulation. Our aim was to analyze the involvement of SIRT2A gene in FTLD pathogenesis.

We have studied patients with probable diagnosis of FTLD, followed in dementia consultation, and healthy controls. Analysis of SIRT2A gene was performed by automated sequencing and statistical analysis using c\textsuperscript{2} and Fisher's exact tests (significance if p < 0.05).

We have found 17 sequence variations (13 known and 4 novel unreported) that possibly do not account for primary risk for FTLD, but may contribute for susceptibility.

The case–control association study suggests that the increase of G allele (rs3125; 3′UTR region) may be a risk factor for bvFTD in females (p = 0.037; OR = 2.5, CI 95%), Determination of mRNA levels has been initiated to further clarify its role in the disease. Supported by “Fundação para a Ciência e a Tecnologia” (SFRH/BD/45387/2008, PTDC/SAU-EPI/121811/2010 and PEst-C/SAU/LA0001/2011).

Apolipoprotein E plasma level and genotype — Risk of dementia in 76,000 individuals from the general population
K.L. Rasmussen\textsuperscript{a}, A. Tybjerg-Hansen\textsuperscript{b,c}, B.G. Nordestgaard\textsuperscript{a,c}, R. Frikke-Schmidt\textsuperscript{a,c}, \textsuperscript{a}Department of Clinical Biochemistry, Rigshospitalet, University of Copenhagen, Copenhagen, Denmark; \textsuperscript{b}Copenhagen City Heart Study, Frederiksberg Hospital, Frederiksberg, Denmark; \textsuperscript{c}Copenhagen General Population Study, Herlev Hospital, Herlev, Denmark

Background: Alzheimer disease and other forms of dementia are devastating neurodegenerative diseases affecting more than 35 million people worldwide, with no currently available curative treatment. The apolipoprotein E (APOE) \(\varepsilon 4\) allele is a major genetic risk factor for dementia. In contrast, it remains unclear whether plasma levels of apoE confer additional risk.

Objective: We tested whether both plasma levels of apoE and APOE genotype associate with dementia.

Material and methods: We included 76,365 participants from the Copenhagen General Population Study and the Copenhagen City Heart Study; 1216 developed dementia. We measured plasma apoE levels and genotyped for rs429358 and rs7412, which combines into six common APOE genotypes (\(\varepsilon 22, \varepsilon 23, \varepsilon 32, \varepsilon 33, \varepsilon 43, \varepsilon 44\)).

Results: Multifactorially adjusted hazard ratios (HRs) increased from highest to lowest tertile of apoE levels and from \(\varepsilon 22\) to \(\varepsilon 44\) for Alzheimer disease (p for trend \(= 9.3 \times 10^{-13}\) and \(2.7 \times 10^{-37}\), respectively), and for all dementia (p for trend \(= 8.0 \times 10^{-11}\) and \(5.9 \times 10^{-32}\), respectively). After further adjustment for APOE genotype, apoE levels remained significantly associated with Alzheimer disease (p = 0.005), and after stratification for APOE \(\varepsilon 43\) genotype, apoE levels remained significantly associated with Alzheimer disease (p = 0.04), and with all dementia (p = 0.02). These associations were independent of cardiovascular risk factors.

Conclusion: Both plasma apoE levels and APOE genotype were associated with risk of dementia, and the association between plasma levels of apoE and dementia was independent of APOE genotype.

Thymoquinone improves cognitive function and increases \(\alpha-7\)nAChRs expression in a rat model of neuroinflammation
O.A. Heikal, N.S. El-Sayed, S. El Menawi, N. Hamdi. Pharmacology & Toxicology, German University in Cairo, New Cairo City, Egypt

Background: Alzheimer's disease (AD) is a neurodegenerative disorder characterized by extracellular deposition of aggregated $\beta$ amyloid protein (A\(\beta\)). Recently, correlation between nicotinic receptors (nAChRs) dysfunction, neurodegeneration and cognitive deficits was shown in AD. nAChRs have protective role against A\(\beta\) toxicity while chronic inflammation damages cholinergic neurons and contributes to neurodegeneration. Thymoquinone (TQ) has anti-oxidant and anti-inflammatory effects besides its acetylcholine modulatory effects in vitro. However, effect of TQ on nAChRs in vivo needs to be clarified.

Aim: To investigate in vivo effects of TQ on cognitive functions and $\alpha-7$ nAChRs expression in a LPS model of neuroinflammation.

Methods: Rats injected with LPS (0.8 mg/kg) were divided into three groups for a five-day-treatment: TQ (5 mg/kg), TQ (10 mg/kg) and control group (0.08% Tween 80). Learning, memory and locomotor
activity were tested using Y-maze, object recognition and open field tests. Brain α-7nAChR protein level was measured by western blot. 

**Results:** LPS significantly reduced alternation % in Y-maze, pattern separation in object recognition test and locomotor activity in open field test. TQ significantly improved these LPS-induced cognitive functions and locomotor activity impairment. 10 mg/kg TQ significantly increased α-7nAChRs protein level compared to the other groups.

**Conclusion:** This study demonstrates beneficial in vivo effects of TQ by improving learning, memory and locomotor activity in a model of chronic neuroinflammation. These effects were accompanied by significant increase in α-7nAChRs protein expression level. These results confirm the impact of neuroinflammation on the cholinergic signaling and suggest TQ as a potential promising treatment for AD.

**Cerebral amyloid angiopathy presenting as a diffuse leukoencephalopathy**

I. Moreira; S. Fontes; R. Taipa; M. Melo-Pires; C. Correia. 

*Neurology Department, Portugal; Neuropathology Unit, Hospital Santo António, Centro Hospitalar do Porto, Porto, Portugal*

**Introduction:** Amyloidosis is a heterogeneous group of disorders, with extracellular deposits of misfolded proteins, in a fibrillar configuration. Amyloid deposits in brain can take many forms: senile plaques (in Alzheimer’s disease), amyloidomas (mimicking brain tumours) or cerebral amyloid angiopathy (CAA) by β-amyloid deposits in meningeal and cortical vessels. Spontaneous cerebral hemorrhage is the usual presentation of CCA. CAA presenting with subacute encephalopathy associated with diffuse white matter disease is extremely rare.

**Clinical case:** A 75 year-old man without relevant medical or toxic exposure history began with progressive attention and memory impairment, confabulation and urinary retention. Objectively had symmetrical white matter lesions, with mass effect, extending to head and limbs resting tremor, without pyramidal, sensory or corticospinal signs. Brain MRI showed bilateral fronto-temporal-insular symmetrical white matter lesions, with mass effect, extending to external capsules and sparing basal nuclei. Electroencephalogram suggested diffuse brain dysfunction. CSF had 0.71 g/L of proteins without cells. Metabolic, microbiological, immunological and occult malignancies investigation were negative. Brain MRI one month later showed lesion expansion. He didn’t improve with methylprednisolone 1 g during 5 days. Brain biopsy diagnosed Aβ cerebral amyloid angiopathy. Patient died by an urosepsis 1.5 month after diagnosis.

**Discussion:** CAA manifested as diffuse white matter disease is a rare and challenging condition. An inflammatory process is thought to be related to the vascular deposits of Aβ in this presentation. We didn’t identify an inflammatory process in the biopsy. In our case the patient didn’t respond to steroids, the proposed standard treatment, and there was a fast worsening of the condition.

**Cholesterol and ultrasensitive C-reactive protein serum levels among patients suffering memory recall deficit**

M. Sierra-Beltrán; J. J. Romero-Flores; C. M. Hernández-Cárdenas; S. Feria-Piñad.

*Integral Diagnosis and Treatment Center, Mexico; Gastroenterology Department, Medica Sur Hospital, Mexico; Critical Care Medicine, INCMNSZ, Mexico; Internal Medicine, Medica Sur Hospital, Mexico City, Mexico*

**Background:** Metabolic syndrome patients have been shown to suffer arteriolar intracranial arteriosclerosis. This in turn leads to subcortical dysfunction expressed as memory recall deficit. So far, until now, memory deficit hasn’t been studied among those patients with subtle cholesterol disturbances.

**Objective:** To present a series of cases of patients with serum cholesterol fraction levels and memory recall deficit.

**Material and methods:** 16 patients with complaints of subtle memory recall deficit undertook a routine medical checkup at Medica Sur Hospital Integral and Diagnosis Center, which included clinical laboratories tests and image studies assessments.

**Results:** It has been observed that memory recall deficit was more frequently reported in patients with low HDL cholesterol serum levels, rather LDL cholesterol serum levels. Ultrasensitive C-reactive protein serum levels were higher than 1.7 Mg/L. Only two patients suffer arteriolar intracranial arteriosclerosis. This in turn leads to subcortical dysfunction expressed as memory recall deficit. So far, until now, memory deficit hasn’t been studied among those patients with subtle cholesterol disturbances.

**Objective:** To present a series of cases of patients with serum cholesterol fraction levels and memory recall deficit.

**Material and methods:** 16 patients with complaints of subtle memory recall deficit undertook a routine medical checkup at Medica Sur Hospital Integral and Diagnosis Center, which included clinical laboratories tests and image studies assessments.

**Results:** It has been observed that memory recall deficit was more frequently reported in patients with low HDL cholesterol serum levels, rather LDL cholesterol serum levels. Ultrasensitive C-reactive protein serum levels were higher than 1.7 Mg/L. Only two patients...
did not suffer sleep disturbances. All of them noticed difficulties in memory recall 5 years prior to the checkup.

**Discussion:** The current findings demonstrated that a mild memory deficit is not a late clinical expression in metabolic syndrome. The fact that low HDL cholesterol serum levels were more frequently found is a rare finding and it does not correlate to a specific lipoprotein phenotype.

**Association between asymptomatic carotid stenosis and cognitive function: A systematic review**

X. Chang. Department of Neurology, West China Hospital, Sichuan University, Chengdu, China

**Background:** Asymptomatic carotid stenosis (CS), defined as the condition in which patients have carotid stenosis without a past history and current clinical evidence of any prior cerebrovascular event, and have traditionally been considered clinically silent. It is less clear whether asymptomatic CS itself is an independent risk factor for cognitive impairment.

**Methods:** We conducted a systematic review of literature using the Cochrane Library, MEDLINE, EMBASE and the China National Knowledge Infrastructure databases. We also searched the reference lists of relevant studies and review articles. Two reviewers used a standardised form to collect data and assess eligibility. The quality of study was assessed by the Newcastle–Ottawa Scale.

**Results:** A total of ten studies comprising of 763 participants in the CS group and 6308 in the non-CS group were included. All studies but one support the association between asymptomatic CS and cognition impairment. When examining the concomitant factors of asymptomatic CS and cognition in seven eligible studies, age (two studies) and reduced cerebrovascular reactivity (two studies) showed positive results associated with cognitive impairment.

**Conclusions:** These results suggest that rather than being clinically silent, asymptomatic carotid stenosis may be associated with cognitive function impairment, which needs to be further investigated with high-quality studies.

**Topic: 5 — Dementia**
**Is AD a medical notion of dementia worth keeping in neurosciences?**

F.C.C. Peng. Neurological Institute, and Neurosurgery, Taipei Veterans General Hospital, Taipei, ROC

**Background:** The eponym of AD has been around since 1910. Its diagnosis varies from senile dementia to senium praecox to MCI leading to AD as the most feared form of dementia.

**Objective:** Most neuroscientists have refused to admit such uncertainties. They prefer to:

1. perpetuate AD to keep it alive for contrast with other forms of dementia;
2. debate on the effect to seek a one-to-one cause–effect relationship, Amyloid-Beta Hypothesis;
3. advocate the intervention or prevention of AD in confusion with dementia, by using animal models to mimic AD;
4. take the liberty to assign lesion sites, unaware of Auguste's brain that had widespread atrophy, as she had four vascular disorders.

**Methods:** Dementia can be tested as the effect of brain atrophy; it is a cluster of behavioral alterations.

**Results:** Dementia is therefore neither a disease nor equivalent to AD. It is an illness. Plaques and tangles should be called Fischer's disease which results in simple dementia leading eventually to presbyophrenia, a dichotomy suggested by Fischer. MCI is a cheap reinvention of Fischer's dichotomy.

**Conclusions:**

1. AD is not worth keeping;
2. dementia can start from atrophy in any brain location, then spreads, because of wear and tear;
3. the cause is vascular or non-vascular in origin; the effect can vary, resulting in various behavioral alterations; and

**doi:**10.1016/j.jns.2013.07.1268
(4) there is no one-to-one cause–effect relation, as the brain atrophy spreads from cortical to cortical, cortical to subcortical, and/or subcortical to cortical regions.

The neuroprotective effects of lithium chloride (LiCl) on anxiety behavior in animal models of Alzheimer’s disease
M. Moghadas, M.A. Edalatmanesh, A. Zarei. Department of Physiology, Science & Research Branch, Islamic Azad University, Fars, Iran

Introduction: One of the neurological disorders associated with Alzheimer disease (AD) includes anxiety. Trimethyltin (TMT), as a tool to model AD in animals, is a potent neuro-toxicant which causes damage particularly in the hippocampus, having the potentiality of decreasing BDNF, while it increases TNF-α. Likewise, lithium has neuroprotective characteristics which decrease neuro-atrophy progression and prevent neuro-cell death, inducing expression of BDNF and decreasing that of TNF-α.

Method: In this study, the neuroprotective effects of LiCl on the treatment of Alzheimer-related anxiety were investigated. To begin with, the rats were subjected to AD using intra-peritoneal injection of 8 mg/kg of trimethyltin. The subjects were randomly divided into the following groups: non operated rats (control), TMT injection + saline administered rats (vehicle treated rats) and TMT injection + LiCl administered rats (Test group). The last step involved taking behavioral tests of open-field and elevated-plus-maze, trying to measure the anxiety of the rats. Then, hippocampal and serum levels of TNFα and BDNF were calculated.

Results: The results indicated that the rats with TMT injection showed more anxiety and that treatment with LiCl would produce a significant improvement in elevated plus maze and open field tests. With the presence of LiCl, the BDNF would be increased and the TNF would be decreased to a significant level.

Conclusion: Injection of LiCl had neuroprotective effects and could be used as a treatment for Alzheimer-related anxiety in an animal model.

Neuroprotective effect of lithium chloride on trimethyltin-induced learning and memory deficits in rats
A. Zarei, M.A. Edalatmanesh, M. Moghadas. Department of Physiology, Science & Research Branch, Islamic Azad University, Fars, Iran

Objective: In order to determine the neuroprotective effect of lithium chloride (LiCl), the present study examined the effects of LiCl on learning and memory in a Morris water maze task and BDNF level of rats with trimethyltin (TMT)-induced neuronal and cognitive impairments.

Methods: The rats were randomly divided into the following groups: non operated rats (control), TMT injection + saline administered rats (vehicle treated rats) and TMT injection + LiCl administered rats (test group). Rats were administered saline or LiCl (20, 40 and 80 mg/kg, i.p.) daily for 2 weeks, followed by their training to the tasks. In the water maze test, the animals were trained to find a hidden platform in a fixed position during 5 days and then received a 60 s probe trial on the 6th day following removal of the platform from the pool.

Results: Rats with TMT injection showed impaired learning and memory of the tasks and treatment with LiCl (specially, in lower dose of LiCl) produced a significant improvement in escape latency to find the platform in the Morris water maze. Consistent with behavioral data, treatment with LiCl also slightly enhanced serum and hippocampal levels of BDNF compared to the vehicle treated group.

Conclusion: These results demonstrated that LiCl has a protective effect against TMT-induced neuronal and cognitive impairments. The present study suggests that LiCl might be useful in the treatment of TMT-induced learning and memory deficit.

Core cell cycle protein Mad2 is differently expressed in AD brains compared to age matched controls
V.P. Bajic, B. Spremo-Potparevic, L. Zivkovic. Department of Pharmacology, Institute for Pharmaceutical Research and Development, Serbia; Department of Pharmacology, Serbia; Department of Biology, University of Belgrade, Belgrade, Serbia

Background and objectives: Anaphase promoting complex (APC), BubR1 and Mad2 are proteins of the late phase of the cell cycle which have shown to express different functions than cell cycle control processes in post mitotic neurons versus mitotic cells. BubR1 and Mad2 proteins are inhibitors of the anaphase promoting complex (APC) thus regulating the anaphase cell cycle checkpoint control ensuring proper chromosome segregation and separation. Here we wish to elucidate the possible role of Mad2 protein in an Alzheimer’s Disease (AD) brains versus age matched controls.

Methods: Immunohistochemical and Western blot analysis were used to evaluate the levels and expression patterns of Mad2 protein in the hippocampal region of AD brains compared to age matched controls.

Results: Our results show that Mad2 protein is differentially expressed, i.e. we found a decreased expression of Mad2 protein in AD brains compared to age matched controls.

Conclusion: The activity of APC is maintained by CDH1 in terminally differentiated cells. It is conceivable that Mad2 protein plays a role in the control of the APC activity in post-mitotic neurons. Our results show changes in expression in the AD brain which may lead us to the possible role of MAD2 in neuronal cell cycle re-entry, thus presenting a novel pathway to AD neurodegeneration.

From prevalent MCI to incident dementia as predicted by baseline neuropsychiatric symptoms: The Mayo Clinic Study of Aging
A. Pink, J.I. Acosta, Y.E. Gedda, R.O. Roberts, T.J. Christianson, V.S. Pankratz, O. Sochor, R.C. Petersen. Mayo Clinic, Scottsdale, AZ, USA; Mayo Clinic, Rochester, MN, USA; International Clinical Research Center and St. Anne’s University Hospital Brno, Brno, Czech Republic

Objective: To determine the incidence of dementia as predicted by baseline neuropsychiatric symptoms in subjects with prevalent mild cognitive impairment (MCI).
Design: Prospective cohort study.

Setting: The Mayo Clinic study of aging.

Participants: Baseline Neuropsychiatric Inventory Questionnaire data were available on 332 people with prevalent MCI who underwent at least 1 follow-up visit.

Method: The diagnosis of dementia was made by an expert consensus panel after reviewing neurological, cognitive, and other pertinent data. We calculated hazard ratios (HRs) and 95% confidence intervals (95% CI) by using a Cox proportional hazards model, with age as a time scale.

Main outcome measure: Dementia as measured by DSM-IV criteria.

Results: We prospectively followed the cohort to incident dementia for a median (inter-quartile range [IQR]) of 3.0 (2.5, 5.3) years. HR (95% CI) was calculated after adjusting for age, sex, education, and medical comorbidity. Baseline agitation (HR = 1.97; 95% CI, 1.13–3.42), nighttime behaviors (HR = 1.68; 95% CI, 1.02–2.78), depression (HR = 1.63; 95% CI, 1.10–2.41) and apathy (HR = 1.62; 95% CI, 1.03–2.54) significantly predicted incident dementia. Conversely, anxiety (HR = 0.93; 95% CI, 0.54–1.61) and irritability (HR = 1.00; 95% CI, 0.61–1.67) do not appear to be related to increased dementia incidence. Psychotic symptoms were rare and none of them reached statistical significance.

Conclusion: Among persons with prevalent MCI, the presence of baseline agitation, nighttime behaviors, depression and apathy predicted incident dementia. Anxiety and irritability were not significant predictors.

Profile and predictors of vascular cognitive impairment in African stroke survivors: The CogFAST — Nigeria study

R.O. Akinyemi1,2, L. Allan3, M.O. Owolabi1, J.O. Akinyemi1, A. Ajani1, A. Ogunniyi2, R.N. Kalaria3. 1Department of Medicine, Division of Neurology, Federal Medical Centre, Abeokuta, Nigeria; 2Institute for Ageing and Health, Newcastle University, Newcastle Upon Tyne, UK; 3Medicine, Nigeria; 4Epidemiology and Medical Statistics, University of Ibadan, Ibadan, Nigeria

Background and purpose: Sub-Saharan Africa faces a growing prevalence of non-communicable diseases including stroke and dementia but little is known about the burden of stroke-related cognitive dysfunction. We assessed baseline profiles and predictors of vascular cognitive impairment (VCI) in Nigerian African stroke survivors participating in the Cognitive Function After Stroke (CogFAST) Nigeria Study.

Methods: We recruited 217 subjects (≥45 years old) comprising of 143 stroke survivors and 74 demographically matched stroke-free healthy controls. We obtained demographic, clinical and lifestyle information and assessed the cognitive status of the subjects at baseline three months after stroke. Standard neuropsychological tests included the Vascular Neuropsychological Battery which assessed executive function/mental speed, memory, language, and visuospatial/visuoconstructive functioning. Cognitive impairment and dementia were defined based on the AHA/ASA VCI guidelines and the DSM-IV criteria.

Results: Among the stroke survivors, 57 (39.9%) had cognitive impairment no dementia (CIND) while 12 (8.4%) were demented at baseline. Multivariate analysis revealed that older age (p = 0.005, OR = 1.05 (1.00–1.09), and low education (p < 0.001, OR = 5.09 (2.17–11.95) independently predicted cognitive dysfunction whereas pre-stroke daily intake of fish (p = 0.022, OR = 0.39 (0.15–0.89) was inversely associated.

The Rowland Universal Dementia Assessment Scale (RUDAS) in an Arabic speaking population with limited schooling

R. Nielsen1, K.T.T. Phung2, M. Chaaya2, K. El Asmar3, S. Atweh1, G. Waldemar1. 1Danish Dementia Research Center, Department of Neurology, Copenhagen University Hospital Rigshospitalet, Copenhagen, Denmark; 2Department of Epidemiology and Population Health, Faculty of Health Sciences, American University of Beirut, Lebanon; 3Department of Neurology, American University of Beirut Medical Center, Beirut, Lebanon

Background: We recently validated RUDAS in 242 Lebanese participants older than 65 years, 142 cognitively intact controls and 100 dementia cases. 50.4% are illiterate. With a cutoff of 22, the Arabic RUDAS demonstrated good sensitivity (84.0%) and specificity (84.5%), but a high false positive rate (15.5%, FPR). 99% of the
illiterate controls failed the RUDAS drawing test (a cube, 3 points on 30 points total).
We aimed to modify the RUDAS drawing test to improve the FPR among illiterate older people.

**Method:** The same participants were asked to draw two intersecting circles with the scoring rules: 1 point for 2 vaguely circular figures, 1 point for 2 clear circles, and 1 point for intersecting circles. Sensitivity, specificity, and FPR of the modified RUDAS were calculated.

**Result:** 32.3% of illiterate controls failed to draw the circles. Overall, the modified RUDAS had a 22 cut-off had 77.0% sensitivity (95% CI: 67.9, 84.2), 88.7% specificity (95% CI: 82.5, 92.9), and 11.3% FPR (95% CI: 7.1, 17.5). Among those who are illiterate (N = 123, 61 cases, 62 controls), the original RUDAS had 90.2% sensitivity (95% CI: 80.1, 95.4), 79.0% specificity (95% CI: 67.4, 87.3), 21.0% FPR (95% CI: 12.7, 32.6); Modified RUDAS had 83.6% sensitivity (95% CI: 72.4, 90.8), 83.9% specificity (95% CI: 72.8, 91.0), 16.1% FPR (95% CI: 9.0, 27.2).

**Conclusion:** The modified RUDAS is not as sensitive as the original RUDAS in screening for dementia among illiterate older people, but is more useful when higher specificity and lower FPR are preferred.

**Report on cluster of three autopsy confirmed cases of sporadic Creutzfeldt-Jakob disease from Luxembourg including videos, imaging, genetics and neuropathology**

D. McIntyre, M. Geschwind, I. Zerr, R. Metz, D. Droste, N. Diederich, S. Beyenburg, Neurology, Centre Hospitalier de Luxembourg, Luxembourg, Luxembourg; Neurology, UCSF School of Medicine, San Francisco, CA, USA; Neurology, CJF Research Group at the University of Göttingen, Göttingen, Germany

**Background:** Creutzfeldt Jakob disease (CJD) is a currently incurable, invariably fatal neurodegenerative disorder of misfolded proteins coined prions. The incidence of prion disease in humans is one in one million people per year with 85% of cases represented by sporadic CJD (sCJD), 15% by genetic prion diseases and less than 1% by acquired forms of CJD, including variant. Sporadic CJD can be further subdivided into six molecular classifications depending on the polymorphism at codon 129 (homozgyous or heterozygous for methionine and/or valine on of the prion protein gene).

**Objective:** To report on a cluster of sCJD during a ten month interval in Luxembourg, population 517,000.

**Patients and methods:** We report on clinical, neuropsychological, laboratory, electroencephalogram, imaging, and neuropathological findings on three patients with rapidly progressive dementia (RPD) in a teaching hospital. Genetic analysis through blood testing was conducted at the German National Reference Center for Surveillance of Transmissible Spongiform Encephalopathies. Serial imaging was retrospectively reviewed by a blinded CJD expert.

**Results:** These cases represent a six-fold adjusted population based incidence of sCJD. Genetic analysis did not reveal any PRNP mutations, suggesting that all cases were sporadic, as none had any other risk exposures. Pathology ruled out variant CJD and confirmed likely sCJD. All patients had Type 1 prions. Two patients initially presented with motor symptoms were homozgyous for methionine and one who presented with a neuro-cognitive disorder was heterozygous at codon 129 of PRNP.

**Conclusion:** This case series illustrates the workup of a cluster of RPD including international collaboration.

**Late-onset familial neuronal intranuclear inclusion disease presenting with dementia and unique MRI findings**

R. Ohtomo, T. Mano, Y. Shirota, H. Ishiura, J. Shimizu, S. Tsuji, A. Iwata. Department of Neurology, The University of Tokyo Graduate School of Medicine, Tokyo, Japan

**Background:** Neuronal intranuclear inclusion disease (NIID) is a rare neurodegenerative disease associated with eosinophilic hyaline intranuclear inclusions in neuronal as well as visceral organ cells. As for its variable onset ages and symptoms, diagnosis cannot be made by clinical presentation alone and is solely dependent on pathological examination.

**Objective:** To describe a new NIID pedigree with characteristic radiological findings.

**Methods:** A 76 year-old woman had a 2-year history of progressive dementia, postural tremor in the upper extremities and retinitis pigmentosa (RP). MRI showed leukoencephalopathy with high intensity area along the arcuate fiber in diffusion-weighted image (DWI). Skin biopsy was performed for definitive diagnosis. Family members were screened for analogous clinical symptoms by Mini-Mental State Examination, neurological examinations, and color vision test. Seemingly affected individuals received MRI scan, nerve conduction study, and funduscopic examination for further investigation.

**Results:** Five affected members with at least 2 of the clinical features resembling those of the proband were identified from 3 consecutive generations. Proband’s mother had dementia and tremor from her 70s. One sister had tremor, hyporeflexia and RP, while her 2 brothers had leukoencephalopathy, dementia, and tremor all starting from their 60s. One nephew had tremor, hyporeflexia, reduction in sensory nerve action potential and nystaglosis from late 50s.

**Conclusion:** In comparison with prior studies, late disease onset and DWI findings were the unique features of this pedigree. DWI could be a diagnostic tool for NIID patients with dementia, but needs accumulation of similar cases to prove its utility.

**Associations of MRI white matter hyperintensities with cognitive functions, depression and quality of life**

A. Amintaeva, M. Kravchenko, O. Andreeva, Y. Varakin, E. Gnedovskaya, G. Gornostaeva, M. Prokopenovich, M. Krotenkova, R. Konovalov, E. Oshepkova, N. Lazareva. Research Center of Neurology, Moscow, Russia; Russian Cardiology Complex, Moscow, Russia

**Objective:** White matter hyperintensities (WMH) are common findings on MRI and are associated with the risk of cerebrovascular diseases and cognitive decline. Associations of WMH with the most common cerebral complaints (headaches, dizziness, tinnitus, memory decline) and such disorders as depression, lowering of quality of life and mild cognitive decline are not clear.

**Methods:** 284 subjects at age 40–59 were examined in cross-section population based study. Two groups were formed depending on finding or not WMH on MRI. Following surveys were performed — Luria’s memory words test (LMWT), Munsterberg’s correction test (MCT), SF-36, Hospital Anxiety and Depression Scale (HADS), and questionnaire for complains.
Results:
Group (1) — 124 women and 69 men mean age 48 ± 5 without WMH. Group (2) — 55 women and 36 men mean age 53 ± 5 with WMH.

Group 2 was older (p < 0.01), sex distribution was similar. Memory decline by LMWT was more frequent in WMH group (52% vs 35%, p = 0.01). Operational integrity by MCT was lowered: 53% group 2 vs 46% group 1, p > 0.05. Cases with SF-36 results < 17 were in 78% of WMH group and 72% of the group without WMH, p > 0.05. HADS ≥ 7 was in 31% vs 28% for anxiety and 22% vs 17% for depression, p > 0.05. Prevalence of dizziness and tinnitus was 52% vs 32%, p = 0.0022; headaches — 76% vs 85%, p < 0.05.

Conclusion: WMH are associated with age, memory decline and dizziness/tinnitus complains. Headaches are less frequent in WMH patients, but this finding was statistically not significant.

Subjective memory complaints, depressive symptoms and cognition in patients attending a memory outpatient clinic

J. Lehrner, D. Moser, S. Klug, A. Gleiss, E. Auff, P. Dal-Bianco, G. Pusswald. 1Department of Neurology, Vienna, Austria; 2Center for Medical Statistics, Informatics and Intelligent Systems, Medical University of Vienna, Vienna, Austria

The goals of this study were to establish prevalence of subjective memory complaints (SMC) and depressive symptoms (DS) and their relation to cognitive functioning and cognitive status in an outpatient memory clinic cohort.

248 cognitively healthy controls and 581 consecutive patients with cognitive complaints who fulfilled the inclusion criteria were included in the study.

A statistically significant difference (p < 0.001) between control group and patient group regarding mean SMC was detected. 7.7% of controls reported considerable degree of SMC whereas 35.8% of patients reported considerable SMC. Additionally, a statistically significant difference (p < 0.001) between controls and patient group regarding Beck depression score was detected. 16.6% of controls showed clinical relevant degree of DS whereas 48.5% of patients showed DS. An analysis
of variance revealed a statistically significant difference across all four groups (control group, SCI group, nA-MCI group, aMCI group) \((p < 0.001)\). Whereas 8% of controls reported considerable degree of SMC, 34% of the SCI group, 31% of the nA-MCI group and 54% of the aMCI group reported considerable SMC. A two factor analysis of variance with the factors cognitive status (controls, SCI group, nA-MCI group, aMCI group) and depressive status (depressed vs. not depressed) and SMC as a dependent variable revealed that both factors were significant \((p < 0.001)\) whereas the interaction was not \((p = 0.820)\). A large proportion of patients seeking help in a memory outpatient clinic report considerable SMC, with increasing degree from cognitively healthy elderly to aMCI. Depressive status increases SMC consistently across groups with different cognitive status.

Background and objectives: Excessive microglial activation by inflammation leads to the progression of neurodegenerative diseases which results in neuronal cell death such as Alzheimer’s disease. Mesuagenin C (MC) was reported to be neuroprotective against H2O2-induced apoptosis in NG108-15 cells. Therefore, the anti-inflammatory effects of MC in LPS-stimulated inflammation in microglial BV2 and H2O2-treated NG108-15 cells were investigated.

Material and methods: The expression of NO, ROS, PGE2, TNF-α, IL-1β, IL-2, IL-6, IFN-γ, iNOS, COX-2, CCL21 and the molecular pathways involved were determined by flow cytometry chip beads array (CBA), Western blot and ICC. NG108-15 and BV-2 were co-cultured, stimulated with LPS and further evaluated. Signaling pathways were validated with inhibitors and siRNA CCL21 was used to assess CCL21 involvement in neuroinflammation.

Results: MC mitigated LPS-induced iNOS, NO, ROS and PGE2 production leading to downregulation of TNF-α, IL-1β, IL-2, IL-6, IFN-γ and COX-2 expression. MC upregulated the pMTOR-Rictor complex leading to the upregulation of PI3K-pAkt expression. Furthermore, MC prevented iNOS degradation and thus, prevented p65 NF-κB translocation in BV2 and NG108-15 cells. Moreover, MC inhibited the CCL21 expression in both LPS-treated BV2 and H2O2-treated NG108-15 cells resulting in the reduction of CCL21 chemotactic activity and mitigation of BV-2 activation. CCL21 siRNA transfection mitigated LPS-induced neuroinflammation, further proved that modulation of CCL21 by MC was indeed important.

Conclusion: MC protects NG108-15 by suppressing BV-2 activation through pMTOR-PI3K-Akt pathway and prevention of p65 NF-κB translocation leading to downregulation of proinflammatory proteins and CCL21. This finding advocates therapeutic potential of MC for the treatment of neurodegenerative diseases.

Various types of neuronal damage have been reported in AIDS dementia complex (ADC). Human immunodeficiency virus (HIV) infected microglial/macrophage, not neuron directly in the brain. However, the damage of the neuron existed after the infection, in which the regulatory protein Tat of HIV-1 could be the critical factor. It has been recently reported that HIV-1 Tat transactivation requires menin, which hints that menin may be involved in the pathogenesis of ADC. However, the mechanism has not been elucidated completely. In this study, we report the up-regulated menin expression in the frontal cortex of SIV-infected macaques, especially in the neuronal nucleus by the double-labeling immunofluorescence, qRT-PCR and Western blot assay. The co-localization of menin and caspase3 is also observed in the frontal cortex of SIV-infected macaques. TGF-β, a cytokine associated with menin expression, is also detected increased in the frontal cortex of SIV-infected macaques. Furthermore, co-localization of SIV Tat and TGF-β appeared in increased TGF-β expressed vertebral neuron. In conclusion, these results indicate that
menin may be involved in the pathogenesis of ADC and the mechanism may be related to the pro-apoptosis of menin and the increased expression of TGF-β induced by SIV Tat. However, the precise mechanism needs to be further explored.

Early detection of abnormal prion protein in genetic human prion diseases now possible using real-time QUIC (RT-QUIC) assay

K. Satoh\(^a\), S. Shirabe\(^b\). \(^a\)Department of Molecular Microbiology and Immunology, Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan; \(^b\)Center for Health and Community Medicine, Nagasaki University Hospital, Nagasaki, Japan

Background: The definitive diagnosis of genetic prion diseases (gPrD) requires pathological confirmation. To date, diagnosis has relied upon the finding of the biomarkers in CSF, but many researchers have reported that these markers are not sufficiently elevated in gPrD, especially in Gerstmann–Sträussler–Scheinker syndrome (GSS). We recently developed a new in vitro amplification technology, designated “real-time quaking-induced conversion (RT-QUIC)”, to detect the abnormal form of prion protein in CSF from sporadic CJD patients.

Objective: In the present study, we aimed to investigate the presence of biomarkers and evaluate RT-QUIC assay in patients with gPrD, as the utility of RT-QUIC as a diagnostic tool in gPrD has yet to be determined.

Patients/method: 56 CSF samples were obtained from gPrD patients, including 20 cases of GSS with P102L mutation, 12 cases of familial insomnia (FFI; D178N), and 24 cases of genetic CJD (gCJD), comprising 22 cases with E200K mutation and 2 with V203I mutation. We subjected all CSF samples to RT-QUIC assay, analyzed 14-3-3 protein and measured t-tau protein.

Results: The detection sensitivities of RT-QUIC were as follows: GSS (78%), FFI (100%), gCJD E200K (87%), and gCJD V203I (100%). On the other hand the detection sensitivities of biomarkers were considerably lower: GSS (11%), FFI (0%), gCJD E200K (73%), and gCJD V203I (67%). Thus, RT-QUIC had a much higher detection sensitivity compared with testing for biomarkers, especially in patients with GSS and FFI.

Conclusion/significance: RT-QUIC assay is more sensitive than testing for biomarkers in gPrD patients.

Blood-borne biomarkers of Alzheimer’s disease pathology and cognitive decline in non-demented elderly

S. Westwood\(^a\), S. Lovestone\(^a\), M. Thambisetty\(^a\), M. Ward\(^b\). \(^a\)King’s College London, Institute of Psychiatry, London, UK; \(^b\)Unit of Clinical and Translational Neuroscience, Laboratory of Behavioral Neurology, National Institute on Aging, Baltimore, MD, USA; \(^c\)Proteome Sciences PLC, Institute of Psychiatry, London, UK

Background: There is an urgent need for Alzheimer’s disease (AD) biomarkers that can detect the disease at the early pre-symptomatic stages. Case versus control study designs often ignore clinical heterogeneity in patients and neuropathology in controls resulting in markers with doubtful clinical utility. Using well-established imaging phenotypes of AD pathology to derive biologically relevant biomarkers is an alternative approach. Neuropathological hallmarks of AD (B-amyloid plaques and neurofibrillary tangles) are commonly reported in brains of non-demented elderly individuals, suggesting these cases might represent preclinical AD and may be a good population in which to detect early AD biomarkers.

Objectives: To identify plasma biomarkers associated with AD endophenotypes in non-demented older individuals using two complimentary longitudinal discovery-phase proteomic analyses.

Materials and methods: Two-dimensional gel electrophoresis coupled with mass spectrometry was performed on longitudinal plasma samples from non-demented older individuals exhibiting a range of C-PrP PET measures of amyloid load (n = 68). The relationship between protein concentrations and measures of brain atrophy, cognitive decline, and amyloid load were examined. A label-free LC-MS/MS approach targeted at low molecular weight proteins (<30kDa) was also performed on a subset of these subjects (n = 38) to further investigate this relationship.

Results: We have identified proteins associated with brain amyloid load, atrophy and cognitive scores, some of which are also capable of predicting future decline. Using longitudinal samples also allowed longitudinal changes in these proteins to be explored.

Conclusions: Our findings support previous reports that plasma biomarkers have the potential to be used as a screening tool for AD.

The effect of memantine in specific behavioural symptoms in AD outpatients. results of a Greek observational, open-label, 6-month study

E. Kerezoudi\(^a\), A.P. Galanopoulos\(^b\), L. Saltos\(^c\), I.A. Parashos\(^b\).
\(^a\)Pammakaristos General Hospital, Greece; \(^b\)Lundbeck Hellas SA, Greece; \(^c\)401 Army General Hospital, Athens, Greece

Objective: To assess the effectiveness of memantine treatment on specific behavioural symptoms of a Greek Alzheimer’s Disease (AD) population.

Patients and methods: In this observational, open-label study, behavioural symptoms were evaluated by NPI Scale at baseline, 3 and 6 months.

Results: 1487 patients were included in the study. The NPI-items rated with the higher scores were “anxiety”, “depression/dysphoria” and “irritability/lability”, with scores (mean ± SEM) of 3.0 (±0.1), 2.8 (±0.1) and 2.6 (±0.1) points. In the “behaviourally disturbed population” (BDP), defined as patients having NPI Score > 0 in any of the symptoms: delusions, hallucinations and agitation/aggression, the symptoms with the higher scores were “anxiety” (3.4 ± 0.1 points), “agitation/aggression” (3.3 ± 0.1) and “irritability/lability” (3.2 ± 0.1). All 12 NPI-items were significantly improved at 6 months (Friedman test, p < 0.001). The bigger absolute improvement was detected in “anxiety” and “depression/dysphoria”, by 1.6 points mean decrease in each item, while the higher percentage improvement was achieved in “agitation/aggression” and “irritability/lability” with 58% and 56% mean decrease over 6 months of treatment. In BDP, the higher improvements were observed, both in absolute and percentage values, in “agitation/aggression” and “irritability/lability” subscores (−2 and −1.9 points, 60.6% and 59.4%, respectively). 5.5% of patients prematurely discontinued treatment and only 0.3% of total population stopped due to adverse event (AE).

Conclusion: Memantine improved all 12 NPI behavioural items assessed in this observational study conducted in Greece in AD outpatients.
Relatively higher improvement was detected in “agitation/aggression” and “irritability/lability”. Memantine treatment was very well tolerated as only 0.3% of patients discontinued due to AE.

Discovery of peripheral biomarkers of Alzheimer’s disease pathology
A. Baird a,b, N. Ashton a,b, M. Ward a,c, C. Bazenet a,b, P. Schelten d, C. Teunissen e, S. Lovestone a,b, 1Department of Old Age Psychiatry, Institute of Psychiatry, UK; 2NIHR Biomedical Research Centre for Mental Health, Kings College London, UK; 3Proteome Sciences PLC, London, UK; 4Alzheimer Centre and Department of Neurology, The Netherlands; 5Department of Clinical Chemistry, VU Medical Centre, Amsterdam, The Netherlands

Background: Alzheimer’s disease (AD) is the most common form of dementia in later life, affecting one in eight people by the age of 65 years. The development of minimally invasive peripheral markers that can better describe and predict the neuropathology of the disease, could greatly aid in overcoming the complexity of AD diagnosis.

Objectives: The aim of this study is to discover novel peripheral markers, that can predict Alzheimer’s disease pathology.

Materials and methods: Peripheral biomarker discovery was undertaken in a cohort of extreme endophenotypes of pathological status, which were determined by the measurement of CSF Abeta/tau. Subjects were selected with very high CSF Abeta/low tau values (n = 25) or very low CSF Abeta/high tau values (n = 25). Isobaric tandem mass tagging (TMT) in combination with SDS-PAGE fractionation and LC-MS/mass spectrometry Orbitrap Velos Pro instrumentation were used to detect and quantify potential plasma biomarkers.

Results: A selection of 10 plasma proteins shows group-wise differences in their levels, according to CSF-measured pathology (Mann Whitney U Test, P < 0.05), and correlations of further 6 proteins with the degree of CSF-measured pathology are observed (Spearman’s Rank Correlation P < 0.05). These include proteins identified in earlier studies as being associated with AD, as well as novel proteins not previously identified as being related to the disease and its pathology.

Conclusion: We have identified a number of plasma proteins as potential candidate markers of AD pathology in relation to CSF Abeta/tau. These markers include proteins related to the complement cascade and amyloidogenic processes.

The use of memantine in a Greek outpatient population. The effect of behavioural disturbances and other comorbidity
L. Saltos a, E. Kerezoudi b, A.P. Galanopoulos c, I.A. Parashos a, 1401 Army General Hospital, Greece; 2Pammakaristos General Hospital, Athens, Greece

Objective: To investigate the effectiveness of memantine treatment on Alzheimer’s Disease (AD) patients’ behaviour and cognition, in relation with common clinical parameters such as the presence of behavioural disturbances and concomitant diseases at baseline.

Patients and methods: This observational, open-label study was conducted in Greece, at an AD outpatient setting. Neuropsychiatric Inventory (NPI) and Mini-Mental State Examination (MMSE) were used for assessing behaviour and cognition. Patients were evaluated at baseline, 3 and 6 months and considered as “behaviourally disturbed population” (BDP) if at least one of the symptoms: delusions, hallucinations and agitation/aggression was present.

Results: 1487 patients were included in the study. Mean NPI score (±SEM) significantly improved from 24.5 (±6.0) at baseline to 15.0 (±4.0) at 3 months and 11.9 (±4.0) at 6 months (Hotelling’s test, p = 0.001). MMSE score accordingly improved from 17.1 (±0.1) to 18.3 (±0.1) and 18.7 (±0.1) (Hotelling’s test, p < 0.001). BDP patients (n = 987) improved significantly more than non-BDP population (n = 404) in NPI and MMSE (t-test, p < 0.001 for both scales). Patients were significantly more improved in both scales if they were behaviourally disturbed at baseline (t-test, p < 0.001) and if they were suffering from concomitant diseases (t-test, p < 0.01). Patients with concomitant diseases reported the significantly more adverse events (AEs, p = 0.033).

Conclusion: Memantine improved behaviour and cognition in Greek AD outpatients over a 6-month treatment. BDP and also patients with concomitant diseases showed greater improvement than non-BDP and patients without concomitant diseases respectively. AEs were few but relatively more in patients with concomitant diseases.

Abstract — WCN 2013

The effectiveness of memantine in a “behaviourally disturbed” AD population. Results from a Greek observational, open-label, 6-month study
A.P. Galanopoulos a, L. Saltos a, E. Kerezoudi b, I. Parashos a, 1Lundbeck Hellas SA, Greece; 2401 Army General Hospital, Greece; 3Pammakaristos General Hospital, Athens, Greece

Objective: To evaluate the effectiveness of memantine treatment on behaviour and cognition of an Alzheimer’s Disease (AD) “behaviourally disturbed” population.

Patients and methods: This observational, open-label study took place in Greece, at AD outpatients. Neuropsychiatric Inventory (NPI) and Mini-Mental State Examination (MMSE) were used for assessing behaviour and cognition. The “behaviourally disturbed population” (BDP), included participants having NPI score > 0 in any of the symptoms: delusions, hallucinations and agitation/aggression. Patients were evaluated at baseline, 3 and 6 months.

Results: 981 out of 1487 patients were classified as BDP. In this population, mean NPI score (±SEM) significantly improved from 31.1 (±0.7) at baseline to 18.5 (±0.5) at 3 months and 14.5 (±0.5) at 6 months (Hotelling’s test, p < 0.001). MMSE score also improved from 16.5 (±0.2) to 17.9 (±0.2) and 18.4 (±0.2) (Hotelling’s test, p < 0.001). Agitation/psychosis subscore (cluster of the 3 aforementioned NPI-items scores) significantly improved from 7.9 (±0.2) to 4.6 (±0.2) to 3.7 (±0.2) at 3 and 6 months (Hotelling’s test, p < 0.001). 5.3% of patients early discontinued treatment (only 0.2% due to adverse event—AE) and 4.6% of patients reported at least one AE.

Conclusion: Memantine improved agitation/psychosis NPI subscore and also total NPI and MMSE scores in Greek behaviourally disturbed outpatients over a 6-month treatment. Memantine was well tolerated as discontinuations and AEs reported were few.

Topic: 5 — Dementia
Rapidly progressive dementia in the “Attikon” University General Hospital of Athens. A one-year experience

Introduction: Rapidly progressive dementia (RPD) is a rare neurological condition which progresses subacutely from days to months. A variety of possible causes of RPD have been reported, such as neurodegenerative, autoimmune, vascular, metabolic/toxic disorders, infections, malignancies, normal pressure hydrocephalus and psychiatric disorders.

Objectives: To describe the causes and the clinical presentation of RPD in the University General Hospital of Athens “Attikon” within a year.

Methods: From a total of 728 patients hospitalized in our department from January 2012 to February 2013, 21 patients presented with RPD. A detailed clinical and laboratory investigation was performed in all cases.

Results: The most common cause of RPD reported in our department was probable sporadic CJD (6 cases). Two patients were diagnosed with normal pressure hydrocephalus (NPH) and four patients developed RPD due to vascular etiology (2 patients with probable CADASIL, 1 patient with probable cerebral amyloid angiopathy and 1 patient with vascular dementia). The rest of the cases had various neurodegenerative disorders: probable AD (1 patient), DBL (1 patient), PSP (2 patients) and frontotemporal dementia (1 patient). One patient developed hydrocephalus and cognitive decline on the basis of Mycobacterium tuberculosis infection and 1 patient developed dementia probably due to chronic abuse of benzodiazepines.

Conclusion: RPD cases are not rare in a university general hospital. Besides CJD, neurodegenerative and secondary causes of RPD are frequent requiring a thorough investigation.

EEG microstates in Alzheimer’s disease computed by continuous wavelet coherence
L. Kopal1, O. Vyšata23, A. Procházka2, M. Schätz2, 1Institute of Chemical Technology, Prague, Czech Republic; 2Institute of Neurology, Charles University Prague, Faculty Hospital, Hradec Králové, Czech Republic

Background: Electrophysiological studies have demonstrated that the brain is active even in the absence of explicit input or output. Microstates represent subsequent coherent activation within the global functional brain networks. Continuous wavelet coherence is a measure of time-frequency changes in linear dependencies between EEG channels.

Objective: Areas of EEG microstates were evaluated in patients with Alzheimer’s disease (AD). Differences in areas pertinent to each pair of electrodes and for frequency bands between patients with AD and healthy controls were calculated.

Patients and methods: EEG data were obtained for 110 patients with moderate dementia (MMSE score 10–19) and a control set of 110 age-matched, healthy subjects who had no memory or other cognitive impairment. Continuous wavelet coherence maps were computed for EEG records using the Matlab computational environment. The values higher than the threshold were considered as microstates corresponding to the coherent activation within the global functional brain networks. Areas of time-frequency plots for the delta, theta, alpha, beta and gamma bands were compared for both groups.

Results: Statistically significant differences were observed, particularly in the alpha, beta and gamma frequency bands of the frontal and temporal regions. The accuracy of distinction between healthy individuals and AD patients for the Fp2-T5, F8-T5, F7-O2, Fp2-O2 pairs of electrodes in the alpha band was more than 0.8.

Conclusion: These results can be interpreted as a decrease in the value of the parameter reflecting the ability of the system self-organization and thus suboptimal information processing clinically manifested as cognitive deficit.

Reproducibility of [18F]flutemetamol PET amyloid image interpretation
Z. Walker4, F. Inglis4, C. Sadowsky5, B. Safirstein5, G. Farrar5, C. Buckley5, L. Thurfjell6, P. Sherwin5, K. Cardinal5, S. De Santi8, R. Vandenbergh6, 4University College London, London; 5Glasgow Memory Clinic Ltd, Glasgow, UK; 6Nova Southeastern University, Fort Lauderdale; 7Beth Safirstein, Hallendale, FL, USA; 8CE Healthcare, Amershams, UK; 4CE Healthcare, Uppsala, Sweden; 5CE Healthcare, Princeton, NJ, USA; 6Catholic University, Leuven, Belgium

Objective: The reproducibility of [18F]flutemetamol PET amyloid image interpretation measured by inter-reader agreement (IRA) and intra-reader reproducibility (IRR), and quantitative test–retest variability was assessed, using CE’s clinical trials data.

Methods: Blinded visual interpretations of color PET images from one Phase II study (Study 1) and two Phase III studies (Studies 2 and 3) were analyzed. In each study, five readers were trained to read [18F]flutemetamol scans via in-person training (Studies 1 and 2) or an electronic training program (Study 3). Readers then interpreted scans from healthy volunteers (HV), patients with Alzheimer’s disease (AD), and amnestic mild cognitive impairment (aMCI) subjects as normal or abnormal for [18F]flutemetamol uptake. Included in each image set (to assess IRR) were randomly selected and inserted duplicates of ~10% of the images. In Study 1 only, intra-subject test–retest variability was calculated for five AD subjects who underwent two [18F]flutemetamol scans as the percentage difference between regional SUVr for a set of cortical regions.

Results:
Study 1: Across all groups, Fleiss’ kappa for IRA (n = 67: 22 AD, 20 aMCI, and 25 HV) was 0.96 and IRR was 97.5%. Test–retest variability of regional SUVr was 1% to 4%.
Study 2: Fleiss’ kappa for IRA (232 aMCI patients) was 0.76 and IRR ranged from 86% to 100%.
Study 3: Fleiss’ Kappa for IRA (80 aMCI patients) was 0.89, and IRR was 100%

Conclusions: Across the three studies, blinded visual interpretations of [18F]flutemetamol PET amyloid images had high IRA and IRR. Regional SUVr determinations had low test–retest variability.

The diagnostic value of Alzheimer's disease-related individual structural volume measurements using IBASPM
S.-H. Han, Y.C. Youn. Chung-Ang University College of Medicine, Seoul, Republic of Korea

Background: Despite the importance of hippocampal volume as a biomarker for AD and the availability of automatic measurement, the optimal cut-off of hippocampal volume using automatic segmentation is still unknown.

Objective: We validated the use of medial temporal volume measurements using the Individual Brain Atlases using Statistical Parametric Mapping (IBASPM), an automated volumetric method, for screening for Alzheimer’s disease (AD). We also determined the age-specific, optimal cut-off values for hippocampal volumes.

Patients and methods: The study included T1-weighted magnetic resonance images (MRI) of 94 patients with AD and 51 normal controls. To determine age-specific cut-off values, we grouped subjects according to age. The hippocampal volumes of each group were measured using individual atlas-based volumetry with IBASPM.

Results: The normalized value of left hippocampal volume in patients with AD was significantly lower than that of the normal controls in all age groups. The areas under the curve (AUC) values of the left hippocampus were also the largest in all age groups, indicating that AUC is the most useful factor of AD screening.

Conclusion: In conclusion, in clinical practice, measurement of left hippocampal volume using automatic measurement (IBASPM) assists in screening for AD, if used with the age specific cut-off value calculated in the present study. Left hippocampal atrophy is the best indicator in all age groups. Automated methods are faster and more feasible in clinical settings than manual segmentation, and provide a useful biomarker for AD.

doi:10.1016/j.jns.2013.07.1297
connectivity of brain network. The default mode network (DMN) is one of prominent networks, which include the hippocampus, posterior cingulate (PCC), medial prefrontal, lateral temporal, and parietal cortices. Many studies found decreased DMN connectivity in Alzheimer’s disease (AD) and suggested distinct involvement of DMN in different types of dementia.

**Objective:** We aimed to differentiate normal pressure hydrocephalus (NPH) from AD on the basis of neural connectivity with rs-fMRI, because these two diseases are sometimes difficult to discriminate only on the morphological examination.

**Patients and method:** Subjects diagnosed as having probable NPH (n = 9; mean age 77.4 ± 4.1 years, range 69–80 years), AD (n = 27; mean age 76.5 ± 5.0 years, range 66–86 years), and 57 healthy controls (HC, n = 57; mean age 67.3 ± 5.2 years, range 61–79 years, MMSE ≥ 27) underwent rs-fMRI. We used PCC as a seed region to determine the functional connectivity to other brain regions in DMN.

**Results:** The functional connectivity between PCC and other brain regions in DMN was decreased in both NPH and AD groups compared to HC group (p < 0.001), and there was no difference in the connectivity between NPH and AD groups.

**Conclusion:** Our findings indicate that the functional connectivity in DMN decreased in NPH as well as AD. However, it is difficult to differentiate NPH from AD on the basis of functional connectivity with rs-fMRI using seed-based analysis.

**Cortical beta-amyloid and microstructural properties of the corpus callosum in patients with mild to moderate ad**

**Background:** Several studies have reported microstructural changes of the corpus callosum (CC) in AD. The pathological basis of these changes remains uncertain.

**Objective:** We investigated whether fractional anisotropy (FA) as a marker of microstructural properties of the CC is associated with cortical beta-amyloid measured by amyloid imaging.

**Methods:** Patients with mild to moderate Alzheimer’s dementia (according to NINCDS-ADRDA criteria and ICD-10 criteria), were recruited.

Patients underwent 11C-PiB-PET for assessment of cortical beta-amyloid and MRI (Siemens Magnetom Trio 3T) including DWI for quantification of white matter microstructure. DWI data were fitted to the tensor model, and FA maps were created. Masks were manually delineated on the midsagittal slice of the FA maps, encompassing the anterior 1/6th of the CC (projecting to prefrontal cortex) and the posterior 1/4th (projecting to parietal, temporal, occipital cortices). For quantification of beta-amyloid standard uptake value ratios (SUVr) from prefrontal cortex, and parietal, occipital and temporal cortices were used in the analysis.

**Results:** Thirty-two patients (age, years: 69.2 ± 3.3; Gender (f/m): 14/18; MMSE: 24.8 (3.5)) were included in the study. Mean FA across subjects for anterior CC was 0.74 (±0.038) and for posterior CC 0.71 (±0.068). No significant associations between FA in anterior CC and prefrontal 11C-PiB uptake or between FA in posterior CC and parietal–temporal–occipital cortex 11C-PiB uptake was found.

**Conclusion:** Cortical deposition of beta-amyloid does not seem to be the underlying mechanism of microstructural changes in the CC in AD patients. However, whether beta-amyloid may affect the CC through cortical atrophy remains undecided.

Complete sequencing of the 7 mtDNA genes encoding for complex I subunits in frontotemporal lobar degeneration
Faculty of Medicine, University of Coimbra, Portugal;†Faculty of Medicine, University of Coimbra, Portugal; ‡Center for Neuroscience and Cell Biology, University of Coimbra, Portugal; ‡Faculty of Medicine, University of Coimbra, Portugal; †CHUC EPE — Neurology Service, Coimbra, Portugal

Background: Mitochondria dysfunction and oxidative damage were reported in aging-related neurodegenerative diseases. A possible mechanism involves mitochondrial DNA (mtDNA) alterations impairing mitochondrial respiratory chain function. Contrary to other neurological disorders, frontotemporal lobar degeneration (FTLD) pathophysiology is still poorly understood, and etiology is often unknown. Recently, two mtDNA alterations were reported in a FTLD patient and an association with mtDNA haplogroup was proposed.

Objective: Sequencing the 7 MT-ND genes in FTLD patients.

Patients and methods: Total DNA was extracted from peripheral blood of 32 patients with probable FTLD recruited at Neurology Unit (CHUC). Analysis of 7 MT-ND genes sequences was performed by automatic sequencing and variants were submitted to in silico study. Statistical analysis was performed using Graph-Pad Prism 5.0.

Results: We found 80 different alterations in 30 patients (93.8%), including 68 polymorphisms (85.0%), 11 sequence variations previously associated to other diseases (13.7%) and 1 unpublished variant (1.3%). An analysis was conducted by dividing these patients in two groups: 1–5 sequence variants (15) and 6–13 alterations (15) per patient. There were no statistically significant differences when comparing both groups, according to age, gender, age of onset, disease duration, and CDR or MMSE results.

Conclusion: To our knowledge, this is the first report of complete sequence of the 7 MT-ND genes in FTLD patients. The high number of mtDNA alterations identified suggests a possible role of these variants in FTLD. However, further studies are needed to determine whether these variants are part of the etiology or an epiphenomenon.

Comparison of complexity, entropy and complex noise parameters in EEG for AD diagnosis
M. Schätz, O. Vyšata, J. Kopal, A. Procházka. Department of Computing and Control Engineering, Institute of Chemical Technology, Prague, Czech Republic

Background: A non-linear analysis of EEG time series offers an alternative approach to understanding changes in Alzheimer’s disease. Parameters used in this study are essentially a measure of the unpredictability, complexity or ‘randomness’ of the neural signal.

Objective: Complexity of EEG signal using fractal dimension, entropy and complex noise characteristics was evaluated in healthy population during aging and for a set of patients with Alzheimer’s disease (AD). The threshold value of EEG complexity biomarker was estimated to distinguish patients with AD from healthy individuals.

Patients and methods: EEG data were obtained for 110 patients with moderate dementia (MMSE scores 10–19) and for a control set of 110 age-matched, healthy subjects who had no memory or other cognitive impairment. With the support of the MATLAB computational environment, EEG complexity was computed for 19 electrodes using Katz’s and Sevcik’s fractal dimension algorithms, permutation entropy and complex noise characteristics.

Results: AD patients and healthy individuals differed in EEG signal complexity. Using the threshold for separation of patients, we estimated the accuracy of 82% (Sevcik’s FD), 72% (Katz’s FD), 85% (color noise) and 70% (entropy).

Conclusion: These results suggest that characteristics based on the complex noise and Sevcik’s fractal dimension provide the best discriminatory value for the non-linear measures of EEG complexity.

Cognitive deficit in Alzheimer’s disease and during aging and self-organized criticality
O. Vyšata, A. Procházka, M. Vališ, J. Horejs, O. Vysata, J. Kopal, A. Procházka. Department of Neurology, Charles University in Prague, Faculty Hospital, Hradec Králové, Czech Republic; Department of Computing and Control Engineering, Institute of Chemical Technology, Prague, Czech Republic; Neurology, Neurocentre Caregroup Ltd., Rychnov nad Kneznou, Czech Republic

Background: Alzheimer’s disease (AD) is associated with cognitive deficits due to neuronal loss, reduced brain neuronal connectivity and modifications to the functional organisation of the brain. Reduced connectivity might manifest as changes in the linear and non-linear synchronisation of collaborating parts of the brain.

Objective: Non-linear and linear measures of synchronicity in Alzheimer’s disease (AD) were compared with those of healthy age-matched control subjects.

Patients and methods: Wavelet coherence (WC) was used to estimate linear synchronisation between electroencephalographic (EEG) channels. Mutual information (MI) was applied to absolute values of complex wavelet coefficients in wavelet scales to estimate non-linear synchronisation. Synchronisation rates for a group of 110 patients with moderate Alzheimer’s disease (MMSE 10–19) and 110 healthy control subjects were compared. Both parameters were estimated using the MATLAB computational environment.

Results: The most significant differences for an increase in mutual information were identified on the second and the third scale in the parietooccipital area, while for wavelet coherence the most significant difference was found between the frontal and parietal electrodes.

Conclusion: This newly proposed method utilises mutual information of complex wavelet coefficient absolute values in wavelet scales and demonstrates larger discriminatory values in Alzheimer’s disease compared to wavelet coherence.

doi:10.1016/j.jns.2013.07.1302

Background: The hypothesis that the electrical activity of neural networks in the brain oscillate around critical points is very important, as many simulations show that the optimal efficiency of information processing is achieved at the critical point.

Objective: Complex noise with the power spectra dependence of the PSD = 1 / f / ^ α frequency was evaluated in an aging healthy population and in patients with Alzheimer’s disease (AD). Correlation between the alpha value and age and significance of difference between patients with AD and healthy controls were estimated.

Patients and methods: EEG data on 3845 truck drivers, 108 patients with moderate dementia (MMSE scores 10–19) and a control set consisting of 108 age-matched, healthy subjects who had no memory or other cognitive impairments were obtained. Power spectral densities (PSDs) of the EEG frequency components were estimated using the Welch method on the MATLAB computational environment. The slope of the log–log scale was estimated in the least squares sense.

Results: Aging correlates with a decrease of alpha towards values characteristic for the white noise in the most electrodes. The slope of the near linear decrease of the power spectra in the log–log scale shows statistically significant differences in the frontal areas of AD patients.

Conclusion: These results can be interpreted as a decrease in the value of the parameter reflecting the ability of the system’s self-organization and thus suboptimal information processing clinically manifested as a cognitive deficit.

Progression of cognitive impairment in parkinsonian patients

Parkinsonisms at onset can be associated to cognitive impairment. To describe the progression of cognitive deficits in patients with parkinsonism at onset.

We consecutively selected patients with parkinsonism and disease duration up to three years to take part in the Bologna-motor and non-motor prospective study on parkinsonisms at onset (Bo-ProPark). All patients underwent, at baseline (T0) and after sixteen months (T1), neuropsychological assessment (Brief Mental Deterioration Battery, Stroop Test, Semantic Fluency Task, Beck Depression Inventory). Progression of cognitive impairment (CI) was defined as a drop of 1.5 SD in the corrected score for age sex and education. For all tests, except Barrage and Stroop, a positive score indicates CI progression.

35 patients were recruited. 27 patients were diagnosed as Parkinson Disease (PD), 2 as Progressive Supranuclear Palsy (PSP), 1 as Multiple System Atrophy (MSA), 1 as Cortico Basal Degeneration (CBD) and 4 as Parkinsonian Syndromes not otherwise specified (PS). At T0 13 patients (8 PD, 1 MSA, 1 CBD, 2 PSP and 1 PS) presented CI. The degree of CI was stable at T1. Global CI was detected in 2 PSP and 1 PD patients; executive function impairment was found in 5 PD, 1 DCB, 1 MSA and 1 PS, and memory impairment in 2 PD patients. Progression of cognitive deficits at T1 was observed in 5 PD patients with only executive functions.

CI can be observed in patients with parkinsonism at disease onset, independent from the clinical diagnosis. Progression of CI should be further evaluated as predictors of the diagnosis and prognosis.

A case of dementia secondary to subacute leukoencephalopathy by carbon monoxide
M.P. Alvarado1, E. Angel2, C. Cisternas2, D. Sáez Mendez2, L. Lay-Son2, 3Departamento Neurología, Hospital Barros Luco Trudeau, Universidad de Chile, Chile; 4Departamento Neurologia, Universidad de Santiago de Chile, Santiago, Chile

Introduction: Delayed hypoxic-ischemic leukoencephalopathy described in 1976 by Ginsberg is a brain white matter demyelination phenomenon that occurred days or weeks after a hypoxic-ischemic injury followed by a complete recovery of the episode. Recovery is frequently observed in 75% of cases. We present the case of a patient exposed to carbon monoxide acutely, without impairment of consciousness that develops a subacute dementia syndrome.

Patients: A male patient of 52 years presented with a history of alcohol consumption, and an exposure to carbon monoxide for about 14 h. The patient was evaluated in the emergency room, with 24 h of observation and was discharged asymptomatic. One month later, the patient has alterations in daily living, he can't make paperwork, he can't work, and he gets lost on public roads. The patient was evaluated by neurology and highlights executive dysfunction without focal signs and without meningeal signs. The Addenbrooke’s Cognitive Examination (ACE) was 60/100.

Material and methods: General exams are normal, HIV was negative, immunological tests were normal, cerebrospinal fluid thyroid tests were normal, and there was no asymmetry electroencephalogram without paroxysmal activity. Brain MRI shows typical leukoencephalopathy.

Results: The patient at 3 months shows a slight recovery of cognitive ability, still requires assistance to perform daily living and he cannot work. The ACE was 70/100.

Conclusion: A rare cause of dementia is subacute carbon monoxide poisoning, especially in this case, where exposure to carbon monoxide is brief and without impairment of consciousness of the patient.

Synaptic alterations in the claustrum in Alzheimer’s disease: A Golgi and electron microscope study
S.I. Baloyannis1, 2, I. Mavroudís2, I.S. Baloyannis3, V.G. Costa2, 3Neurology, Aristotelian University, Thessaloniki, Greece; 4Institut for Research on Alzheimer's Disease, Iraklion, Greece; 5Neurosurgery, Aristotelian University, Thessaloniki, Greece

Alzheimer’s disease is a heterogeneous neurodegenerative disorder of presenium and senium, characterized by a progressive decline of mental faculties, loss of professional skills, impairment of behavior, social performance and communication and various neurological manifestations. Since basal ganglia play an important role in cognitive functions, motor control and behavior, we attempted to study the pathological alterations of the claustrum whose enigmatic function may be related to cognition. We attempted to figure out the synaptic alterations in early cases of Alzheimer’s disease. The morphological analysis is based on examination of twenty brains. Samples from the three parts of the claustrum, based on dorsoventral and anteroposterior axons, were processed for the Golgi technique and electron microscopy. The morphological and morphometric analysis revealed substantial neuronal loss and marked synaptic alterations mostly in the anterior
part of the claustrum. The dendritic arborization was decreased. Dendritic spines of the elongated and fusiform neurons were dramatically decreased. Mitochondrial alterations and fragmentation of Golgi apparatus were seen in a considerable number of neurons. Synaptic alterations were seen in all the parts of the claustrum, although the synapses were better preserved in the ventroposterior part than in the anterior dorsal one. Neurofibrillary tangles were frequently seen. Reactive astrocytosis was more prominent in the anterior part than in the middle and the posterior ones. The neuronal loss and the synaptic alterations in the claustrum may underline a broad cholinergic deficit in Alzheimer’s disease and a substantial decline of cortico-subcortical cooperative activity in the early stages of Alzheimer’s disease.

The early identification of neuropsychiatric symptoms in MCI could improve further the prediction of the complex clinical course of the dementia illness, possibly helping improve treatment approaches, and ultimately the prognosis.

Methods: We included 101 outpatients of a memory clinic in Maryknoll Hospital (48 AD; 53 amnestic-MCI-multidomain) and 25 controls. Categorical disorders of depression and apathy were diagnosed with structured interviews. Symptoms were evaluated with the neuropsychiatric inventory (NPI). The odds ratios (OR) of patients having neuropsychiatric symptoms compared to controls were calculated with logistic regression, adjusted for sociodemographic and clinical variables.

Results: A large proportion of AD (62.5%), amnestic-MCI-multidomain (39.6%) patients had a depressed disorder. Apathy disorder was common in AD (68.7%) but less frequent in amnestic-MCI-multidomain (9.4%). AD patients were five times more likely to have depression disorders (OR = 5.1, CI = 1.1–23.1) compared to amnestic-MCI-multidomain. After apathy and depression, the most prevalent neuropsychiatric symptoms in AD and MCI were anxiety, agitation, irritability, night-time behaviors, and appetite disturbances.

Conclusions: Clinicians should consider the relevance of neuropsychiatric symptoms in patients with cognitive disturbances, and incorporate a thorough psychiatric examination in the evaluation of patients.

Increased PPAR-gamma levels in the CSF of patients with multiple sclerosis

L. Szalardy1, D. Zadori2, E. Tanczos3, M. Simu1, K. Bencsik1, L. Vecsei1,2, P. Klivenyi1,2,3, Department of Neurology, University of Szeged, Faculty of Medicine, Szeged, Hungary; 2Department of Mathematics and Computer Science, Eindhoven University of Technology, Eindhoven, The Netherlands; 3Department of Neurology, University of Medicine and Pharmacy Victor Babes, Timisoara, Romania; Hungarian Academy of Sciences, University of Szeged, Szeged, Hungary

Peroxisome proliferator-activated receptor (PPAR)-gamma, a ligand-activated transcriptional factor involved in the regulation of glucose and lipid metabolism, has gained interest as a possible therapeutic target in multiple sclerosis (MS) owing to its potent immunoregulatory effects and the therapeutic efficacy of its ligands in experimental autoimmune encephalitis (EAE). Elevated expression of PPAR-gamma has been detected in the spinal cord of EAE mice and in an in vitro model of demyelination; however, no reports have yet been available on the PPAR-gamma status in the central nervous system (CNS) of MS patients. Aiming to identify a possible alteration, the present study assessed the concentration of PPAR-gamma protein in the cerebrospinal fluid (CSF) of MS patients via ELISA method. We report a robust increase in the CSF levels of PPAR-gamma in MS patients (n = 35) compared to non-inflammatory controls (n = 22). This increase was independent of blood–CSF barrier dysfunction, but correlated with CSF cell count and IgG index, associating the observed increase with CNS inflammation. Controlling for potential confounders, CSF concentration of PPAR-gamma further showed a moderate but statistically significant association with clinical severity (EDSS). Corroborating with previous experimental findings, these results may contribute to our understanding about the role of PPAR-gamma in MS, and may implicate this protein as a potential CSF biomarker of clinical severity in MS.

Endocrine disorders of patients with multiple sclerosis

E.M. Ivanova, M.A. Barabanova, Г.Г. Музлаев. Nervous and Neurosurgery, Kuban State Medical University, Krasnodar, Russia

Introduction: While multiple sclerosis (MS) affects the nervous system, extra-neural pathology is also observed. Objective detection of endocrine disorders and determination of its dependence on the degree of the disease severity.

Methods and materials: 85 patients were examined with relapsing–remitting type of MS clinical course. Severity of patient’s state was rated on a scale: EDSS, FS Kurtzke. Mild severity — 2.33 ± 0.09 points (EDSS), moderate severity — 4.1 ± 1.08, heavy severity — 6.3 ± 1.2.

Results: Endocrine disorders were diagnosed in 25 (23.8%) patients. 17 (68%) patients developed mild MS and 8 patients (32%) — moderate MS severity. Cortisol level was 1.4 times more than normal of 10 (40%) patients. The correlation between stem disorders and cortisol levels (r = −0.29) was defined. 8 (32%) patients developed autoimmune thyroiditis in hypertrophic form. Thyrotropin hormone concentration
was 8 times higher than normal, the level of free thyroxine was 2 times less than normal. The correlation between hormone levels and severity of movement impairment \((r = -0.21)\), cerebellar symptoms \((r = 0.55)\), sensory disturbances \((r = -0.25)\), pelvic disorders \((r = 0.74)\) was established. 7 (28%) patients showed prolactin levels for 38.2% higher than normal. The correlation is established between hormone levels and the severity of movement impairment \((r = -0.61)\), cerebellar symptoms \((r = 0.44)\), stem disorders \((r = -0.35)\), sensory disturbances \((r = -0.35)\).

**Conclusion:** Endocrine disorders prevailed in mild severity of disease, were characterized by the presence hypercortisolema, hyperprolactinemia, hypothyroxinemia, and an increased content of thyroid stimulating hormone. The correlation between level of thyroid stimulating hormone and EDSS score \((r = 0.43)\) is established.

**TLR 3 ligand poly I:C does not induce encephalitogenic T cells nor alter cytokine production in SJL EAE**

H.H. Hoßfetter, C. Zimmermann, A. Weber, B.C. Kieseier, H.P. Hartung. Neurology, Heinrich Heine University, Düsseldorf, Germany

**Background:** Toll-like receptor (TLR) ligands have the ability to alter an autoantigen-specific immune response both when they are present during the priming phase as well as when they are present when the primed T cell reencounters its antigen, e.g. in the inflamed CNS.

**Objective:** Poly I:C, a viral mimic and ligand for TLR 3 is widely used as a paradigm for a viral infection. Since viral infections are both linked with the initiation of multiple sclerosis (MS) as well as with relapses, we here investigated the effect of poly I:C both as an adjuvant as well as a co-stimulant during PLP-specific recall.

**Material and methods:** PLPp 139–151 injected in CFA subcutaneously and systemic administration of Pertussis toxin were generated to induce EAE in female wild-type SJL mice. Alternatively, mice were injected with PLPp 139–151 and poly I:C as an adjuvant. PLPp-specific T cell responses were assessed by cytokine ELISPOT for pro-and anti-inflammatory cytokine production both in the spleen and in the inflamed CNS.

**Results:** We find that poly I:C as an adjuvant does not prime an encephalitogenic T cell population, nor does it do so effectively the PLPp-specific T cell cytokine signature during recall in the immune periphery or in the inflamed target organ.

**Conclusion:** We conclude that different TLR ligands can have fundamentally different effects on an ongoing CNS-autoantigen specific autoimmune process.

**Neuromyelitis optica and optic spinal multiple sclerosis are different diseases?**

M.P. Alvarenga, M.P. Alvarenga, C.C. Ferreira Vasconcelos, U.C. Linhares, C. Bento, G. Santos, R.M. Papais-Alvarenga. Neurology, UNIRIO, Rio de Janeiro, Brazil; Rede Sarah de Reabilitação, Rio de Janeiro, Brazil; UNIRIO, Rio de Janeiro, Brazil

**Objective:** To compare neuromyelitis optica (NMO) and optic spinal multiple sclerosis (OS-MS).

**Method:** Consecutive patients with NMO phenotype attended in Rio de Janeiro from 2009 to 2011 were classified in two groups: defined NMO according to Wingerchuk et al. (2006) (recurrent or monophasic) and optic spinal multiple sclerosis (OS-MS).

**Results:** We analyzed 99 patients: 66 were NMO-R, 8 NMO-M and 25 MS-OS. In NMO-R group, 91% were women, 65.2% African–Brazilian, mean age at onset is 13.03 years, median EDSS of 6.0 (2.0 to 10) in the last evaluation after median disease time of 8 years (2–35); the positivity of anti-AQP4 was 56.1%. In group NMO-M, 62.5% were women, 65.5% African–Brazilian, mean age at onset is 19.77 years, median EDSS of 3.0 (2.0 to 6.0) in the last evaluation after 7 years of median disease time (3–14); the positivity of anti-AQP4 was 0.0%. In MS-OS group 84% were women, 16% African–Brazilian, mean age at onset is 8.12 years, median EDSS of 3.0 (1.0 to 6.5) in the last evaluation after a median disease duration of 8 years (3.0 to 27.0); the positivity of anti-AQP4 was 0%. There was a statistically significant difference between NMO and OS-MS groups concerning to race, long term disability, extension of the MRI vertebral lesion, positivity of anti-AQP4 and frequency of HLA DR2.

**Conclusion:** NMO and OSMS in Brazilian population are different demyelinating inflammatory diseases although they share the same clinical phenotype presentation.

Understanding mechanisms of axonal loss in non-optic neuritis eyes of MS patients
A. Klistorner<sup>a,b</sup>, P. Sriram<sup>c</sup>, N. Vootakuru<sup>c</sup>, C. Wang<sup>c</sup>, M. Barnett<sup>c</sup>, R. Garrick<sup>d</sup>, J. Parratte<sup>e</sup>, N. Levin<sup>f</sup>, A. Bick<sup>f</sup>, L. Masters<sup>b</sup>, S.L. Graham<sup>b</sup>, C. Yiannikas<sup>d</sup>, <sup>a</sup>Save Sight Institute, Australia; <sup>b</sup>Macquarie University, Australia; <sup>c</sup>Sydney University, Australia; <sup>d</sup>St Vincent’s Hospital, Australia; <sup>e</sup>North Shore Hospital, Sydney, NSW, Australia; <sup>f</sup>Hebrew University, Jerusalem, Israel

Background: Axonal injury is a major cause of disability in MS. Numerous studies demonstrated loss of retinal ganglion cell axons in MS patients with no history of ON. However, the pathological basis of this loss at present is not clear.

Objective: To investigate links between loss of RGC axons and MS-related injury of anterior (outer retina) and posterior (optic tract and optic radiation) parts of the visual pathway.

Patients and methods: Thickness of temporal RNFL was assessed in 55 RRMS with no history of ON at least in one eye. Integrity of the outer retina was assessed using electroretinogram (ERG) and measurements of outer retinal layers. Latency of the mfVEP indicated previous inflammatory demyelination along the posterior visual pathway. FLAIR T2 optic radiation lesions were identified using tractography.

Results: There was significant delay of photopic ERG b-wave, which correlated with loss of RNFL. Significant reduction of RNFL was also observed in patients who displayed functional (mVEP delay or abnormal DTI) or structural (lesions) evidence of previous OR damage. No indication of OT lesions was found. Linear regression analysis explained 50% of the tRNFL variability. However, while contribution of ERG delay was significant, estimated predictive power of OR lesions was by far the largest.

Conclusion: Study result suggests dual nature of RGC axonal loss in NON eyes of MS patients. While strong tract-specific relationship between loss of RNFL and OR damage advocates retrograde transneuronal process as a major factor, significant association of RNFL thickness with ERG delay also implies primary retinal pathology.

MicroRNA, a critical regulator of an autoimmune demyelination
M.P. Mycko, M. Cichalewska, M. Mariasiwicz, B. Siwińska, H. Cwiklinska, K.W. Selmaj. Department of Neurology, Laboratory of Neuroimmunology, Medical University of Lodz, Lodz, Poland

Background: MicroRNAs (miRNA) are short, non-coding RNAs regulating expression of classical genes and emerge as a mechanism controlling immune reactions. However, a detailed role of miRNA in regulation of autoimmunity remains unclear.

Objective: To analyze microRNA involvement during the development of autoimmune demyelination.

Material and methods: We utilized an animal model of multiple sclerosis — experimental autoimmune encephalomyelitis (EAE). Sorted T helper (Th) cell from lymph nodes of C57Bl/6 mice immunized with MOG peptide 35–55 as well as from MOG-TCR transgenic mice were used for the analyses. We have performed a global miRNA profiling as well as individual miRNA assays during the development of the Th cell autoimmune recognition of myelin antigen.

Results: We have found a specific expression of miRNA in Th cell highlighting three miRNA to be upregulated: mmu-miR155, mmu-miR21 and mmu-miR301a. Mmu-miR155, mmu-miR21 and mmu-miR301a were also upregulated in brain infiltrating cells isolated from EAE. The changes in the above miRNA correlated with both in vitro and in vivo Th17 differentiation. Use of specific miRNA antagonists revealed that miR-301a contributed to the development of the Th17 subset via targeting of the interleukin 6/STAT3 pathway. The analysis of MS patients (n = 48) and controls (n = 36) revealed that stimulation of peripheral blood T cells lead to significantly higher overproduction of miR-301a in MS patients v. controls (2.9 v. 0.7 fold induction, p < 0.015).

Conclusion: We have identified a previously unknown critical role of miR-301a in regulation of autoimmune demyelination and development of autoreactive subset of Th cells.

Fingolimod (FTY720) oral for the treatment of chronic inflammatory demyelinating polyradiculoneuropathy (CIDP): Study design of the phase 3 FORCIDP trial

R. Hughes4, M. Dalakas4, N. Latov1, J.-M. Léger2, I. Merkies4, E. Nobile-Orazio4, C. Achorpoulou4, D.A. Häringer4, L. Zhang-Auberson4, P. von Rosenstiel3, H.-P. Hartung4, National Hospital for Neurology and Neurosurgery, London, UK; Department of Neurology, University of Athens Medical School, Athens, Greece; Weill Cornell Medical College, New York, NY, USA; Boulevard de l’Hôpital, Paris, France; Spaarne Ziekenhuis, Hoofddorp, The Netherlands; Maastricht University Medical Center, Maastricht The Netherlands; Instituto Clinico Humanitas, Rozzano Italy; Novartis Pharma AG, Basel Switzerland; Department of Neurology, Heinrich-Heine-University, Düsseldorf, Germany

Background: CIDP is a chronic sensorimotor neuropathy causing significant disability. Fingolimod, a sphingosine-1-phosphate receptor modulator, completely prevented paraparesis, significantly decreased T-/B-cell, macrophage infiltration and demyelination of sciatic nerves in experimental autoimmune neuritis.

Objective: Evaluate efficacy in delaying disability progression (≥1 point increase from baseline on the adjusted Inflammatory Neuropathy Cause and Treatment (INCAT) disability scale), safety and tolerability of oral fingolimod 0.5 mg daily compared with placebo in CIDP patients.

Patients and methods: FORCIDP study is a double-blind, randomised, multi-centre, placebo-controlled, parallel-group study in adult patients with CIDP and history of disease activity upon discontinuation of CIDP therapy. Patients are randomised in 1:1 to either fingolimod 0.5 mg or placebo. The primary outcome is the time-to-first disability progression. The study has ~90% power at a one-sided 2.5% significance level to detect a hazard ratio of 0.5; 111 events are anticipated in approximately 156–200 randomised participants for the final analysis. Participants fulfilling the disability event criterion will discontinue the study medication immediately and complete the study with a standard CIDP treatment. A group-sequential design with one planned interim analysis after 50 events for futility stopping (one-sided stratified log-rank test; futility boundary at p-value ≥ 0.2282) will be used to prevent patients from prolonged exposure to potentially inefficacious study drug. The study otherwise will continue until the required number of events are observed, or up to a maximum of three years from the trial initiation.

Results and conclusion: This study will provide evidence whether fingolimod can delay disability progression in patients with CIDP.

Discontinuation of natalizumab — Reasons and implications

S. Salhofer-Polanyi, A. Baumgartner, F. Leutmezer. Department of Neurology, Medical University of Vienna, Vienna, Austria

Background: Long-term treatment of multiple sclerosis with natalizumab is limited due to the risk of progressive multifocal leucencephalopathy.

Objective: To evaluate reasons of treatment discontinuation and its effect on disease activity within 12 months after cessation of natalizumab.

Methods: We retrospectively analyzed data of 131 MS patients who discontinued natalizumab between 2007 and 2012. Patient data was taken from the Austrian natalizumab registry and completed by a questionnaire sent to 19 MS centers. Patients with data available both from the registry and the questionnaire were included.

Results: Duration of therapy exceeded 3 years in only 15.3%, while mean duration was 24.3 months (range 4 months – 56 months). Most frequent reasons for discontinuation were: disease activity (14%), seropositivity for JC-virus (14.7%), and long-term treatment in JCV-seropositive patients (14.7%). Only 103 patients again started MS specific-therapies, 15 of them natalizumab. Annualized relapse rate (ARR) increased from 0.53 ± 0.97 on natalizumab to 1.2 ± 1.44 post-natalizumab (p < 0.001). Compared to pre-treatment levels (mean ARR 2.1), ARR after cessation was significantly lower (p < 0.001). Disease activity after 12 months exceeded pre-treatment levels in 14%, and was the same in 16.5% and lower in 69.4% of patients. At the beginning and end of natalizumab median EDSS was 3.5 and 3.0, respectively, and 12 months after cessation it increased to 3.5 (p = 0.028).

Conclusion: We could not find a rebound phenomenon within 12 months after cessation of natalizumab. While EDSS remained the same, ARR was significantly lower 12 months after discontinuation as compared to the pre-treatment year.

The role of T-cells in the pathogenesis of neuromyelitis optica

M. Pohl1, N. Kawakami1, J. Bauer1, M. Kitic1, S. Mader1, J.W. Ellwart1, R. Martins1, T. Misu1, K. Fujihara1, H. Wekerle1, M. Reindl1, H. Lassmann1, M. Bradl1, Medical University Vienna, Center for Brain Research, Vienna, Austria; Max-Planck-Institute for Neurobiology, Munich Germany; Insbruck Medical University, Department of Neurology, Innsbruck, Austria; Institute for Molecular Immunology, GSF-National Research Center for Environment and Health, Munich Germany; Departments of Multiple Sclerosis Therapeutics and Neurology, Tohoku University Graduate School of Medicine, Sendai, Japan

Neuromyelitis optica (NMO) is a severely disabling, demyelinating inflammatory disease of the central nervous system (CNS). The diagnostic hallmark of NMO is the presence of antibodies in the serum, which are specifically directed against Aquaporin 4 (AQP4), a water channel enriched on astrocytic endfeet at the glia limitans. These antibodies have shown to be pathogenic. Once inside the CNS, they find their target on the surface of astrocytes, fix complement and initiate the complement mediated destruction of these cells. We have previously shown in our animal-NMO-models that acute lesions with AQP4 loss can form when CNS antigen specific T cells initiate CNS inflammation, whereas no lesions can be induced with AQP4 antibodies only. Furthermore we could see that the antigen specificity had an impact on the speed of lesion formation, peripheral organ affection and recruitment of other inflammatory cells. We found that T cells which produce the largest lesions in AQP4 antibody treated microglia produced complement factors, downregulated complement inhibitors and upregulated Fcγ, and hence significantly contribute to the complement mediated destruction of astrocytes.

We have previously shown in our animal-NMO-models that acute lesions with AQP4 loss can form when CNS antigen specific T cells initiate CNS inflammation, whereas no lesions can be induced with AQP4 antibodies only. Furthermore we could see that the antigen specificity had an impact on the speed of lesion formation, peripheral organ affection and recruitment of other inflammatory cells. We found that T cells which produce the largest lesions in AQP4 antibody positive rats were best reactivated within the CNS and produced the most IFN-γ. We then analyzed the effects of IFN-γ on the gene expression by microarray analysis. IFN-γ treated microglia produced complement factors, downregulated complement inhibitors and upregulated Fcγ, and hence significantly contribute to the complement mediated destruction of astrocytes.

The experience of the management of pregnant women with multiple sclerosis
T. Yakushina, V. Lizhdvoy. Neurology, MRRICI, Moscow, Russia

Due to the fact of the high percentage of women of childbearing age among patients with MS, the problems of the management of pregnancy are given a special attention. The object of study is learning the characteristics of the management of pregnancy and partus of pregnant women with MS. Forty pregnant women with MS entered the study. 24 women received immunomodulatory treatment: Copaxone — 14, interferons — 6, Cladribine (in anamnesis) — 2, Mitoxantrone — 2. 24 women had normal pregnancy. 16 had abnormal pregnancy. There were no exacerbations of MS during the pregnancy. 26 women had partus in time. 7 women had premature labor. 10 women had cesarean section. The pregnancy of 6 women has been continuing. First woman, who was receiving Cladribine earlier, parturited the boy with low weight, plural congenital abnormalities. Second woman, who was receiving Cladribine earlier, parturiated the normal child. 2 women, who were receiving Mitoxantrone earlier, had normal pregnancy and premature labor, parturiated the children with low weight. The women, who was receiving Copaxone, interferons and no immunomodulatory treatment earlier, had normal pregnancy and partus.

The management of pregnancy and partus isn’t different from the general population. After immunomodulatory treatment the risk of congenital abnormalities isn’t different from the general population. After the immunosuppressant treatment the risk of congenital abnormalities increases.

Next-generation sequencing for detection of mutations associated with rare disorders in patients meeting diagnostic criteria for primary progressive multiple sclerosis
J.D. Weisfeld-Adams, A. Ludtke, S.A. Scott, I. Katzsand, H. Naik, M.D. Linderman, C. Paizan-Ruiz, M.P. Wasserstein, L. Shi, T. Brandt, C.A. McGraw, R. Kornreich, C. Farrell, E.E. Schadt, F.D. Lublin, J.S. Oksenberg, Albert Einstein College of Medicine, Bronx, NY, USA; Department of Neurology, Mount Sinai School of Medicine, New York, USA; Department of Neurology, Mount Sinai School of Medicine, New York, USA; Albert Einstein College of Medicine, Bronx, NY, USA; Department of Neurology, University of California, San Francisco, CA, USA

Background: Rare Mendelian disorders have diverse phenotypes and many show variable expressivity. Given that some spastic paraparesis (SP) disorders show phenotypic overlap with primary progressive multiple sclerosis (PPMS), we hypothesized that sequence variants in these known disease genes confer susceptibility for progressive ‘MS-like’ phenotypes that meet McDonald criteria for PPMS.

Objective: To evaluate PPMS patients for sequence variants in genes associated with Mendelian causes of SP.

Patients and methods: DNA from 250 phenotyped PPMS patients are being interrogated using a custom next-generation sequencing panel (Nimblegen SeqCapEZ) of 72 genes associated with rare, progressive SP phenotypes. All identified variants were assessed by expert consensus and classified based on pathogenicity. Pathogenic and likely pathogenic mutations were confirmed by Sanger sequencing.

Results: 3/35 (8.6%) PPMS patients analyzed to date harbor previously reported heterozygous disease-causing mutations in genes associated with dominant phenotypes that explain or significantly contribute to presenting phenotypes. Five patients (14.3%) had novel mutations predicted to be disease-causing in genes associated with dominant phenotypes, and six (17.1%) were heterozygous for known disease-causing mutations in genes associated with recessive disorders.

Conclusion: The results to date demonstrate that this novel sequencing strategy is effective at detecting variants in known SP genes among PPMS patients. We report identified mutations and the algorithms used to indicate pathogenicity. Data from this ongoing study may lead to further characterization of the clinical spectrum and prevalence of several rare Mendelian neurologic disorders, and provide guidelines for genetic evaluation of patients meeting PPMS criteria.

Movement disorders in demyelinating diseases
B. Dönmez Colakoglu, E. Idiman, S. Ozakbas. Dokuz Eylul University Medical Faculty, Department of Neurology, Izmir, Turkey

Background: In multiple sclerosis (MS), movement disorders other than cerebellar tremors are rare.

Objective: The study aims to determine movement disorders in patients diagnosed with demyelinating diseases and to investigate clinical manifestations.

Patients and methods: 2783 patients are followed in our demyelinating disease outpatient clinic. Of these 2783 patients, those who presented to the demyelinating disease outpatient clinic in the past one year and had different types of movement disorders were evaluated.

Results: Last year, ten cases were diagnosed with movement disorders. Of them, seven had dystonia (three upper extremity dystonia, three paroxysmal dystonia and one writer’s cramp), one Parkinsonism, one choreoathetosis and one postural tremor. Of these cases, seven were diagnosed with definite MS according to McDonald criteria and two with clinically isolated syndrome (CIS) and one with neuromyelitis optica. In two patients, MS symptoms began before the age of 18. While movement disorders were the initial symptom in one patient, in the other patients, movement disorders developed during the course of the disease.

Conclusion: Although tremor is the most common symptom in MS patients, movement disorders other than tremors can also occur, even as the first symptom. Movement disorders can occur not only in MS but also in other demyelinating diseases such as neuromyelitis optica. We consider that the careful evaluation and follow-up of these patients would be of great importance in order to reveal the relationship between multiple sclerosis and movement disorders.

EAE disease prevention by a potent oral RORγt inverse agonist INV-17: A promising safe & efficacious ms treatment
A. Gaweczab, S. Palmer, R. Shamilov, M. Fisher, J. Tilley. aInnovimmune Biotherapeutics, Inc., Brooklyn, NY, USA; bSUNY Downstate Medical Center, Brooklyn, NY, USA

Background: T helper 17 [Th17] cells and its production of Th17 cytokines play a critical role in the pathogenesis of MS and EAE. Retinoic acid receptor-related orphan receptor gamma t [RORγt] is a
nuclear hormone receptor that specifically regulates \( T_{h}17 \) cells by acting as a control switch for \( T_{h}17 \) differentiation and function. We have discovered proprietary novel lead chemical scaffolds of the INV-17 portfolio of small molecule ROR\( \gamma \)t inverse agonists.

**Objective:** To establish the in vivo proof of concept of the lead clinical compound candidate INV-17 in the chronic mouse EAE model.

**Method:** INV-17 was administered p.o. for 28 days as a prophylactic treatment in \( \text{MOG}_{35-55} \)-induced C57BL/6 mice to assess the therapeutic benefit of preventing disease in a chronic-progressive EAE model.

**Result:** Disease was successfully prevented in INV-17-treated mice with cumulative EAE scores (Scale: 0–5) of 3.3 ± 3.3 (p = 0.008) which is in striking contrast to 27.9 ± 6.2 of vehicle-treated animals with 100% disease incidence. Worse clinical score AUC of 26.50 ± 6.28 for the group was significantly different from 3.00 ± 3.00 (p = 0.0097) for the INV-17 group. INV-17 was well tolerated and INV-17-treated mice were unremarkable with optimal body conditions.

**Conclusion:** The superior safety and efficacy data following chronic oral INV-17 dosing provide compelling evidence of the effectiveness of ROR\( \gamma \)t inverse agonism and support advancing INV-17 into Preclinical/IND-enabling development stage. These findings highlight the potential promise of INV-17 as a safe & efficacious novel MS treatment.

-*The prevalence of autoantibodies in ms patients in Riga East Clinical University Hospital, Latvia*

G. Karelis, G. Karelis, \( a \) L. Vainisteine, L. Vainisteine, I. Mihailova, I. Mihailova, \( \text{Riga Stradins University, Riga, Latvia; Riga East Clinical University Hospital, Riga, Latvia; } \text{Tumour Immunology Research Centre, Riga Stradins Clinical University Hospital, Riga, Latvia.} \)

**Introduction:** Multiple sclerosis (MS), lupus erythematosus (LE), antiphospholipid syndrome (APS) are chronic, immune-mediated, relapsing–remitting disorders. Neurological symptoms and MRI can have the same picture, but pathogenesis and treatment are different.

**Objectives:** To analyse antinuclear antibodies (ANA), antiphospholipid antibodies (APA) and lupus anticoagulant (LA) in MS patients with specific symptoms and MRI findings and determination of specificity, sensitivity in MS differential diagnosis.

**Methods:** 31 MS patients from Riga East Clinical University Hospital were included in the study. The patients were in remission and did not get any disease modifying therapy before. The diagnosis was established in a classic way — with MRI by McDonald’s criteria. Clinical symptoms, MRI, AFA IgG, IgM, LA, and ANA were analysed.

**Results:** Of 31 patients 17 (55%) were female with mean age of 34.4 ± 9.8 and male 14 (45%), were mean age of 36.1 ± 8.8. All patients had changes in MRI according to McDonald’s criteria. Spinal cord changes were detected in 90% of patients and optic neuritis in 59%. Spinal cord and optic nerve injury was noted more in females 55%. Positive autoantibody were detected in 90% of patients and optic neuritis in 59%. Spinal cord and follow-up procedure. Mean age rates were 34.18 ± 8.23 in the study group and 35.32 ± 8.12 in controls (p < 0.005). While mean duration of complaints, and EDDS, BDI and total FSFI scores were 7.66 ± 5.47 years, 1.52 ± 1.43, 18.20 ± 10.56 and 20.31 ± 8.91 in patients respectively, the mean age of 34.18 ± 8.23 in the study group and 35.32 ± 8.12 in controls (p < 0.005). While mean duration of complaints, and EDDS, BDI and total FSFI scores were 7.66 ± 5.47 years, 1.52 ± 1.43, 18.20 ± 10.56 and 20.31 ± 8.91 in patients respectively, the scores of BDI and total FSFI were 7.61 ± 5.43 and 30.55 ± 4.29 in controls, respectively. Compared to controls, BDI was higher, and total and subscores of FSFI were lower in women with MS (p < 0.001). In MS patients, a negative correlation was present between EDDS, and BDI (p < 0.001, r: −0.779), orgasm (p < 0.001, r: −0.781), satisfaction (p < 0.001, r: −0.762), and among FSFI subscores, desire (p < 0.001, r: −0.779), orgasm (p < 0.001, r: −0.781), satisfaction (p < 0.001, r: −0.762), pain (p < 0.001, r: −0.711), lubrication (p < 0.001, r: −0.819) and arousal (p < 0.001, r: −0.812). Fifty-one premenopausal women with MS were included into the study group, and 57 healthy premenopausal women constituted controls. Functional status of MS patients was evaluated with Expanded Disability Status Scale (EDSS); depression levels with Beck Depression Inventory (BDI); and, sexual functions with Female Sexual Function Inventory (FSFI). While

**Conclusions:**

1. ANA, AFA positivity is not frequent in MS patients with classic MS symptoms and MRI findings.
2. Autoantibody tests in MS patients are to be considered when the symptoms of the disease are atypical.
3. MS patients with positive autoantibody tests, should be further reevaluated by repeating the autoantibody tests and observing the clinical symptoms, in order to review of the diagnosis on time.

Disability improvement in the first case treated by Natalizumab in Libya
E.I. Darmun, M. Estuti, Neurology, Ali Omar Ascar Hospital, Tripoli, Libya

A 31 year old Libyan lady presented with left lower limb cramps & sole numbness 6 years ago which spontaneously cured within 1 week. 4 months later she had the same symptoms & received IV steroids, then she was put on injectable Interferon-beta. She was stable & relapse free till Jan 2010 when she had left lower limb weakness & received IV steroids. 10 months later she had left side body numbness & left lower limb weakness & received IV steroids. 3 months later she had diplopia & right eye blurred vision with right 3rd nerve palsy followed by left lower limb weakness & received steroids, but neurological deficit & EDSS worse than before. 7 months later she had bilateral lower limb weakness & numbness up to the waist & received IV steroids. 4 months later she had left lower limb weakness, unsteadiness, right side body numbness with right side facial numbness & urinary incontinence & received steroids. At that time she started the 1st dose Natalizumab in Mar 2012 then once every 4 weeks till this month when she received the 13th dose. Clinically she had treatment ataxic paraparesis with right side hypoesthesia and urinary incontinence & we noticed that the patient started to improve clinically at the 3rd dose & the EDSS is getting better since then. Nowadays she has no neurological disability just mild past pointing in the left side & high DTR all over the body (Lt > Rt). MRI brain & cervicodorsal spine were done several times in each relapse and follow up MRI after Natalizumab treatment started which showed incredible improvement so far.

Retrograde diagnosis of tumifactive multiple sclerosis
E. Darmun1, N. Habib2, 3Neurology, Tripoli Medical University, Ali Omar Askar Hospital, Tripoli, Libya; 2Neurology, Ali Omar Ascar Hospital, Tripoli, Libya

A 40 year old Libyan lady presented with acute severe headache & bilateral blurred vision with nausea & vomiting which happened 8 years ago. Clinically she had left temporal hemianopia & brisk reflexes all over the body with bilateral Babinsky sign. MRI brain showed large high signal intensity peripherally enhancing lesion in the right occipito-parietal region surrounded by edema and marked compression on the occipital horn of the lateral ventricle. They thought it was a tumour & surgical resection was done followed by an IV steroid therapy. Clinically post-operative she had permanent left temporal hemianopia only otherwise she was fully ambulatory without disability in spite of the huge brain tissue defect. 4 months later she had acute severe headache & MRI brain revealed recurrence of right occipital enhancing lesion with new involvement of the splenium of the corpus callosum. A 2nd operation was done with resection of the new lesion & no clinical disability except left temporal hemianopia. A histopathology study showed nonconclusive inflammatory changes. 2 months later she had severe headache & bilateral blurred vision with tunnel vision. Clinically she had papilledema. MRI brain showed new hyperintense lesion noted in the left occipital region with marked enhancement in addition to the previous right occipital one & the splenium. IV steroids were given with dramatic improvement. 3 months later follow up MRI brain showed a decrease in size of the enhancing areas of both occipital regions after steroid therapy. 1 month later a stereotactic biopsy was done abroad & revealed a confirmed diagnosis of Multiple Sclerosis. IV Metoxantrone was started & she is stable till now.

Disability assessment results of MS patients in Armenia
G. Avagyan, A. Sahakyan, A. Avetisyan, H. Manvelyan. Neurology, Yerevan State Medical University, Yerevan, Armenia

Background: Multiple sclerosis (MS) is a degenerative, inflammatory, immune-mediated disease affecting, 2.5 million individuals worldwide presenting the most common disabling disease of the CNS in young adults. The wide range of symptoms affects all aspects of physical and mental health. Unfortunately, no officially published up-to-date data exists on MS prevalence in Armenia.

Objective: The primary aim of the study is to establish association between the EDSS score and overall quality of life among MS patients. This study will also reevaluate the prevalence and incidence of MS in Armenian population, and assess the disability status and quality of life.

Methods: Cross-sectional study design was used to assess all patients with definite MS admitted to our clinic. The quality of life was measured by a Multiple Sclerosis Quality of Life (MSQOL)-54 questionnaire, which was translated and adapted for use with Armenian speakers. The Expanded Disability Status Scale (EDSS) evaluated disability. The data was analyzed using descriptive statistics, correlation and regression analysis.

Results: 45 MS patients were interviewed and underwent neurological examination. Mean age and duration of disease were 34 and 5.5 years respectively. Mean physical health and mental health composite scores were 105.5 and 54.4. Statistically significant correlation was established between (MSQOL)-54 physical composite score, mental health composite score and EDSS (p < 0.01) score implying that poorer QoL was associated with higher EDSS scores and more severe disability.

Conclusion: The findings being consistent with previous studies indicate that measures should be taken to improve the quality of life and disability status of these patients.

Duration of multiple sclerosis on quality of life: Preliminary results of Armenian study
A. Sahakyan, G. Avagyan, A. Avetisyan, H. Manvelyan. Neurology, Yerevan State Medical University, Yerevan, Armenia

Background: Multiple sclerosis (MS) is an inflammatory, immune-mediated disease of the central nervous system, affecting and disabling young adults with complexity of manifestations varying from benign up
to devastating disease. It is obvious that the disease affects all aspects of the patient’s mental and physical health negatively impacting on overall quality of life of a person.

**Objective:** The aim of the study was to study correlation between the quality of life and disease duration.

**Methods:** In this cross-sectional study all patients with definite MS included in 3 year long research were evaluated for quality of life measured by a Multiple Sclerosis Quality of Life (MSQOL)-54 questionnaire previously validated and adjusted for use with Armenian speakers and disability measured by the Expanded Disability Status Scale (EDSS). Descriptive statistics, correlation and regression analyses were included in statistical analysis.

**Results:** In total, 45 MS patients were interviewed and assessed. The mean age of the participants was 34 with male predominance (24/21). The average disease duration was 5.5 years. Mean physical health and mental health composite score were 105.5 and 54.4 respectively. Totals of each of the domains of (MSQOL)-54 were also calculated and analyzed. Statistically significant correlation was found between disease duration and (MSQOL)-54 physical composite score (p = 0.001) and mental health composite (p = 0.003) indicating that poorer QoL was associated with relapsing – remitting MS patients; also there was a reduction of circulating immune complexes, proproliferation, oxygen-dependent metabolism of neutrophils, and increased levels of IgM and IgG. After a course of probiotic complete or partial regression of dysbiosis observed in 80% of patients; also there was a reduction of circulating immune complexes, CD-HLA-DR, initially increased helper–suppressor ratio, as well as reducing the severity of dyspepsia.

**Conclusion:** Probiotic therapy may be considered as a promising pathogenetic (immunomodulatory) and symptomatic therapy of MS.

**The influence of thyroid autoimmune reactivity in the course of multiple sclerosis**

*N.N. Spirin, E.V. Kiseleva. Neurology, Yaroslavl State Medical Academy, Yaroslavl, Russia*

**Background:** Many authors have noted a higher frequency of autoimmune thyroid disease occurrence in patients with multiple sclerosis (MS). The influence of the autoimmune response to thyroid antigens on the course of MS is very interesting.

**Objective:** The objective of this study was to determine the characteristics of MS in patients with thyroid autoimmune reactivity.

**Patients and methods:** 84 patients (16 males, 68 females) with clinical definite relapsing–remitting MS were examined. All patients had clinical remission. The average age was 37.1 ± 10.03 years (18–56 years). Severity of neurological deficit was assessed according to the EDSS. All patients underwent ultrasonography of the thyroid gland, serum for thyroid hormones (TG), and anti-thyroid peroxidase and thyroglobulin. All statistical analyses have been made using a standard statistical package.

**Results:** 17% of patients had elevated titers of antibodies to thyroid antigens. 26% of patients without thyroid pathology were the comparison group. These groups were comparable in age and gender composition. The continuance of first remission in patients with thyroid autoimmunity was significantly shorter (1.4 ± 1.11 and 2.7 ± 3.81 years, p = 0.048). In patients with thyroid antibodies progression rate was 0.9 ± 0.75 score/year, in the comparison group it was 0.5 ± 0.34 score/year, r = 0.03. There was a statistically significant correlation between the duration of antibodies antibodies to thyroglobulin with the total number relapse, t = 0.59, p = 0.01.

**Conclusion:** The presence of the patient autoimmune reactivity to antigens of the thyroid can be a predictor of severe MS.

**Multiple sclerosis in Armenia: Quality of life and depression**

*A. Arevtisiyan, G. Avagyan, A. Sahakyan, H. Manvelyan. Neurology, Yerevan State Medical University after M. Heratsi, Yerevan, Armenia*

**Background:** Multiple sclerosis (MS) is an inflammatory demyelinating disease affecting the Central Nervous System, and is a leading cause of disability in young adults. Quality of life (QoL) usually decreases in MS patients. Many of them develop depression. Currently there are no accepted publications showing different aspects of MS in Armenia.

**Objective:** We aimed to evaluate QoL, its correlation with disease duration and type, depression and their intercoupling in MS patients.

**Patients and methods/material and methods:** 45 patients with different types of MS had been investigated. For all patients diagnosis was based on clinical symptoms and McDonald MRI criteria. Average age and disease duration were 34 and 6.2 years, respectively. Quality of life was assessed by Multiple Sclerosis Quality of Life (MSQOL)-54 questionnaire which includes both physical and mental health assessment scales. Beck’s Depression Inventory (BDI) was used in order to diagnose depression.

**Results:** Average physical and mental health composite scores for MS patients were 82.06 and 54.4, respectively. Statistically significant correlation was established between (MSQOL)-54 physical composite and BDI scores, mental health composite and BDI scores, intimating that...

Carbonyl proteins as marker of oxidative stress derived protein damage in neuroinflammatory and neurodegenerative diseases
P. Rommer1, J. Greilberger2, R. Herwig3, E. Auff3, F. Leutmezer1.
1Neurology, Medical University of Vienna, Vienna, Austria; 2Physiology, Medical University Graz, Graz, Austria; 3Urology, Medical University of Vienna, Vienna, Austria

Background: The importance of oxidative stress in the genesis of neuro-immunological diseases has been discussed extensively. Carbonyl groups may be the end link of a series of metabolic processes leading to apoptosis and neuron damage.

Multiple sclerosis (MS) is the most common chronic neuro-inflammatory disease and a major cause for disability in young adults. Oxidative stress is driven by inflammation and leads to degeneration. By now, established markers of oxidative stress in CSF are rare.

The aim of the study is to detect carbonyl proteins in CSF in patients with MS, neurodegenerative diseases and healthy controls.

Materials and methods: CSF from diagnostic lumbar punctures was tested. To determine levels of oxidative stress in cerebrospinal fluid (CSF) Carbonyl Protein was measured by the Carbonyl Protein ELISA Kit (ImmunoDagnostik AG, Germany).

Results: Patients were divided in three subgroups (neuro-immunological disease, neurodegenerative disease, healthy controls). Level of CP differed significantly between subgroups (p = 0.025) (Kruskal–Wallis-Test), mean values: neuro-immunological disease 630.8, neurodegenerative disease 756.1, and healthy controls 356.5.

Conclusion: In this pilot trial we tried to detect carbonyl groups (proteins?) as markers of oxidative stress. The results of this trial showed a significant difference in the mean levels of proteins in CDMS and neurodegenerative diseases in comparison to healthy controls. In conclusion, the trial showed that carbonyl proteins are able to serve as marker for oxidative stress. Larger trials have to show whether carbonyl proteins may be able to serve as biomarker for more severe course of disease or for developing CDMS in patients with CIS.

NK cell expansion predicts treatment response to rituximab
P.S. Rommer, E. Auff, F. Leutmezer. Neurology, Medical University of Vienna, Vienna, Austria

Background: Rituximab is used in a plenty of neuro-immunological diseases although it has not been approved for any neurological disease. Positive results have been published for relapsing–remitting Multiple Sclerosis (RRMS), Neuromyelitis optica (NMO) as well as case reports on secondary progressive MS (SPMS), and myasthenia gravis (MG). Results in RRMS and NMO are impressive, whereas results are inconsistently in progressive MS and MG. Because of possible side effects of rituximab, biomarkers to predict clinical response to rituximab would be of particular interest. In rheumatoid arthritis, a favourable response to CD20 therapeutics was associated with an increase in NK. The aim of this study was to detect predictors of efficacy in patients with neuro-immunological diseases treated with rituximab.

Methods: We determined the levels of CD3+, CD3+CD8+, CD3+HLADR+, CD3−CD16&56+ and CD3+CD16&56+ cells in patients with neuro-immunological diseases.

Results: Overall fourteen patients were included in this study. Patients were grouped in responders and non-responders according to clinical disease progression during rituximab therapy. Responders showed a higher β and R2 for NK-cells in contrast to non-responders. The difference between these groups differed significantly (p < 0.001).

Conclusion: We found a statistically significant difference between responders and non-responders to Rituximab therapy in patients with neuro-immunological diseases. Responders showed a higher increase in the NK-cell population following initiation of Rituximab treatment as compared to non-responders. Our results are in line with those in rheumatoid arthritis. Therefore we suggest that NK-cells might serve as a predictor of clinically favourable treatment response to Rituximab in patients with neuro-immunological diseases.

Microrna regulation of B cells in multiple sclerosis: MIR-320 and its specific targets
L.L. Aung, S. Dhib-Jalbut, K.E. Balashov. Neurology, Rutgers-Robert Wood Johnson Medical School, New Brunswick, Nj, USA

Background and objective: B cells are strongly implicated in the pathogenesis of multiple sclerosis (MS). The role of microRNA (miRNA) in MS is not well understood. We studied if miRNAs regulate pro-inflammatory capabilities of B cells in MS.

Patients and methods: B cells and monocytes were separated from untreated patients with MS and age- and gender-matched control healthy subjects (CHS). Expression of 904 miRNAs was tested by microarrays followed by validation with real-time qPCR. Expression of molecules targeted by miRNAs was analyzed by Western blot, ELISA and Flow cytometry. Transfection experiments with miRNA inhibitors were conducted to prove the inhibitory effect of endogenous miRNAs on expression of its targets.

Results: Expression of miR-320 was significantly decreased in B cells of MS patients compared to CHS, p = 0.014, but not in monocytes. Expression of molecules specifically targeted by miR-320, Matrix metallopeptidase 9 (MMP-9), the protein implicated in disruption of blood–brain barrier, and Transferrin receptor protein 1 (TFRC), was significantly increased in B cells of patients. To test whether endogenous miRNA-320 inhibits MMP-9 secretion and TFRC expression, B cells from CHS were transfected with specific miR-320 inhibitor which led to increased TFRC expression and MMP-9 secretion to levels seen in patients with MS.

Conclusion: miR-320 expression is selectively decreased in B cells of patients with MS. This is associated with increased expression of miR-320-specific targets, TFRC and MMP-9, which promote cell proliferation and blood–brain barrier disruption, respectively.

Correlation between retinal nerve fiber layer thickness and expanded disability status scale in Iranian patients with relapsing–remitting multiple sclerosis

N. Mohibi, M. Moghaddasi, H. Karimi, Neurology, Rasool Akram Hospital, University of Medical Sciences, Tehran, Iran; University of Medical Sciences, Tehran, Iran

Objective: To evaluate the peripapillary retinal nerve fiber layer (RNFL) thickness in relapsing–remitting multiple sclerosis (RRMS) and its association with disability scales.

Patients and methods: In this cross-sectional study, 69 patients with RRMS, with or without history of optic neuritis (ON), were coincidentally included. The patients’ expanded disability status scale (EDSS) scores were evaluated by a neurologist. Peripapillary RNFL thickness was assessed by an ophthalmologist, using a Heidelberg Retinal Tomography (HRT) II device.

Results: 56 females and 13 males, with mean ± SD age of 29.4 ± 4.1 (range = 17–59) years old, disease duration from 2 months to 20 years were studied. EDSS score measurements 2.83 ± 0.56, mean of 2.69 and 2.86 for men and women respectively. Mean ± SD of RNFL thickness of both eyes 0.223 ± 0.051 in all patients, 0.215 ± 0.053 in patients with history of ON, and 0.231 ± 0.051 in those without history of ON. Mean RNFL thickness were not statistically different in patients with and without history of taking interferon. We did not find any statistical relation between disease duration and mean RNFL thickness of both eyes, in all patients and patients with or without ON. There was no significant correlation between EDSS and mean RNFL thickness of both eyes, in all patients and patients with or without history of ON.

Conclusion: Although not statistically approved, measurement of RNFL thickness appears to be a good strategy in evaluating the natural course of RRMS and the level of disability.

Assessment of natural course and prognosis of CIS: A prospective study on Iranian patients

M. Moghaddasi, N. Mohibi, H. Karimi, Neurology, Rasool Akram Hospital, University of Medical Sciences, Tehran, Iran

Objective: To assess natural course of clinically isolated syndrome (CIS) and the role of some probable risk factors for the development of CDMS, in an Iranian population.

Materials and methods: In this prospective study, we studied 50 consecutive patients with CIS, presented in the neurology clinic of Rasul-e-Akrar hospital in Tehran, from April 2007 to March 2011. We followed up each patient in 3-month intervals. The endpoint of the study was either diagnosis of CDMS or the end of considered period for follow up.

Results: We studied 50 patients with CIS (40 women, 10 men), age 29.0 ± 8.4 years. 76% of patients were between 20 and 40 years old. The most common presenting syndrome was optic neuritis (46%). Clinical conversion rate was 44%, during the follow up time 29.4 ± 11.4 months. It took 9.1 ± 9.6 months for CIS to convert to CDMS. The primary EDSS scores 1.3 ± 1.0. Initial brain MRIs were space positive in 58% of cases, and initial cervical MRIs were normal in 45.8% of patients. In this study, we did not observe any statistical association between age at onset of disease, sex, CIS type, primary MRI findings, primary EDSS scores and progression of CIS to CDMS.

Conclusion: Since early diagnosis and treatment of MS are very helpful in proper management of the disease, it would be of great benefit to assess the likelihood of developing CDMS in every patient presenting with a first episode suggestive of MS.

Safety and tolerability of BG-12 (dimethyl fumarate) in relapsing–remitting multiple sclerosis: Interim results from the endorse extension study

K. Selmai, J.T. Phillips, R.J. Fox, K. Raghupathi, H. Yuan, M. Novas, M.T. Sweetser, N.C. Kurukulasuriya, V. Viglietta, K.T. Dawson, R. Gold, Department of Neurology, Medical University of Lodz, Lodz, Poland; Multiple Sclerosis Program, Baylor Institute for Immunology Research, Dallas, TX; Mellen Center for Multiple Sclerosis Treatment and Research, Cleveland Clinic, Cleveland, OH; Biogen Idec, Weston, MA, USA; St. Josef Hospital, Ruhr University, Bochum, Germany

Background: Multiple Sclerosis (MS) can cause a reduction of functional independence in daily living, employment and community participation. Previous studies suggested that MS patients are more prone to incur in accidents, such as falls, during their lifetime. However, few data are currently available about domestic and work accidents.

Objectives: Our goals were reporting frequencies of main types of domestic (DA) and work accidents (WA) in MS, and assessing possible influence of cognitive and physical symptoms on their occurrence.

Patients and methods: We enrolled two cohorts of MS patients and matched control groups (CTRL). Thirty-one MS workers were interviewed about accidents and related risks on working places, while fifty MS subjects were chosen to respond about domestic traumas. Scales of neurological disability, cognitive impairment, mood and fatigue were also performed.

Results: While no statistical difference was found in the amount of WA and DA types between MS and CTRL, bumps emerged as the most recurrent type in MS. Significant correlation was found between bumps and Raven Matrices within MS DA group, while only risk of accident positively correlated with both cognitive fatigue and self-perceived depression in WA. Notably, EDSS and MSFC scores did not seem to influence WA and DA.

Conclusion: Our report showed the prevalence of bump, both in DA and WA MS cohorts. Interestingly, disability does not seem to play a major role in determining the event. Cognition, fatigue and self-perceived depression might be crucial in predicting the risk of WA.

Work accidents in patients with multiple sclerosis: A global survey on risk and occurrence of both domestic and work accidents in patients with multiple sclerosis

C.C. Incerti, O. Argento, G. Magistral, C. Caltagirone, U. Nocentini, V. Pisani, Neurology and Neurorehabilitation Unit, I.R.C.C.S. Santa Lucia Foundation, Roma, Italy

Background: Multiple Sclerosis (MS) can cause a reduction of functional independence in daily living, employment and community participation. Previous studies suggested that MS patients are more prone to incur in accidents, such as falls, during their lifetime. However, few data are currently available about domestic and work accidents.

Objectives: Our goals were reporting frequencies of main types of domestic (DA) and work accidents (WA) in MS, and assessing possible influence of cognitive and physical symptoms on their occurrence.

Patients and methods: We enrolled two cohorts of MS patients and matched control groups (CTRL). Thirty-one MS workers were interviewed about accidents and related risks on working places, while fifty MS subjects were chosen to respond about domestic traumas. Scales of neurological disability, cognitive impairment, mood and fatigue were also performed.

Results: While no statistical difference was found in the amount of WA and DA types between MS and CTRL, bumps emerged as the most recurrent type in MS. Significant correlation was found between bumps and Raven Matrices within MS DA group, while only risk of accident positively correlated with both cognitive fatigue and self-perceived depression in WA. Notably, EDSS and MSFC scores did not seem to influence WA and DA.

Conclusion: Our report showed the prevalence of bump, both in DA and WA MS cohorts. Interestingly, disability does not seem to play a major role in determining the event. Cognition, fatigue and self-perceived depression might be crucial in predicting the risk of WA.

Patients and methods: Patients previously randomized to BG-12 240 mg twice (BID) or three times daily (TID) continued on the same dose in ENDORSE. Patients previously randomized to placebo (both studies) or glatiramer acetate (CONFIRM) were re-randomized 1:1 to BG-12 240 mg BID or TID. Analyses were performed according to treatment groups defined by whether patients were continuing BG-12 treatment or new to BG-12 treatment in ENDORSE.

Results: This analysis included 1,960 patient-years of follow-up. In the continuing groups, the incidence of adverse events (AEs), serious AEs, and discontinuations due to AEs was 80–82%, 10–12%, and 2–4%, respectively. In groups new to BG-12, these incidences were 75–85%, 8–16%, and 10–22%, respectively. The most common AEs (≥10% in any group) were MS relapse and nasopharyngitis for the continuing groups, and flushing, MS relapse, nasopharyngitis, diarrhea, and upper abdominal pain for the newly treated groups. Serious infection incidence was ≤2% in each group. There were 14 malignancies (13 patients), diverse in type/location: six malignancies in patients continuing BG-12 and eight malignancies in patients newly treated. There were three deaths, none considered related to BG-12.

Conclusion: No new or worsening safety signals were identified for patients continuing BG-12. The safety profile for patients newly treated in ENDORSE was consistent with that in DEFINE and CONFIRM.

Neuroradiological efficacy of oral BG-12 for relapsing–remitting multiple sclerosis (RRMS): Integrated analysis of the Phase 3 DEFINE and CONFIRM studies

R.J. Fox, R.J. Fox, R. Gold, D. Macmanus, T. Yousry, D. Bar-Or, R. Zhang, N.C. Kurukulasuriya, V. Viglietta, M. Stephan, K.T. Dawson, D.L. Arnold, Mellen Center for Multiple Sclerosis Treatment and Research, Cleveland Clinic, Cleveland, OH, USA; Institute of Neurology, University College London, London, UK; St. Josef Hospital, Ruhr University, Bochum, Germany; Montreal Neurological Institute and Hospital, McGill University, Montreal, QC, Canada; Biogen Idec, Weston, MA, USA

Background: Oral BG-12 (dimethyl fumarate) demonstrated positive clinical and neuroradiological efficacy and an acceptable safety profile in the Phase 3 DEFINE and CONFIRM trials.

Objective: To present the results of a pre-specified, integrated analysis of DEFINE and CONFIRM, conducted to obtain a more precise estimate of the therapeutic effect of BG-12 on MRI endpoints.

Patients and methods: Eligible patients were aged 18–55 years and had a diagnosis of RRMS (McDonald criteria) and an Expanded Disability Status Scale score of 0–5.0. In DEFINE, patients were randomized 1:1:1 to receive BG-12 240 mg twice (BID) or three times daily (TID) or placebo. In CONFIRM, patients were randomized 1:1:1:1 to receive BG-12 240 mg BID or TID, placebo, or glatiramer acetate (reference comparator). MRI was performed in a subset of patients at sites with validated MRI capability.

Results: A total of 1,046 patients (MRI cohort) were randomized and received placebo (n = 347), BG-12 BID (n = 345), or BG-12 TID (n = 354). At 2 years, BG-12 BID and TID reduced the number of new/newly enlarging T2-hyperintense lesions by 78% and 73%, respectively; new non-enhancing T1-hypointense lesions by 65% and 64%, respectively; and the odds of having more gadolinium-enhancing lesions by 83% and 70%, respectively, as compared to placebo (all comparisons p < 0.0001).

Conclusion: The results of the integrated analysis demonstrate consistent benefits of both dosing regimens of BG-12 on MRI activity. Alongside strong clinical efficacy and an acceptable safety profile, these results suggest that BG-12 has the potential to become a valuable oral treatment option for RRMS patients.

Gastrointestinal tolerability events in relapsing–remitting multiple sclerosis patients treated with BG-12 (dimethyl fumarate): Integrated analysis of the Phase 3 DEFINE and CONFIRM studies

E. Havrdova, J.T. Phillips, K. Selmaj, R. Gold, R.J. Fox, G. Giovannoni, A. Face, M. Novas, N.C. Kurukulasuriya, C. Hotermans, L. Meltzer, K.T. Dawson, Department of Neurology, Charles University in Prague, 1st Medical Faculty, Hradec Kralove, Czech Republic; Department of Neurology, National Institute of Neurology, Research Centre, Prague, Czech Republic; Department of Neurology, Maastricht University Medical Centre, Maastricht, The Netherlands; Section of Neurology, University of Sheffield, Sheffield, UK; Section of Neurology, University of Oxford, Oxford, UK; Section of Neurology, University of Leeds, Leeds, UK; Department of Neurology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany; Department of Neurology, Sheba Medical Center, Tel-Hashomer, Israel; Department of Neurology, Bambino Gesu Children’s Hospital, Rome, Italy; Department of Neurology, Medical University of Vienna, Vienna, Austria; Department of Neurology, University of L’Aquila, L’Aquila, Italy; Department of Neurology, University of Turin, Turin, Italy; Department of Neurology, The Royal Melbourne Hospital, Melbourne, Australia; Department of Neurology, Cefalù Hospital, Cefalù, Italy

Background: Oral BG-12 (dimethyl fumarate) demonstrated clinical and neuroradiological efficacy and an acceptable safety profile in the Phase 3 DEFINE and CONFIRM studies.

Objective: To report the results of a pre-specified, integrated analysis of health-related quality of life (HRQoL) endpoints in DEFINE and CONFIRM.

Patients and methods: HRQoL endpoints assessed in both studies were the Short Form-36 (SF-36) Physical and Mental Component Summary (PCS/MCS) scales, global assessment of well-being visual analog scale (VAS), and the EuroQOL-5D (EQ-5D) VAS. Higher scores indicated better HRQoL.

Results: A total of 2,301 patients were randomized to receive placebo (n = 771) or BG-12 240 mg twice (BID; n = 769) or three times daily (TID; n = 761). Physical and mental health and functioning were significantly improved with BG-12 versus placebo. At 2 years, mean SF-36 PCS scores increased from baseline by 0.47 (BID) and 0.43 (TID) versus a reduction of −1.05 (placebo; both p < 0.0001). SF-36 MCS scores increased by 0.31 (BID) and 0.63 (TID) versus a reduction of −0.60 (placebo; p = 0.0246 and p = 0.0107, respectively). BG-12-treated patients reported a significantly better sense of well-being and perception of health status than placebo-treated patients. Mean changes from baseline to 2 years with BID and TID versus placebo were −0.3 and +0.1 versus −4.0 for global well-being VAS (both p < 0.0001) and −0.90 and −0.31 versus 3.37 for EQ-5D VAS (p = 0.0011 and p = 0.0002, respectively).

Conclusion: BG-12 treatment resulted in significant improvements in physical and mental aspects of health and functioning, general well-being, and overall health status compared with placebo in RRMS patients.

Mean changes from baseline to 2 years with BID and TID versus placebo were −0.3 and +0.1 versus −4.0 for global well-being VAS (both p < 0.0001) and −0.90 and −0.31 versus 3.37 for EQ-5D VAS (p = 0.0011 and p = 0.0002, respectively).

Conclusion: BG-12 treatment resulted in significant improvements in physical and mental aspects of health and functioning, general well-being, and overall health status compared with placebo in RRMS patients.

Faculty of Medicine, Prague, Czech Republic; Multiple Sclerosis Program, Baylor Institute for Immunology Research, Dallas, TX, USA; Medical University of Lodz, Lodz, Poland; St. Josef Hospital, Ruhr University, Bochum, Germany; Mellen Center for Multiple Sclerosis Treatment and Research, Cleveland Clinic, Cleveland, OH, USA; Blizard Institute, Barts and The London School of Medicine and Dentistry, Queen Mary University, London, UK; Biogen Idec, Weston, MA, USA

**Background:** Oral BG-12 (dimethyl fumarate) demonstrated an acceptable safety profile in the Phase 3 DEFINE and CONFIRM studies. Common adverse events (AEs) included flushing and gastrointestinal (GI) events.

**Objective:** To further characterize GI AEs in patients treated with BG-12 240 mg twice daily (BID) in DEFINE and CONFIRM.

**Patients and methods:** A post-hoc, integrated analysis of the incidence, nature, severity, and management of GI AEs in DEFINE and CONFIRM was conducted, focusing on the initial treatment period (through Month 3). Management of GI AEs was evaluated by manual review of concomitant medications temporally associated with and indicated for each GI event.

**Results:** A total of 1,540 patients in DEFINE and CONFIRM were randomized to receive placebo (n = 771) or BG-12 BID (n = 769). The most common (≥5%) GI AEs during the initial treatment period were abdominal/lower abdominal pain, nausea/vomiting, and diarrhea; of these events, 91%, 95%, and 96%, respectively, were mild or moderate in severity, and 38%, 33%, and 26% were treated with symptomatic therapies. Symptomatic therapies included omeprazole, paracetamol, ranitidine, metoclopramide, domperidone, and loperamide (efficacy not assessed). Few patients (<1% placebo, 3% BG-12) discontinued treatment due to GI events.

**Conclusion:** GI AEs associated with BG-12 during the initial treatment period generally are mild or moderate in severity and infrequently lead to treatment discontinuation. Further studies are needed to evaluate the efficacy of individual management strategies.

**Case-report: Scleroderma with longitudinally extensive myelitis**

J.P.R.P., T. de Azevedo; G.D.C. Ferreira; F.K.M.S. Pinto; L.A.A. Reis; L.V. de Oliveira; D.S. Diniz; Neuroscience Nucleus, Clinical Hospital of Goiás Federal University, Goiânia, Brazil; Faculty of Medicine, Federal University of Goiás, Goiânia, Brazil

**Background:** There is an intrinsic relationship between systemic autoimmune diseases and myelitis. Most of them are reported with acute transverse myelitis, some of them with longitudinally extensive myelitis (LETM) and by now in the Neuromyelitis optica spectrum disorders (NOSD) Researching in major scientific directories there are no cases reporting the association between acute myelitis and Scleroderma.

**Objective:** Describe an unreported association with Scleroderma and LETM.

**Patients and methods:** A 53-year old man was admitted with progressive weakness in the last 24 h. Symptoms began with sudden pain and leg paresthesia and evolved to a complete medullary syndrome with paraplegia, bladder dysfunction and a sensory impairment by the level of T8. He was previously diagnosed with Scleroderma four years ago. He presented by Raynaud fenomena, sclerodactylty and telangiectasia in the face, chest, and upper and lower limbs. He presented a positive nuclear pattern ANA. Lab tests have shown elevated proteins in CSF and elevated CRP and ESR. A full spinal MRI has shown a contiguous T2 increased signal beginning from the bottom of the medulla oblongata to the level of T8 confirmed in the transactional view.

**Results:** The patient was submitted to a five-day course of Methylprednisolone followed by a course of Intravenous Human Hyperimmune gammaglobulin. The patient was discharged with prednisone, colchicine and chloroquine. He returned 27 days later fully walking, without bladder or sensory dysfunctions. Anti-aquaporin-4 IgG autoantibody was negative.

**Conclusion:** This case reported the association between Scleroderma and LETM in the NOSD.

**Neurological symptoms in demyelinating disease mimicking an acute ischaemic stroke—Case report**

K. Maistorovic; A. Arsovskia; M. Perovskab; Institute of Nephrology, Struga, The Former Yugoslav Republic of Macedonia; University Clinic of Neurology, Skopje, The Former Yugoslav Republic of Macedonia

**Background:** The case presented here emphasizes the role of an accurate diagnosis for proper targeting of therapy.

**Objective:** Demyelinating disease should be considered even in older patients with focal and fluctuating neurological symptoms.

**Patients and methods:** In March 2013, a 50-year-old woman was admitted with acute left hemiplegia and severe dysarthria, which occurred three days ago. Ten days earlier the patient had intense vertigo, nausea, vomiting, diplopia, speech difficulty and unstable gait. Neurological status on admission showed severe dysarthria, bilateral rhythmic nystagmus, left hemiplegia, vivid generalized muscle tendon reflexes with asymmetry in the right and positive Babinski sign on the right. In the following days MRI of the brain and lumbar puncture were performed. MRI of the brain showed hyper signaling changes in T2 and FLAIR images. CSF electrophoresis showed mild immune activity in the central nervous system. VEP showed a prolonged latency in P100 on the right eye.

**Results:** Therefore, disseminated demyelinating process was diagnosed and intravenous methylprednisolone treatment was initiated (1 g/day for 5 days) with a subsequent progressive improvement of the neurological symptoms.

**Discussion:** Our case has shown that sudden, rapid and unusual neurological deficits can be observed in multiple sclerosis (MS). In such cases, there is a wide range of diseases in the differential diagnosis, including ischemic cerebrovascular events. The presented case demonstrates rare Multiple Sclerosis cases with late onset of the disease by the age of 50. The correct diagnosis of these two entities is essential for proper treatment.

**Memory impairment in patients with clinically isolated syndrome**

E. Hynčićová; E. Meluzínová; M. Vyhnanelt; I. Vécénová; J. Libertínová; I. Kovárová; T. Nikolai; J. Hort; J. Laczó; Department of Neurology, 2nd Faculty of Medicine, Charles University and Motol University Hospital, Prague, Czech Republic; International Clinical Research Center, St. Anne's University Hospital Brno, Brno, Czech Republic; Department of Neurology, 1st Faculty of Medicine, Charles University and General University Hospital in Prague, Prague, Czech Republic
Background: Multiple sclerosis (MS) is a chronic disease affecting young adults, manifesting beside motor and visual deficits also by cognitive impairment, including memory. Recent studies indicated that cognitive impairment can be present already in patients with clinically isolated syndrome (CIS), who are at higher risk of developing CDMS (clinically definite MS) but specific studies focused on memory in CIS patients are lacking.

Objective: To assess whether verbal and non-verbal memory recall and recognition are impaired in patients with CIS.

Patients and methods: 14 patients on interferon-β fulfilling criteria for CIS and 14 healthy matched controls underwent brain MRI (magnetic resonance imaging) and detailed neuropsychological testing including tests of verbal (Rey Auditory Verbal Learning Test — RAVLT) and non-verbal (Brief Visual Memory Test Revised — BVMT-R) memory.

Results: Patients with CIS and controls did not differ in basic demographic characteristics. Patients with CIS were impaired on RAVLT-trials 1–6 (p = .03) and delayed recall after 30 min (p = .024), but not in recognition (p = .789). Patients with CIS were impaired on BVMT-R-trials 1 to 3 (p = .001), and borderline on recall (p = .057), but not in recognition (p = .327).

Conclusion: Our results suggest that impairment of both verbal and nonverbal memory recall may be present already in patients with CIS. The memory recognition is spared. There is ongoing a follow-up study to determine whether patients with CIS and more pronounced memory impairment are more likely to develop CDMS and to find structural correlates of memory impairment in patients with CIS on brain MRI.

Cortical activation changes following botulinum-toxin treatment of leg spasticity in multiple sclerosis: Pilot study

J. Kłosowa, Neurology, Faculty Hospital Olomouc, Palacky University, Olomouc, Czech Republic

Background: Botulinum neurotoxin (BoNT) treatment affects multiple levels of the sensorimotor system and can relieve spasticity of lower limbs caused by multiple sclerosis. The aim of our functional magnetic resonance imaging study was to evaluate cortical activation changes following botulinum-toxin treatment of leg spasticity in multiple sclerosis.

Methodology: Four patients (1 man, 3 women, mean age 46.5, SD 9.3 years) with multiple sclerosis affected with leg spasticity were studied. Patients performed repeated knee extension–flexion movements during brain functional MRI which was acquired in three sessions: before and 4 and 12 weeks after BoNT treatment into the spastic muscles. The change of leg spasticity was assessed using the Snow scale.

Results: BoNT treatment decreased leg spasticity across the group. fMRI pre-BoNT treatment showed extensive bilateral task-related activation of frontoparietal sensorimotor cortical areas, whereas post-BoNT treatment caused retraction to midline and contralateral sensorimotor cortex. Third examination after 12 weeks of BoNT treatment showed re-expansion to a similar extent as seen in the pre-BoNT session.

Conclusions and relevance: This pilot study suggests that relief of leg spasticity may be associated with temporary partial normalization of activation in primary and association sensorimotor cortical areas. Spasticity may be contributing to the documented compensatory overactivation of the sensorimotor system in multiple sclerosis.

Prognostic value of magnetization transfer parameter in clinically isolated syndromes (CIS)

C. Oreja-Guevara1, A. Royo1, S. Novoa1, C. Valencia2, C. Utrilla3, J. Alvarez-Linera3, 1Neurology, University Hospital San Carlos, Spain; 2Radiology, University Hospital La Paz, Spain; 3Ophthalmology, University Hospital La Paz, Spain; 4Hospital Ruber Internacional, Madrid, Spain

Background: Magnetization transfer is a quantitative imaging technique which can assess tissue integrity. A clinically isolated syndrome (CIS) is the initial presentation form in multiple sclerosis (MS) patients.

Objective: To evaluate the use of magnetization transfer (MT) MRI in clinically isolated syndromes (CIS) in order to know the prognosis of the disease course.

To compare the prognostic value of MT parameters with conventional MRI markers like black holes and infratentorial lesions.

Methods: Patients with clinically isolated syndrome (CIS) were followed for 3 years.

Complete neurological explorations were performed every six months. 3 T MRI was performed at the diagnosis and after three years. MTR histograms of whole brain, normal appearing white matter (WM) and grey matter (GM) were produced and calculated using JIM (Xinapse).

Results: 17 patients were examined (9 females). The baseline mean EDSS was 1.68 and 1.15 after three years. Only 8 patients had black holes during the study.
A significant correlation was found between baseline peak WM MTR at baseline and EDSS at the end of the study (r: −0.82, p<0.001). The correlation between average MTR values at baseline and EDSS at the end was moderate (r: −0.68, p: 0.01). The EDSS at three years was also associated with the number of infratentorial lesions at baseline (r: 0.75, p: 0.002) and the black holes volume (r: 0.82, p<0.001).

Conclusion: Our data suggest that MTR parameters at baseline are associated with disability progression. Black holes and infratentorial lesions are good markers for disease progression but they are not always present at the beginning.

CNS demyelination associated with TNFα antagonists: A pathologically proven case with an unusual presentation

A.S. Aleixo Correiaa, M. Chorãoa, R. Amorimc, J. Valed, P. Alegridad

aNeurology, Hospital Egas Moniz (Centro Hospitalar de Lisboa Ocidental), Lisbon, Portugal;

bPathology, Hospital Egas Moniz (Centro Hospitalar de Lisboa Ocidental), Lisbon, Portugal;

cInternal Medicine, Hospital Caldas da Rainha, Caldas da Rainha, Portugal;

dNeurology, Hospital Beatriz Ângelo, Loures, Portugal

Introduction: Biological agents have revolutionized the treatment of several inflammatory diseases with a growing number of reports of the paradoxical induction of autoimmune reactions, including CNS demyelination. On the other hand, monoclonal antibodies have been linked to the development of progressive multifocal leukoencephalopathy (PML).

Case report: A 46-year-old man presented with right arm paresis and hypoteresis progressing over 1 month. He had a medical history of seronegative spondylarthropathy, treated with TNFα antagonists (sequentially Etanercept, Adalimumab and Golimumab). The brain MRI showed a lesion involving the left perirolandic white-matter, with T2-hyperintensity, no mass effect, mild gadolinium enhancement and heterogeneous restriction on diffusion, and a smaller lesion on the right hemisphere. A PML was considered and Golimumab treatment was interrupted but there was clinical aggravation during the next 2 months. CSF cytometry was normal but oligoclonal bands were detected. JC virus DNA was not found on PCR analysis of CSF and urine. A brain biopsy of the main lesion was subsequently performed and showed white matter demyelination with macrophage infiltration, thickened vessels surrounded by T-lymphocyte infiltration and astrocyte hyperplasia, without viral inclusions. PCR analysis for JCV in brain tissue was negative. The diagnosis of CNS demyelination associated with TNFα antagonists was considered and the patient was treated with high dose corticosteroids followed by slow oral tapering with clinical and radiological amelioration and subsequent stabilization.

Conclusion: CNS demyelination associated with TNFα antagonists has a heterogeneous clinical and radiological presentation. Our case discloses a clinical picture that may simulate a PML.

Mitochondrial dysfunction at the onset of neurological deficits in a neuroinflammatory model of MS studied using in vivo imaging

M. Sadeghian a, A. Moseley a, V. Mastrolia a, M. Sajic b, M. Duchen b, K. Smithh, aNeuroinflammation, UCL Institute of Neurology, University College London, London, UK; bCell and Developmental Biology, University College London, London, UK

Reversible neurological deficits in multiple sclerosis (MS) have been attributed to demyelination. Increasing evidence now implicates inflammation as a key player, but mechanisms remain unknown.

Objective: To assess the potential role of mitochondria in causing temporary loss of function in a model of MS.

Methods: Experimental autoimmune encephalomyelitis (EAE) was induced in adult female mice transgenic for expression of cyan fluorescent protein in axonal mitochondria. The spinal cord of symptomatic and asymptomatic animals was imaged at the onset of neurological deficit, or 6 weeks post-immunization. Fluorescent potentiometric dye (TMRM) was applied to the exposed spinal cord to reveal mitochondrial function.

Results: At the onset of neurological deficits, symptomatic animals were distinguished from time-matched asymptomatic and naive controls by fragmentation and loss of function of axonal mitochondria. The number of small mitochondria (1.5–3 μm) increased by ~54% (p<0.01), and longer mitochondria (6–9 μm) decreased by ~39% (p<0.001) compared with controls. 40% of the total mitochondrial mass was non-functional in symptomatic animals, vs. ~28% of mass in asymptotics (p<0.01), vs 0% in naïves. Mitochondrial defects were mainly observed in areas infiltrated with T-cells and macrophages that were producing NO in vivo. Additionally, in inflamed areas activated astrocytes showed increased

doi:10.1016/j.jns.2013.07.1355
glycolysis (phosphofructokinase-2,3+). In chronic animals with severe deficits ~51% of the mitochondrial mass was non-functional, although the inflammation had subsided.

**Conclusions:** Mitochondrial bioenergetic failure is implicated as a cause of neurological deficits at the onset of EAE, in association with increased glycolysis in astrocytes consistent with a mitochondrial energy insufficiency.

**Demyelinating disease affecting both the central nervous system (CNS) and peripheral nervous system (PNS): Study of 2 cases**

**Background:** Chronic inflammatory demyelinating polyneuropathy (CIDP) is a condition affecting the peripheral nervous system; however, it has been associated with central nervous system (CNS) involvement in rare conditions.

**Methods:** We report on two patients with a demyelinating disease affecting the central nervous system (CNS) and peripheral nervous system (PNS).

**Results:** The first case was a 50-year-old man who presented a relapsing-remitting course in which CNS involvement preceded PNS involvement. He begun in 1985 to experience paresthesia in the four limbs followed 6 months later by left optic neuritis. The clinical examination then found pyramidal signs. He improved after steroid treatment. Since 1993, signs of peripheral nerve impairment appeared with repeated episodes of paresthesia, and asymmetric sensory motor signs predominating in distal segments. Clinical examination found areflexia predominating in the lower limbs. Nerve conduction study showed demyelinating motor and sensory neuropathy with persistent conduction blocks. CSF analysis showed albuminocytologic dissociation.

The second case was a 56-year-old man presenting since 2003 a CIDP with conduction block asymmetry predominant in the lower limbs. But the clinical examination found brisk reflexes. MRI examination documented few T2 high signals in brain white matter. No systemic inflammatory disease and no metabolic or inflammatory factor for peripheral neuropathy were found. An improvement in clinical status and neurophysiological parameters was observed after treatment with steroids and azathioprine (Imurel).

**Conclusion:** CIDP with conduction blocks may rarely be associated with central demyelination lesions. Our 2 cases are compared to rare similar ones in the literature and the favourable effect of steroid treatment is emphasized.

**IL-6, AQP4 and CX33 modulations by estrogen in a model of astrocyte-microglia: Insight to the NMO and pregnancy outcome**

Z. Moinfar\textsuperscript{ab}, H. Dambach\textsuperscript{b}, R. Gold\textsuperscript{c}, D. Hinkerohe\textsuperscript{d}, P.M. Faustmann\textsuperscript{ab},  
\textsuperscript{a}International Graduate School of Neuroscience, Ruhr University Bochum, Bochum, Germany; \textsuperscript{b}Neuroanatomy and Molecular Brain Research, Ruhr University Bochum, Bochum, Germany; \textsuperscript{c}Department of Neurology, St. Josef Hospital, Faculty of Medicine, Ruhr University Bochum, Bochum, Germany; \textsuperscript{d}Department of Neurology, Knappschafts Hospital, Ruhr University Bochum, Bochum, Germany

**Background:** Neuromyelitis optica (NMO) is more frequent in women than men (9:1). Astrocytes, the main target in NMO, express Aquaporin-4 (AQP4) (with major role in NMO pathology) and Connexin43 (Cx43) (with unknown but probable impact on brain diseases). Recently, monoclonal antibody blocking IL-6 receptor was successfully applied to treat severe cases of NMO.

**Objective:** To investigate the role of 17-beta Estradiol (Es) on Cx43, AQP4 and IL-6 on a cultured model of astrocytes–microglia.

**Material and methods:** Primary astrocytes and microglia were prepared from postnatal Wistar rats (P0-P2). Cultures with about 5% (M5) or 30% (M30) of microglia were subjected to non-inflammatory and inflammatory condition and they were treated with 100 nM Es for 24 h. Cultures were evaluated for the expression of AQP4 and Cx43 expression by Western blotting (WB) and IL-6

**doi:** 10.1016/j.jns.2013.07.1358
ELISA. All experiments were performed at least four times from different primary cultures. Data were analyzed with GraphPad Prism using *t*-test (mean ± SEM) and were considered significant with *P* value of <0.05.

**Results:** Cx43 (73.49% ± 5.258, *P* value = 0.009) and AQP4 (83.42% ± 3.27, *P* value = 0.001) were decreased in M5 conditions, while they were increased in M30: Cx43 (122% ± 4.97, *P* value = 0.0005), AQP4 (166% ± 27.15, *P* value = 0.02). IL-6 was decreased in M30 cultures (*P* value = 0.02) but not in M5 cultures.

**Discussion:** We showed that, Es overexpressed AQP4 and Cx43 and decreased IL-6 in M30 cultures. Our *in vitro* study is in line with recent study in humans and supports the idea that pregnancy can worsen NMO. However, there is a need to understand the anti/pro-inflammatory role of IL-6 in NMO with further *in vivo* experiments.

**Predictive factors of early visual recovery in patients with optic neuritis**

M.H. Choi, I.S. Joo, Neurology, Ajou University, Suwon, Republic of Korea

**Background:** Optic neuritis is an acute inflammatory disease of the optic nerve. Abrupt visual loss followed by spontaneous improvement over several weeks is a typical course of the disease. The Optic Neuritis Treatment Trial demonstrated the effect of intravenous corticosteroid. However, 10 to 15% of patients experience poor or slow recovery of vision.

**Objectives:** To elucidate predictive factors of early visual recovery in patients with optic neuritis treated by intravenous corticosteroid.

**Patients and methods:** Thirty-four consecutive patients with acute optic neuritis received intravenous corticosteroid were enrolled. According to the improvement of visual acuity during first 7 days, patients were divided into 2 groups — good response group (n = 21); Snellen visual acuities had more than 2 line increases at day 15, and poor response group (n = 13). Demographic, clinical, laboratory and radiological features were compared between the groups.

**Results:** The duration of symptom was numerically shorter in the good response group (12.5 ± 12.9 vs. 23.7 ± 48.7 days, *p* = 0.433) but not statistically significant. Demographic, clinical, and laboratory features did not show a significant difference between the groups. The optic nerve enhancement on orbit MRI was more frequent in the good response group (12.5 ± 12.9 vs. 23.7 ± 48.7 days, *p* = 0.433) but not statistically significant. The optic nerve enhancement on orbit MRI was more frequent in the good response group (12.5 ± 12.9 vs. 23.7 ± 48.7 days, *p* = 0.433) but not statistically significant.

**Conclusion:** The effect of corticosteroid is the result of anti-inflammatory action. Gadolinium-enhancement of the optic nerve represents the degree of inflammation. The optic nerve enhancement on orbit MRI could be used as a predictive factor on early visual recovery in optic neuritis treated with intravenous corticosteroid.

**FAMVIR significantly improves the curative effect of the Normoxic compression in chamber in progressive multiple sclerosis**

N.V. Kazantseva, Neurology, State Medical Academy of Tver, Tver, Russia

Progressive MS is always accompanied by marked axonal injury with significantly reduced tissue respiration in the brain. A new protocol for the therapeutic use of pressure, the so-called Normoxic Curative Compression (NCC), allows the recovery of the tissue respiration in the brain in stroke, trauma and neurodegeneration. The aim of the study is to analyze the efficacy of Famvir in combination with NCC in progressive MS.

**Materials and methods:** In a main group comprising 81 patients with progressive MS, the patients received a course of NCC (1.1 ATA in air chamber for 20 min) in combination with Famvir. In control groups patients with progressive MS received either only Famvir or only NCC. The complex assessment of the patients included a dynamic of immune status, EEG, and acid-base blood condition.

**Results:** Maximum clinical effect was observed in the main group of patients who received combined therapy including anti-viral therapy, NCC and a short course of Dexam. A therapeutic effect was observed in reduced degree of disability, regression of neurological symptoms and changes in the course of MS. Only the main group of patients had a statistically significant decrease in the amount of B lymphocytes and apoptosis. The control group treated with Farmavir did not demonstrate a noticeable effect.

**Discussion:** The study confirms the viral nature of MS and demonstrates the necessity of complex therapy for MS to recover the tissue respiration in the brain and microcirculation. The use of the developed complex allows conversion of progressive MS into the remitting form of MS.

doi:10.1016/j.jns.2013.07.1361
axons and thus rendering them more vulnerable to degeneration in some peripheral neuropathies.

Endothelial dysfunction in patients with multiple sclerosis
N. Spira, A. Boyko, c, N. Spirina, a, bYaroslavl State Medical Academy, Yaroslavl, Russia; 2Russian National Research Medical University, Moscow, Russia

Background: The vascular component plays an important role in the pathogenesis of multiple sclerosis (MS). Few studies confirm the presence of endothelial dysfunction (ED) in MS and its role in the pathogenesis of the disease.

Objective: Identification of ED in patients with MS, an assessment of its relation with the course and disease modifying therapy (DMT) of MS.

Patients: 32 patients (22 female, 10 male), age 34.7 (±2.03), with a definite diagnosis of MS (McDonald criteria, 2005), disease duration − 8.1 (± 1.5) years (%4% – relapsing–remitting MS (RRMS), 16% – secondary-progressive MS (SPMS)). 43.75% was naïve for DMT, 25% without DMT, 15.5% with short term of DMT, 6.3% with long term of DMT and SPMS. In 15.6% the value of vWF was at the upper limit of normal (patients without DMT and patients with SPMS). Level of vWF in patients with RMS without DMT or with short term of DMT was significantly higher than in patients receiving DMT for more than 1 year (p* = 2.48, p ≤ 0.01).

Conclusion: A significant proportion of patients with MS have ED. vWF depends on received DMT, and can be one of the predictors of the effectiveness of the therapy.

Longitudinal assessment of the multiple sclerosis impact scale (MSIS-29) amongst A treated relapsing remitting multiple sclerosis cohort
K. O'Connell, M. Duggan, L. Buckley, M. Hutchinson, N. Tubridy, C. McGuigan. St. Vincent's University Hospital, Dublin, Ireland

Background: The Multiple Sclerosis Impact Scale (MSIS-29) is a commonly used outcome measure of the physical and psychological impact of multiple sclerosis (MS) however long-term reliability has yet to be established.

Objective: To determine reliability of the MSIS-29 longitudinally in a treated cohort of relapsing remitting MS patients.

Patients and methods: A cohort of patients diagnosed with highly active RRMS on natalizumab were assessed every 6 months for 3 years. All patients completed MSIS-29 and Beck Depression Inventory (BDI). Physical assessment was measured using the Expanded Disability Status Scale (EDSS). Correlation between variables was investigated using the Spearman rho correlation coefficient and p < 0.05 was considered statistically significant. Only complete paired data sets were analysed.

Results: Comparison between the BDI and MSIS-29 psychological and EDSS and MSIS-29 physical showed strong correlation at 0 (n = 96), 12 (n = 78), 24 (n = 54), 36 (n = 30) months. The MSIS-29 physical score showed appropriate responsiveness when EDSS improved, remained stable or disimproved from time 0 to 36 months. Good correlation (r = 0.564, p < 0.02) was seen in change between the BDI and MSIS-29 psychological between 0 and 36 months.

Conclusion: The results demonstrate correlation between BDI and MSIS-29 psychological over time. EDSS and MSIS-29 physical scores correlate strongly at set time points and show a trend to longitudinal responsiveness. These findings support the longitudinal reliability of MSIS-29 as an outcome measure for MS patients.

Background: In CARE-MS I, alemtuzumab reduced relapse rate by 55% vs. subcutaneous interferon-1a (SC IFNB-1a) (p < 0.0001) over 2 years in treatment-naive patients with early, active relapsing–remitting multiple sclerosis (RRMS; CARE-MS I study)

Objective: Describe adverse events (AE) of alemtuzumab over time in CARE-MS I.

Patients and methods: Patients were randomized 2:1 to two annual courses of alemtuzumab 12 mg/day IV (Month 0: 5-day course; Month 12: 3-day course) or SC IFNB-1a 44 μg 3×/week. Safety measures included monthly AE monitoring, clinical/laboratory measures, and patient/investigator education about autoimmunity.

Results: Of 563 patients, >90% per group experienced AEs, most of mild/moderate severity; few AE-related study discontinuations occurred (alemtuzumab, 0%; SC IFNB-1a, 2.7%). AEs were most frequent with alemtuzumab during Months 0 and 12, coinciding with treatment administration, largely attributable to infusion-associated reactions (IARs: Month 1, 85.9%; Month 13, 65.7%; non-IAR, Month 1, 44.7% vs. 60.4% SC IFNB-1a; Month 13, 29.3% vs. 30.9% SC IFNB-1a). Secondary autoimmunity increased over time after alemtuzumab and primarily comprised thyroid disorders (Year 1, 6.9%; Year 2, 13.8%); immune thrombocytopenia was uncommon (Year 1, 0.3%; Year 2, 0.8%). Infections decreased from Year 1 (56.6%) to Year 2 (47.3%); serious infections were uncommon (Year 1, 1.6%; Year 2, 0.3%). Two occult malignancies (thyroid cancer) were identified in alemtuzumab patients 11 months after Course 1 and 10 months after Course 2.
Conclusion: AE incidence was similar between groups, except in proximity to alemtuzumab administration, when excess AEs for alemtuzumab were mostly attributable to IARs. Increased incidence of secondary autoimmunity in Year 2 is consistent with previous studies.

Alemtuzumab improves visual outcomes in treatment-naive patients with relapsing-remitting multiple sclerosis (RRMS): Analysis from the phase 3 CARE-MS I study

L.J. Balcer, D.L. Arnoldbcd, J.A. Cohen, A.J. Coles, C. Confavreux, E.J. Fox, H.-P. Hartung, E. Havrdova, K.W. Selma, H.L. Weiner, V. Brinar, G. Giovannoni, M. Stojanovic, A. Cinar, D.H. Margolin, M. Panzarab, D.A.S. Compston, aDepartment of Neurology, NYU Langone Medical Center, New York, NY, USA; bMontreal Neurological Institute, Montreal, QC, Canada; cAddenbrooke’s Hospital, Cambridge, UK; dUniversity of Texas Medical Branch, Round Rock, TX, USA; eHeinrich-Heine University, Dusseldorf, Germany; fCharles University First Medical Faculty, Prague, Czech Republic; gKlinika J Katedra Neurologii Akademii, Lodz, Poland; hBrigham & Women’s Hospital Center, Boston, MA, USA; iZagreb Medical School and University Hospital Center, Zagreb, Croatia; jBarts and The London Centre for Neurosciences, London, UK; kClinical Centre Krugujevac, Krugujevac, Serbia; lGenzyme Corporation, a Sanofi Company, Cambridge, MA, USA; mUniversity of Cambridge, Cambridge, UK

Background: Alemtuzumab demonstrated clinical efficacy in the treatment of RRMS. Sloan low-contrast letter acuity can identify MS-related visual dysfunction.

Objective: Compare alemtuzumab and subcutaneous interferon beta-1a (SC IFNB-1a) effects on visual outcomes in CARE-MS I.

Patients and methods: Patients (N = 581) were randomized to alemtuzumab 12 mg/day IV on 5 consecutive days initially and 3 consecutive days 12 months later or SC IFNB-1a 44 μg 3 ×/week. MS Functional Composite (MSFC; disability composite) and binocular Sloan (letter acuity) assessments were performed twice yearly, with combined scores creating a normalized 4-dimensional composite (MSFC + Sloan) that incorporates visual impairments in the overall disability assessment. Worsened or improved visual function was defined as ≥0.5-point changes in MSFC + Sloan scores.

Results: Mean changes in low-contrast (2.5%) Sloan scores from baseline were smaller with alemtuzumab vs. SC IFNB-1a (significantly at 12 months, p = 0.0019; non-significantly at 24 months, p = 0.1205). When Sloan 2.5% was added to MSFC, treatment differences significantly favored alemtuzumab at 12 (p = 0.0001) and 24 months (p = 0.009). Proportions of patients with worsened or improved Sloan 2.5% scores significantly favored alemtuzumab vs. SC IFNB-1a (worsened: 15.3% vs. 23.6%; improved: 18.5% vs. 13.4% at 12 months; p = 0.029). At 24 months, results again numerically favored alemtuzumab in terms of the proportion who worsened or remained stable, although not significantly (p = 0.2832).

Conclusion: Low-contrast letter acuity by Sloan charts favored alemtuzumab. Use of a visual component measure is likely to augment ability to detect treatment effects across a variety of clinical dimensions in MS trials.

Employment in multiple sclerosis

M. Ben Halima, A. Hassine, S. Ben Amor, S. Naïja, I. Chatti, M.S. Harzallah, S. Ben Ammou, aDepartment of Neurology, Hospital Sahlioul of Sousse, Sousse, Tunisia

Introduction: Multiple sclerosis (MS) is a chronic neurological condition affecting young adults during critical years of work life. Mobility-related symptoms, arm and hand difficulties could adversely affect independence, employment and quality of life. This study determined variables associated with unemployment and risk factors for the development of unemployment in people with MS.

Materials and methods: A case-control study was performed on patients followed by the Department of Neurology, Hospital Sahlioul of Sousse. Demographic, medical and professional data were gathered using a questionnaire.

Results: A total of 45 patients were included in the study:15 were working (group T1),16 lost employment (group T2) and 14 had never worked (group T3). Hence, the employment rate was 33%, with an average time since disease onset of seven years. Lower educational level, disease progression, the presence of motor symptoms, and a worse EDSS were found to be negative factors. For group T2, the loss of the job is related to MS in 87.5% of patients. For group T3, disability represents 30.7% and the lack of suitable employment is 46.1%.

Discussion: In a recently published meta-analysis the mean unemployment rate in MS was 59%. Similar to many studies, lower educational attainment and the presence of motor symptoms predict the loss of employment. The progressive form predisposes also to employment loss. Other studies proved the role of a high EDSS scale as a predictive factor for unemployment which is consistent with our obtained results. Other reasons reported by people with MS for their loss of employment were workplace-related factors including insufficient flexibility of employment conditions.

Conclusion: These data suggest that low educational level, progressive form, high EDSS and presence of motor symptoms predict employment loss.

**Neurological manifestations revealing Gougerot Sjogren syndrome: 18 cases**  
I. Bedoui, M. Malek, A. Riahi, O. Ben Waddy, J. Zouali, R. Mrissa.  
*Department of Neurology, Military Hospital, Tunis, Tunisia*

**Introduction:** Neurological manifestations in Gougerot Sjogren syndrome (GSS) are valued differently and are sometimes in front of the dry syndrome.  

**Purpose:** To analyze the epidemiologic and clinical aspects of 18 patients having SGS revealed by neurological manifestations.  

**Patients and methods:** We report 18 cases of neurological manifestations revealing SGS collected over a period of 8 years.  

**Results:** There were 18 patients with a sex ratio 15 W/3 M whose average age was 44.14 years old. Peripheral nervous system manifestation occurred in 44.44% (axonal polyneuropathy in 37.5%, trigeminal and other cranial nerves neuropathies in 37.5%, multiple mononeuritis in 12.5% and anterior horn involvement in 12.5%). Central nervous system involvement was observed in 88.88% (chronic myelopathy, multiple sclerosis like manifestations, psychiatric manifestations).  

All the patients received oral corticosteroids, cyclophosphamide was used in 5 cases. Evolution was good in 9 cases.  

**Discussion and conclusions:** Neurological affection in the SGS is noticed in 8 to 70% of the cases according to studies. It is marked by clinical diversity dominated by peripheral neuropathies. The central affection is usually polymorphic. In our series, results were different. Isolated central affection was noted in 11 cases versus isolated peripheral affection in one case and was mixed in 7 cases.

impaired mobility and lower quality of life. The impact of spasticity on healthcare utilization (HCU) is poorly understood.

**Objective:** Assess association of spasticity and HCU among North American Research Committee on Multiple Sclerosis (NARCOMS) registry participants.

**Patients and methods:** NARCOMS maintains a self-report database of MS patients who volunteer health-related information through online or paper questionnaires at enrollment and semi-annually thereafter. Among 5172 individuals who completed surveys in 2005 and 2011, we evaluated the association of HCU with spasticity reported using the 5-point Performance Scales spasticity subscale (PSss).

**Results:** Responders were predominantly female (76.2%) and white (96.2%). In 2005 mean (SD) age was 52 (9.8) years, disease duration 13.7 (9.1) years, and 50.8% could walk unassisted. 18.8% reported no spasticity, 36.2% minimal, 17.5% mild, 15.7% moderate, 9.9% severe and 1.9% total. In the prior 6 months, 653 (13.2%) reported an ER visit while 358 (7.1%) reported hospitalization. Frequencies for both increased with spasticity severity (p < 0.001 for linear trend). Over 6 years, PSss improved or remained stable in 74.9% and worsened in 25.8%. Versus participants whose PSss score worsened, those with improved spasticity were less likely to report an ER visit (OR 0.83; 95%CI: 0.67–1.03) or hospitalization (OR 0.76; 95%CI: 0.59–0.99) even after accounting for disability and sociodemographic factors.

**Conclusion:** More severe spasticity is associated with greater HCU, emphasizing the adverse impact of spasticity and suggesting that effective treatment of spasticity might reduce HCU.

**Absence of delayed facilitation and post-exercise facilitation at early stage of multiple sclerosis: Evidence of altered cortical plasticity?**

**University of Udine Medical School, Neurology, Udine, Italy**

**Background:** By means of transcranial magnetic stimulation (TMS) multiple sclerosis (MS) has been studied. Disabilities correlate with alterations of TMS parameters such as prolonged central motor conduction time, prolonged motor evoked potential (MEP) latencies and increased motor threshold (MT). TMS has also been used to explore movement-related cortical plasticity.

**Objective:** To compare cortical excitability in patients at early stage of MS versus healthy controls.

**Material and methods:** In each subject TMS of non-dominant hemisphere was used to define MEP amplitude and motor threshold (MT). Then subjects performed 3 blocks (30-s, 60-s, and 90-s duration) of a bimanual motor task (exercise condition). Amplitudes of MEPs elicited immediately after each block, and then after a 15-minute rest period were compared with baseline to evaluate the presence of post-exercise facilitation and delayed facilitation. Patients were not receiving any therapy and their Expanded Disability Status Scale score was between 1 and 2.5.

**Results:** MT resulted significantly higher in patients compared to controls. Compared with baseline, controls had larger MEP amplitudes after 30 and 60 s of exercise (post-exercise facilitation) and also after the rest period (delayed facilitation). In contrast, MEP amplitudes in patients were not significantly different from baseline after any of the exercise conditions or following the rest period.

**Conclusion:** Patients do not show the normal fluctuations of cortical excitability usually found after a bimanual finger motor task. These results suggest an alteration in the cortical plasticity. We speculate that in SM patients capability to recover from functional impairments caused by demyelination is compromised.

**Transorbital sonography in the hyperacute stage of optic neuritis: A bicentric case–control longitudinal, blind study**

P. Lochnera, b, R. Cantellob, L. Coppoa, R. Nardone, F. Tezzonb, O. Raymkulovb, M. Leoneb, F. Brigoc, c. “Department of Neurology, General Hospital of Merano, Merano, Italy; “Department of Neurology, University A. Avogadrow, Novara, Italy; “Department of Neurological, Neuropsychological, Morphological and Movement Sciences, Section of Clinical Neurology, University of Verona, Verona, Italy

**Background:** Acute unilateral optic neuritis (ON) is known to be associated with an increased optic nerve sheath diameter (ONSD) as revealed by ultrasonographic investigations. However, there is no consensus in the literature on the diagnostic cut-off of ONSD.

**Objective:** The goals of this study were to evaluate the accuracy/sensitivity of US in the diagnosis of acute ON, and to assess the association between ONSD threshold and ON.

**Patients and methods:** A prospective blinded observational (case-control) bicentric study was performed. Seventeen consecutive patients with an acute non-compressive unilateral ON and onset of visual loss during the prior 10 days were included. We enrolled 20 healthy controls, matched by gender and age (±5 years). Two experienced vascular sonographers, blinded to the status of case or control and to the affected eye, performed the study using B mode US. ONSD was defined as a sign of nerve thickening, if the difference in nerve diameter of 0.3 mm or more, compared with the contralateral side or controls.

**Results:** A significant ONSD increase on the affected compared to the health side, was found in all patients by both investigators (6.6 mm ± DS 0.85 versus 5.5 mm ± DS 0.66 p < .001). ONSD was normal in all controls (5.2 ± DS 0.62) mm and in all the non-affected eyes.

**Conclusions:** Our findings suggest that transorbital sonography has a very high sensitivity in recognizing ON, similar to that of the visual evoked potentials.

**Klüver–Bucy Syndrome in a multiple sclerosis patient**

J.P.R.P.T. de Azevedoa, G.L. Vasquesb, C.D. Rochac, J.A.D.O. Júniorb, F.O. Gomesb, D.S. Dinizb. 1Hospital das Clínicas, Universidade Federal de Goiás, Goiânia, Brazil; 2Faculdade de Medicina, Universidade Federal de Goiás, Goiânia, Brazil

**Background:** Multiple sclerosis (MS) can result in a complex net of neuropsychiatric symptoms. Klüver–Bucy Syndrome (KBS) is a rare complex behavioral syndrome. It’s composed of psychic blindness, hyperorality, hypermetamorphosis, hypersexuality, disturbed dietary habits and placidity. It’s widely related to temporal lobe lesions.

**Objective:** Report the rare association between Multiple Sclerosis and Klüver–Bucy Syndrome.

**Material and methods:** Case report.
Results: A 32 year old woman diagnosed with MS by the age of 20 started a multiple incipient behavioral change. She was already in Secondary-Progressive phase of the disease. She presents with placidity, hyperorality, hypermetamorphosis and a complex disturbed dietary habit. She used to avoid non-sweet and usually add sugar or sweetener in all kinds of food. The MRI showed diffuse cerebral atrophy especially in the temporal lobes with poor inflammatory lesion in both of them. Topiramate and valproic acid were introduced and controlled well the sweet compulsion. Antipsychotics were tried in other behavioral symptoms.

Conclusion: MS is a complex disease composed of both inflammatory and degenerative lesions. Neuropsychiatric symptoms can be related to both of them. There is a complex role of cognitive and special behavioral symptoms that compose MS spectrum, as KBS is shown in this abstract.

Background: Anxiety and depression are commonly reported by persons with multiple sclerosis (PwMS) but no data, to our knowledge, have emerged from Arab Islamic population.

Objective: The study aims to investigate the prevalence of anxiety and depression among PwMS attending tertiary care hospital in Oman, Neurology Clinic, Sultan Qaboos University Hospital (SQUH).

The characteristics such as socio-demographic and clinical variables were also explored.

Methods: Consecutive and consenting PwMS were subjected to the following measures. The Hospital Anxiety and Depression Scale (HADS) was used to measure anxiety (cut-point > 7) and depression (> 7).

Results: 54 patients with MS participated in our study and approximately 87% were on Interferon. The age range from 17 to 50 and the average age was 31.4 ± 8.84. In terms of gender, majority were female (males = 30% vs. 70% females). Approximately 50% of the attendees have acquired university or higher graduate education while 39% had completed secondary education. The rest acquired on the lower strata of education with one illiterate. The majority (69%) of attendees were married while 31% were single. Approximately 83% were employed, students or job-seekers. The majority of the patients had < 4 in the EDSS. Prevalence of anxiety was 53%, depression 39% on HADS.

Conclusions: Anxiety and depression are common in PwMS among the attendees of tertiary care in Oman. Such psychosocial variables have been largely unreported from non-western population. As these variables are strong indicators of burden of MS, concerted efforts are needed to address such psychosocial dysfunctions in the algorithms of care for PwMS.

Percept: A prospective multicenter observational study on benefit/risk perception of natalizumab in neurologists and their patients in Germany

C. Heesen², S. Meuth³, V.C. Zingler¹, C. Wernsdorfer⁴, S. Koepke⁵, I. Kleiter⁶, C. Wettmershausen⁷, ²University Hospital Hamburg Eppendorf, Hamburg, Germany; ³University Hospital Muenster, Muenster, Germany; ⁴Biogen Idec, Ismaning, Germany; ⁵University Hospital Schleswig-Holstein, Luebeck, Germany; ⁶University Hospital Bochum, Bochum, Germany

Background: For decision making on NAT use, neurologists (NLs) and patients (pts) should be adequately informed on NAT efficacy and PML risk stratification.

Methods: PERCEPT investigates NAT benefit/risk perception and information levels of NLs and pts in routine practice. We present an interim analysis of BL data.

Results: Most NLs (n = 77) rated their MS expertise “excellent” (52.8%) or “very high” (41.9%). BL characteristics of 599 pts [means]: treatment in practices 76.3%; MS duration 10.3 years; NAT duration: 26.6 months; IS pretreatment: 9.0%; anti-JCV tested: 93.7% (45.5% positive). On visual analogue scales (1–10), NLs and pts rated MS as “serious threat” (NLs 18.3, pts 18.6), and PML as “moderate risk” (NLs 8.11; pts 10.8).

98.5% of NLs rated NAT “very effective”; 48.4% tolerated a PML risk of 1/100, 18.8% up to 1/10. 80.5% of NLs rated the anti-JCV assay “clearly helpful”.

NL information level: correct answers regarding pivotal trial data on freedom from progression on NAT and placebo: 58.4% and 35.1%. Correct answers on PML risk during 1st/2nd + year of NAT: 97.3% (40.2%); on the risk factors IS pretreatment and JCV serostatus: 79.5% and 84.6%; on risk stratification 76.6%.

Conclusions: NLs and pts perceived MS as serious threat and PML as moderate risk. NLs had limited awareness of data on freedom from progression. Knowledge on risk stratification was generally good. The anti-JCV assay was regarded very useful. The PML risk tolerated by 50% of NLs was in the range for pts with 3 risk factors.

Measurement and estimation of relaxation times in magnetic resonance imaging of brain tissue in patients with multiple sclerosis (MS)
S.S. Anvari1, M.A. Oghabian1, N. Riyahi-Alam1, H. Ghanati1.
1ICSS (Institute for Cognitive Science Studies), Tehran, Iran;
2Tehran University of Medical Sciences, Tehran, Iran

Contrast of conventional MRI images is influenced by different parameters such as T1, T2 and proton density. Effect of these parameters together; sometimes cause invisibility of some lesion especially small ones in patient with multiple sclerosis. However, each brain tissue has specific values of T1 & T2 that usually change in different pathologic lesions, and can be diagnosed by first creating specific MR images with contrast based on one of the relaxation times T1 or T2 only without the involvement of each other and the measurement of these relaxation times T1 & T2. Present study has been performed on 1.5 T MRI system. In the study, with optimization of interpulse time intervals (TE, TI & TR) to minimize errors, first T1 & T2 maps were computed from two images using spin Echo (SE) and inversion Recovery (IR) pulse sequences in some healthy volunteers as controls and patients with definite Multiple sclerosis. Then T1 & T2 values in 26 different regions of brain tissues were measured in controls and patients and finally compared together. Findings of this study indicate that not only T1 & T2 values in MS plaques increase considerably but also these values in normal appearing white matter (NAWM) increase meaningfully, whereas T2 value in normal appearing white matter (NAGM) decreases meaningfully. As a result, increasing of T1 & T2 values in NAWM and decreasing of T2 values in NAGM can be considered as a diagnostic parameter of MS disease.

The mesenchymal stem cells labelled by magnetic nanoparticles applying in experimental autoimmune encephalomyelitis
N. Drazhina1, E. Petrova2, E. Semenova3, S. Kolomiets4.
1Neurological and Neurosurgical Diseases Department, BSU, Minsk, Belarus;
2Scientific-Research Part, BSU, Minsk, Belarus

Introduction: The application of mesenchymal stem cells (MSCs) labelled by magnetic nanoparticles in medicine attracts a great scientific interest.

Objective: To realize the control of MSC labelled by magnetic nanoparticle allocation in experimental autoimmune encephalomyelitis (EAE).

Methods: The laboratory animals (rats) with clinical signs of EAE were assigned into four groups: the control group with one fold saline solution injected, the second group injected with MSC, the third one with magnetic nanoparticles injected, and the fourth — MSC labelled by magnetic nanoparticles. As magnetic nanoparticles were used iron oxide 5.9 nm nanoparticles stabilized by oleic acid and triethanolamine. The clinical signs of EAE were estimated according to the International Criteria of Assessment of clinical signs of EAE in laboratory animals. All animals underwent MRI control on the 1st, 10th, 20th, and 22nd days after procedure.

Results: The regression of clinical signs of EAE realized in shorter terms in the second and the fourth groups simultaneously (p < 0.05). The magnetic nanoparticles were detected by MRI in the brain of the animals only in the fourth group.

Conclusions: The application of MSC labelled by magnetic nanoparticles amplifies the possibilities of non-invasive control methods of cell technology application in CNS diseases.

Switching from natalizumab to fingolimod
1Centro Sclerosi Multipla, Dipartimento di Sanità Pubblica, Medicina Clinica e Molecolare, Italy;
2Dipartimento di Sanità Pubblica, Medicina Clinica e Molecolare, University of Cagliari, Cagliari, Italy

Background: Natalizumab(N) is an efficient treatment for Multiple Sclerosis (MS). Unfortunately, recent data show that the disease activity returns after N discontinuation. Fingolimod (F), recently approved in highly active MS, might represent an alternative treatment after N suspension.

Objective: To evaluate the MS disease activity in patients who switched from N to F.

Results: In two patients with either clinical or radiological disease activity, the natalizumab saturation on CD8+ and CD4+ T cells was less than 30%, respectively. In contrast, the remaining three patients with the absence of disease activity had a median natalizumab saturation of 70% (range 59–79%) on CD4+ and 66% (range 52–68%) on CD8+ T cells.

Conclusions: The data of this pilot study indicate that clinical and radiological disease activity is closely linked to natalizumab saturation at the time point of switch. The determination of natalizumab saturation may be an essential tool to monitor cessation of natalizumab treatment.

doi:10.1016/j.jns.2013.07.1383
Patients and methods: We analyzed retrospectively 44 patients who switched to F (F-Group) after N suspension, and compared them with a group of 17 patients who restarted N after a drug holiday (N-Group). We assessed the recurrence of disease activity evaluating the relapse rate in 4 periods of time: before N (pre-N), during N (on-N), during wash-out (WO), and during the second treatment (post-N).

Results: In the F-Group: the number of patients experiencing relapses was 40 (90%) in pre N, 8 (18%) in on-N, 13 (29%) in WO, 4 (15%) in post-N. During WO the relapse-rate was significantly higher than on-N, as well as in post-N. There were no significant differences with the N-Group in any of the period considered.

Conclusion: Our experience shows that the beneficial effects of N rapidly deteriorated after its withdrawal. In our cohort the disease activity during treatment with F was not significantly different than during WO and on-N. However, it was still significantly lower than pre-N (p = 0.02), as we experienced with patients in the N-Group. Nowadays, an early resumption of alternative treatments after N suspension is recommended. F seems to be an option, but the optimal strategy is still to be determined.

Birth outcomes of pregnancies fathered by men with multiple sclerosis
E. Lu², F. Zhu³, Y. Zhao³, M. van der Kop³, A. Synnes³, L. Dahlgren³, A.D. Sadovnick¹,², A. Traboulsee¹, H. Tremlett¹, ¹Medicine/Neurology, University of British Columbia, Vancouver, BC, Canada; ²Pediatrics, University of British Columbia, Vancouver, BC, Canada; ³Obstetrics and Gynaecology, University of British Columbia, Vancouver, BC, Canada

Background: Studies have examined the association between multiple sclerosis (MS)-related clinical factors and birth outcomes in mothers but not fathers with MS. Autoimmune diseases in fathers have been associated with preterm and lower birth weight babies; poor sperm quality has also been reported in men with MS.

Objective: To investigate if paternal MS disease duration or disability (as measured by the Expanded Disability Status Scale) is associated with newborn birth weight or gestational age.

Patients and methods: The British Columbia (BC) MS database (containing >80% MS patients in BC, Canada) and the BC Perinatal Database Registry (capturing >99% of births in BC) were linked, along with the BC Vital Statistics Birth Registry to enable linkage of individual-level data for newborns, mothers and MS fathers in this retrospective cohort study. We investigated the association between paternal MS disease duration, disability (±3 years of conception) and neonatal outcomes using multivariate regression models to adjust for confounding and familial effects.

Results: There were 202 singleton births fathered by men with MS (1996-2010). Mean birth weight of newborns was not associated with MS disease duration (adjusted p = 0.20) or disability (adjusted p = 0.25). Mean newborn gestational age was also not associated with MS disease duration (adjusted p = 0.42) or disability (adjusted p = 0.32).

Conclusion: We did not find an association between paternal MS-related clinical factors and birth outcomes. As one of the first studies investigating paternal MS clinical factors on birth outcomes, our findings are reassuring for fathers with MS and their families.

Monitoring and management of MS patients starting natalizumab therapy in Germany — Final results of the prospective TYSTART study
A. Chan¹, U. Walter¹, B. Kallmann², C. Werndsoefer³, V.C. Zingler⁴
¹Neurological Hospital, Ruhr University Bochum, Bochum, Germany; ²Neurological Practice, Fulda, Germany; ³Neurological Center, Bamberg, Germany; ⁴Biogen Idec, Isuming, Germany

Background: In AFFIRM, 37% of natalizumab patients (pts) remained free from disease activity (placebo: 7%) over 2 years. JCV-infected pts have an increased PML risk on natalizumab, particularly after previous immunosuppression and natalizumab therapy ≥2 years. Natalizumab therapy requires structured monitoring.

Methods: TYSTART documented MS outcomes and monitoring in patients starting natalizumab (≥2 infusions received) in clinical routine. Clinical, MRI and laboratory parameters (JCV antibodies since 01/2012) were recorded at 5 three-monthly visits.

Results: Patient characteristics (n = 258; 65.9% women) baseline [mean (±SD)]: age 39.6 yrs (±10.5); MS duration 8.3 years (±7.0); natalizumab infusions before BL 3.9 (±5.6); EDSS 3.6 (±1.6); Fatigue Severity Score (FSS) 4.2 (±1.7). 89.5% of patients had received ≥1 immunomodulator, 19.0% ≥1 immunosuppressant. MRIs before/at baseline showed: contrast-enhancing lesions: 2.9 (±4.1) cerebral and 0.9 (±1.5) spinal; T2 lesions: 11.5 (±11.3) cerebral and 2.2 (±2.7) spinal. Observation duration was 10.5 months (±2.9). Common lab tests were transaminases (42.7–69.8% at the 5 visits) and blood counts (53.0–68.6%). 91.1% of patients had MRIs before/at baseline; 44.3% had 1–4 MRIs during study. 28.1% of 228 JCV antibody assays were positive. In patients with 12 months data, the EDSS remained stable (3.6 (±1.7) vs. baseline 3.5 (±1.7)); the FSS improved from 4.1 (±1.7) to 2.2 (±2.1). Four patients had serious adverse events, including 2 MS relapses and no PML.

Conclusions: TYSTART confirmed the high efficacy of natalizumab. The mean EDSS remained stable, the FSS improved during observation. No PML occurred. Monitoring comprised MRI and laboratory investigations including JCV antibodies.

The meaning of herpetic infection in the progression of multiple sclerosis
V. Lishdvo, T. Yakushina. Neurology, MRRICI, Moscow, Russia

The aetiology of MS has multifactorial factor, in which the considerable part belongs to viruses. Objective of study is learning the prevalence of herpetic infection of patients with MS, the influence of different types of herpes on the progression of MS.

Thirty patients with MS (28 — RR MS in the remission, 2 — PP MS) entered the study. Patients’ age = 30.5 ± 8.1 (M ± σ) years, the duration of the disease = 5.8 ± 4.4 years, the number of all exacerbations in time of disease = 4.0 ± 2.7 and EDSS 2.4 ± 1.2. Enzyme-linked immunoelectrodiffusion assay and polymerase chain reaction to antigen of herpetic viruses (1, 2, 3, 4, 5, 6 types) were used.

All patients had herpetic infection. In the group with the virus (1, 4 or 5 type) in the replication phase (N = 5) EDSS = 2.8 ± 1.2, the duration of the disease — 6.8 ± 4.6 years and the number of

BG-12 (dimethyl fumarate) and pregnancy: Preclinical studies and pregnancy outcomes reported during the clinical development program
R. Gold, J.T. Phillips, H. Havrdova, A. Bar-Or, L. Kappos, J. Clarke, H. Yuan, M. Novas, M.T. Sweetser, N.C. Kurukulasuriya, V. Viglietta, R.J. Fox. 1Neurology, St. Josef Hospital, Ruhr University, Bochum, Germany; 2Multiple Sclerosis Program, Baylor Institute for Immunology Research, Dallas, TX, USA; 3Department of Neurology, McGill University, Montreal, QC, Canada; 4Department of Neurology, University Hospital, Basel, Switzerland; 5Biogen Idec, Weston, MA, USA; 6Mellen Center for Multiple Sclerosis Treatment and Research, Cleveland Clinic, Cleveland, OH, USA

Background: No formal studies of BG-12 (dimethyl fumarate) were conducted in pregnant women, but pregnancies have occurred during the BG-12 clinical development program.

Objective: To present data from animal reproductive toxicology studies and pregnancy outcomes reported during the BG-12 clinical development program.

Patients and methods: Reproductive and developmental toxicology was evaluated in rats and rabbits given dimethyl fumarate during organogenesis or pregnancy and lactation. Subjects in BG-12 clinical trials were required to use contraception and discontinue drug in the event of pregnancy.

Results: There was no evidence of impaired fertility in rats or teratogenicity in rats and rabbits given dimethyl fumarate at doses that caused reductions in maternal weight gain. As of January 2, 2013 (data cutoff), 38 pregnancies in subjects exposed to BG-12 (37 MS patients, 1 healthy volunteer) and 14 pregnancies in placebo recipients were reported in clinical studies. In patients exposed to BG-12, 22 live births (65%), 3 spontaneous abortions (9%), and 9 elective terminations (26%) were reported; information is pending for 3 subjects and 1 subject was lost to follow-up. In placebo recipients, 9 live births (64%), 3 spontaneous abortions (21%), and 2 elective terminations (14%) were reported. No fetal abnormalities have been reported. The incidence of spontaneous abortion was consistent with the expected rate in the general population.

Conclusion: Based on limited data, no increased risk of fetal abnormalities or adverse pregnancy outcomes associated with gestational exposure to BG-12 during the first trimester has been observed. Further data will be collected through a pregnancy registry.

A case of very late onset multiple sclerosis
E.D. Ciftci, S. Kibaroglu, U.S. Benli. Neurology, Baskent University, Faculty of Medicine, Ankara, Turkey

The onset of multiple sclerosis (MS) after the age of 60 is very rare and classified as very late onset MS. The prevalence of very late onset MS ranges between 0.6% and 1.3%. We report a 71-year-old Caucasian female presenting with monoparesis of her left leg. Fifteen days after her first symptoms she developed paresthesia on the upper thoracic region. Cerebral magnetic resonance imaging (MRI) showed multifocal white matter lesions with gadolinium enhancement and the most prominent one located at the pons and thoracic MRI revealed hyperintense lesion with gadolinium enhancement at the T3–4 level. Metastatic diseases, vasculitis, sarcoidosis and other demyelinating central nervous system disorders were ruled out with extensive tests. CSF analysis showed positive oligoclonal band type 2. She had a family history of MS in her daughter. Patient received intravenous corticosteroid therapy 1 g/day for 5 days and improved clinically. She didn’t accept any disease modifying therapy and during 2 months follow-up period no new attack was observed.

This case has been presented to emphasize the possibility of multiple sclerosis in differential diagnosis of elderly patients with first onset multifocal neurological symptoms.

Benefit 11: Long-term follow-up study of patients with clinically isolated syndrome treated with interferon beta-1b

Department of Neurology and Neurosurgery, Belarusian State Medical University, Minsk, Belarus; bDepartment of Neuroimmunology, Belarusian Medical Academy of Postgraduate Education, Minsk, Belarus; cDepartment of Bone Marrow Transplantation, 9th Minsk City Hospital, Minsk, Belarus; dDepartment of Neuroradiology, Minsk Diagnostic Center, Minsk, Belarus; eDepartment of Ophthalmology, 3d Minsk City Hospital, Minsk Belarus

Background: MS is a demyelinating disease that often begins as a clinically isolated syndrome (CIS). Long-term follow-up may provide important insights into outcomes for these patients; however, ascertainment is a challenge.

Objectives: To review the key findings over the 8-year study period of BENEFIT and to describe the design of the ongoing 11-year cross-sectional follow-up.

Patients and methods: 468 patients with CIS were randomized to either interferon beta-1b (early treatment) or placebo (delayed treatment) for 2 years or until CDMS. Analyses were conducted at 2, 3, 5, and 8 years. Comprehensive 11-year follow-up, including clinical, MRI, and OCT assessments, is ongoing through 2013–2014. To increase ascertainment in the BENEFIT 11 Study, the design includes telephone assessments as an alternative to face-to-face interviews and referrals from inactive to active sites.

Results: 93.6% completed the placebo-controlled phase. 84% and 75.5% completed 3 and 5 years and 60.7% gave consent for the extension, with a final ascertainment of 55%. Risk for CDMS was significantly lower in the early vs delayed treatment group (Year 2: 27% vs 45%, Year 3: 36% vs 51%, Year 5: 46% vs 57%, Year 8: 57% vs 66%). EDSS scores were not significantly different, and remained low in both groups (median 1.5 throughout the study).

Conclusion: Available follow-up of up to 8 years showed persistent advantages of early vs delayed treatment with interferon beta-1b in patients with CIS. The ongoing comprehensive reassessment at Year 11 will provide important information on disease course and long-term treatment effects.

Severe thrombocytopenia in patient with multiple sclerosis during interferon-beta-1B treatment — Case report
E. Bejniak, H. Bartosik-Psujek, K. Mitosek-Szewczyk, Z. Stelmasiak, K. Rejdak. Dept of Neurology Medical University of Lublin, Lublin, Poland

Introduction: Interferon-beta-1B (Betaferon) is an established treatment for relapsing-remitting multiple sclerosis (MS) and haematological changes are commonly reported in clinical trials and clinical practice of this drug. Treatment with interferon-beta-1B led predominantly to asymptomatic dose-related reductions in white blood cells. At least two-thirds of patients affected by cytopenia experienced the onset of cytopenia within the first 6 months of therapy.

Methods: Observational case report.

Results: A 23-year-old man affected by MS, started treatment with interferon beta1B (Betaferon, 250 mg every other day, sc) on January 2011. Baseline blood examination and, in particular platelet count (276 G/L) were normal. There was no history of any haematologic abnormalities or allergy. After 6 months of interferon-beta-1B treatment he developed thrombocytopenia hemorrhagic diathesis with platelet count 1 G/L. Betaferon was immediately stopped. Patient was admitted to the hospital and received five infusions of packed red blood cells, and then steroids until platelet count was normalised. From February 2011 he is without steroids, and platelet count is 320 G/L. Betaferon treatment was not.

Conclusion: Although haematological abnormalities are common and dose-related in patients with MS receiving interferon-beta-1B, the thrombocytopenia, especially so deep occurs quite rare.

Uncommon ocular and visual signs of relapsing remitting multiple sclerosis

Background: Ocular manifestations in multiple sclerosis (MS) are classic, including both visual and motor ocular systems. Optic neuritis remains the most frequent manifestation.

Objective: To report two MS patients revealed by isolated homonymous lateral hemianopsia (HLH) and sixth cranial nerve palsy (SCNP).

Case 1: A 29-year-old woman, who presented a sudden right visual field defect. Neurological examination revealed an isolated right HLH. CT scan demonstrated a left occipital hypodensity. The diagnosis of ischemic stroke was made. Brain MRI showed a large T2-weighted lesion in the left juxtacortical occipital region, associated to multiple T2-weighted lesions in the periventricular regions. The visual evoked potential was normal. Oligoclonal bands were present in the cerebrospinal fluid (CSF). MS was diagnosed and the patient was treated with intravenous methylprednisolone with clinical improvement.

Case 2: A 30-year-old woman, who presented sudden horizontal diplopia. The neurological examination showed isolated left SCNP. The eyeground was normal. MRI showed a T2-weighted lesion of the sixth cranial nerve, associated to multiple T2-weighted lesions in the brainstem and spinal cord. Oligoclonal bands were present in the CSF. The diagnosis of MS was made with a complete spontaneously recovery within two weeks.

Discussion: HLH is infrequent in MS, occurring in less than 1% of patients, due to the large required lesions in post-chiasmal visual pathway. Isolated sixth nerve palsy is a rare presenting sign of MS, with an incidence of 1.6%.

Conclusion: The diagnosis of MS should be considered in young adults with HLH or ocular motor cranial nerve involvement.

Rheumatoid arthritis and amyotrophic lateral sclerosis association: A case report and literature review

Introduction: Neurological complications are reported with rheumatoid arthritis (RA), involving especially the central nervous system. Degenerative motor neuron disease is unusual.

Objective: The objective is to describe a rare association between RA and amyotrophic lateral sclerosis (ALS) and to discuss the relation between these two diseases.

Case report: A 20-year-old woman presented rapidly progressive walking disorder and limb weakness without dysphagia and dysphonia. The physical examination showed signs of bilateral degeneration of upper and lower motoneurons involving the four limbs, without sensory disturbance and cranial nerve involvement. We noted also a deforming polyarthropathy of the hands. Electromyography found signs of impairment of the anterior horn of the spinal cord. Brain and spine MRI was normal. Serological test for rheumatoid factor was positive. The diagnosis of ALS associated with seropositive erosive RA was made.

Discussion: ALS is a chronic disease of unknown cause. To date, only seven cases similar to our patient have been reported, most of them having long-standing but quiescent joint disease at the time of ALS onset. Our patient has an atypical bilateral presentation, without signs of medulla’s involvement. There are other cases of ALS in combination with autoimmune diseases such as systemic lupus erythematosus, scleroderma, Wegener granulomatosis and Gougerot Sjögren’s Syndrome. There is no evidence in favor of a common pathophysiologic mechanism, and thus the possibility of a fortuitous association must be raised.

Conclusion: The simultaneous presence of RA and ALS represents a difficult diagnostic challenge. There is no argument in favor of a shared physiopathological mechanism.

A diagnostic challenge: Tumefactive demyelinating lesions, our clinical experience in Baskent University
S. Kibaroglu, U.S. Benli, E.D. Ciftci, M.K. Toprak, O.Y. Cakmak, U. Can. Neurology, Baskent University, Faculty of Medicine, Ankara, Turkey

Background: Tumefactive demyelinating lesions (TDLs) are a rare variant of multiple sclerosis (MS), characterized by the presence of large lesions in white matter (>2 cm) with mass like features and edema. Differential diagnosis of TDLs from other intracranial space occupying lesions is essential to avoid unnecessary interventions and treatments.

Methods: Demographic, clinical, radiological and laboratory data of 6 patients with TDLs were retrospectively collected.

Results: All patients were female with a mean age of 42.8 (33–57 years) and mean age at disease onset was 38.8 (31–47 years). The mean duration of disease was 4 years (range 1–10 years). All patients had solitary TDLs, five had tumefactive lesions at onset and one patient developed tumefactive lesion during the course of MS. One patient with RRMS developed two tumefactive relapses during follow-up. Clinical presentations varied but headache, visual changes, and sensory and motor symptoms were the most common. Brain MRI showed tumefactive lesions with mild to moderate edema and contrast enhancement. MR spectroscopy was performed in all cases and revealed findings suggesting demyelination. CSF analysis was available for three patients. Oligoclonal IgG band was positive in one case. Biopsy was performed in one case, revealing nondiagnostic pathology; final diagnosis was TDLs. All patients responded to corticosteroids. Three patients were treated with interferon and one patient was treated with azathioprine.

Conclusion: Six patients with TDLs who had different clinical and radiological characteristics were presented with review of the literature with a special emphasis on spectroscopic investigation.

Paraneoplastic neuromyelitis optica associated with stomach carcinoid tumor
T.M. Al-Harbii, M.F. Bin Falahii. "Neurology, King Fahad Specialist Hospital, Dammam, Saudi Arabia;" Neurology, Dr.Sulaiman Al-Habib Hospital, Manama, Bahrain

Background: Neuromyelitis optica (NMO), or Devic’s Syndrome, is an autoimmune central nervous system demyelinating disorder affecting
primarily the spinal cord and the optic nerves. It is characterized by the presence of NMO antibodies, besides clinical and radiological findings. NMO and NMO-spectrum disorders have been reported in autoimmune disorders, such as systemic lupus erythematosis and Sjogren's syndrome. Rarely, they have been described as a paraneoplastic syndrome with cancers of lung, breast, and carcinoid tumor of thyroid.

**Objective:** To report a case with longitudinally extensive demyelinating lesion of medulla and cervical spinal cord, associated with carcinoid tumor of the stomach, high serum gastrin level, and positive serum anti-aquaporin-4 antibody (NMO IgG).

**Case:** A 40-year-old Saudi lady, who presented with severe nausea, vomiting, blurring of vision, vertigo, nystagmus and ataxia, was found to have a longitudinally-extensive demyelinating lesion at the cervico-medullary junction and cervical spinal cord on MRI. Her gastric endoscopy revealed carcinoid tumor of the stomach, and classic paraneoplastic antibodies in the serum and CSF were negative. She had extremely high serum gastrin level and high titer of NMO IgG autoantibody.

**Conclusion:** NMO may present as a paraneoplastic neurological syndrome associated with carcinoid tumor of the stomach.

**Atypical neurological presentation of GSS: Case report**

O.H. Daoud, O. Hdiji, I. Bouchchina, E. Turki, A. Boukhris, M. Damak, M.J. Miladi, I. Feki, C. Mhiri. Habib Bourguiba Hospital, Sfax’s Medecine University, Sfax, Tunisia

**Introduction:** Gougerot-Sjogren Syndrome (GSS) is an auto-immune exocrinopathy characterized by xerophthalmia and xerostomia. Neurological complications occur between 8.5 and 70%. Data concerning central nervous system (CNS) symptoms have been rarely described. We analyze the clinical, radiological and therapeutic aspects of a patient with CNS signs revealing primitive GSS and we discuss some particularities.

**Case report:** A 52-year-old woman was hospitalized for recurrent clinical focal signs of CNS involvement. It consisted on sudden left hemiparesis on 2009 and two sudden regresssed episodes of aphasia on 2011 and 2013. Brain MRI revealed micro nodular lesions appearing as hyper-signal in T2 on periventricular white matter and frontotal cortex. Both lacrymal and salivary gland secretions were affected. A high level of antinuclear antibodies to SSA was associated with inflammatory lesions in minor salivary glands biopsy. The diagnosis of GSS was established. An oral corticosteroid therapy was prescribed during 6 weeks followed by progressive degeneration, with good outcome.

**Discussion:** CNS damages are less frequently associated with GSS’s systemic damages, and are often inaugural. The pathophysiology remains unknown. Some authors suggest the pathologic role of the anti-SSA based on their higher frequency in patients with CNS manifestation. Neurological focal manifestations are the most observed, but deficit signs are polymorphic. Aphasia is rarely described. The onset may be sudden as stroke. The MRI can reveal T2 hyperintensities on periventricular white matter or juxtacortical, more rarely on the cerebral cortex. Treatment of GSS’s neurological manifestations is usually based an oral corticosteroid with high dose.

**Onset of secondary progression and long-term prognosis in multiple sclerosis**

A. Scalfari, A. Neuhaus, M. Daumer, P. Muraro, G. Ebers. Centre of Neurosciences, Department of Medicine, Imperial College, London, UK; Sylvia Lawry Centre, Munich, Germany; Oxford University, Oxford, UK

**Background:** Prognosis in multiple sclerosis (MS) remains largely unpredictable.

**Objectives and methods:** Among 806 relapsing-remitting (RR) patients from the London Ontario database, we assessed:

1. the effect of baseline features on the risk of secondary progression (SP);
2. the risk of becoming disabled (DSS 6–8) according to latency to SP.

**Results:** Longer latency to SP predicted lower risk of reaching DSS 6 (OR = 0.76 for 5 years and OR = 0.44 for 15 years of latency); same results were observed in patients matched for early (year-1 + year-2) relapses number. However, RR phase duration did not influence SP evolution. The latency to SP conversely related to the number of total relapses (1–2 = 8.8 years; 3–4 = 11.3 years; ≥5 = 12.2 years). Predictors of the risk of SP were male sex (HR = 1.41), older age at onset (age > 30 years vs ≤20 years, 21–30 years HR = 0.52, 0.65, respectively) and high early relapse frequency (≥3 vs 1, 2 attacks HR = 0.63, 0.75, respectively). Disease duration affected the probability of becoming SP (OR = 1.07), increasing by 9% every 5 years. At baseline, OR for risk of SP yielded by 3 relapses were 3.6, 5.8, 9.5 in patients aged 20, 30 or 40 at onset respectively, and increased by 2-fold at 10 years (OR 7.5, 12.1, 19.8, respectively) and by 5-fold at 20 years (OR 15.6, 25.5, 41.4, respectively).

**Conclusions:** Prevention/delay of SP represents a potential therapeutic target. Early relapse number and age at onset can be used for selecting patients at higher risk of developing severe disability and requiring more aggressive treatments.

Functional and structural disruption of the precuneus contributes to cognitive impairment in pediatric multiple sclerosis
P. Preziosi, A. Ferioli, G. Trovato, M. Ambrosio, M. Maffi, V. Tusa, S. Bolognesi, S. Ferrero, F. Vaccher, A. Ghetti, L. Moioli, F. Fornesi, M. Comi, F. Filippi

Background: Cognitive impairment affects ≥40% of pediatric MS patients.

Objectives: To combine structural and functional MRI to define the mechanisms responsible for cognitive impairment in pediatric MS.

Methods: Brain dual-echo, 3D T1-weighted and resting state (RS) fMRI scans were acquired from 35 pediatric MS patients and 16 matched healthy controls. Patients with ≥2 abnormal neuropsychological tests were classified as cognitively impaired (CI). Regional distribution of lesions and gray matter and white matter (WM) atrophy were assessed using SPM8. Functional connectivity (FC) of the default mode network (DMN) was assessed using an independent component analysis.

Results: Forty-five percent of patients were CI. Compared to cognitively normal (CN), CI patients had a higher probability to harbor lesions in the right (R) thalamus, bilateral cingulum, R precuneus and bilateral parieto-occipital WM. Compared to CN, CI patients had atrophy of the R precuneus, left middle temporal gyrus, splenium of the corpus callosum (CC), posterior cingulum, WM close to precuneus, and R superior longitudinal fasciculus. CI patients showed a reduced DMN RS FC of the precuneus, whereas CP patients had an increased RS FC of the anterior cingulum. MRI findings correlated with the number of abnormal tests and performance at spatial, verbal memory and attention tests (r = 0.42–0.70, p < 0.001).

Conclusions: In pediatric MS patients, cognitive dysfunction is associated to structural and functional abnormalities of the DMN, mainly in posterior brain regions. Increased RS FC of regions of the frontal lobe might contribute to cognitive preservation. Partially supported by a grant from Italian Ministry of Health (GR-2009-1529671).

doi: 10.1016/j.jnss.2013.07.1402
Materials and methods: Formalin-fixed, paraffin-embedded autopsy brain tissue of 33 MS cases, including 7 acute MS cases, and 30 controls was studied. For detection of non-heme iron, the diaminobenzidine-enhanced Turnbull blue staining was applied. The iron storage protein ferritin, the ferrooxidases hephaestin and ceruloplasmin, and oxidized phospholipids as marker for oxidative stress (E06 epitope) were detected by immunohistochemistry.

Results: Compared to controls, MS brains showed a global reduction of iron in non-lesioned white matter oligodendrocytes and myelin. We observed a shift of iron storage and ferritin expression from oligodendrocytes to microglia/macrophages at active lesion edges. Upon iron accumulation, microglia became dystrophic and vanished towards inactive lesion cores, where iron was either completely removed or stored within astrocytes and axons. A minor proportion of active lesions harbored elevated amounts of iron in astrocytes and axons. Rarely, a direct colocalization of iron and oxidized phospholipids could be detected.

Conclusion: MS leads to a global iron loss in the brain white matter. Demyelination in MS leads to waves of iron liberation from intracellular stores, which may promote oxidative damage.

Intrinsic damage to the cerebellar peduncles is associated to multiple sclerosis clinical disability

P. Preziosa, M.A. Roccab, S. Mesaros, E. Pagani, T. Stosic-Opcinca, M. Filippia, *Neuroimaging Research Unit, Institute of Experimental Neurology, Vita-Salute San Raffaele University, Milan, Italy; †Department of Neurology, San Raffaele Scientific Institute, Vita-Salute San Raffaele University, Milan, Italy; ‡Clinic of Neurology, Faculty of Medicine, University of Belgrade, Belgrade, Serbia; §Clinic of Radiology, Faculty of Medicine, University of Belgrade, Belgrade, Serbia

Background: The cerebellum is a region frequently affected by multiple sclerosis (MS).

Objectives: To apply a voxel-wise analysis to metrics from diffusion tensor (DT) MRI tractography and T2 lesions of the middle (M) and superior (S) cerebellar peduncles (CP) to quantify their structural damage in MS, and to assess the relationship between CP damage vs global clinical disability, impairment of cerebellar (C) and brainstem (B) functional systems (FS).

Methods: Brain dual-echo and DT MRI sequences were collected from 172 MS patients and 46 healthy controls (HC). The EDSS score and degree of impairment of different EDSS FS were rated. Patients were dichotomized using CFS and BFS (impaired: FS ≥ 1, unimpaired: FS = 0) and EDSS (ambulatory impaired: EDSS ≥ 4.0, fully ambulatory: EDSS < 4.0). Using DT MRI tractography, probability maps of the SCP and MCP were produced. Voxel-wise analysis was used to assess the topographical distribution of damage along these tracts.

Results: Compared to HC, MS patients showed increased mean (MD), axial (AD), radial (RD) diffusivity and decreased fractional anisotropy (FA) of both tracts. Diffusivity abnormalities were more pronounced in impaired patients. Patients with EDSS ≥ 4.0 had a higher probability of having T2 lesions in the MCP bilaterally, while patients with BFS ≥ 1 had a higher probability of having T2 lesions in one small cluster in the left SCP.

Conclusions: In MS, the assessment of MCP and SCP damage, in terms of T2 focal lesions and diffuse white matter tract injury (probably due to Wallerian degeneration), contributes to explain global clinical impairment and impairment at single FS.

Spinal cord expression of stathmin-1, SCLIP and SCG10 in experimental autoimmune encephalomyelitis (EAE)
O. Touloumi1, T. Irinopoulou2, R. Lagoudaki1, P. Theotokis1, A. Lourbopoulos3, C. Cifuentes-Diaz1, E. Nousiopoulou3, E. Kofidou1, D. Karacostas1, N. Grigoriadis1, 1AHEPA University Hospital, Aristotle University of Thessaloniki, Thessaloniki, Greece; 2INSERM, Institut du Fer à Moulin, Paris, France

Background: The role of stathmins is the regulation of microtubule equilibrium and cytoskeleton reorganization. They alternate between assembly and disassembly of the cell with the purpose of correct formation of mitotic spindle.

Objective: We studied the stathmin expression in the spinal cord in EAE.

Material and methods: EAE mice were examined at three time-points (D10, acute, chronic) and compared with controls (D0). Stathmin1, SCG10 and SCLIP mRNA and protein expression was studied using Real Time-PCR and optical and confocal microscopy.

Results: There was reduced mRNA expression in acute phase of stathmin1 (p < 0.05); SCLIP was reduced both in acute and chronic phase of EAE (p < 0.01). An overall decrease of spinal cord stathmin1 and SCG10 protein expression was noticed in acute phase (p < 0.001, p < 0.05). However, our sub-analysis in the inflamed white matter showed increased expression of all stathmins (p < 0.05, p < 0.001, p < 0.01). Moreover, stathmin1 was predominantly expressed in NG2+ (p < 0.001) and O4+ (p < 0.05) cells whereas in lower levels in CNPase+ (p < 0.05) cells during the acute phase. SCG10 and SCLIP were expressed in axons already during the acute phase and throughout the entire EAE course though not in controls. In addition, inside the inflammatory lesions SCG10 was co-expressed with APP (p < 0.05), a marker of axonal regeneration.

Conclusions: The stathmin protein family kinetic in inflammatory demyelinating areas indicates their potential involvement in the underlying pathology and reorganization of the degenerative spinal cord during EAE.

Predictive factors of physical component of quality of life in multiple sclerosis patients
S. Sabanagic-Hajric, N. Subasic, A. Alajbegovic, Department of Neurology, Clinical Center University of Sarajevo, Sarajevo, Bosnia and Herzegovina

Background: Multiple sclerosis is a chronic progressive disease with multiple neurological and psychological impairments that can affect all aspects of quality of life.

Objective: The objective of this study was to investigate the predictive factors of physical component of quality of life in MS patients.

Patients and methods: 100 MS patients treated at the Neurology Clinic in Sarajevo were involved. Each patient underwent a complete clinical assessment, including disability status (EDSS), cognitive function (MMSE) and measurement of quality of life (MSQOL-54). Linear regression analyses were performed to identify significant predictors from sociodemographic and clinical characteristics in predicting MSQOL-54 physical and mental composite scores.

Results: The mean age of 100 patients (69% female and 31% male) was 39.88 ± 10.03. The mean EDSS score was 3.57 ± 1.73 and 72% were of the relapsing–remitting clinical subtype. Linear multivariate regression analyses revealed that presence of pain (eta square = 0.29), EDSS (eta square = 0.27), sphincter disorders (eta square = 0.19), employment status (eta squared = 0.15), type of disease (eta squared = 0.10) and age (eta square = 0.06) proved to be main predictors of MSQOL-54 physical composite scores (r² = 0.83). Among the patients with relapsing-remitting type of disease number of relapses (eta squared = 0.260), EDSS score (eta squared = 0.24), sphincter disorders (eta squared = 0.17), presence of pain (eta squared = 0.16), employment status (eta squared = 0.15) and age (eta squared = 0.08) proved to be main predictors of MSQOL-54 physical composite scores (r² = 0.87).

Conclusion: Assessment of quality of life in MS patients provides additional information on the patient status. Management of pain on patterns of spatiotemporally consistent neural activity while the brain is at “rest”. With regard to this, Fair et al. (2007) suggested a method how existing datasets could be re-analyzed via extracting specific volumes of conventional (c) block design fMRI data to emulate (e) RS-fMRI.

Objective: We here aimed to investigate the similarity or diversity of results obtained with this approach (eRS) compared to cRS regarding connectivity network identification in a clinical cohort.

Patients and methods: 12 Multiple Sclerosis patients (MS, age: x = 30.82 ± 10.8) and 18 healthy controls (HC, age: x = 32.28 ± 6.8) underwent conventional task-related fMRI and cRS in the same imaging session. In the first step, the total cognitive paradigm has been treated as a RS-dataset, and both datasets were analyzed in total length. Then, the cognitive paradigm was truncated according to the criteria by Fair to emulate RS. The cRS dataset was truncated equally.

Results: Whereas visual inspection of seed based analyses of functional connectivity from the anterior cingulate cortex suggested almost identical patterns in MS patients and HC, higher-level within and between group analyses of eRS vs. cRS revealed distinct differences in connectivity networks.

Conclusion: Generally, using the eRS approach allows the identification of connectivity networks (similar to those obtained using cRS-data) also in diseased brains. However, results of higher-level contrasts yielded different results and thus have to be interpreted with caution.

Reduced intrathecal IgG synthesis in the cerebrospinal fluid from natalizumab-treated patients with active multiple sclerosis
A. Harrer†, G. Pilz‡, P. Wipfler‡, K. Oppermann‡, B. Höll§, W. Hitzl∥, S. Afazel‖, E. Haschke-Becher‖, E. Trinka‖, J. Kraus‚, Department of Neurology, Paracelsus Medical University, Christian-Doppler-Klinik, Salzburg, Austria; Research Office, Biostatistics, Paracelsus Medical University, Salzburg, Austria; Central Laboratory, Paracelsus Medical University, Christian-Doppler-Klinik, Salzburg, Austria

Oligoclonal bands (OCB) have been reported to disappear from the cerebrospinal fluid (CSF) in natalizumab (NZB)-treated patients with multiple sclerosis (MS) although OCB are considered to persist in MS. Detection of OCB is qualitative evidence of intrathecally produced IgG. We investigated if this NZB-effect on intrathecal IgG synthesis can be quantitatively assessed by analyzing the fraction of intrathecally produced IgG (IgGIF). We included 31 MS patients, 17 were untreated (first diagnosis) and from 14 patients CSF was collected to rule out progressive multifocal leukoencephalopathy (PML) during NZB treatment. From 6 of the 14 NZB-treated patients CSF data from the first diagnosis were also available. IgG and albumin concentrations of CSF and serum samples were measured by immunonephelometry and used to calculate the CSF/serum quotients and IgGIF (in %) according to Reiber (1998). Quantification of intrathecal IgG synthesis showed a reduced IgGIF in NZB-treated patients compared to untreated MS patients (p = 0.0026). Intraindividual comparisons of baseline and follow-up data in the NZB-treated group of 6 showed disappearance of intrathecal IgG production in 2 and an overall reduction of the IgGIF (p = 0.018). Quantifying intrathecal IgG synthesis revealed a pronouncedly reduced IgGIF in NZB-treated MS patients. This corroborates previous reports about disappearing OCB and suggests effectiveness of NZB therapy on intrathecal IgG production. Since lumbar punctures were performed to rule out PML this observation is limited to NZB-treated patients with active disease. Clarification of the underlying mechanisms will provide important knowledge about the clinical relevance of this finding and the pathogenesis of NZB-associated PML.

Incidence of multiple sclerosis in the region of Sarajevo before and after the war events
J. Djeljilovic-Vranic, A. Alajbegovic, M. Tiric-Campara, S. Salcic, E. Djovic, E. Eljubovic. Neurology Clinic, Clinical Center of Sarajevo University, Sarajevo, Bosnia and Herzegovina

Introduction: Multiple sclerosis is an autoimmune demyelinating disease and degeneration of axons, in the appearance of which stress has an important role. The goal is to determine the incidence of multiple sclerosis in the region of Sarajevo in the period before and after the war (1986–2012).

Material and methods: We analyzed all new cases of multiple sclerosis in the region of Sarajevo in the period January 1986–December 2012. Diagnostic criteria included anamnesis, clinical presentation, MRI findings and evaluation of the spine, evoked potentials-visual and cerebrospinal fluid examination.

Results: During the period 1986–1990, there were 45 new cases of MS, in the period 1991–1995, there were 27 new MS cases, from 1996 to 2000 107 new cases were registered of MS, and from 2001–2005 there were 150 new cases of MS. In the period 2006–2010, there were 174 new cases of MS. In 2011 there were 34 new cases of MS and during the 2012, 41 new cases. Stress as provoking factor was present in the first five-year period at 11.1% in the second at 18.5%, in the third with 19.6%, in the fourth five-year period at 36.5% of cases and in the final at 43.8% of cases.

Conclusions: In the period after the war, the MS in the region of Sarajevo has increased in incidence. Multiple sclerosis in the region of Sarajevo is more frequent in women than in men, most frequently in the age 20–40 years. But it also tends to occur in a relatively advanced age, after 50 years.

Multiple sclerosis prevalence study: The comparison of two coastal cities, located in the Black Sea and the Mediterranean Sea in Turkey
Ü. Türk Börü, A. Duman, AŞ. Kululp, N. Güler, M. Taşdemir. Neurology, Dr. Lütfü Kurtar Kartal Training and Research Hospital, Istanbul, Turkey; Neurology, Arvinit State Hospital, Marmara University, Istanbul, Turkey; Public Health, Marmara University, Istanbul, Turkey

Background: The studies about Multiple Sclerosis (MS) epidemiology have increased in the last years. The studies, we conducted in Turkey, which have been compared with new studies were made in Turkey. These studies show that there are also distinct variations between the same geographical areas.

Objective: We carried out this study in order to determine the prevalence and to compare the difference between Mediterranean and Black Sea regions.

Patients and methods: This descriptive, cross-sectional, door-to-door survey was carried out in the Mediterranean coastal city Gazipaşa and the Black Sea coastal city Artvin in 2012. All people, who live in the city, were visited and interviewed in their houses. The center town of Artvin and Gazipaşa had been screened by door to door. A population of 16.116 people was screened in Artvin and 13.451 of the people were screened in Gazipaşa. Poser criteria were used as diagnostic criteria in the study.

Results: Seven patients were diagnosed as clinically definitive MS with the definitive anamnesis and MR investigation. Female to male ratio was 1.33. The prevalence of MS was found to be 52.0/100.000 in Gazipaşa. Three female patients were diagnosed as clinically definitive MS. The prevalence of MS was found to be 18.6/100.000 in Artvin.

Conclusion: According to the results, the countries in the Mediterranean area is also now in the high MS prevalence zone. More than 2 times of the difference was found between prevalences of Artvin and Gazipaşa. Our recent studies, conducted in Turkey, provide evidence that the latitude gradient in the distribution of MS is disappearing.

Validation of a screening to detect cognitive and psychoaffective deficits in children and juveniles with multiple sclerosis: The MUSICADO study

P. Calabrese, K. Storm van's Gravesande, E. Kalbe, U. Fulda, V. Mall, University of Basle, Basel, Switzerland; Neurupediatries, Gottfried von Preyersches Kinderspital, Vienna, Austria; Gerontologie, Universität Vechta, Vechta, Germany; Merck Serono S.A., Darmstadt, Germany; Sozialpädiatrie/Kinderzentrum, Technische Universität München, München, Germany

Background: Neurocognitive deficits may already appear in children affected by multiple sclerosis (MS). The most vulnerable areas include attention, visual–perceptual abilities, executive functions, and language. However, these deficits are mostly underrecognized since there is a lack of specific screening tools which might be used during regular clinical visits for children and adolescents.

Objective: The aim of the MUSICADO-study is to validate a modified screening tool (MUSICADO) adapted for ADOScients. Additional clinimetric methods are used to validate this measure together with a questionnaire for depression and fatigue.

Patients and methods: A number of 100 healthy controls and 100 patients, aged between 12 and 18 years will be included with and without treatment. The adopted psychometric tool MUSIC and additional methods to assess IQ, attention, visual–perceptual abilities, executive functions, verbal skills, quality of life, depression, and fatigue are performed at one visit by a psychologist. The duration of the tests is about 2 to 2.5 hours. Currently, 2 study sites in Austria and 22 study sites in Germany are registered. The study has started in May 2012 and will end in December 2013 until the planned amount of patients has been included.

Results and conclusion: We aim to establish a screening tool to detect cognitive deficits and related comorbidities at an early stage of the disease. Such a tool may help to apply interventions timely. A detailed study-protocol and data about the already included patient cohort are presented in this contribution.

Extensive semi-automated gait analysis by Zebris FDM during treatment of multiple sclerosis associated gait disturbances with PR-fampridine

B. Holl, G. Wewerka, H. Bartsch, M. Malisa, C. Illhardt, G. Wewerka, G. Pilz, P. Wipfler, E. Trinka, B. Iglseder, J. Kraus, Paracelsus Medical University, Christian-Doppler-Klinik, Department of Neurology, Salzburg, Austria; Paracelsus Medizinische Privatuniversität, Christian-Doppler-Klinik, Universitätssklinik für Geriatrie, Salzburg, Austria

The prolonged-release PR-formulation of fampridine (PR-fampridine; syn. modified or sustained-release fampridine, dalfampridine extended release) has been approved for the treatment of walking impairment in multiple sclerosis (MS) patients with walking disability. Pivotal trials showed a significant effect of PR-fampridine on the Timed 25 Foot Walk (T25FW). However, the relevance of this primary outcome measure and its correlation with gait improvement needs further evaluation.

To investigate the effect of PR-fampridine treatment on gait disturbance parameters obtained by an extensive semi-automated gait analysis was the purpose of this study.

Zebris FDM is a semi-automated gait analysis system which uses a 300 × 60 cm mat containing more than 22,500 pressure sensors. This analysis system has been evaluated broadly and is commonly applied by physiotherapists in rehabilitation centres. We included 20 patients with MS-associated walking disability (EDSS 4.0 to 7.0) and performed a gait analysis to determine gait velocity and variability of gait velocity before and during PR-fampridine treatment.

Treatment with PR-fampridine led to a sustained improvement of gait velocity and variability of gait velocity in 10 out of 20 patients for at least 6 months. Two patients had to discontinue treatment due to side effects (nausea, headaches) despite improvement. Seven patients showed no improvement after initiation of fampridine-SR. One patient had to stop treatment due to vertigo before assessment of gait. Both gait parameters obtained by semi-automated gait analysis correlated tightly with the T25FW test.

We observed a measurable positive effect of PR-fampridine on MS-associated gait disturbances which is relevant in daily life in patients with gait disturbances.

The relationship between the internal capsule DTI parameters and cognition in relapsing remitting multiple sclerosis (RR MS) patients

Neurology, Haseki Training and Research Hospital, Istanbul, Turkey; Radiology, Haseki Training and Research Hospital, Istanbul, Turkey
Objective: To assess the relationship between cognition and internal capsule lesion distribution and frequency in patients with relapsing-remitting multiple sclerosis (RR MS).

Methods: We analyzed 37 patients with definitive diagnosis of RR MS and 37 gender-matched with the same age range control subjects. Conventional MRI and DTI were used to assess the relevance of brain lesion location for cognitive impairment all of the study subjects. The Rao Brief Repeatable Battery was administered to determine the cognitively impaired. Statistical comparison was conducted using repeated measures ANOVA type analysis to detect the relationships between the DTI and Brief Repeatable Battery test.

Results: We observed strong positive correlation between cognition and FA and ADC values which is in agreement with the observation of a statistically significant reduction in FA values for RR MS patients compared to the control group (p < .0001). Moreover, there exists a significant inverse relationship between the age FA values (p = .0027). On the other hand, we observed that ADC values are significantly higher for RR MS patients compared to the control group (p < .0001). Low scores of the Symbol Digit Modalities Test correlated with FA and ADC values in these regions.

Conclusions: This supports the notion of a functional (multiple) disconnection among gray matter structures, secondary to damage located in WM areas, as one of the most important mechanisms leading to cognitive impairment in MS.

Balo’s concentric sclerosis: Report of four cases and literature review

M. Zouari, A. Bouhouri, E. Farhat, S. Ben Sassi, F. Hentati. Neurology, National Institute Mongi Ben Hamida of Neurology of Tunis, Tunis, Tunisia

Background: Balo’s concentric sclerosis (BCS) is a rare variant of multiple sclerosis (MS), differing from typical MS in terms of initial presentation, symptom severity and radiological features.

Objective: We report four patients with BCS. The diagnostic process and the follow-up are described, with a brief literature review.

Material and methods: We studied four patients (three women and a man) affected by BCS. All patients underwent a brain and spine MRI, visual evoked potentials (VEP) and cerebrospinal fluid (CSF) study.

Results: The age of onset varied from 17 to 47 years. The symptoms at onset were: acute left-sided weakness and numbness in one patient, diplopia and progressive visual field restriction in two patients, and seizure and dysarthria in the last patient. Three patients had a history of relapsing-remitting symptoms, while one patient had a monophasic course. Expanded disability status scale (EDSS) scores were between zero and one. Brain MRI revealed in all patients, periventricular lesions with onion-like structure in T2 and FLAIR sequences with a diameter exceeding 2 cm. Spine MRI, revealed lesions in only two patients. VEP showed optic neuritis in one patient. The CSF study revealed the presence of IgG oligoclonal bands in one case. The patients improved after intravenous steroids and were diagnosed with MS according to MS criteria 2010.

Conclusion: BCS is classically considered as a severe variant of MS with a rapid and malignant course leading to severe irreversible disability or death. However, our patients had a mild to moderate disease course at follow-up. Few studies reported similar findings.

doi:10.1016/j.jns.2013.07.1417
**Results:** Out of 82 patients, 19 (21.95%) were diagnosed with AT. Mean EDSS value is 1.5 in patients with normal thyroid function and 2.0 in AT patients.

**Conclusions:** AT is much more frequent in MS patients than in general population and in Italian MS patients compared to other European series. Although the sample is not sufficiently numerous to identify a clear correlation between high values of EDSS and thyroid dysfunction, our data show a trend in that direction. So, management of MS people should include an endocrinological screening to verify thyroid function.

**Asymptomatic electrophysiologic carpal tunnel syndrome in diabetes: Ultrasonographic study**

J.H. Park, D.H. Jang, Catholic University of Korea, Catholic Medical Center, Seoul, Republic of Korea

**Background:** Carpal tunnel syndrome (CTS) is considered more common in diabetes mellitus (DM) patients. Asymptomatic electrophysiologic CTS is frequently found on screening nerve conduction study (NCS) for DM neuropathy, but the pathophysiology has been little known. We investigated the symptoms, electrophysiologic findings and median nerve ultrasonography (US) findings of DM patients, and compared those between no CTS, asymptomatic CTS and symptomatic CTS group.

**Method:** Thirty four hands with DM were prospectively assessed by three clinical scales, one electrophysiological scale and median nerve cross section area (CSA) through ultrasonography. The clinical scales adopted were the Boston carpal tunnel syndrome questionnaire (BTQ), quantitative clinical scale by Simovic (Simovic clinical scale) and Historical-Objective (Hi-Ob) scale. The scale for electrophysiological assessment is the American Association of Neuromuscular & Electrodagnostic Medicine (AANEM) classification. US was performed in all participants, and CSA of the median nerve at carpal tunnel inlet site was evaluated.

**Results:** There is no valid difference of median nerve bland scales between asymptomatic (2.36) and symptomatic (2.73) electrophysiologic CTS group. The median nerve CSA in non electrophysiologic CTS (0.086 cm², ±0.012) was smaller than others (p < 0.05), and there is no valid difference of median nerve CSA between asymptomatic (0.117 cm², ±0.023) and symptomatic electrophysiologic CTS group (0.123 cm², ±0.031).

**Conclusion:** These findings suggest that asymptomatic electrophysiologic CTS in DM could be a prodromal phase of symptomatic CTS, because they may have the same pathophysiology. Therefore clinicians have to carefully monitor the DM patients with asymptomatic electrophysiologic CTS.

**Does OCT predict conversion to MS?**

3Neurology, University Hospital San Carlos, Spain; 4Ophthalmology, University Hospital La Paz, Spain; 5Radiology, University Hospital La Paz, Spain; 4Hospital Ruber Internacional, Madrid, Spain

**Background:** Optical coherence tomography (OCT) is a simple high resolution noninvasive technique to quantify the thickness of retinal nerve fiber layer (RNFL) and an indirect measurement of axonal damage in multiple sclerosis (MS).

**Objectives:** To determine whether RNFL thickness predicts conversion to clinically definite multiple sclerosis (CDMS) in patients with clinically isolated syndromes (CIS) over the subsequent three years.

**Methods:** Patients with CIS (McDonald criteria 2005) were recruited in two months after the event and underwent a complete neurological examination. High field brain MRI and cervical MRI were performed within two months of the first attack and after three years. An ophthalmological evaluation including visual acuity and optical coherence tomography (Stratus) was done within the first week after diagnosis and after three years. The sensitivity and specificity of OCT to predict conversion to CDMS were analyzed.

**Results:** 23 patients with CIS with a mean EDSS of 1.72 were recruited and followed during three years. Eight patients did not have demyelinating lesions on baseline cranial MRI. 54.2% of all patients showed the presence of at least one quadrant of an optic nerve with a decreased RNFL thickness.

The presence of at least one quadrant of an optic nerve with a RNFL thickness at a P < 5% cut-off value had a sensitivity of 69% and a specificity of 60% for predicting conversion to CDMS in a period of three years.

**Conclusion:** Axonal damage in very early stages of the disease may be useful for predicting conversion in multiple sclerosis and useful for follow-up.

**Disease-specific mechanisms in cortical multiple sclerosis lesions**

1Department of Neuroimmunology, Center for Brain Research, Medical University of Vienna, Vienna, Austria; 2Institute of Neurology, Medical University of Vienna, Vienna, Austria; 3Institute for Ageing and Health, Mitochondrial Research Group, Newcastle University, Newcastle Upon Tyne, UK; 4Department of Laboratory Medicine, Medical University of Vienna and Center for Molecular Medicine (CeMM) of the Austrian Academy of Sciences, Vienna, Austria; 5Institute of Clinical Neuroimmunology, Ludwig Maximilian University of Munich, Munich, Germany

Multiple sclerosis (MS) is an immune-mediated demyelinating disorder of the central nervous system. Traditionally, research focused on white matter lesions but within the last years, cortical lesions gained importance. Although inflammation appears to play a fundamental role in the formation of cortical MS lesions, disease-specific mechanisms leading to plaque-like primary demyelination and neurodegeneration are poorly understood.

We aim at identifying MS-specific mechanisms by combining neuropathological analysis of inflammatory and neurodegenerative diseases with gene expression studies. For immunohistochemistry, archival formalin-fixed and paraffin-embedded autopsy tissue was used. Apart from cortical MS tissue, we also included cortical tissue from other inflammatory (tuberculous meningitis, Rasmussen’s encephalitis, B-cell lymphoma, and meningitis) and neurodegenerative (Alzheimer’s disease) diseases. Whole-genome microarrays were performed using microdissected cortical material from MS, tuberculous meningitis, and Alzheimer’s disease patients and control cases.

Immunohistochemistry showed that despite complex and fulminant immune responses in many investigated diseases, primary demyelination was only present in MS. Using microarrays, we identified 301 genes being

---
differentially expressed in cortical MS lesions. Of these, 80% were assigned to inflammation, oxidative stress, tissue injury, DNA damage/repair and regenerative processes. Immunohistochemically, we confirmed that significantly more oxidatively damaged neurons were present in cortical MS lesions than in other examined diseases. Additionally, neurons and oligodendrocytes stained positive for DNA strand breaks. Interestingly, oxidative stress-mediated tissue damage seemed to be driven by NADPH oxidases rather than by nitric oxide synthases. We show that MS-specific primary demyelination is driven by mechanisms of tissue injury that differ from any other investigated inflammatory and neurodegenerative disease.

Psychosocial complications of multiple sclerosis
A. Fine, Clinical Social Work/Psychology, Allison Fine, MSW, LICSW — Counseling for Inner Balance, Seattle, WA, USA

Background: Multiple sclerosis affects individuals diagnosed on both a physical and cognitive level, as well as an emotional one. Depression, anxiety, grief, other mental health concerns, and environmental factors all affect a patient’s life with MS. Understanding this psychosocial impact is necessary to provide the best possible care for the MS patient.

Objectives: Recognizing the emotional flux of an MS patient is essential to learn how to both treat and prevent these challenges from impacting the patient physically. Psychotherapy provides insight into an MS patient’s life. This work demonstrates the psychosocial challenges many patients face and analyzes how mental health and environmental problems can both be a precursor to and aggravated further by MS.

Patients and methods: Three case study examples of MS patients will be used to demonstrate psychosocial impact. All patients engaged in psychotherapy for at least one year to examine concerns related to their illness.

Results: The psychosocial impact on those living with MS is clear but inconsistent. These individuals along with many others will continue to need emotional support throughout their illness.

Conclusions: Examining the psychosocial component of patients living with MS allows medical professionals to take a more comprehensive look at treating the illness. While there is always no causation between emotional and physical health, the two often correlate. Research examining what happens physically to the patient when emotional health is exacerbated will go a long way in helping medical professionals understand the full impact of emotions on MS.

Epidemiological analysis of multiple sclerosis in Goiás and in Brazil from 2008 to 2011
J.A.D. Oliveira Júnior, C.D. Rocha, M.O.F. Iwamoto, K.O.F. Iwamoto, F.O. Gomes, D.S. Dini — Faculdade de Medicina, Universidade Federal de Goiás, Goiânia, Brazil; Hospital das Clínicas, Universidade Federal de Goiás, Goiânia, Brazil

Background: Multiple sclerosis (MS) is a chronic inflammatory demyelinating disease, autoimmune, confined to central nervous system. It affects about two times more women than men and causes great socioeconomic impact by having higher incidence among young adults, which may lead them to early failure.

Objectives: To describe and compare profile of patients hospitalized due to MS in Goiás and Brazil, according to sex and age, from 2008 to 2011, noting correlation with the literature.

Material and methods: An observational, descriptive, retrospective epidemiological approach with qualitative and quantitative data from hospital admissions in Brazil and Goiás, from 2008 to 2011, registered by Brazilian Health System based on database (DATASUS).

Results: Of the total hospitalizations due to MS in Brazil (6838), 2087 (30.5%) were in males and 4751 (69.5%) in females. Of this total, 4733 (69.2%) occurred between 20 and 49 years. Goiás had 219 hospitalizations, 58 (26.5%) in males and 161 (73.5%) in females. In terms of age, 164 (74.9%) were between 20 and 49 years.

Conclusion: The state of Goiás was responsible for 3.2% of admissions for MS in Brazil. In both scenarios MS predominates among women. In Brazil, there were 2.3 women for every man hospitalized by MS, while in Goiás, that relation was 2.8, which is equivalent to the literature. Age group was also in accord to the literature, varying from 20 to 49 years. The highest number of admissions occurred between 30 and 39 years, the age group with the largest percentage of economically active population in Brazil, justifying the impact of MS.

Demyelinating peripheral neuropathy without conduction block in two patients with tumor necrosis factor α antagonist therapy
F. Konoeda1, S. Suzuki2, T. Shimizu3, N. Suzuki4. 1Department of Neurology, Saiseikai Central Hospital, Koto University School of Medicine, Tokyo, Japan; 2Department of Neurology, Keio University School of Medicine, Tokyo, Japan

Background: Tumor necrosis factor α (TNF-α) antagonist has been successfully used in patients with various autoimmune diseases. Demyelination of the nervous system had been reported as a side effect occurring with these agents. However, polyneuropathy associated with TNF-α antagonist has been rarely described.

Objective: To report our two patients with demyelinating polyneuropathy receiving TNF-α antagonist therapy.

Patient and methods: Two patients (two women, patient 1 was 26 years old, patient 2 was 57 years old) who developed a demyelinating peripheral polyneuropathy during TNF-α antagonist therapy. Their clinical findings and electrophysiological results were retrospectively reviewed.

Results: Patient 1 was a 26-year-old-woman. She has polyarthritisis for 4 years and received etanercept for 7 months. Weakness and numbness occurred on her distal and proximal extremities progressively. Dysphagia, dysarthria and diplopia were presented in parallel. She underwent intravenous immunoglobulin (IVIG) therapy (0.4 g/kg/day, 5 days) and improved completely in a month. Patient 2 was a 57-year-old-woman with a 6-year history of rheumatoid arthritis and started on infliximab therapy. Two months after initiating infliximab, she developed numbness in both hands and weakness in both lower limbs. She was treated with IVIG (0.4 g/kg/day, 5 days) and almost improved with remaining mild gait and sensory disturbance. The electrodiagnostic studies revealed demyelinating sensory and motor peripheral polyneuropathy without conduction block. Anti ganglioside antibody was absent in both patients.

Conclusion: Although previous cases after treatment of TNF-α antagonist revealed demyelinating peripheral polyneuropathy with conduction block, we hereby report novel findings in electrodiagnostic studies in two patients.

Increased frequency of multiple sclerosis, the influence of environmental and immunological factors
JC Duran. Fisiologia, Universidad Mayor de San Andres, La Paz, Bolivia

Background: For decades, consistent geographical pattern of MS, with prevalence and increased risk in countries farther from Ecuador in both directions has been recognized. Bolivia is situated in the central part of South America, between the meridians 57° 26′ and 69° 38′ longitude west of Greenwich and the parallels 9° 38′ and 22° 53′ south latitude. Traditionally the frequency of multiple sclerosis in this area has been described as low; we have observed an increase in frequency in recent years.

Objective: To analyze the increase in the frequency of multiple sclerosis in a clinic for neurological diagnosis in recent years.

Material and methods: 16,779 medical records were reviewed in a clinic for neurological diagnosis from January 1992 to December 2012. Patients who met the clinical criteria and who had brain MRI compatible with multiple sclerosis were included.

Results: We identified 26 patients with multiple sclerosis. 19 female and 7 male, median age at diagnosis 31.6 years for women and 32 years for males. 1 (3.8%) case from 1992 to1996, 3 (11.5%) cases from 1997 to 2001, 8 (30.7%) cases from 2002 to 2006 and 14 (53%) cases from 2007 to 2012.

Conclusion: Changes in environmental or immunological profiles which have been developed in our country may have contributed to the increased frequency of multiple sclerosis in the last 5 years.

Cerebrospinal fluid oligoclonal IgG bands in Japanese patients with clinically isolated syndrome
M. Daiti1, K. Tanaka2, M. Tanaka3. 1Multiple Sclerosis Center, Utano National Hospital, Kyoto, Japan; 2Neurology, Kanazawa Medical University, Uchinada, Japan

Background: Oligoclonal IgG bands (OCBs) in the cerebrospinal fluid (CSF) in clinically isolated syndrome (CIS) predict multiple sclerosis (MS) development in European patients.

Objective: Evaluating the potential of OCBs in predicting MS development in Japanese patients.
Patients and methods: Thirty-four Japanese patients with CIS were consecutively enrolled in this prospective study conducted from Feb 2006 to July 2012 with a mean follow up period of 38 months. Anti-aquaporin (AQP) 4 antibodies were examined using a cell-based assay.

Results: Five patients developed MS (14.7%); of these, 2 revealed relapses of the different lesions and 3 revealed other lesions on brain MRI. Moreover 21 were classified as still having CIS (61.8%). The remaining 8 patients had a neuromyelitis optica-related disorder (NMOrd); 3 patients demonstrated anti-AQP4 antibodies, and 5 revealed a centrally located long spinal cord lesion on MRI (1 patient demonstrated both lesions). OCBs were observed in CSF at the first visit in 2 of 5 (40%), 3 of 21 (14.3%), and 3 of 8 (37.5%) patients who revealed conversion to MS, non-conversion, and NMOrd, respectively.

Conclusion: Two of 5 patients with CIS and OCBs developed MS for only for 38 months; moreover, NMOrd was observed in 8 of 34 with CIS (23.5%). This study suggests that CSF-OCBs could be helpful in predicting MS development in Japanese patients with a low incidence of OCB (47.6% of different our series) and that Japanese patients with CIS have a low risk of MS development.

Impact of HLA DRB1*1501 gene and oligoclonal bands in multiple sclerosis. Clinical radiological/imunogenetic correlations
S. Daoudi, M. Lounsi, M. Ait-Kaci-Ahmed. Department of Neurology, Nédir Mohamed Hospital, Tizi-Ouzou, Algeria; Department of Neurology, Ait Idir Hospital, Algiers, Algeria

Introduction: The aim of this study was to determine the value of immunogenetic risk factors and estimate their relationship with clinical and radiological characteristics and disability status of patients with multiple sclerosis in a population in northern Algeria.

Material and methods: This is a prospective study concerning 60 patients with MS. We noted the age, sex, and clinical manifestations since the beginning of the disease. Paraclinical analyzes systematically included in our patients, immunology of CSF, brain and spine MRI. We evaluated the frequency of HLA DRB1*1501.

Results: The mean age was 34.4 years with a sex ratio F/M = 2. The HLA DRB1*1501 was positive in 30% of cases, with an odds ratio of 2.3. In the HLA DRB1*1501 positive group, 38.8% were male and 26.2% were female. We observed the presence of oligoclonal bands in 85% of patients, 25% of the HLA DRB1*1501 positive group. No significant association between clinical and genetics has been found. The brain stem lesion on MRI was associated with the presence of HLA DRB1*1501 (P < 0.01). The relapsing multiple sclerosis represented 83.3% of the HLA DRB1*1501 positive group. The mean EDSS score was 1.2 in the HLA DRB1*1501 positive group and 0.91 in the negative group (P = 0.41).

Conclusion: The presence of oligoclonal bands in the CSF was associated with many exacerbations of the disease. The brain stem-lesion on MRI was significantly associated with the presence of HLA DRB1*1501.

Cerebrospinal fluid transferrin levels are reduced in patients with early multiple sclerosis
M. Khalil, B. Riedlbaumer, C. Langkammer, C. Enzinger, S. Ropele, T. Stojakovic, H. Scharnagl, V. Culea, A. Perzold, J.J. Archelos, S. Fuchs, F. Fazekas. Medical University of Graz, Graz, Austria; Free University Medical Center, Amsterdam, The Netherlands

Background: Abnormally high cerebral iron deposition has been described in multiple sclerosis (MS), which is mainly evidenced by applying advanced MRI techniques. Up to now it is not completely clear whether alterations of iron metabolism markers in body fluids are present in MS and if these markers are related to clinical and imaging parameters.

Objective: We aimed to investigate if iron metabolism markers in cerebrospinal fluid (CSF) and serum of patients with clinically isolated syndromes (CIS) and MS differ from those of control patients with other neurologic diseases of non-inflammatory aetiology (NC).

Methods: We included non-anaemic patients with CIS/MS (n = 77, CIS 62; MS 15) and 69 NC. None of the patients received any immunomodulatory treatment at time of lumbar puncture. We nephelometrically assessed serum levels of ferritin, transferrin and soluble transferrin receptor and CSF levels of ferritin and transferrin. The serum transferrin saturation was calculated from serum ferritin and transferrin levels.

Results: CSF transferrin levels were significantly reduced in CIS/MS compared to NC (p = 0.001). Higher CSF transferrin levels correlated with lower physical disability (r = -0.3, p < 0.01). There were no significant differences comparing CIS/MS and NC regarding CSF ferritin and serum ferritin, transferrin, soluble transferrin receptor and the transferrin saturation.

Conclusion: Our results indicate that CSF transferrin levels are altered in early phases of MS with some relation to physical disability. Further longitudinal studies are currently undertaken to investigate if CSF...
transferrin levels are predictive of developing abnormally high cerebral iron deposition as measured by MRI.

The benefits of visual evoked potential examination in the diagnosis and prognosis of multiple sclerosis
M.K. Onar1, M. Terzi1, S. Sen3, S. Cambaz1, 2Neurology, Samsun, Turkey; 2Ondokuz Mayis University, Samsun, Turkey

Background: Visual evoked potentials (VEPs) have been used in the diagnosis of multiple sclerosis (MS). But, in the revised form of McDonald criteria it was not included.

Objective: We wanted to investigate the relation between the VEPs and the clinical types and the prognosis of MS.

Patients and methods: In 354 MS patients VEPs were evaluated. The relation between VEP results and neurologic findings at onset of the disease, IgG index, oligoclonal band positivity, EDSS scores at onset, 1st year, 5th year, 10th year and transition from clinical isolated syndrome to MS was determined. The patients were grouped according to their initial neurological findings such as optic neuritis, supratentorial involvement, brain-stem–cerebellar involvement and spinal involvement. The VEP findings were classified as monococular, bilateral pathology and no pathology.

Results: VEP abnormalities were more frequent in patients in optic neuritis group as expected. VEP abnormalities were less in the spinal group. In patients with bilateral VEP abnormality EDSS scores at onset, 1st, 5th and 10th years were higher than the patients with monococular abnormality and no abnormality. No relation was found between the VEP abnormalities and the clinical types of the disease and transition from clinical isolated syndrome to MS.

Conclusions: We suggest that VEP examination can predict the evolution of disability in MS patients.

Characteristics of headaches in cases diagnosed with neuro-behçet’s disease
D. Selcuki1, A. Kisabay1, T. Pruldar2, 3Neurology, Manisa, Turkey; 2Celal Bayar University, Manisa, Turkey

Introduction and aims: Behçet’s disease (BD) is a chronic disease which progresses with the involvement of many organs and systems. It is a vascular-inflammatory disease with an obscure pathogenesis. Characteristics of headaches in patients diagnosed with Behçet’s disease, their differences from other types of headaches, methods of imaging and treatment were planned to be assessed in accordance with literature.

Method: In this study, patients applying to the outpatient Behçet clinic between 2000 and 2013 were examined retrospectively. The types of headaches of the patients diagnosed with Behçet’s disease were made in compliance with the 2011 diagnosis criteria of the International Headache Society. Localization of headaches, the existence of aura, frequency, severity, duration of attacks, neurological examinations, accompanying diseases, clinic, methods of imaging, treatment, and treatments for prophylaxis in the acute and chronic period of the patients who applied to the clinic were reviewed.

Discussion: Headaches are the most common neurological complaint of cases diagnosed with neuro-behçet. Cases were given appropriate treatment for their clinical findings and symptoms and nearly all of them showed full or partial remission.

The clinical, electrophysiological and morphological peculiarities of sensory CIDP
E. Gavriliuc1, J.-M. Léger2, V. Lisnic3, V. Nemtan3, L. Munteanu2
1State Medical and Pharmaceutical University ‘Nicolae Testemiţanu’, Chisinau, Moldova; 2Reference Center for Neuromuscular Diseases, Hôpital Pitié-Salpêtrière, Paris, France

Background: Chronic inflammatory demyelinating polyneuropathy (CIDP) is an acquired disorder of peripheral sensory and motor nerves. In 5–6% of patients with CIDP only sensory symptoms are present.

Conclusion: Different from Behçet’s syndrome, in the 50% of the cases it was found in compliance with intracranial increase in pressure. Lumbar function opening pressures changed between 250 and 350 mm of water. In the imaging examinations (cranial MRG, MRA) the existence of venous thrombosis (43%), and the ratio of parenchymal involvement (50%) were rather high. Corticosteroid infusion is given to neuro-behçet patients during attacks and immunosuppressant treatment added following this. Nearly 90% of the cases benefited from the treatment given.

Discussion: Headaches are the most common neurological complaint of cases diagnosed with neuro-behçet. Cases were given appropriate treatment for their clinical findings and symptoms and nearly all of them showed full or partial remission.

Objectives: Determination of the most sensitive tests to be performed in sensory CIDP and the most frequent clinical findings.

Patients and methods: We examined medical records of 16 patients with sensory CIDP according to the EFNS/PNS guideline (revised 2010). In all patients were performed: clinical evaluation, electrophysiological investigations and cerebro-spinal fluid (CSF) macroscopic/microscopic examination. A full routine blood biochemistry was done. Biopsy specimens of the sural nerve were prepared for light and electron microscopic examination.

Results: Sex ratio: 12 male and 4 female patients (55–79 years). Duration of progression from onset to maximal disability ranged from 4 months–8 years. CSF protein was elevated in 10 patients, ranging from 0.5–1.9 g/l and normal in 6 cases. Motor and sensory nerve conduction abnormalities were present in 7 cases. Somatosensory evoked potential (SSEP) tests showed involvement of proximal segments or roots of sensory nerves in all patients. Sural nerve biopsy was performed in 5 cases. A definite decrease in the population of myelinated fibres was in all cases.

Conclusion:
1. Nerve conduction study is not a sensitive test to diagnose sensory CIDP, in 56% cases results were normal.
2. SSEP is a highly sensitive test to be used for identifying a possible CIDP.
3. Nerve biopsy is used mainly when electrophysiological studies fail to establish the diagnosis of CIDP.

Estimation of the gene polymorphisms role in the progression of multiple sclerosis using MSSS method
K. Baćić Baronica, K. Milinac, A. Vladić, R. Baraba, I. Zuntar, S. Kalanj-Bognar, aUniversity Department of Neurology, University Hospital Sveti Duh, Croatia; bCroatian Institute for Brain Research, School of Medicine, University of Zagreb, Croatia; cFaculty of Pharmacy and Biochemistry, University of Zagreb, Zagreb, Croatia

Background: The estimation of the MS progression is important for therapeutic and rehabilitation approach. Commonly used scale for disability evaluation EDSS is not reliable for assessment of progression so MSSS method was developed.

Objective: To explore the association of polymorphisms in arylsulfatase A (ASA) and glutathione S-transferase P1 (GSTP1) gene with disability and progression of MS.

Subjects and methods: The frequency of N350S and 1524 + 95 A-G polymorphisms associated with ASA-pseudodeficiency (ASA-PD), and of A313G and C341T polymorphisms in GSTP1 gene, was determined in 56 and 58 MS patients, respectively, using PCR-RFLP method. EDSS was used to estimate disability level and MSSS to estimate disease progression. Correlation between genotypes and progression was analyzed by Kruskal–Wallis test.

Results: Presence of one or both ASA-PD polymorphisms was determined in 13 patients, from which 9 had mild, 1 moderate and 3 severe disability. No correlation was found between ASA-PD genotypes and MSSS (p > 0.05). However, 10 polymorphism carriers had MSSS > 5 which indicates faster disease progression. 32 and 12 patients were found to be carriers of A313 and C341 GSTP1 polymorphism respectively. No correlation was found between investigated GSTP1 genotypes and disability (p > 0.05), however patients-homozygous carriers of mutated A313G genotype had significantly higher mean MSSS than patients with normal or heterozygous genotype (p < 0.05).

Conclusion: These results suggest that investigated polymorphisms may be associated with MS disability and progression. MSSS method was proved to be useful for estimation of MS progression as well as for identifying factors affecting disease progression such as gene polymorphisms.

Neurologic manifestations in inflammatory bowel diseases
M. Ben Djebara, A. Nasri, Y. Sidhom, Y. Hizem, I. Kacem, A. Gargouri-Berrechid, R. Gouider, Department of Neurology/Research Unit 03/UR/08-09, Research Unit 12S2P21, Razi Hospital, Tunis, Tunisia

Introduction: Crohn’s disease (CD) and ulcerative colitis (UC) are known as inflammatory bowel diseases (IBD). The association of IBD with neurologic involvement is rare (3%) and controversial.

Objective: To report neurologic manifestations in patients with IBD in order to address its clinical characteristics.

Patients and methods: We conducted a retrospective study over an 11-year period including all patients diagnosed with IBD and neurologic manifestations. Demographic data, neurologic examination, studies and imaging, and treatment were analyzed.

Results: We identified thirteen patients diagnosed with IBD and CNS symptoms: eight with CD and five with UC. Mean age was 51.1 years, mean age of onset of IBD was 38.1 and of neurologic symptoms was 43.3. Sex ratio was 2.5. Most of the patients developed neurologic manifestations after digestive symptoms appeared (11). Cognitive deficits were the most frequent manifestation observed (8 patients), followed by headache (4), epilepsy (3), cerebro-vascular disorders (2), movement disorders (2) and primary progressive MS (1). Two patients had peripheral neuropathy. CNS imaging showed cortical atrophy, white matter abnormalities or vascular lesions. Half of the patients have undergone surgery for their IBD.

Conclusion: The high frequency of cognitive deficits in our series constitutes a peculiar feature, in opposition to higher prevalence peripheral neuropathies, cerebro-vascular disorders (0.12–4%) and CNS white matter diseases in other series. The pathogenesis of neurologic manifestations of IBD is probably related to a common dysimmune basis. Neuropsychological assessment and CNS imaging are needed in patients with IBD for a better understanding of CNS involvement in those diseases.

A new model of focal inflammatory demyelination in the neocortex of the rat
S. Hochmeister, T. Birngruber, M. Zeitzelhofer-Adzemovic, M. Haindl, T.R. Pieber, F. Sinner, Department of Neurology, Medical University Graz, Austria; Biomedical Technology and Monitoring, Joanneum Research, Graz, Austria; Department of Clinical Neuroscience, Center of Molecular Medicine, Karolinska Institute, Stockholm, Sweden; Department of Endocrinology, Medical University Graz, Austria; Joanneum Research, Biomedical Technology and Monitoring, Graz, Austria

Experimental Autoimmune Encephalomyelitis (EAE) is a widely used model which mimics many histopathological features of multiple sclerosis. However, there are some important disadvantages; firstly, the lesions commonly affect predominantly the spinal cords. Secondly the
lesion's exact localization is not predictable. We present a new technique of creating a focal lesion in the neocortex of the rat by cerebral open flow microperfusion (cOFM). cOFM is a minimal invasive sampling technique involving implantation of a probe into the neocortex without causing a glial scar encapsulation and enables direct access to the brain tissue. After a healing phase liquids can be introduced continuously into the brain tissue via the cOFM probe and sampling of interstitial fluid with cOFM allows monitoring of biomarkers and metabolites. Two weeks after probe implantation, the animals are subcutaneously injected with 100 μg MOG in incomplete Freund's adjuvant to induce a stable IgG antibody titer against MOG. Then 250 ng recombinant TNF-alpha and 150 U IFN-g in phosphate buffered saline are injected via the cOFM probe. This results in a selective disturbance of the blood brain barrier and an influx of the MOG antibodies. An inflammatory demyelinating lesion forms in direct vicinity of the probe.

Conclusion: Our new method enables us to predictably produce an EAE lesion in the neocortex of the rat. The cOFM probe allows monitoring of all stages of lesion formation.

Pseudotumoral presentation of multiple sclerosis: Report of seven cases

Background: Multiple sclerosis (MS) with focal demyelinating lesions of the cerebrum mimicking a tumor of the central nervous system is a rare phenomenon.

Objective: To assess the clinical and radiological characteristics of pseudotumoral forms of MS.

Methods: Among the patients seen at the neurological department between 2000 and 2012, we identified all patients fulfilling McDonald Criteria and whose initial MRI (brain or spinal) presented a large tumefactive lesions. Only patients who have had onset since at least 5 years were included.

Results: Seven young women with tumor-like lesion on initial MRI (brain and/or spinal) are described. The average age of onset was 29 years. The beginning of neurological signs was progressive in four cases and acute in three cases. The main presentations included motor deficits in three cases, headache in two cases and a partial seizure in two cases.

MRI showed a single large lesion in three cases and multifocal tumefactive lesions in four cases. The average duration of follow-up was seven years. In our study no biopsy and no surgery were undertaken. The favorable response to steroid therapy (4 cases), the spontaneous remission of symptoms (3 cases), the MRI control findings and the prolonged survival of patients supported the diagnosis of pseudotumoral MS.

Conclusion: This study illustrates the wide variety of MS presentation and underlines the importance of considering MS in the differential diagnosis of a brain mass.

Comparison of McDonald 2005, McDonald 2010 and Swanton criteria for prediction of conversion from clinically isolated syndrome to multiple sclerosis
B. Piricinar, S. Ozakbas. Dokuz Eylul University School of Medicine, Izmir, Turkey

Background: In 2006, Swanton and colleagues modified the MRI criteria to simplify and speed the diagnosis. Recently the Panel has proposed new MRI criteria for the diagnosis of MS in patients with CIS.

Purpose: To compare the ability of the McDonald 2005, McDonald 2010 and Swanton's modified criteria to predict conversion CIS to clinically definite multiple sclerosis (CDMS) from baseline MRI findings. We also aimed to evaluate the accuracy of these new criteria for lesions dissemination in space (DIS) and time (DIT).

Patients and methods: 44 patients presenting with CIS included in the study, and followed up for at least 2 years. The sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV) and accuracy of MRI dissemination-in-space criteria were calculated.

Results: Overall conversion rate was 86.4%. Out of 44 patients, 38 converted to CDMS a mean of 10.1 months after onset of first clinical event. Swanton's modified criteria showed a sensitivity of 84%, a specificity of 23%, PPV is 88%, NPV is 25%, with an accuracy of 77%. Barkoff–Tintore criteria showed a sensitivity of 81%, a specificity of 50%, PPV is 91%, NPV is 30% with an accuracy of 77%. The McDonald 2010 modified criteria a sensitivity of 47.3%, a specificity of 83.3%, PPV is 94.7%, and NPV is 20%, an accuracy of 52.2%.

Conclusion: In conclusion, McDonald 2010 criteria seem to be simpler and more specific than previous criteria. Besides, lesions in corpus callosum and Gd-enhanced lesions have critical value to make an early diagnosis in CIS.

Neuromyelitis optica in Brazilian woman with myasthenia gravis

Background: Despite the rarity of myasthenia gravis (MG) and neuromyelitis optica (NMO), several cases or small series of patients with both disorders have been reported over the years. Here we describe one Brazilian patient with MG and NMO. To our knowledge, less than 50 cases have been reported in the medical literature.

Patient and methods: A Brazilian woman was diagnosed with generalized MG at age 16 years and underwent thymectomy one year after diagnosis. Ten years later she presented with leg weakness, sensory loss below T3 level and urinary retention. At age 27 years, she developed bilateral acute visual loss. Visual evoked response was absent on the left and of delayed latency on the right. At age 37 and 48 years, she had relapses of optic neuritis in the right eye.

Results: During the relapses, a cervical-dorsal lesion was detected on spinal cord magnetic resonance imaging (MRI), brain MRI showed non-specific white matter lesions and aquaporin-4 antibody was positive (titer of 1:640). The diagnosis of NMO was made according to the 2006 revised diagnostic criteria.

Conclusion: The exact contribution of thymectomy to the development of NMO is not clear. Future research is required to establish whether there is indeed a small long-term excess risk of developing autoimmune disease in individuals with MG who undergo thymectomy.

Pattern of cognitive impairment and related factors in clinically isolated syndrome
S. Ozakbas, B. Piri Cinar, A. Gurkan, O. Ozturk, E. Idiman. Dokuz Eylul University School of Medicine, Izmir, Turkey

Background: The presence of cognitive dysfunction in a sizeable proportion of patients with clinically isolated syndrome (CIS) has been reported. The prevalence of the cognitive deficits usually encountered could vary with the clinical course of the disease.

Objective: The aim of the present study was to investigate the prevalence and pattern of cognitive impairment in CIS patients.

Patients and methods: 25 patients with CIS (mean age 36.3) included in the study. Age and sex matched 22 healthy control subjects (mean age 36.0) were also included. Cognitive performance was assessed by using a battery of tests consisting of Paced Auditory Serial Addition Test (PASAT), Stroop, Controlled Oral Word Association (COWAT), Rey Auditory Verbal Learning (RAVLT), Benton’s Judgment of Line Orientation (BJLO), Trail making test (TMT), and digit span test (DST), Beck depression scale, Fatigue impact scale (FLS), and Multiple Sclerosis International Quality of Life (MUSIQoL) were administered.

Results: Globally, 21% of patients were found to be cognitively impaired at least two tests. When compared healthy controls, 44% of patients failed in Stroop test. Impairment in COVAT was 56%. Impairment in RAVLT, BJLO, TMT and DST was relatively rare (10%, 9%, 5% and 12%, respectively). Impairment in PASAT was 12%. CIS patients were found more depressed (p = 0.045) and more fatigued (p = 0.011).

Conclusion: Our results supported the early onset cognitive impairment in demyelinating diseases. The most prominent impairment was found to be in verbal fluency (COVAT), attention and executive functions (Stroop). Fatigue (especially cognitive sub-group) found to be related with cognitive impairment in CIS.

Interferon’s flu-like syndrome and mental state: Possible interactions
D. Kasatkin. Neurology, Yaroslavl State Medical Academy, Yaroslavl, Russia

Background and objectives: Interferons-beta are currently the most used drugs for disease modifying of multiple sclerosis. One of the most common side effects of the therapy is a flu-like syndrome (FLS). FLS means a combination of at least 2 and the following adverse events: fever, chills, myalgia, arthralgia and sweating. The basis of the syndrome is probably on the change in the level of cytokines. But there are other factors that determine the severity and duration of the existence of this syndrome, in particular, the state of psychoemotional sphere.

Materials and methods: 90 patients (28 men and 62 women), RRMS, remission, age – 39.1–43.4 (95% CI) years, with disease duration of 117–156 (95% CI) months; interferon beta (i.m. and s.c.) use for 33.2–44.4 (95% CI) months; EDSS, Original adverse event questionnaire, Zung Depression and Anxiety Scale, Boyko’s Euphoria Scale, Modified Fatigue Impact Scale. Statistical analysis — nonparametric statistic: R Spearman, U Mann–Whitney, φ Fischer.

Results and conclusion: FLS presents in 57 cases (63%) and is more common in women — 69% than in men — 50% (φ = 1.75, p < 0.05). Anxiety is significantly higher in group with FLS (U = 569, p = 0.002) and increases with the severity of FLS (R = 0.35, p = 0.0005). Depression (R = 0.23, p = 0.034) and asthenia (R = 0.24, p = 0.025) increase with the severity of FLS. Euphoria does not affect the severity of FLS (R = – 0.01, p = 0.92).

Thus, the patient’s mental state has a significant impact on the occurrence and severity of FLS, which may be important to determine the risk of the syndrome and improve patient compliance.

Tumefactive MS lesions under fingolimod: A case report and literature review

G. Pilz, A. Harrer, P. Wipfler, K. Oppermann, J. Sellner, F. Fazekas, J. Kraus, E. Trinka. 1Department of Neurology, Christian-Doppler-Klinik, Paracelsus Medical University, Salzburg, Austria; 2Department of Neurology, Medical University of Graz, Graz, Austria

Objective: The formation of atypical lesions in patients with multiple sclerosis (MS) on novel disease modifying treatments for MS like fingolimod is diagnostically challenging and pathophysiologically unclear. We report a patient who developed a tumefactive demyelinating lesion (TDL) 8 months after a switch from natalizumab to fingolimod and a second extensive lesion after another 6 months on continued fingolimod therapy.

Methods: We performed serial clinical and radiological assessments, and immunophenotyping of blood and CSF immune cells. Accessorily we present a literature review about recent similar cases.

Results: Clinical course and radiological findings were consistent with diagnosis of tumefactive demyelinating lesions. Immune cell phenotyping showed pronounced shifts in the immune cell composition related to fingolimod treatment. In addition, we observed a subset of highly differentiated effector cells (CD45R0negCCR7neg) within the CD8+ T cell population which was about 2-fold enriched in the CSF compared to the peripheral blood.

Conclusion: Our observation adds further evidence for the development of atypical demyelinating lesions in some patients under fingolimod treatment. This notion may be due to a treatment-associated shift in the immune pathology of individuals with specific susceptibility.

Epidemiology and mortality of MS: A nationwide population study in Taiwan

I.-J. Chou, C.-F. Kuo, L.-C. See, K.-H. Yu, H.-S. Wang, K.-L. Lin, J.-J. Lin, W.P. Whitehouse, C.S. Constantinescu, Academic Division of Clinical Neurology, University of Nottingham, Nottingham, UK; Academic Division of Child Health, University of Nottingham, Nottingham, UK; Division of Paediatric Neurology, Chang Gung Memorial Hospital, Taoyuan, Taiwan, ROC; Division of Academic Rheumatology, University of Nottingham, Nottingham, UK; Division of Rheumatology, Allergy, and Immunology, Chang Gung Memorial Hospital, Taiwan, ROC; Department of Public Health, Chang Gung University, Taoyuan, Taiwan, ROC

Background: There are few nationwide population-based studies of multiple sclerosis (MS).

Objective: To describe the epidemiologic features and mortality of MS in Taiwan.

Material and methods: The catastrophic illness registry of the Taiwan National Health Insurance Research Dataset and the National Death Registry of Taiwan were used to estimate the incidence and mortality of MS during 2003 to 2007.

Results: A total of 832 incident MS patients (180 males, 652 females) were identified during 2003 to 2007. The mean age at diagnosis was 39.4 ± 13.9 (range 5–83) years. The incidence of MS in Taiwan was 6.79 cases (males, 2.86; females, 10.92) per million person-years. The incidence in individuals aged <20, 20–39, 40–59 and ≥60 years was 2.21, 8.83, 10.65 and 3.16 per million person-years. Period prevalence of MS during 2003 to 2007 was 28.1 per million people. There were 64 deaths (males, 16; females, 48) during the study period; 1-, 2-, and 5-year survival rates were 98.4%, 95.8%, and 90.6%, respectively. Crude mortality rate was 24.5 deaths per 1000 patient-years, without sex difference (log-rank test, p = 0.480). MS patients had a standardized mortality ratio (SMR) of 4.00 (95% confidence interval [CI], 3.11–5.08) for all-cause mortality, as compared with the national population in 2003. SMRs (95% CI) for male and female MS patients were 3.20 (1.89–5.09) and 4.36 (3.25–5.74), respectively.

Conclusion: MS is rare in Taiwan but entails 4-fold risk of all-cause mortality in comparison with the general population.

Interferon-beta up-regulates suppressor of cytokine signaling 1 in T cells of multiple sclerosis patients

R. Schneider, D. Beauséjour, P. Duquette, A. Prat, H.M. Johnson, N. Arbour, Neurology, University of Toronto, Toronto, ON, Canada; Université de Montréal, Montreal, QC, Canada; University of Florida, Gainesville, FL, USA

Background: Although interferon-beta (IFN-β) is commonly prescribed for the treatment of MS, its mode of action is not fully understood. Previous work suggests a beneficial role of suppressors of cytokine signaling 1 (SOCS-1) in experimental autoimmune encephalomyelitis (EAE), a widely used animal model of MS. We postulate that IFN-β attenuates immune responses in MS via induction of SOCS-1 in CD4 and CD8 T cells.

Objectives: To assess SOCS-1 expression in T cells of MS patients and to evaluate anti-inflammatory functions of SOCS-1 in human CD4 and CD8 T cells.

Methods: We quantified SOCS-1 mRNA in CD4 and CD8 T cells from untreated or IFN-β-treated MS patients. We tested the impact of a SOCS-1 mimic, tyrosine kinase inhibitory peptide (Tkip) on CD4 and CD8 T cell responses to cytokines with pro-inflammatory properties using flow cytometry-based assays.

Results: We found that SOCS-1 is significantly more expressed by both CD4 and CD8 T cells from IFN-β-treated MS patients compared to untreated patients. Mimicking the effect of SOCS-1 in vitro significantly reduced cell proliferation, and production of IFN-γ (IFN-γ) and granzyme B by human CD4 and CD8 T cells.

Conclusions: Our results indicate that IFN-β increases SOCS-1 expression in CD4 and CD8 T cells. Our in-vitro assays show that SOCS-1 interferes with cytotoxic T cell functions and the production of the Th1 signature cytokine IFN-γ. Hence, IFN-β may indeed mediate anti-inflammatory effects via an upregulation of SOCS-1 in CD4 and CD8 T cells.

Results of idiopathic TN group: HIT-6 mean score was 61.1, HADS-anxiety 10, HADS-depression 6.7, SF-36/physical terms 56.1 and SF-36/emotional terms 55.6.

**Conclusion:** Unexpectedly, both groups showed very similar SF-36 scores and HADS scores were higher in idiopathic TN. Median time between MS diagnosis and eligibility was 6.3 years, and median follow-up was 6.5 years. Baseline EDSS was ≤ 2.5 in 70%. Thirty-three eligible patients (60%) started DMT after a median delay of 2.1 years. Nineteen (57%) commenced on β-interferon, and 9 (27%) on glatiramer acetate. Eighteen pwRRMS converted to SPMS; 14 started using a walking aid. Kaplan–Meier analysis did not reveal significant difference between treated and untreated patients with respect to sustained use of a cane, and conversion to SPMS.

**Conclusions:** The London MS Database is a new dataset recording disease relevant details in an ethnically heterogenic population. The characterization of the included pwMS and the outcome of DMT in this population is ongoing. Our preliminary analysis failed to detect an effect of DMT on two robust outcomes. Further data collection is underway to clarify whether this result is due to the limited sample size.

**Objectives:**
1. To present first assessments based on ‘The London MS Database’.
2. To review eligibility for Disease Modifying Therapy (DMT) in a geographically defined cohort of people with relapsing-remitting multiple sclerosis (pwRRMS).
3. To evaluate the effect of DMT on disease progression.

**Patients and methods:** Medical records of 94 pwMS living in the London Borough of Tower Hamlets were reviewed for DMT eligibility according to the Association of British Neurologists’ 2001 criteria. Outcomes were (i) sustained use of a walking aid (cane) and (ii) onset of secondary progressive (SP) MS; assessed using Kaplan–Meier analysis.

**Results:** Fifty-five pwRRMS were eligible for 1st line DMT, 17 were not eligible, and 21 were excluded for incomplete information. Median time between MS diagnosis and eligibility was 6.3 years, and median follow-up was 6.5 years. Baseline EDSS was ≤ 2.5 in 70%. Thirty-three eligible patients (60%) started DMT after a median delay of 2.1 years. Nineteen (57%) commenced on β-interferon, and 9 (27%) on glatiramer acetate. Eighteen pwRRMS converted to SPMS; 14 started using a walking aid. Kaplan–Meier analysis did not reveal significant difference between treated and untreated patients with respect to sustained use of a cane, and conversion to SPMS.

**Conclusions:** The London MS Database is a new dataset recording disease relevant details in an ethnically heterogenic population. The characterization of the included pwMS is ongoing. Treatment of IVIG was generally well-tolerated by all patients without any serious adverse effects.

**Discussion and conclusion:** Our study suggests possible effect of early IVIG therapy in anti-aquaporin 4 antibody seropositive ON who fail to respond to IVMP. A large controlled trial is indicated to confirm these results.

**Spectrum of idiopathic inflammatory demyelinating diseases of the CNS in a tertiary care hospital in India**

G. Butchi Raju, S. Deshmukh, S. Gopi, T. Sateesh Kumar. *Neurology, Andhra Medical College, King George Hospital, Visakhapatnam India*

**Background:** Idiopathic inflammatory demyelinating diseases (IIDD’s) of the CNS include broad spectrum of CNS disorders. There are very few studies of its kind in India.

**Objectives:** To study the clinical, radiological and laboratory profile of IIDD’s of the CNS prospectively.

**Material and methods:** Patients fulfilling the criteria for IIDD’s in our hospital between October, 2010 and January, 2013 were included. Clinical, radiological & laboratory features were evaluated.

**Results:** 56 patients fulfilling the criteria for IIDD’s were included and analyzed. The mean age was 24.97 years and was lowest in acute disseminated encephalomyelitis (ADEM). The female to male ratio was 1.55:1. Females predominated in all subtypes except in ADEM & ATM. Clinical spectrum was highest with clinically isolated syndrome (CIS) (n = 16) followed by neuromyelitis optica (NMO) spectrum (n = 12), acute transverse myelitis (ATM) (n = 11), ADEM (n = 9) and multiple sclerosis (MS) (n = 8). In MS, motor weakness, subcortical white matter lesions, and VEP abnormalities were the common findings. Two rare variants of MS were diagnosed. In NMO spectrum, NMO is the most common subtype (n = 6). Cervico-dorsal involvement, and VEP abnormalities were the common findings. NMO IgG was positive in two cases. In ADEM, altered sensorium (n = 6), and supratentorial lesions (n = 9) were the common findings. In ATM, dorsal cord was involved in 8 cases with significant motor & sensory involvement. In CIS, isolated Optic Neuritis (n = 13) was the most common presentation.

**Conclusions:** IIDD’s of CNS had a wide spectrum of disorders. The frequencies of these disorders seen are quite different from those seen in the West.

**Efficacy of fingolimod treatment in relapsing multiple sclerosis patients in clinical practice: A multicenter experience**

R. Alroughani1,2, J. Al Hashelc,d, R. Behbahani2,e, S. Ahmedc,f.  
1Amiri Hospital, Kuwait City, Kuwait; 2Dasman Diabetes Institute, Kuwait City, Kuwait; 3Ibn Sina Hospital, Kuwait City, Kuwait; 4Kuwait University, Kuwait City, Kuwait; 5Al Bahar Eye Center, Kuwait City, Kuwait; 6Al-Mina University, Minia, Egypt

**Background:** Fingolimod is the first oral disease modifying therapy (DMT) approved for the treatment of Multiple Sclerosis (MS). Post-marketing studies are important to confirm what were established in clinical trials.

**Objective:** To evaluate efficacy of fingolimod in a cohort of relapsing MS patients treated with fingolimod in a real clinical practice setting.

**Methods:** We identified patients who had been prescribed fingolimod using the MS registry in 3 MS clinics in Kuwait. Patients with EDSS ≤ 6 and at least 6 months of follow-up were included. Patients with progressive MS were excluded. Primary endpoint was the proportion of relapse free patients at 6 months. Secondary endpoints included mean change in EDSS and proportion of MRI activity (new T2 or Gadolininium-enhancing lesions).

**Results:** Out of 101 eligible patients, 61 were women and 40 men. Mean age and mean disease duration were 33.97 ± 9.70 years and 7.32 ± 3.03 years respectively. 78.2% patients received prior DMTs. Mean duration of fingolimod exposure was 16.04 ± 5.36 months. Proportion of relapse-free patients increased significantly (10.5% versus 78.2%; p < 0.0001) at 6 months. Mean EDSS score at baseline was 2.97 ± 1.51; which decreased significantly to 2.08 ± 1.25. At 6 months, 19.8% of patients were free from MRI activity compared to 86.1% at baseline (p < 0.0001). No serious adverse events were reported.

**Conclusion:** In clinical practice, fingolimod is effective in reducing disease activity and progression of disability over the observational period. The extent of efficacy was more pronounced than what was reported in the pivotal trials.

Multiple sclerosis (MS) developing in a patient first diagnosed with chronic inflammatory demyelinating polyneuropathy (CIDP) — A case report

D. Sisak, Z. Pál, A. Illicsov, D. Bereczki, M. Simó. Semmelweis University Faculty of Medicine, Budapest, Hungary

Background: It has been previously reported that demyelinating inflammatory diseases of the central (CNS) and peripheral nervous system (PNS) have common aethiopathogenesis, probably due to an autoimmune response against a common myelin antigen. However, to date, only a few case reports document the coexistence of CIDP and MS.

Objective: We describe a 34 year old woman with CIDP whose disease went into remission, and who developed MS years after the diagnosis of the polyneuropathy.

Patients and methods: Case report with a 15-year-long follow-up.

Results: The patient's first symptoms occurred at the age of 20 with paraesthesia of the limbs, and progressive weakness of the feet. Neurological examination, nerve conduction studies, as well as cerebrospinal fluid examination supported the diagnosis of CIDP. She received steroid treatment and plasmapheresis several times. The disease went into complete remission. Two years after the diagnosis of the polyneuropathy, the patient developed brainstem symptoms, and brain MRI showed multiple demyelinating lesions. Three years later spastic paraparesis, urinary retention, and double vision developed. MRI disclosed lesion characteristic for MS, and cerebrospinal fluid examination proved OGP. Immunomodulatory treatment was introduced. In the last four years, the patient had residual signs of MS only.

Conclusion: Here we demonstrate a rare case of sequentially occurring CIDP and MS. While most previously published similar reports demonstrated a demyelinating disease affecting the CNS prior to the occurrence of peripheral demyelination, we describe a case where the PNS was affected before the symptoms of MS appeared, furthermore, CIDP became inactive.

Immunosuppressive treatment in relation to different phenotypes of clinical presentation of chronic inflammatory demyelinating polyneuropathy (CIDP)

C. Marcoci, V. Lisnic, V. Nemtanu. Neurology, State University of Medicine and Pharmacy 'Nicolae Testemitanu', Moldova; Institute of Neurology and Neurosurgery, Chisinau, Moldova

Chronic inflammatory demyelinating polyneuropathy (CIDP) is uncommon, but an important disease. Learning about diseases of the peripheral nervous system in general, the diagnostic strategies required to sort them out. The only population-based studies suggest a prevalence of one or two per 100,000, but these are probably underestimated because of lack of referral or recognition of cases. In our population-based study of 52 patients with CIDP in the Republic of Moldova, for the confirmation of the diagnosis we used the criteria of the American Academy of Neurology, later revised by EFNS and PNS criteria, MRC score, neuropathy score, and electrophysiological examination. In some cases nerve biopsy was performed. The objective of the study was the determination of the phenotypes of clinical presentation of CIDP and the efficiency of various methods of immunosuppressive treatment: corticosteroids, corticosteroids in association with azathioprine, corticosteroids in association with plasmapheresis and intravenous immunoglobulins, in relation to different phenotypes. Three phenotypes of clinical presentation of CIDP were distinguished: motor-sensory, motor and sensory. The motor-sensitive phenotype develops as a distal symmetric neuropathy with or without signs of central nervous system impairment and multifocal motor-sensitive neuropathy. Administration of corticosteroids is efficient in the short-term management of CIDP. Corticosteroids are not efficient in the treatment of motor phenotype of CIDP. Intravenous immunoglobulins significantly ameliorate the evolution of all the phenotypes of CIDP. The treatment of corticosteroids in association with azathioprine is cost-efficient in the treatment of symmetric motor-sensory and sensory neuropathies.

Multiple sclerosis in men: A Tunisian hospital cohort

Background: Symptom prevalence as well as characteristics differs between the sexes in Multiple Sclerosis (MS).

Objective: We describe on clinical course in a cohort of a Tunisian men affected by MS.

Patients and methods: We selected men affected by MS followed in the service of Neurology of Charles Nicolle Hospital (2000–2012). Patients had a neurological examination, a cerebral and medullar magnetic resonance imaging (MRI), an analysis of cerebrospinal fluid and visual evoked potentials (VEP). All the results were analysed.

Results: From 160 patients MS followed, 41 (25 %) were males. Median age of the disease onset was 25 years. Clinical onset was monosymptomatic in 50% of cases (pyramidal sign in 50%). Of 78% of patients who are initially diagnosed with relapsing remitting MS, 32% had transitioned to secondary progressive phase. 22% had a primary progressive form. The median time to convert from EDSS 1 to EDSS 3 was 3 years and from EDSS 6 was 5 years. The lesions on MRI were supratentorial in all cases, subventricular in 22% and cervical in 33%. VEP were altered in 64% of cases and oligoclonal bands were found in 36% of patients. The EDSS was improved or stabilised after immunomodulator treatment in 2/3 of cases. The median time of follow-up was 7 years.

Conclusion: Gender appears to affect MS prevalence, clinical course, pathology and response to immunotherapy. The effects of gender need to be taken into consideration when designing and interpreting research relating to MS, particularly in the development of new therapeutic agents.

Complement regulator factor H as a serum biomarker of multiple sclerosis: Correlation with disease state and MRI

L. Elabili. Neurology, Ain Shams Faculty of Medicine, Cairo, Egypt

Background: Multiple sclerosis (MS) has a variable phenotypic presentation and subsequent disease course that, although unpredictable at disease onset, is of crucial importance in guiding interventions. Effective
and accessible biomarkers are required in order to stratify patients and inform treatment.

**Aim of the work:** To determine the predictive value of serum complement factor H in MS patients and if they correlate with magnetic resonance imaging (MRI).

**Subjects and methods:** We prospectively studied sixty patients with MS. They were subjected to full clinical and neurological assessment, laboratory tests, and MRI study. Thirty healthy subjects matched patient group with age and sex were selected as a control group.

**Results:** Serum complement factor H levels were highly significantly elevated in all MS patients compared to controls (p value = 0.000), with sensitivity and specificity 98.3% and 93.3%, respectively, with positive predictive value 98.33%. Within the RRMS group, serum complement FH levels in remission patients were higher than in control (P = 0.000) and lower than in relapping group (p = 0.000). Moreover, serum complement FH concentration had a highly significant value as a surrogate marker for the prediction of relapse in MS patients with sensitivity and specificity of 79% and 90%, respectively (test cut-off value of relapse ≥6.25 ng/ml). Serum complement factor H level was not related to the localization of lesion in MS patients with acute relapse.

**Conclusion:** Serum complement factor H may be an effective indicator of progression, an accessible biomarker and stratifying tool in determining disease course, providing objective evidence to help guide therapeutic decisions.

**Memory deficits in multiple sclerosis subtypes**

G. Adler, M. Bektas, N. Baumgart, Y. Lembach. *Institut für Studien zur Psychischen Gesundheit (ISP), Mannheim, Germany*

In MS patients, episodic short-term memory (ESTM) is frequently affected. It is assumed that cognitive deficits are less severe in patients with a relapsing-remitting (RR) than in those with a secondary-progressive (SP), primary-progressive (PP) or progressive-relapsing (PR) course. This difference is attributed to a difference in neurodegeneration. We examined the relationship between episodic short-term memory and course of the disease. ESTM was assessed by means of the computer-based Memory and Attention Test (MAT) in not-acutely-ill MS outpatients. Severity of neurological symptoms was determined by the EDSS. ESTM group differences were calculated with unpaired Student’s t-tests before and after matching the groups for EDSS, age, sex and education. We assessed 531 patients (349 women, 182 men) aged between 17 and 60 years (mean/SD: 39.7/9.8 years). The course of the disease was RR in 409 patients (77.0%), SP in 71 (13.4%), PP in 15 (2.8%) and PR in 12 (2.3%); a CIS was found in 24 patients (not further considered here). ESTM was worse in patients with an SP, PP or PR course compared to RR (p < 0.001). However, patients with SP, PP and PR were older (p < 0.05) and had a higher EDSS (p < 0.01). Recalculating group differences in the matched groups revealed no significant differences anymore. The noticeable severity of memory impairment in patients with a progressive course compared to RR patients may not be specific for these forms of the disease, because after controlling for severity of neurological symptoms, age, sex and education it can no longer be ascertained.

**Is multiple sclerosis a prothrombotic disease?**

T. Koudriavtseva, G. D’Agostino, I. Speduti, P. Cordiali-Fei. *Neurology Unit, Regina Elena National Cancer Institute, Rome, Italy; Clinical Pathology, San Gallicano Dermatology Institute, Rome, Italy; ‘Biostatistic Unit, Regina Elena National Cancer Institute, Rome, Italy*

**Background:** The exact prevalence and pathogenic role of antiphospholipid antibodies (aPL) in multiple sclerosis (MS) remain unclear.

**Objective:** The aim of this prospective study was to evaluate the rate of aPL positivity in different MS phases in order to recognize their involvement in the pathogenesis of MS.

**Patients and methods:** We studied the reactivity for aPL including anticardiolipin, anti-β2glycoprotein I, anti-prothrombin, anti-annexin V in healthy controls and MS patients in different phases: secondary progressive (SPMS), relapsing-remitting in relapse (REL) or remission (REM).

**Results:** We analyzed the sera of 60 controls and 100 consecutive MS patients (58 REM, 26 REL and 16 SPMS). The rate of positivity for at least one aPL was significantly higher in MS patients compared to controls (32 vs 7%, p < 0.0001), in particular for anti-prothrombin IgM (7% vs 0, p = 0.05), and in REL compared to REM and SPMS (53.8, 20.7, 37.5% respectively, p = 0.002), specifically for anti-β2glycoprotein I IgM (26.9, 1.7, 6.3% respectively, p < 0.0001), anti-prothrombin IgM (15.4, 3.4, 6.3% respectively, p = 0.05) and IgG (19.2, 5.2, 0% respectively, p = 0.05). Likewise, the absolute values of anti-β2glycoprotein I IgM (p < 0.0001) and IgG (p = 0.007), anti-prothrombin IgM (p = 0.007) and IgG (p = 0.01) were significantly higher in REL compared to REM and SPMS.

**Conclusion:** Our results showed a significant increase of antiphospholipid antibodies in MS patients compared to healthy controls, with a strong association of anti-β2glycoprotein I and anti-prothrombin antibodies with disease exacerbation. Based on our results and on review of literature, we supposed that MS may be a primarily prothrombotic disease.

**Educational attainment moderates the effect of T2 lesion load and atrophy on cognition in multiple sclerosis**

D. Pintera, J. Sumowskib, A. Pichlera, M. Khalila, C. Langkammera, S. Fuchs, J. Deluca, F. Fazekas, C. Enzinger. *Department of Neurology, Medical University Graz, Graz, Austria; 4Neuropsychology & Neuroscience Laboratory, Kessler Foundation Research Center, West Orange, NJ, USA; 5Department of Physical Medicine and Rehabilitation, Kessler Foundation Research Center, West Orange, NJ, USA*

**Background:** The relationship between MR-markers of disease-related tissue changes and cognition in multiple sclerosis (MS) is variable. Previous work suggested that greater educational attainment (EA) might moderate the negative impact of brain changes on cognition, but this has not been replicated in independent cohorts and restricted to a limited set of MRI-metrics so far.

**Objective:** To test the cognitive reserve hypothesis in a large sample of MS patients from a single centre (Graz), using an extended set of MRI-metrics.

**Patients and methods:** The cohort comprised 137 patients (33 CIS, 92 RRMS, 12 SPMS). Cognition was assessed by the “Brief Repeatable Battery of Neuropsychological Tests” (composite Z-scores of all
Multiple sclerosis (MS) is a chronic autoimmune disease of the central nervous system, histopathologically characterized by inflammation, demyelination and gliosis. A disease-promoting role of the innate immune system has been proposed, based e.g. on the observation that innate immune receptors modulate disease severity of experimental autoimmune encephalomyelitis (EAE). Recent studies of our group provided first evidence for a key role of the innate immune LPS receptor (CD14) in the pathophysiology of EAE. CD14 deficient EAE mice showed increased clinical symptoms and enhanced infiltration of monocytes and neutrophils in brain and spinal cord. In the current study, we further investigated the cause of this disease aggravation and examined T cell activation and inflammatory cytokine production by FACS analysis and T cell migration capacity over the blood brain barrier by in vitro adhesion and transmigration assays. In the results, we observed a significantly increased migration of CD14 deficient lymphocytes across an endothelial monolayer. In contrast, we did not see any difference in T cell activation, cytokine production or lymphocyte adhesion to endothelial cells. Thus, the key innate immune receptor CD14 may play a pathophysiological role in the migration of inflammatory cells across the blood–brain barrier in EAE.

VZV encephalitis in a multiple sclerosis patient treated with natalizumab

M. Baruca, S. Šega Jazbec. Department of Neurology, University Medical Center Ljubljana, Ljubljana, Slovenia

Background: Natalizumab is a humanized monoclonal antibody approved for the treatment of patients with RRMS who have failed other disease-modifying therapies or who have aggressive disease. In MS clinical trials, herpes infections (varicella-zoster virus, herpes simplex virus) occurred slightly more frequently in natalizumab-treated patients than in placebo-treated patients (7.1% vs. 6%). In post-marketing experience, there have been three published cases of serious CNS infections due to HSV (one of which was fatal) and one report of VZV meningitis. Reactivation of latent herpes infections due to impaired immune surveillance on natalizumab therapy has been proposed.

Case report: A 46-year-old woman with a 10 year history of RRMS, previously treated with s.c. IFN-β-1b, developed worsening headache and vertigo two days after receiving her 15th treatment with natalizumab in February 2013. Five days after symptoms onset a LP was performed, which showed elevated proteins (0.86) and WBC count (95 cells). PCR for VZV was positive whereas PCR for JCV was negative. Brain MRI showed no additional lesions or meningeal enhancement. The patient improved gradually after a 21-day course of intravenous acyclovir. Natalizumab treatment was discontinued and glatiramer-acetate has been introduced.

Conclusion: To our knowledge, this is the first report of a VZV encephalitis in a MS patient treated with natalizumab. Our case supports the hypothesis that treatment with natalizumab is associated with reduced immune surveillance resulting in the reactivation of latent herpes infections.

Reversible splenial lesion in a Caucasian adult

C. Hornyak a, G. Rudas b, A. Csillika c, D. Bereczki c, T. Kovács d. aDepartment of Neurology, Semmelweis University, Budapest, Hungary; bMRI Research Center, Semmelweis University, Budapest, Hungary

Background: Reversible lesion in the splenium of the corpus callosum (SCC) caused by various agents and conditions was previously described, usually with mild encephalopathy/encephalitis without residual symptoms. In few days or weeks, complete radiologic regression is typical. Most cases are pediatric ones reported from South-East Asia.

Objective: To present a case of mild encephalopathy with reversible corpus callosum splenial lesion (MERS) in a Caucasian adult.

Methods: Case report.

Results: A 32-year old Caucasian male with unremarkable clinical history was referred because of severe headache and fatigue developed after 3 weeks of upper respiratory tract infection. Physical and neurological examination was normal. MRI of the head showed solid lesion in the splenium of the corpus callosum with restricted diffusion and without contrast enhancement. Laboratory tests, routine and immunoelectrophoretic examination of the CSF were performed. MERS was diagnosed based on the typical MRI finding and clinical presentation. CSF, serum, throat swab and stool were examined for different viruses (entero-, rota-, adeno-, influenza- and parainfluenza viruses and retrovirus) and bacteria (Borrelia, Mycoplasma, Chlamydia) with negative results. Fatigue and headache gradually improved. In two weeks, the size of the lesion in the SCC slightly increased but the high diffusion signal nearly resolved; complete radiographic regression was seen after 10 weeks on MRI.

Conclusion: To our knowledge, this is the first case of a Caucasian adult. MERS can occur at any age and population, although South-East Asian predominance is remarkable.

Anxiety in patients with multiple sclerosis
G. Toncev, S. Miletic Drakulic, T. Boskovic Matica, Z. Knezevic, A. Azanjac, K. Vesic, S. Simovic, D. Mijailovic, Clinical Center Kragujevac, Clinic of Neurology, Faculty of Medical Sciences, University of Kragujevac, Serbia; Faculty of Medical Sciences, University of Kragujevac, Kragujevac, Serbia

Introduction: Anxiety is common but often unrecognized and untreated disorder in patients with multiple sclerosis.

Objectives: The aim of our study was to determine the prevalence of anxiety in MS patients and to determine possible correlation with fatigue, sexual dysfunction and disorders in the fields of physical and emotional health.

Material and methods: In our study, we used Multiple Sclerosis Quality of Life-54 (MSQoL-54), Fatigue Severity Scale, and Hamilton Anxiety Rating Scale. Statistical data processing, we used the Pearson correlation test and Student’s t test.

Results: We enrolled 120 MS patients (68 females and 52 males; average age 47.36 years, mean disease duration 17 years). Normal values for the Hamilton Anxiety Rating Scale were found in 24 patients (20%), while in 96 or 80% we found anxiety (8.6% — mild, 13.33% — moderate and 60% — severe). Statistically significant negative correlation was observed between anxiety and MSQoL54 Emotional Well-Being ($r = -0.563$, $p = 0.01$), Energy ($r = -0.540$, $p = 0.02$), the Physical Component Summary Score ($r = -0.601$, $p = 0.0001$) and Mental Component Summary Score ($r = -0.590$, $p = 0.01$). We find the positive significant correlation between values of Fatigue Severity Scale and anxiety ($r = 0.620$, $p = 0.0001$). We also found statistically significant negative correlation between the Sexual Dysfunction and anxiety ($r = -0.418$, $p = 0.022$).

Conclusions: Anxiety has significant association with mental and physical health disorders, sexual dysfunction and fatigue in MS patients. Unlike other aspects of MS, anxiety is treatable and with proper treatment of these patients, the quality of their life could be much better.

Impact of smoking on mortality and life expectancy in multiple sclerosis
A. Manouchehrinia, M. Weston, C.R. Tench, C.S. Constantinescu, J. Britton, Neurology, University of Nottingham, Nottingham, UK; UK Centre for Tobacco Control Research, University of Nottingham, Nottingham, UK

Objective: To examine the relationship between smoking and mortality in a cohort of Multiple Sclerosis patients.

Method: Clinical and demographic characteristics of 968 individuals were obtained from a large population-based cohort of MS patients. Records were linked to the NHS data to obtain data about death on Dec 2012 (index date). Patients were followed from onset age to death age or index date, whichever occurred first. The impact of sex, disease clinical type at onset, ≥ 1 year exposure to treatment, year of MS onset and smoking status (ever vs. never) were investigated using Cox proportional hazard model.

Results: Of 923 patients with clinically definitive MS and full data for analysis, 80 (47 male and 33 female) were deceased at index date. Mean survival age was 77.3 years (95% CI: 75–79). Compared with ever-smokers, never-smokers lived 7 years less (81 vs. 74). Mean MS survival was 56.1 (95% CI: 53–59) in never-smokers and 43 (95% CI: 40–46) in ever-smokers. Smokers were at higher risk for death; hazard ratio 2.24 (95% CI: 1.30 to 3.85; $p = 0.004$) than never-smokers after stratifying by sex and controlling for onset age, initial type of disease (RR vs. PP) and ≥1 year exposure to treatment. Compared to UK general population, standardised mortality rates were 1.71 (95% CI: 1.37–2.13) for all patients, 2.64 (95% CI: 1.97–3.53) for ever-smokers and 1.14 (95% CI: 0.74–1.75) for never-smokers.

Conclusion: Mortality in MS is in part due to smoking. Smoking is a significant yet preventable risk factor for death in patients with MS.

Lipid profile in interferon and glatiramer acetate using patients with multiple sclerosis
Z. Yildirim, S. Oncel, M. Ozturk, N. Kaya Tutar, S. Baybas, Bakirkoy Prof. Dr. Mazhar Osman Mental Health and Neurological Diseases Training and Research Hospital, Istanbul, Turkey; Neurology, Bakirkoy Prof. Dr. Mazhar Osman Mental Health and Neurological Diseases Training and Research Hospital, Istanbul, Turkey

Background: In studies focusing on MS patients that claim there is a change in lipid profile depending upon drugs being used has been found to have a difference in cholesterol and triglyceride levels.

In our study, we aimed to compare the lipid profile of MS patients using interferon or glatiramer acetate of untreated MS patients and control group of migraine patients, and to investigate the relation retrospectively along with the disease progress in both groups.

Conclusions: Anxiety has significant association with mental and physical health disorders, sexual dysfunction and fatigue in MS patients. Unlike other aspects of MS, anxiety is treatable and with proper treatment of these patients, the quality of their life could be much better.

doi:10.1016/j.jns.2013.07.1470
Materials and methods: This study included 42 MS patients under treatment (group 1), 19 untreated MS patients (group 2) and 15 migraine patients (group 3). Sociodemographic features, Expanded Disability Status Scores (EDSS), disease characteristics of patients and the lipid profiles were recorded through a form. Lipid profiles were measured before treatment three times for group 1 with an average of 10 and after 18 months of treatment, lipid profiles were measured two times for group 2 and one time for group 3. SPSS for Windows 18 was used for statistical analysis. Results: There was no statistically significant difference between the values of group one before treatment and after treatment. There was no correlation between these values and the EDSS’s of patients. There was no statistically significant difference between the second measurements of group 1 and group 2 (p < 0.05). There was no statistically significant difference between all three groups before and after treatment (p < 0.05). Conclusion: Our results showed that lipid profiles of patients don’t change under MS treatment, and don’t have relation with activity of disease.

Features of the first clinical symptoms of multiple sclerosis in the population of Tomsk region Russian Federation
M. Titova, V. Alifirova, I. Zhukova, N. Musina. Neurology and Neurosurgery, Siberian State Medical University, Tomsk, Russia

Aims: Some symptoms of multiple sclerosis (MS) at different frequencies are found in the first episode and in the developed stage of the disease. The aim of this study was to receive a feature of the first clinical episode of MS in the Siberian region of Russian Federation.

Method and materials: The data of the patients with MS in the Tomsk region in the period from 2003 to 2012 have been examined.

Results: Often the first clinical symptoms of demyelination were disorders of the cranial nerves, especially the optic neuritis. Pyramidal disorders in patients were presented as central mono-, hemi-, para- and tetrapareses with varying severity. The sensation disorders were diagnosed as decrease in vibration, pain, touch, sense of temperature and position. In the separation of patients by gender, predominance of any symptoms, as the manifestation of MS, was not found. We compared the data of the first clinical symptoms of the disease in 2003 with 2012. The results of the study showed an increase in 2012 cases of optic neuritis by 11.6% and cases of sensation disorders by 5.5%.

Conclusion: Diagnosis of MS in clinical practice is difficult. Symptoms of the disease are similar the symptoms of other pathological processes in the nervous system and don’t have particular features. Clinical features of the first demyelinating symptoms in MS patients may determine the prognosis of the disease progression, treatment response and further patients management.

Atorvastatin protects NSC-34 motor neurons against oxidative stress through the activation of PI3K, ERK and free radical scavenging

2Department of Neurology, Hanyang University College of Medicine, Seoul, Republic of Korea; 3Department of Neurology, Kwangmyeong Sungae Hospital, Seoul, Republic of Korea

Objective: Although statins, hydroxymethylglutaryl coenzyme A (HMG-Co A) reductase inhibitors, are generally used to decrease circulating cholesterol levels, they have also been reported to have neuroprotective effects through diverse mechanisms. However, recent reports have shown controversial results as to whether statins might be harmful in patients with amyotrophic lateral sclerosis (ALS). In this study we investigated the direct effect of atorvastatin on motor neuron like cells (NSC-34D) against oxidative stress.

Material and methods: To evaluate the effect of atorvastatin and/or hydrogen peroxide on NSC-34D cells, the cells were treated with several conditions: 3,4-(5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) assay and trypan blue stain were performed for the evaluation of viability. Free radical level and intracellular signaling proteins were evaluated with fluorescent probe 2,7-dichlorodihydrofluorescein diacetate (DCFH-DA) and western blotting, respectively.

Results: Atorvastatin protected NSC-34D cells against oxidative stress in a concentration-dependent manner. This neuroprotective effect of atorvastatin was blocked by LY294002, a phosphatidylinositol 3-kinase (PI3K) inhibitor and FR180204, a selective extracellular signal-related kinase (ERK) inhibitor. Atorvastatin treatment increased the expression levels of p85αPI3K, phosphorylated Akt, phosphorylated glycogen synthase kinase-3β (GSK-3β) and phosphorylated ERK which are proteins related to survival, and decreased the levels of cytosolic cytochrome and cleaved caspase-3, cleaved caspase-9 and Bax which are associated with death, in oxidative stress–injured NSC-34D cells.

Conclusion: We conclude that atorvastatin has neuroprotective effect against oxidative stress in motor neurons via the activation of the PI3K pathway, ERK pathway and free radical scavenging. These findings indicate that statins could be helpful in protecting motor neurons.

worse than in immunocompromised patients. PML should be included in the differential diagnosis of rapidly progressive white matter lesions, even in immunocompetent patients.

Susac’s syndrome — A case with unusual cardiac vestibular and imaging manifestations
Y. River1, V. Danilov2, I. Braverman2, A. Shupak4, 1Neurology, Technion Medical School, Israel; 2Neurology, Hillel Yaffe Medical Center, Hadera, Israel; 4Otolaryngology, Hillel Yaffe Medical Center, Hadera, Israel; 3Otolaryngology, Carmel Medical Center, Haifa, Israel

Susac’s syndrome is a rare, idiopathic, microangiopathy affecting the brain, retina, and cochlea.

Methods: Detailed description of a patient with Susac’s syndrome.

Results: A 38 year old patient developed dizziness and transient right eye visual disturbance one day prior to his admission. He was examined in the hospital because of confusional state with restlessness that lasted 24 h. Three days after his admission he developed right eye cilioretinal artery occlusion. In the fifth day of hospitalization he developed bilateral asymmetric deafness, tinnitus and upbeat nystagmus. Brain MRI was normal. CT angiography was normal. LP showed significant albumino-cytologic dissociation. A detailed oto-laryngological and ophthalmological work up was performed. Of note was the persistence of significant bradycardia without additional cardiological abnormalities. Work up which included brainstem evoked potentials, Otoacoustic-electrocochleography, caloric tests and electronystagmography was positive for a significant peripheral and central vestibular and auditory involvement. The patient was successfully treated with IV steroids and Immunoglobulins. Brain MRI following a repeated episode of vertigo 3 month later showed a diffuse T2 hyper intense, ill-defined, left hemispheric lesion superior to the Lateral ventricles not seen in previous two MRI scans.

Conclusions: This patient developed the typical clinical picture of Susac’s syndrome. However, additional features are unusual: Persistent bradycardia, significant vestibular involvement of both peripheral and central origin, and the late appearance of atypical white matter lesions on MR scan. The possibility of microangiopathy involving the heart and central auditory and vestibular involvement in the absence of initial MRI findings is discussed.

In vitro persistence of saffold virus type 3 which is isolated from cerebrospinal fluid of the patient with aseptic meningitis
Y. Ohara, T. Himeda, T. Okuwa, Y. Muraki. Department of Microbiology, Kanazawa Medical University School of Medicine, Ishikawa, Japan

Background and objective: Saffold virus (SAFV) was identified in 2007 as a novel human Cardiovirus. SAFV type 3 (JPN08-404) has been isolated from cerebrospinal fluid of the patient with aseptic meningitis. This finding is of interest since Theiler’s murine encephalomyelitis virus (TMEV), which is the closely related virus, is known to cause a multiple sclerosis-like syndrome in mice. During demyelination, TMEV persists in mouse. Therefore, we studied the possibilities of the in vitro persistence of SAFV.

Material and methods: HeLa cells were used as host cells. SAF404 virus derived from infectious cDNA clone of JPN08-404 was used as a challenge virus. The cells persistently infected with SAF404 were analyzed by Western blotting, immunocyto-staining and plaque assay. To investigate the mechanisms of SAFV persistence, the treatment with anti-IFN antibody was performed. Furthermore, the virus binding assay in HeLa cells maintained with CS or FCS was performed.

Results: SAFV persistence was first demonstrated in this study. The persistence of SAF404 was not influenced by the treatment with anti-IFN-α/β antibody, although TMEV persistence was collapsed. SAFV persistence was collapsed by the maintenance with FCS. Furthermore, the virus binding assay indicated that the densities of the virus binding molecule(s) were significantly higher in HeLa cells cultured with FCS.

Conclusion: The present study demonstrated that SAFV is able to persist in human-derived cell line. Furthermore, it was suggested that SAFV persistence may depend on the receptor densities. The present findings of the SAFV persistence will be helpful for further studies on the SAFV pathogenicity.

Clinical inflammatory activity associated with response to second-line treatments in multiple sclerosis
T. Gholipour1b, B.C. Healy2a, E.C. Dimakopolous3b, G. Buckle3b, H.L. Weiner2a, T. Chitnis2a, 1Harvard Medical School, Partners Neurology Residency Program, Boston, USA; 2Harvard Medical School, Partners MS Center, Brookline, MA, USA

Background: Suboptimal outcome on first-line MS treatments often necessitate initiation of second-line treatment. There is limited information on how to choose a second-line agent.

Objective: We examined the ability of 11 candidate demographic and clinical factors to predict treatment response in an observational MS cohort.

Patients and methods: Patients treated with one of the four most commonly used second-line MS treatments in our center at the time of this study were selected: cyclophosphamide, daclizumab, mycophenolate mofetil, and natalizumab. Outcomes were time to subsequent inflammatory event (clinical relapse or new MRI activity) and occurrence of progression in disability confirmed at six months. The association between potential predictors and the time to events was investigated using univariate Cox proportional hazards regression models. An additional analysis regarding whether patients remained disease-activity-free on specified measures for two years after treatment start was also performed.

Results: 101 cyclophosphamide, 57 daclizumab, 83 mycophenolate and 140 natalizumab patients were included. In all treatment groups except natalizumab, and among studied factors, those generally known to be associated with inflammatory disease activity (younger age at treatment start, shorter disease duration, and higher baseline relapse rate) were associated with more disease activity on second-line treatments. A similar set of factors were negative predictors for a disease-activity-free course independent of treatment duration.

Conclusion: High baseline inflammatory activity is associated with suboptimal response to the studied drugs, except for natalizumab. Identification of underlying mechanisms may aid in further optimizing second-line treatment response in MS.

Bickerstaff brainstem encephalitis without ophthalmoplegia: A reappraisal of current diagnostic criteria
N. Yuki, B. Wakerley. National University of Singapore, Singapore, Singapore

Background: External ophthalmoplegia is a cardinal feature of Bickerstaff brainstem encephalitis.
Objective: Clinical and immunological evaluation of “incomplete” Bickerstaff brainstem encephalitis.
Methods: We studied 2 patients with post-infectious brainstem syndromes who presented at National University Hospital Singapore. Laboratory work-up included measurement of anti-ganglioside antibodies.
Results: Both patients displayed hypersomnolence and cerebellar-like ataxia in the absence of external ophthalmoplegia and carried high serum titers of IgG anti-Q1b antibodies, strongly indicative of Bickerstaff brainstem encephalitis.
Conclusion: Ophthalmoplegia can be absent or incomplete in Bickerstaff brainstem encephalitis, and the absence of this clinical feature should not exclude Bickerstaff brainstem encephalitis from the clinicians’ differential. Such cases of incomplete BBE could be defined as “ataxic hypersomnolence without ophthalmoplegia”.

Veins in plaques of multiple sclerosis patients — A longitudinal magnetic resonance imaging study at 7 Tesla
A. Dal-Bianco, G. Grabner, S. Hametner, M. Schernthaneb, C. Kronnerwetterb, M. Weber, C. Vass, K. Kircher, A. Reitner, E. Auff, K. Vass, H. Lassmann, S. Trattning. "Department of Neurology, Medical University of Vienna, Vienna, Austria; bDepartment of Radiology, Medical University of Vienna, Vienna, Austria; cCenter for Brain Research, Medical University of Vienna, Vienna, Austria; dDepartment of Ophthalmology, Medical University of Vienna, Vienna, Austria

Background: Multiple Sclerosis (MS) is a chronic inflammatory disease of the central nervous system associated with demyelination, axonal loss and neurodegeneration. MS plaques are generally found to be centered by a vein. The role of blood vessels gains again attention due to ultra-highfield magnetic resonance imaging (MRI).
Objective: Susceptibility-weighted-imaging (SWI) at 7 Tesla MRI allows precise depiction of veins. The purpose of this study was to monitor the intrathecal veins over a period of 2 years in plaques and corresponding normal appearing white matter (NAWM) of patients with relapsing–remitting and secondary-progressive MS compared to age-matched controls.

Patients and methods: Ten MS patients and nine age-matched control subjects were enrolled in a prospective 2-year follow-up annual clinical and 7 T-Flair-SWI-MRI protocol. Veins were manually segmented in plaques, their contralateral NAWM and in the white matter of controls. Proportion of veins was assessed by dividing the volume of veins by their according tissue volume. Non-parametric tests were used for area-wise comparison.

Results: Established MS plaques showed a significantly higher proportion of SWI-detected veins compared to corresponding control tissue without significant change within 2 years. We found a trend of an increasing venous proportion in pre-plaque areas and a significant increase of venous proportion in newly developed plaques compared to controls. Proportion of veins in the NAWM was in accordance with values of matched control-areas.

Conclusion: Inflammation-induced metabolic activity, vasodilatation and angiogenetic factors may contribute to the significantly higher proportion of intrallesional veins compared to control and NAWM tissue.

Application of the modified McDonald criteria of multiple sclerosis in Chinese demyelinating disease patients
R. Li, S. Cheng, K.L. Shiu, E. Yeung, C.N. Lee, M. Au Yeung, C.M. Cheung, T.H. Tsoi. Medicine, Pamela Youde Nethersole Eastern Hospital, Hong Kong, Hong Kong S.A.R.
Background: The International Panel on diagnosis of multiple sclerosis (MS) has revised the McDonald criteria in 2010. There is scarce data on its application in the Chinese population.

Objective: To evaluate the application and usefulness of the 2010 McDonald criteria in Chinese patients with idiopathic demyelinating diseases.

Methods: All patients who have been seen for idiopathic demyelinating diseases in a single regional hospital from 1996 to 2012 were recruited. They were retrospectively analyzed based on their most updated diagnosis as of March 2013. The Poser criteria for clinically definite MS (CDMS), the 2005 and 2010 McDonald criteria for MS were applied to all subjects and compared.

Results: A total of 114 patients were recruited. After a mean disease duration of 8.0 years, 38 patients (33.3%) converted from clinically isolated syndrome (CIS) to CDMS; 40 (35.1%) to MS by the 2005 criteria; and 44 (38.5%) by the 2010 revision. 18 (15.8%) converted to neuromyelitis optica (NMO), and 4 (3.5%) to recurrent optic neuritis or brainstem disease. Of the 38 patients with CDMS, the mean conversion time from CIS is 26.9 months, but is shortened to 22.7 and 20.4 by the 2005 and 2010 criteria respectively. 26.3% of CDMS cases fulfilled the 2010 criteria by the initial MRI. None of the patients with other recurrent demyelinating diseases, including NMO, fulfilled the 2010 criteria on presentation.

Conclusion: The latest revision of the McDonald criteria is applicable to the Chinese population. It can speed up the diagnosis of MS, and is highly specific.

the 2nd group the symmetric activation in all brain regions evaluated with AP = (−0.12 to 0.037) were found. We have found the progressive decreasing NAA/Cr in the PG, and SMA, that is associated with poorer motor function.

**Conclusion:** fMRI and MRS data give us new quantitative approach for understanding metabolic basis of decreasing of the brain plasticity in RRMS-patients.

**Electrophysiological evaluation of dysphagia in the mild or moderate patients with multiple sclerosis**

Y. Beckmann, A. Cakır, N. Gurgor, T.K. Incesu, S. Arıcı, Y. Secil, C. Ertekin. Katip Celebi University, Atatürk Education and Research Hospital, İzmir, Turkey

**Objective:** This study aims to evaluate the presence of subclinical dysphagia in mild MS patients using electrophysiologic methods.

**Study design and methods:** A prospective study of 51 patients with RRMS and 18 age-matched healthy adults. Electrophysiologic evaluations were performed on submental EMG activity during attack, after the attack and in remission period. Dysphagia limit was determined during as single and 50 ml of sequential water swallowing in all patients and control group to detect dysphagia objectively.

**Results:** Clinical dysphagia was found in 12% of patients while the electrophysiological dysphagia was encountered in 33% of MS patients. Dysphagia limit was in normal limits in normal subjects while it was pathological in 23% MS patients. Duration of swallowing signal of submental muscles in all MS patients was longer than in normal subjects (P = 0.001). The forebursts of sequential water swallowing was recorded significantly more often in patients in remission period than in patients in attack or after attack groups (P = 0.003). The total swallowing duration was prolonged in MS patients (P = 0.001). The existence of dysphagia was significantly higher among MS patients who had higher disease disability (P = 0.001).

**Conclusion:** This is the first study investigating subclinical dysphagia from the electrophysiologic aspect in RRMS patients. In agreement with our data, dysphagia is common in MS patients even in early stage or mild forms of the disease. The presence of subclinical dysphagia should be searched even in the absence of any clinical signs because dysphagia may impact the daily life negatively and increase the morbidity.

**Low dose aspirin for MS-related fatigue: Results of a pilot, double-blind, randomized trial**

S.M. Nabavi, M. Sadeghi. MS Research Group. Neurology, Shahed University, Tehran, Iran

Fatigue is one of the most common and disabling symptoms in multiple sclerosis (MS), occurring in more than 60% of patients during the course of the disease. Despite high prevalence of fatigue in MS patients, its pathophysiology was not understood completely yet and this would difficult introduction of new medication for this symptom. Wingergchuk et al. for the first time assess the effectiveness of Aspirin (ASA) on MS related fatigue and show high dose ASA (1300 mg) would significantly decrease fatigue in these patients. According to severe complications in high dose use of ASA, we try to evaluate low dose ASA (80 mg) for primary fatigue in MS patients.

This was a single-centre, randomized, double-blind and parallel trial with 1:1 ratio allocation of two treatment groups of low dose Aspirin (80 mg) and placebo in outpatients with MS-related fatigue. Ninety five patients with MS were randomized among them, 76 patients enter final analysis. No significant effect in FSS and MFIS was found using ANOVA for repeated measures when missing value were replaced. When we examine absolute changes for MFIS score, significant difference between two groups was seen (P value = 0.047, Mean difference = 8.84903, CI = 18.84578 to −13.430).

**Role of serum TRAIL level and TRAIL apoptosis gene in multiple sclerosis and their relation with brain atrophy**

M. Nada, M. Tawdy, M. Abd El Nasser, S. Abd El Shafy, M.N. El Sirafy, A. Abol Magda. "Neurology, Cairo University, Cairo, Egypt; aClinical Pathology and Immunology, Beni Suef University, Beni Suef, Egypt; bRadiodiagnosis, Alexandria Faculty of Medicine, Alexandria, Egypt

**Background:** One of multiple sclerosis (MS) presumed pathological mechanisms is failure of apoptosis of autoreactive T lymphocytes.
Objectives: To determine the relationship between tumor necrosis factor-related apoptosis-inducing ligand (TRAIL) mRNA gene expression ratio and serum TRAIL levels with MS and brain atrophy.

Materials and methods: This study was conducted on 53 relapsing remitting MS Egyptian patients and 25 matched healthy volunteers. The expression of TRAIL on peripheral blood lymphocytes was analyzed by RT-PCR, serum levels of soluble TRAIL (sTRAIL) was determined by ELISA and MRI brain for measurement of black holes and the bicaudate ratio (BCR) as a measure of brain atrophy were done for all patients.

Results: The serum TRAIL level was lower in multiple sclerosis patients compared to the control but no difference in the TRAIL mRNA gene expression ratio. No significant correlation detected between the serum TRAIL level and the TRAIL mRNA expression ratio in either group. No statistically significant correlation was found between the serum TRAIL levels or the TRAIL mRNA expression ratio with the number of black holes or the bicaudate ratio.

Conclusion: Apoptosis of T lymphocytes is deficient in MS patients which can be implicated in the treatment. No difference between TRAIL mRNA gene expression ratio between MS patients and controls.

Late onset multiple sclerosis (LOMS): A diagnostic challenge

Background: LOMS is an unusual entity presenting after the age of 50, commonly with progressive course and motor symptoms.

Patients and methods: A 67 years old woman with a previous stroke, suffered diplopia attributed to ischemic neuropathy. She developed progressive paraparesis, spastic gait, ataxia and urinary urgency during the following five years. A 56 years old smoker man, with hypertension and dyslipidemia, was studied due to a gait disturbance for fourteen months. Right lower limb weakness, vibratory hypoesthesia and hyper-reflexia in lower limbs were detected.

Results: Laboratory blood tests were normal. Case1 had CSF oligoclonal bands. Visual Evoked Potentials were normal, but Somato-sensory Evoked Potentials (SSEP) were consistent with demyelization at cervical levels in both.1.5 T MRI showed non-specific subcortical hyper-intensities and cortical protrusions without spinal cord lesions. Finally, 3 T MRI was conclusive showing non-enhanced hyper-intensities at C3, C5, C6, D9 cord levels and periventricular white matter in case 1, and at C2 and D6 levels in case 2. Both improved with corticosteroids pulses.

Conclusion: LOMS frequently presents as primary progressive, with greater tendency to affect the spinal cord. It is characteristic the diagnostic delay due to comorbidities, progressive form and nonspecific MRI. In our cases, a high suspicion and the results of SSEP led us to complete the study with 3 T MRI. We remark that in LOMS, standard tools may be non-diagnostic, requiring more specific tests (3 T MRI and SSEP) to confirm the diagnosis and try specific therapy.

Arterial and venous hemodynamics in patients with multiple sclerosis

R.A. Norman, E. Motta, J. Soltyk, A. Golba, M. Debski. Silesian Medical University, Katowice, Poland

Background: Chronic cerebro-spinal venous insufficiency (CCSVI) is a new controversial theory of multiple sclerosis (MS) pathogenesis. Though the role of venous insufficiency in MS has not been fully explored surgical procedures are offered to MS patients.

Objective: The aim of the study was to evaluate extracranial and intracranial arterial and venous flow in MS patients.

Material and methods: 120 MS patients (mean age 38.9 ± 8.7 years; median EDSS — 3.3 range 0–8; disease duration 1–27 years) were compared with 80 healthy controls (mean age 34.7 ± 7.2 years).

Arterial and venous flow was examined using a Philips duplex ultrasound machine.

A subject was considered CCSVI if ≥2 ultrasonographic criteria (Zamboni’s five criteria) were fulfilled.

Results: No MS patient and no control had CCSVI. Internal jugular vein stenosis (venous cross-sectional area ≤0.3 cm²) was the only criterion found for CCSVI (no significant differences p = 0.87 between MS patients and controls). Arterial blood flow (mean velocity, pulsatility index) was similar in both group, p = 0.35.
Conclusion: Our findings indicate that CCSVI has no role in multiple sclerosis.

A study of total-tau and phospho-tau (181) in the cerebrospinal fluid of patients with multiple sclerosis
E. Koutsouraki, E. Hatzifilippou, T. Kalatha, P. Gerasimidou, A. Orologas. 1st Dept. of Neurology, Laboratory of Neuroimmunology, Aristotle University, AHEPA Hospital, Thessaloniki, Greece

Biomarkers connected with clinical parameters and the process of MS could be very important for understanding and managing the disease. The aim of the present study was the determination of total tau (tTAU) and phosphorylated tau (pTAU -181) concentrations in the CSF of MS patients vs controls and the correlation with clinical parameters (age, gender, type of MS, disability and treatment).

We examined 50 CSF samples, 40 patients with definite MS, 33 females (42.6 ± 11.9 years) and 7 males (42.4 ± 10.0 years), as well as 10 controls, 3 females (43.3 ± 7.4 years) and 7 males (40.3 ± 15.5 years), who didn’t suffer from MS or any acute inflammation. 12 of the patients suffered from Clinical Isolated Syndrome (CIS), 22 from relapsing/remitting (RRMS), 3 from primary (PPMS) and 3 from secondary progressive type of MS (SPMS). The samples were centrifuged after the lumbar puncture and freezed at −80 °C. We used the Elisa technique and the commercial available kits (Inno-Genetics, Belgium).

Our study indicated increased tTAU-Ag levels in older patients (rho = 0.371, p = 0.024 < 0.05), while in the controls’ group was demonstrated a reversed connection (rho = −0.679, p = 0.022). In both (patients’ and controls’) groups, females demonstrated higher levels of tTAU (p = 0.011). The study of pTAU-181 showed an important correlation between PPMS and decreased levels (p = 0.038), while patients with more than a year duration of MS demonstrated higher concentrations (p = 0.045).

Our results indicated that tTAU could be correlated with the age and the sex of MS patients and phosphoTAU 181 with the type and the duration of the disease.

Endocrinologic disorders in patients with multiple sclerosis
M. Barabanova, E.M. Ivanova, G.G. Muzlaev, V.K. Oranskaya, I.A. Nikitina. Nervous System Diseases and Neurosurgery, Kuban State Medical University, Krasnodar, Russia

Background: Extranervous lesions are observed in multiple sclerosis (MS).

Objective: To detect endocrine disorders in MS and to investigate their correlation to the disease severity.

Patients and methods: We examined 85 patients with relapsing–remitting MS of various severity. EDSS and FS Kurtzke were used to describe patients’ state, hormone concentrations defined using laboratory methods.

Results: The following endocrine disorders were diagnosed in 25 (23.8%) patients with mild (17 (68%)) to moderate (8 (32%)) MS severity: cortisol 1.4 times exceeding normal levels (p < 0.05) in 10 (40%) patients that correlated to brainstem disorders (FS3) (r = −0.29, p < 0.05), but no other neurological lesions. 8 (32%) patients developed autoimmune thyroiditis with thyroid stimulating hormone concentration 8 times higher than normal (p < 0.05), and that-one of free thyroxine 2 times lower than normal (p < 0.05), that correlated to the movement impairment severity (FS1) (r = −0.21, p < 0.05), cerebellar (FS2) (r = 0.55, p < 0.05), sensory (FS4) (r = −0.25, p < 0.05), and pelvic disorders (FS5) (r = 0.74, p < 0.05). The increased for 38.2% prolactin level (p < 0.05) correlating to the neurologic disorders (p < 0.05) was found in 7 (28%) patients.

Conclusion: The correlation between cortisol, TSH and thyroxine, and prolactin levels and EDSS score was established (r = 0.43, p < 0.05). The possibility of the neurological state improvement by correcting patients’ endocrine profile will be the subject of our future investigations.

L.V. autologous bone marrow derived mesenchymal stem cell in multiple sclerosis, double blind randomized clinical trial: Preliminary report of safety
S.M. Nabavi a, N. Aghdami b, L. Arab b, MS Research Group.
aNeurology, Shahed University, Royan Institute, Tehran, Iran; 
bCell Biology Stem Cell, Royan Institute, Tehran, Iran

Introduction: Adult bone marrow derived stromal cells (MSC) were shown to induce immunomodulatory and neuroregenerative effects and to induce neuroprotection in the animal models. A randomized clinical trial, semi cross over, phase I/II study to evaluate the safety and efficacy L.V. injection of autologous bone marrow derived mesenchymal stem cell in patients with multiple sclerosis has been designed.

Methods: 30 MS patients (18–55 years, 3 < EDSS < 6.5) who were resistant to the approved DMDs, were randomly recruited. After bone marrow aspiration the patients were randomly divided into 2 groups: early treatment group and delayed treatment group. Mesenchymal stem cells were transplanted I.V. to the first group and for second one injected after 6 months. All followed for immediate and late side effects, relapses, EDSS, RAO Test, MRI, CSF markers and quality of life questionaire at the Baseline and after 1th, 3th, 6th and 12th months.

Results: Up to January 2013, 15 patients were injected and 8 out of them had their second injection. After 6 months of follow up, any clinical or laboratory adverse events and immediate clinical reactions within the first 6 h and between 48 h and 6 months of follow up were seen. Some patients got better with EDSS improvement. 2 patients had relapses and in one patient 3 severe disabling relapses occurred within 5 months. We did not detect any new GAD + lesions on MRI.

Conclusion: The intravenous transplantation of autologous MSC is safe without any adverse effect. Efficacy should be proved at the end of the study.

Motor sequence learning in relapsing remitting MS patients
M. Zahiri a, A. Abdollahi b, S.M. Nabavi a, MS Research Group.
aNeurology, Shahed University, Royan Institute, Tehran, Iran; 
bPhysiotherapy, Tehran University of Medical Sciences, Tehran, Iran

Abstracts / Journal of the Neurological Sciences 333 (2013) e358–e421
Introduction: Motor learning is sub-served by two interrelated systems (explicit and implicit). However, attempts to guide learning commonly are done using explicit instructions concerning “how to” perform a movement task. We investigated the impact of explicit information (EI) on motor-sequence learning in MS patients.

Material and methods: 30 RRMS (24 female and 6 male; mean age: 29.5 ± 5.6; mean duration disease: 64.43 ± 48.38; mean EDSS: 1.5 ± 0.4) and 30 healthy subjects were randomly divided in 2 explicit and implicit subgroups.

Explicit subgroup was provided with EI and another subgroup was not. All subjects performed serial reaction time task (SRT). In this task four squares with different colors appeared on the computer screen and subjects were asked to press 1 of 4 keys corresponding to the appropriately colored square immediately after observing it with a retention test after 48 h.

Results: Patients performed this task significantly slower than healthy groups (mean RT in MS patients: 1356.57 ± 348.89 s and in the healthy subjects: 1018.60 ± 210.49 s, P < 0.05). Time of final blocks decreased significantly in both groups (P < 0.05). Motor learning in healthy subjects was higher and the implicit subgroup more than explicit in the patient group (P < 0.05).

Conclusion: Although patient groups performed this motor task slower than the healthy subjects, there was motor learning in the patient in both subgroups (implicit and explicit). In the patients implicit subgroups indicate better motor learning rather than explicit subgroups. Explicit information was detrimental for motor-sequence learning in RRMS patients.

The relationship between fatigue and the severity of disability, in multiple sclerosis

M. Heidary1, M. Akbarfahimi1, S.M. Nabavi1, M. Salehi2
1MS Research Group.
2Occupational Therapy, Tehran University of Medical Sciences, Tehran, Iran.
3Neurology, Shahed University, Tehran University of Medical Sciences, Tehran, Iran;
4Biostatistics, Tehran University of Medical Sciences, Tehran, Iran

Introduction: Fatigue in multiple sclerosis is a very common symptom, can be the early manifestation and encompasses physical, social and cognitive inefficiencies. There are different conflicting results in relation to fatigue and the level of disability in MS. The aim of this study is to demonstrate the relationship between fatigue and the severity of disability in patients with multiple sclerosis.

Methods: In this cross sectional study, 140 patients with multiple sclerosis (114 F/26 M, age: mean ± standard deviation = 32/77 ± 8/22) were assessed in three subtypes (relapsing–remitting, primary progressive and secondary progressive). The fatigue and the severity of fatigue were assessed and validated by Persian version of the Fatigue Impact Scale (PER-FIS) and fatigue severity scale (FSS) respectively. The severity of disability was measured by the Expanded Disability Status Scale (EDSS). The PER-FIS consists of three subscales (cognitive, physical, social role) and allows a multidimensional evaluation. Data was analyzed by Spearman’s rho rank correlation coefficient.

Results: The EDSS was correlated with total scores of PER-FIS (r = 0.36 p < 0.0001) as well as with the cognitive (r = 0.17 p < 0.05), physical (r = 0.42 p < 0.0001) and social (r = 0.36 p < 0.0001) subscales. Furthermore EDSS among three subgroups of participants has positive relationship with FSS (r = 0.32 p < 0.0001). However, neither total nor the subscales score of PER-FIS were not linked to EDSS.

Conclusion: These data confirmed that the degree of the neurological disability in multiple sclerosis is correlated with the degree of fatigue. But, in the different subtypes, the fatigue remains independent from EDSS.

The course of washout period at JCV seropositive RRMS patients after natalizumab withdrawal and planned switch to fingolimod

E. Klimová1, M. Daňová2, 3Neurology, J.A. Reiman’s Teaching Hospital and Faculty of Health, University of Prešov in Prešov, Slovak Republic;
4Magnetic Resonance, ProMagnet Ltd., Prešov, Slovak Republic

Background: Natalizumab withdrawal at JCV seropositive RRMS patients may cause disease reactivation/rebound. The switch to fingolimod, as one of the therapy options, is preceded by the washout, for its duration there has not existed an unequivocal consensus so far.

Objective: To assess the course of the washout at JCV seropositive RRMS patients after natalizumab with planned switch to fingolimod.

Patients and methods: We realized such a switch in 9 patients. All patients taking natalizumab have failed first-line therapies, in average of 4.2 years, number of relapses the year before natalizumab at least 2. The patients had no relapses under natalizumab and no new lesions in the brain MRI performed every 6 months. Natalizumab was discontinued at the patients’ request after the evidence of JCV-antibody at 5 cases (examined for the first time) average number of infusions 17. Seroconversion was recorded in 4 patients by an average of 33 infusions (23–48).

doi:10.1016/j.jns.2013.07.1497
Results: The course of washout (average duration of 3.3 months) was different in individuals. An uncomplicated course of a 3-month washout was recorded in 2 ill. Between the 2nd and 3rd month of washout MRI reactivation of MS was observed in 1 patient, 5 patients had relapses, 1 rebound, with actually EDSS 7.0. Except this patient, the others continue the fingolimod treatment with stable clinical course.

Conclusion: Available news from the literature draw attention to shortening the washout despite the increased risks of PML. Practical experience in our small group of the ill supports these tendencies.

New oral treatment designed for clinical stabilization in multiple sclerosis
E. de Font-Réaulx, Centro Neurológico, ABC Medical Center, Methodist International Network, Mexico, Mexico

It is mandatory to have a safe and effective treatment to stop the Multiple Sclerosis’ progression. Previous clinical trials designed to stop MS progression have failed to demonstrate the ideal clinical stabilization and most of them have potential severe adverse effects. We administered to MS patients a new oral treatment to stop its progression. This treatment called Cervô, contains four substances that have effect in controlling the most important known mechanisms of disease progression as: aberrant apoptosis, oxidative damage, mitochondrial degeneration, caspase activation and Mitogen-Activated Protein-Kinase (MAPK) activation, among others. We had previously demonstrated that it is safe to use Cervô in humans. We gave Cervô as monotherapy during the follow-up period to all the patients.

Results: We included 23 patients with MS. Age: 20 to 60 years old (mean 39.6 years, SD +/- 12.81), 16 female (69.6%), 7 male (30.4%). Basal EDSS score: 0–8 (mean 3.0). Follow-up period: 3–67 months (mean 30.35, SD +/- 21.75). No adverse effects were observed.

Clinical evaluation: There was no deterioration in EDSS score in 21 patients (91.30%), and 9 of them (39.13%) improved their basal UPDRS score. The mean EDSS score at 12 months was 2.62 (SD +/- 2.76), at 24 months 2.61 (SD +/- 2.77), and at 46 months 2.71 (SD +/- 2.92). Only 2 patients (8.69%) had worse UPDRS score.

Conclusions: Cervô is a new promising medication that according with this study may stop MS progression in most patients. This needs to be confirmed with a randomized multi-centric study.

Correlation of multiple sclerosis incidence trends with solar and geomagnetic indices: New roadmap for solving the puzzle of multiple sclerosis
S.A. Sajedi*a, F. Abdollahib, aDepartment of Neurology, Ahvaz Jundishapur University of Medical Sciences, Ahvaz, Iran; bDepartment of Internal Medicine, Ahvaz Jundishapur University of Medical Sciences, Ahvaz, Iran

Background: Recently, we introduced solar related geomagnetic disturbance (GMD) as a potential environmental risk factor for multiple sclerosis (MS). We showed that it can describe MS prevalence distribution better than other geophysical factors and can explain special MS features such as birth month effect, relapsing–remitting nature and migration effect.

Objective: To test probable correlation between solar activities and GMDs with long-term variations of MS incidence.

Materials and methods: We studied the association between alternations in solar wind velocity ($V_{SW}$) and Planetary A index ($A_p$; a GMD index) with previously published data of MS incidence trend in Tehran by Elhami et al. and western Greece by Papathanasopoulos et al., during the 23rd solar cycle (1996–2008), through an ecological–correlational study. Cross-correlation analyses were used for finding possible lead–lag relationships.

Results: We found strong correlations among MS incidence of Tehran with $V_{SW}$ ($r_s = 0.665$, $p = 0.013$) with one year delay, and with $A_p$ ($r_s = 0.864$, $p = 0.001$) with 2 year delay. There were very strong correlations among MS incidence data of Greece with $V_{SW}$ ($r = 0.906$, $p < 0.001$) and with $A_p$ ($r = 0.844$, $p = 0.001$) both with one year delay.

Conclusion: For the first time in the history of MS, a hypothesis has introduced an environmental factor that can describe MS incidence variations. Important message of these findings for researchers is to provide MS incidence reports with higher resolution, based on the time of disease onset, not the time of diagnosis. Then, it would be possible to conduct superposed epoch analyses to better investigate the validity of GMD hypothesis.

Geomorphic disturbances may be environmental risk factor for multiple sclerosis: An ecological study of 111 locations in 24 countries
S. A. Sajedi1, F. Abdollahi2, 3Department of Neurology, Ahvaz Jundishapur University of Medical Sciences, Ahvaz, Iran; 4Department of Internal Medicine, Ahvaz Jundishapur University of Medical Sciences, Ahvaz, Iran

Background: We noticed that a hypothesis based on the biological effects of geomagnetic disturbances (GMD) has the ability to explain special features of multiple sclerosis (MS) such as the cause of its relapsing–remitting nature, the birth month effect and migration effect.

Objective: As areas around geomagnetic 60 degree latitude (GM60L) experience the greatest amount of GMD, the easiest way to evaluate our hypothesis was to test the association of MS prevalence (MSP) with “angular distance to geomagnetic 60 degree latitude” (AMAG60) and compare it with the known association of MS with geographical latitude (GL). We did the same with “angular distance to geographic 60 degree latitude” (AGRAPH60) as a control.

Material and methods: 111 MSP data from 1980–2010 published papers were retrieved and entered in the study. By meta-regression analyses, relationship of MSP with GL, AMAG60 and AGRAPH60 was evaluated separately. Models were compared by their adjusted R square (AR2) and standard error of estimate (SEE).

Results: In each continent, AMAG60 had the best correlation with MSP, the largest AR2 and the least SEE. Merging both hemisphere data, AMAG60 explained 56% of MSP variations with the least SEE (R = 0.75, AR2 = 0.56, SEE = 57), while geographic latitude explained 17% (R = 0.41, AR2 = 0.17, SEE = 78.5) and AGRAPH60 explained 12% of those variations with the highest SEE (R = 0.35, AR2 = 0.12, SEE = 80.5).

Conclusions: Results confirmed that AMAG60 is the best descriptor of MSP variations and has the strongest association with MSP distribution. These results supported the fact that GMD may be an environmental risk factor for MS.

The effect of free testosterone on course, severity, disease activity and disability in the patients with multiple sclerosis
A. Nikseresht1, B. Saafpour Lima2, M. Sharifian Dorche2
1Shiraz University of Medical Sciences, Shiraz, Iran; 2Student Research Committee, Shiraz University of Medical Sciences, Shiraz, Iran

Introduction: Sex related difference in the course and severity of Multiple Sclerosis (MS) could be mediated by several sex hormones. This study aimed to investigate the relation between free testosterone concentrations and course, severity, brain damage and disability in Iranian patients with MS.

Methods: 37 women with MS and 25 healthy subjects were included in the study as case and control groups. Free testosterone level was assessed by ELISA method. Brain MRI with and without contrast was performed. Expanded Disability status scale (EDSS) and MS subtypes in the patients were collected via a questionnaire.

Results: Serum testosterone was significantly lower in women with MS than controls (P value: 0.026). The free testosterone levels were not associated with EDSS, MS subtype and MRI findings.

Discussion: The hormone related modulation of pathological changes does not support the hypothesis that sex hormones play a role in the inflammation, damage and repair mechanism in MS, although serum level of these hormones in the patients was significantly lower than controls.

Significant increase in the prevalence of MS in Iran
S. Izadi1, A. Nikseresht2, M. Sharifian Dorche3, M. Sahraian3
1Shiraz University of Medical Sciences, Shiraz, Iran; 2Student Research Committee, Shiraz University of Medical Sciences, Shiraz, Iran; 3Tehran University of Medical Sciences, Tehran, Iran

Introduction: Iran was previously considered to have a low prevalence rate of MS patients, but this rate has significantly changed over time.

Methods: This study was performed on the bases of the new reports of Iran Ministry of Health and Medical education about the patients who registered to receive beta interferon in Iran. Although these data doesn’t show the exact number of the patients with MS in Iran but these information may be considered as the least prevalence rate of these patients in each province.

Results: To the end of 2011, there were 34,605 MS patients who were registered by ministry of health in Iran. With consideration of Iran population in this year prevalence rate is 30.75 per 100,000
populations. 77% of the patients are females. Maximum prevalence rate was seen in Isfahan province (80 per 100,000) at the central parts of Iran and the minimum prevalence rate is seen in Sistan–Baluchestan province (6 per 100,000) which is located in southwest of Iran with a warm and dry climate.

**Discussion:** According to our new information and regarding to the previous studies it seems that the prevalence of MS in Iran and of its provinces is similar to what is seen in western countries.

**Background:** Alexander disease (AxD) is an inherited demyelinating disease that primarily inflicts upon the white matter of the central nervous system (CNS), and is caused by mutation in a gene encoding glial fibrillary acidic protein (GFAP). The pathognomonic feature of AxD is eosinophilic Rosenthal fibers (RFs) in astrocytes.

**Objective:** To develop a new method to determine if identified mutations found in a GFAP gene are disease-causing, because of the difficulty in procuring the CNS tissues from patients.

**Patients and methods:** We found a family with slowly progressive gait disturbance and dysarthria. MR images of the brain showed a marked atrophy of the medulla oblongata and upper cervical cord. Under the provisional diagnosis of adult-onset AxD, DNA sequence analysis of GFAP gene revealed D128N mutation with autosomal dominant transmission. There was no previous report on the formation of RFs in GFAP (D128N) mutant. Therefore, various human GFAP mutants including previously well-known R79C, R79H, R239C or R239H by site-directed mutagenesis were generated and their expression levels in HEK-293T cells by Western blotting were compared. GFAP (D128N) DNA was microinjected into zebrafish embryos.

**Results:** Expression levels of mutant GFAP proteins are comparable to that of wild-type GFAP protein. However, mutant GFAPs including induced more aggregations than wild-type GFAP in zebrafish embryos. Electron microscopy displayed dense osmophilic inclusions in the cells of zebrafish embryos.

**Conclusions:** This finding indicates that D128N is the disease-causing mutation that causes AxD. Therefore, zebrafish can be used as a tool for molecular diagnosis of AxD.

**Acute compressive myelopathy mimicking transverse myelitis**

S.-B. Kwon, H.-J. Park, S.-S. Hong, Y.-K. Minn, S. Jung, S.-H. Hwang, K.-H. Kwon, Neurology, Hallym University College of Medicine, Seoul Hospital, Seoul, Republic of Korea; Radiology, Soonchunhyang University College of Medicine, Seoul Hospital, Seoul, Republic of Korea.

**Background:** Acute compressive myelopathy (ACM) is occasionally associated with fusiform T2 signal changes on MRI. When this occurs, the radiologic appearance can result in misdiagnosis as transverse myelitis, either idiopathic or as a NMO spectrum disorder. This misdiagnosis can delay appropriate surgical referral, and may result in inappropriate treatments.

**Objectives:** To reveal clinical and radiologic findings that facilitate the recognition of surgically treatable ACM mimicking transverse myelitis.

**Methods:** Consecutive patients with suspected longitudinally extensive transverse myelitis (LETM) were enrolled during a 5-year period. Among these LETM patients, we ultimately identified ACM by determining that lesions were caused by compressive myelopathy due to cervical spondylotic lesion. We reviewed all clinical and radiologic data of the ACM patients.

**Results:** We identified 8 patients with ACM from a total of 26 suspected LETM patients. The mean age of symptom onset was 55.6 ± 9.4 years in the ACM. 7 of ACM patients (87.5%) were men (P = 0.09). All 8 ACMs were treated with intravenous corticosteroids. 1 of ACM patients experienced improvement (P = 0.001). No ACM patient had recurrence. ACM showed limited lateral or posterior patterns (P = 0.014), more upper cervical cord involvement (P = 0.004), and multiple lesions (P = 0.014) than those of LETM. Focal contrast enhancement was identified in all ACM patients, and occurred at the point of maximal focal stenosis. These characteristic enhancement findings were not observed in LETM group.

**Topic: 6 — MS & Demyelinating Diseases**

**Relapsing Devic disease treated with rituximab (case discussion)**

A 33 year old Libyan lady presented with left eye blurred vision 13 months ago which was remitted within 1 week after oral steroid usage. 3 months later she got bilateral lower limb numbness & paraesthesia followed by weakness, urinary retention & unsteadiness & those symptoms were cured partially after usage of IV steroids, then 2 months later she got severe neuropathic pain & allodynia all over the body with bilateral lower limb numbness which was cured partially after usage of IV steroids & oral pregabalin, clinically she has ataxic paraparesis with brisk reflexes all over the body & bilateral lower limb hypesthesia and allodynia up to the level of D4, with positive Lhermitte sign.

**Investigations:** MRI cervicodorsal spine showed single long continuous enhancing cord lesion extending from D4 to D12 (which is going with Devic disease) with another 2 small ovoid cervical spine lesions which are going with Multiple Sclerosis. MRI brain showed 5 white matter demyelinating lesions in the brain 4 of them disappeared after steroids. CSF Aquaporin 4 Antibodies were negative as well as the CSF oligoclonal bands, with normal CSF IgG index. VEP showed delayed p100 response on the left eye.

**BSEP was normal.**

**Treatment:** She has been treated with full course of IV rituximab with excellent improvement clinically & radiologically.

**Conclusion:** The patient has relapsing remitting neurologic disease with changing MRI brain lesions & continuous enhancing dorsal spine lesion extending from D4 to D12 which is suggestive of relapsing Devic disease in spite of negative CSF Aquaporin 4 Antibodies.
Conclusion: The above characteristic clinical and radiologic findings may distinguish ACM from inflammatory myelopathies such as LETM and have therapeutic implications.

Antiretroviral treatment in patient with secondary progressive multiple sclerosis — Impact on disease progression and safety

H. Maruszak, J. Gold, G. Giovannoni. The Albion Centre, Prince of Wales Hospital, Sydney, NSW, Australia; The Blizzard Institute, Centre for Neuroscience and Trauma, Queen Mary University of London, London, UK

A 58-year-old white female with multiple sclerosis was treated with antiretroviral therapy (ART) of raltegravir and lamivudine. Over two years prior to the commencement of ART the patient reported progressive worsening of weakness in right arm and legs requiring use of a walking stick, burning sensations in limbs and persistent fatigue. MRI showed areas of demyelination in the spine but without involvement of the brain. CSF analysis showed oligoclonal IgG bands. The patient was treated with interferon beta for seven years but it was stopped due to disease progression. No other disease modifying therapy had been used.

Methods: Neurological examination, EDSS, Multiple Sclerosis Functional Composite (MSFC), Multiple Sclerosis Quality of Life Inventory (MSQU) and blood safety parameters were performed at baseline then monthly over six months of treatment. Z-scores for MSFC and MSQU were calculated and adjusted to reference population.

Results: There was no significant change from baseline in the EDSS, MSFC and MSQU scores. There were no side effects of ART reported by patient or detected by blood safety parameters. The patient reported marked improvement in fatigue during the first two months of treatment.

Conclusions: ART in this patient was safe and may have stabilising impact on disease progression and quality of life. A possible mode of action of ART in MS includes suppressive effect on MS-associated Human Endogenous Retrovirus and herpes viruses triggering MS. This is the first case of patient with MS receiving antiretroviral therapy with formal evaluation of disease progression and safety.

Polarization of macrophages and T cells to anti-inflammation in EAE mice treated with Fasudil

C.-G. Ma, C.-Y. Liu, J.-Z. Yu, Y.-H. Li, H.-F. Zhang, M.-F. Guo, L. Feng, J.-J. Huang, B.-G. Xiao. Department of Encephalopathy and National Major Clinical Department of Ministry of Health, Third Hospital, Shaxi University of Traditional Chinese Medicine, Taiyuan, China; Institute of Brain Science, Department of Neurology, Medical School, Shaxi Datong University, China; Department of Neurosurgery, First Hospital, Datong Coalmine Hospital, Datong, China; Institute of Neurology, Huashan Hospital, Shanghai Medical College, and Institutes of Brain Science, Fudan University, Shanghai, China

Background: Macrophages play paradoxical roles in the pathogenesis of neurological disorders, exerting both inflammatory M1 and anti-inflammatory M2 phenotypes. However, besides macrophages, the dynamic balance between effector Th1/Th17 and Treg cells also regulates the development and improvement of diseases.

Objective: To observe the therapeutic effect of Fasudil on EAE, and explore its mechanisms.

Material and methods: Mouse EAE was induced by MOG35–55 immunization and passive transfer of primed lymphocytes treated with Fasudil in vitro.

Results: Fasudil significantly ameliorated the clinical severity of EAE, and decreased the expression of CD4 and CD68 in spinal cords, accompanied by an improvement of demyelination and inhibition of inflammatory cells in both active and passive EAE models. Fasudil shifted inflammatory M1 to anti-inflammatory M2, being shown by inhibiting the expression of F4/80CD16/32, F4/80MHC-II, and F4/80P2X7 and the production of NO as well as increasing the expression of F4/80CD200 and F4/80IL-10 and activity of Arg-1. Simultaneously, Fasudil significantly downregulated CD4+IFN-γ and CD4+IL-17 and upregulated CD4+IL-10 in Fasudil-treated T cells which were delivered into animals via adoptive transfer. The polarization of M2 macrophages may be associated with the decrease of inflammatory cytokines IL-6 and TNF-α and the increase of anti-inflammatory cytokine IL-10.

Conclusion: Using a passive transfer model, we find that MOG-primed cells treated with Fasudil in vitro did not trigger EAE generation by controlling the specific polarization of macrophages and T cells, which may represent a therapeutic opportunity for treatment of MS. This study was supported by National Natural Science Foundation of China (81272163).

Perception of muscular effort in multiple sclerosis

A. Kiselka, A. Greisberger, M. Heller. Day Care Center for Multiple Sclerosis, Caritas Socialis, University of Vienna, Vienna, Austria; Department of Health Sciences, FH Campus Vienna, Australia; Centre for Sport Science and University Sports, University of Vienna, Vienna, Austria

Background: Resistance exercise is effective in improving muscle strength and preventing muscle weakness in multiple sclerosis (MS) patients. Control of resistance training intensity based on perceived muscular effort is applicable to healthy individuals, yet there is no evidence of its utility for MS patients.

Objective: To compare perception of muscular effort in MS patients to healthy controls.

Material and methods: Based on their perception of muscular effort, twenty-five MS patients and twenty-eight controls adjusted static elbow extension tasks according to five levels on the OMNI-Resistance Exercise Scale. Elbow extension strength and muscle activity were measured via load cell dynamometer and surface electromyography (EMG) and related to each participant’s maximal voluntary contraction (MVC) strength and muscle activity. Two-way analysis of variance was used to evaluate statistical significance.

Results: There were no statistically significant differences between MS patients and healthy controls, they produced similar relative torque values (F1 = 0.196; p > 0.05) and extensor muscle activities (F2,617 = 1.556; p > 0.05) across all effort levels.

Conclusion: No differences were found in the perception of muscular effort in MS patients and the age-matched control group. Future studies should explore, whether rating of perceived exertion is an effective instrument to control resistance training intensity in MS patients.

Postural orthostatic tachycardia syndrome associated with multiple sclerosis
L. Adamec, M. Lovric, D. Zaper, A.K. Barusic, I. Bach, A. Mismas, M. Habek. UHC Zagreb, Zagreb, Croatia; aUniversity Hospital Center Zagreb, Zagreb, Croatia

Background: Postural orthostatic tachycardia syndrome (POTS) is an autonomic disorder characterized by an exaggerated increase in heart rate that occurs during standing, without orthostatic hypotension.

Objective: The aim of this study was to determine if there is a difference in the frequency of postural orthostatic tachycardia syndrome (POTS) in patients with multiple sclerosis (MS) compared to patients with symptoms of orthostatic intolerance and with no evidence of MS or other neurological illness.

Methods: We analyzed data gathered from 293 (112 with MS and 181 without MS) patients who underwent the head-up tilt table test protocol. If POTS was identified the head-up tilt table test was repeated and supine and standing serum epinephrine and norepinephrine were determined.

Results: POTS was identified in 39 patients: 21 (19%) in the MS group compared to 18 (10%) in the non-MS group ( p = 0.035). There was no difference between groups in the occurrence of POTS associated syncope ( p = 0.52). There was no difference between groups in the epinephrine or norepinephrine in supine and standing positions. While both standing epinephrine and norepinephrine levels were significantly higher compared to laying levels in the non-MS group, only standing norepinephrine levels were significantly higher in the MS group.

Conclusions: The results of this study suggest that POTS is associated with MS.

Pathogenetic role of T helper 17 cells and cytokines in Guillain–Barré syndrome
H. Zhang, X. Wang, J. Zhu, aDepartment of Neurology, First Hospital, Jilin University, Changchun, China; bKarolinska Institute, Stockholm, Sweden

Background: The role of T helper (Th)17 cells, a newly found Th cell subset, has been scarcely studied in Guillain–Barré syndrome (GBS). Emerging evidence points to a pathogenetic role of Th17 cells in GBS.

Objective: To further clarify the roles of these Th 17 cells and cytokines in the pathogenesis of EAN.

Materials and methods: The EAN model was induced by immunizing animals with P0 protein peptide 180–199 together with complete Freund’s adjuvant and pertussis toxin. The dynamic expression of Th1/Th2/Th17/Treg cells and cytokines in GBS and EAN was studied.

Results: The clinical signs of IFN-γ KO mice were significantly more severe than those of WT controls, along with higher proliferation of splenic mononuclear cells in KO mice. At the peak of EAN, the proportion of IL-17A-expressing cells in cauda equina (CE) infiltrating cells, and the levels of IL-17A in sera were elevated in IFN-γ KO mice. We further investigated Th17 cells and IL-17A in GBS patients. Circulating Th1, Th17 and Th22 cells were significantly increased in GBS patients during the acute phase. Moreover, CSF and plasma levels of IL-17A and IL-22 were also elevated. The levels of Th17 cells and IL-17 from CE infiltrating cells and splenic mononuclear cells as well as in serum paralleled the disease evolution. Compound 1, a synthetic compound that can specifically block the production of Th17 cells, suppressed the severity of EAN.

Conclusion: Th17 cells are a neuritogenic T helper cell subset in GBS and EAN.

Auditory evoked potentials and vestibular evoked myogenic potentials in evaluation of brainstem lesions in multiple sclerosis
M. Krbot Skoric, A. Ivankovic, V. Nesek Madaric, K. Starcevic, T. Gabelic, I. Adamec, M. Habek. aUniversity Hospital Center Zagreb, Zagreb, Croatia; bUniversity Clinical Hospital Mostar, Mostar, Bosnia and Herzegovina

Objective: The aim of this study was to determine the role of magnetic resonance imaging (MRI), auditory evoked potentials (AEP) and vestibular evoked myogenic potentials (VEMP) in the evaluation of brainstem involvement in multiple sclerosis (MS).

Patients and methods: Altogether 32 patients with the diagnosis of MS participated in the study. The following data was collected from all patients: age, gender, Expanded Disability Status Scale (EDSS) score, brainstem functional system score (BSFS) (part of the EDSS evaluating brainstem symptomatology), and involvement of the brainstem on the brain MRI. AEP and ocular VEMP (oVEMP) and cervical VEMP (cVEMP) were studied in all patients.

Results: BSFS, MRI, AEP, oVEMP and cVEMP involvement of the brainstem was evident in 9 (28.1%), 14 (43.8%), 7 (21.9%), 12 (37.5%) and 10 (31.0%) patients, respectively. None of the test used showed statistically significant advantage in the detection of brainstem lesions. When combining oVEMP and cVEMP 18 (56.3%) patients showed brainstem involvement. This combination showed brainstem involvement in greater percentage than BSFS or AEP, with statistical significance (p = 0.035 and p = 0.007, respectively).

Conclusion: VEMP is a reliable method in detection of brainstem involvement in MS. It is comparable with MRI, but superior to clinical examination or AEP.

Knowledge and attitude assessment of Iranian patients with MS receiving interferon beta
R. Abolfazli, A. Elyasi, M. Javadi, K. Gholami, H. Torkamandi, S. Samadzadeh. Tehran University of Medical Sciences, Tehran, Iran

Background: There are few studies on patient knowledge in multiple sclerosis (MS), and there are only three published questionnaires. The purpose of this study was to describe MS patients’ understanding of their treatments. Consequently, to provide guidance for developing educational programs for MS patients.

Method: A total of 425 randomly selected MS patients participated in this survey (response rate 85%). The knowledge levels of correctly using IFN beta and their attitude towards some aspects of medical care were measured using self-reported questionnaires which consisted of 25 items with validity of multidisciplinary panel and
pre-testing on 20 patients. The data were analyzed using descriptive statistical methods.

**Results:** Acceptably, knowledge and attitude internal consistency (Cronbach’s alpha = 0.73, 0.71) and content validity were established. MS patients’ knowledge of treatment with IFN beta was very low, however their attitudes were at a very high level. Female patients, self-injection ability, the higher educational level, normal functional status, longitudinal delay from the start of diagnostic workup to definite diagnosis, and being younger were related to higher level of knowledge. Attitude was associated with functional status, family history of disease and the summary of knowledge variable (positive association).

**Conclusion:** Low levels of patients’ knowledge disclose their needs for developing educational interventions, with considering key role of some other important factors on patients’ attitude.

Cerebral hemodynamic changes in head-up tilt test in patients with orthostatic hypotension, postural orthostatic tachycardia syndrome and other orthostatic intolerance

K.J. Shin*, J.K. Kim†. *Department of Neurology, Haeundae Paik Hospital, Inje University, Busan, Republic of Korea; †Department of Neurology, Dong-A University, College of Medicine, Busan, Republic of Korea

Orthostatic hypotension (OH) and paroxysmal orthostatic tachycardia syndrome (POTS) are the common causes of orthostatic intolerance (OI). However the hemodynamic changes of cerebral blow in head-up tilt (HUT) test were not well known. The purpose of this study is to compare the cerebral hemodynamics in HUT test among patients with OH, POTS and other OI without OH and POTS (OII). Two hundred and forty-three patients, who complained of orthostatic intolerance, were enrolled in this study. All patients performed the HUT test. Heart rate, blood pressure, and blood flow velocity (BFV) of the middle cerebral artery of the dominant hemisphere were obtained during supine position, just after and every one minute for 10 minutes after 80° HUT. Thirty-eight patients were included in group with OH, 28 patients group with POTS, and the other 117 patients group with OII. We calculated the critical closing pressure (Pcrit), CPP, and CVR between baseline and HUT were compared. The BFV were significantly decreased after HUT in all three groups, however the changes of BFV were not significantly different among three groups. The CPP and CVR were significantly decreased during head-up tilt in OH, however the MAP and CPP were decreased during HUT in OH, the CVR was also decreased, which showed the operation of cerebral autoregulation.

Sampling of the myelinated fibers for morphometric studies: How much is enough?

F.B.C. Silveira, L.S. Sanada, V.P.S. Fazan. Department of Neuroscience and Behavioral Neurosciences, School of Medicine of Ribeirão Preto, Ribeirão Preto, Brazil

Background: There is no documented consensus if there is a sampling method that reproduces with reliability the complete evaluation of the endoneural space of a determined nerve.

Objective: To investigate the viability of myelinated fiber sampling in normal nerves and on aging.

Methods: Female Wistar rats, aged 3, 6, 12, 18 and 24 months (N = 6 per group) had their right sural nerves prepared for epoxy resin embedding and light microscopy analysis. Myelinated fiber morphometry was performed with the KS-400 software and the sampling method consisted in the morphometric analysis of 30%, 50% and 70% of the microscopic frames generated from the fascicle and automatically selected by the software.

Results: Myelinated fibers and respective axons increased in size with aging, reaching the highest values at age 360 days. Assessment of 70% of the images showed no difference in average values or the histograms

Background and objective: It has been demonstrated that progranulin (PGRN) is a neurotrophic factor that enhances neuronal survival and axonal growth. Several lines of evidence have indicated that PGRN plays a role in the pathomechanism of amyotrophic lateral sclerosis (ALS). So far studies of ALS skin have shown unique pathological and biochemical abnormalities. The lack of bedsore formation in ALS patients is considered characteristic. However, there has been no study of PGRN in ALS skin.

Patients and methods: We made a quantitative immunohistochemical study of the expression of PGRN in the skin from 18 patients with sporadic ALS and 13 control subjects.

Results: Immunohistochemistry for PGRN demonstrated cytoplasmic activity in the epidermis and in some blood vessels and glands. Numerous PGRN-positive (PGRN+) cells were observed in the epidermis in ALS patients, which became more marked as ALS progressed. On the other hand, PGRN+ cells of the epidermis, dermal blood vessels and glands in control subjects showed a weak positive reaction. PGRN immunoreactivity of PGRN+ cells was markedly positive in the epidermis in ALS patients. The proportion of PGRN+ cells in the epidermis in ALS patients was significantly higher (p < 0.001) than in controls. There was a significant positive relationship (r = 0.83, p < 0.001) between the proportion and duration of illness in ALS patients.

Conclusion: These data suggest that changes of PGRN in ALS skin are related to the disease process and that metabolic alteration of PGRN may take place in the skin of patients with ALS.

Decreased amount of collagen in the skin of amyotrophic lateral sclerosis in the Kii Peninsula of Japan

T. Tsukie, S. Ono. Department of Neurology, Teikyo University Chiba Medical Center, Ichihara, Japan

Background: The Kii Peninsula of Japan, together with Guam and West New Guinea, has one of the highest incidences of amyotrophic lateral sclerosis (Kii ALS) in the world. There is a controversy whether the etiology is the same or not between sporadic ALS and Kii ALS. Skin studies from patients with sporadic ALS have shown unique pathological and biochemical abnormalities. However, there has been no report of collagen content of the skin of Kii ALS patients.

Objective: To measure collagen contents of the skin from Kii ALS patients.

Patients and methods: The skin tissues from 7 Kii ALS patients and 12 controls were studied by electron microscopy and their collagen contents were examined.

Results: On electron microscopy the most conspicuous finding in Kii ALS was the smaller diameter of collagen fibrils. The longer the duration of Kii ALS, the more marked these findings were. The collagen content per dry weight (mg) of the samples in Kii ALS was significantly decreased (p < 0.001) than in controls. There was a significant negative correlation (r = −0.88, p < 0.001) between the collagen content and duration of illness in the Kii ALS patients, but there was no such correlation in controls.

Conclusion: These results indicate that the metabolism of skin collagen might be affected in the disease process of Kii ALS.

Immunohistochemical studies of angiogenin in the skin of patients with amyotrophic lateral sclerosis

K. Higashida, S. Ono. Department of Neurology, Teikyo University Chiba Medical Center, Ichihara, Japan

Background: Angiogenin (ANG) is a member of the ribonuclease superfAMILY which is implicated in angiogenesis. ANG maintains normal
vasculature and thereby protects motor neurons from various stress conditions. It is suggested that ANG may play a role in the pathomechanism of amyotrophic lateral sclerosis (ALS). However, there have been no studies of ANG in ALS skin.

Objectives: To make an immunohistochemical study of ANG in the skin of ALS patients.

Patients and methods: We made a quantitative immunohistochemical study of the expression of ANG in the skin from 20 patients with sporadic ALS, 20 patients with other neurologic or muscular disorders (control group A), and 20 patients without neurologic or muscular disorders (control group B).

Results: The nuclei of the epidermal cells showed a weak ANG immunoreactivity in ALS patients. These findings became more marked as ALS progressed. On the other hand, the nuclei in control groups A and B show a strong positive reaction. The optical density for ANG immunoreactivity of the nuclei in the epidermal cells in ALS patients was significantly lower (p < 0.001) than in control groups A and B. There was a significant negative relationship (r = −0.82, p < 0.001) between the optical density for ANG immunoreactivity of the nucleus and duration of illness in ALS patients.

Conclusion: These data suggest that changes of ANG in ALS skin are related to the disease process and that metabolic alterations of ANG may take place in the skin of ALS patients.

The role of cervical and ocular vestibular evoked myogenic potentials in the follow-up of vestibular neuronitis
I. Adamec, M. Krbot Skoric, J. Handzic, A.K. Barusic, I. Bach, T. Gabelic, M. Habek. UHC Zagreb, Zagreb, Croatia

Background: Vestibular evoked myogenic potentials (VEMP) are used in the assessment of patients with vestibular neuronitis (VN). Objectives: The aim of this study was to evaluate recovery of vestibular nerve function after superior vestibular neuronitis (VN) by vestibular evoked myogenic potentials (VEMP).

Methods: Twenty-six patients with the diagnosis of VN were included in the study. All patients underwent ocular VEMP (oVEMP) and cervical VEMP (cVEMP) recordings, at six days and six months from onset of symptoms.

Results: Of the 26 patients, 14 showed improvement on oVEMP at month 6 (group 1), and 12 showed worsening on oVEMP at month 6 (group 2). At the same time there was no change in the amplitudes of the cVEMP on neither healthy nor affected sides in both groups. Inability to perform Fukuda test and chronic white matter supratentorial lesions present on brain MRI were more frequent in patients with worse outcome on oVEMP (p = 0.044 and 0.045, respectively). While involvement of the inferior branch of the vestibular nerve was not associated with oVEMP outcome, oVEMP latencies (N10 and P13) were associated with improvement or worsening of oVEMP amplitudes, showing that prolonged latencies correlate with 6 month improvement in oVEMP amplitudes (Pearson correlation −0.472, p = 0.041 and Pearson correlation −0.580, p = 0.009, respectively).

Conclusion: This study identified clinical, MRI and neurophysiological predictors of recovery in patients with superior VN and offers additional insight in better understanding the role of VEMP in diagnosis and prognosis of VN patients.

Ischemic neuropathy in patients with peripheral arterial occlusive disease
KJ Shin1, J.K. Park2. 1Department of Neurology, Haeundae Paik Hospital, Inje University, Busan, Republic of Korea; 2Department of Surgery, Haeundae Paik Hospital, Inje University, Busan, Republic of Korea

Peripheral arterial occlusive disease (PAD) is not only just a vascular disease but also a neuropathy and a myopathy. The neuropathy and myopathy in PAD may occur as a result of ischemic insult caused by arterial occlusion. We prospectively investigated the neurological and electrophysiological assessment to define the ischemic neuropathy and which factors affect the outcome of neurological and electrophysiological parameters in PAD. A total of thirty-two PAD patients (68.9 and their sixty-four lower limbs were enrolled. Primary outcomes were neurologic symptoms score (NSS) and neurological disability score (NDS) of lower extremities. Secondary outcomes were the data of nerve conduction study (NCS) of lower extremity — sensory nerve action potential (SNAP) amplitude and compound muscle action potential (CMAP) amplitude. The NSS and NDS of 64 lower limbs were 2.43 +/- 1.77 and 6.9 +/- 7.44. Age and Fontaine classification were positively correlated and weight, BMI and ABI were inversely correlated with NSS and NDS. Height inversely correlated with NDS. Patients with female sex and distal arteries occlusion below knee showed increased NSS and NDS. Diabetes was associated with increased NDS and hypertension was associated with increased NSS. Age and Fontaine classification were positively correlated and weight and BMI were inversely correlated with SNAP amplitude of sural, superficial peroneal and medial plantar nerves and CMAP amplitude of posterior tibial and common peroneal nerves. Diabetes patients showed more decreased SNAP and CMAP amplitude than non-diabetes patients. Hypertension patients showed decreased CMAP amplitude in only common peroneal nerve. NDS and NCS could be good indicator to assess the ischemic neuropathy in PAD.

OX40-OX40L expression in idiopathic inflammatory myopathies
C. Papadopoulos, G.K. Papadimas, G. Terzis, E. Mastoroglou, P. Manta. University of Athens, Athinaia, Greece

Background: The idiopathic inflammatory myopathies constitute a heterogeneous group of autoimmune diseases of skeletal muscle. OX40, member of the tumor necrosis factor receptor/tumor necrosis factor superfamily costimulatory molecules and its ligand, OX40L, are linked with the development of various autoimmune diseases.

Objectives: To examine whether both OX40 and its ligand OX40L are expressed in idiopathic inflammatory myopathies and to investigate the types of inflammatory cells expressing OX40L.

Materials and methods: Immunohistochemistry was performed in limb muscle specimens from dermatomyositis, polymyositis and inclusion body myositis patients to analyze the expression of OX40 and its ligand OX40L. Double immunofluorescence labeling was performed to clarify the phenotype of inflammatory cells expressing OX40L.

Results: OX40 and OX40L expressing cells were observed in all subsets of inflammatory myopathies following a similar pattern of distribution. In polymyositis and inclusion body myositis inflammatory cells expressing the receptors invaded non-necrotic muscle fibers. OX40L expression was also found in endothelial blood cells in all dermatomyositis and some
polymyositis specimens. In all subsets of inflammatory myopathies, OX40L was expressed by T cells (CD4+ and CD8+), macrophages (CD68+), B-cells (CD20+) and myeloid dendritic cells (BDCA1+). Plasmacytoid dendritic cells (BDCA2+) expressing OX40L were only found in dermatomyositis and polymyositis. 

**Conclusions:** The simultaneous expression of both OX40 and its ligand OX40L in idiopathic inflammatory myopathies suggest that they might participate in disease pathogenesis. Expression of OX40L by different types of cells within the inflamed muscle implies that OX40–OX40L interaction may contribute in disease mechanisms through different pathways.

Chilhood onset familial nemaline rod myopathy: A report of two siblings

G. Sharma, S. Sood. Department of Physiology, University of Health Sciences, Rohtak, India

**Objectives:** Nemaline myopathy (NM) is an uncommon disorder with no inclusions known as nemaline bods/rods presence in muscle fibers. Muscle weakness and hypotonia are apparent from the neonatal period. We report a rare presentation of NM seen in two siblings with similar symptoms. Both had slender physique, delayed motor milestones including delayed walking, normal language and cognitive milestones and difficulty in fast movements and change of posture. They had slowly progressive weakness. There was positive family history.

**Methods:** Investigations included CK levels, motor-sensory conduction velocities, EMG studies, Muscle biopsy, MGT (Modified Gomori's Trichrome) stain and histo-chemistry studies.

**Results:** CK levels were raised (279 U/l) with myopathic pattern of EMG with decreased motor unit potentials, recruitment with markedly decreased amplitude; mild decrease in motor conduction velocity in tibial–peroneal nerves in both with decreased ulnar nerve sensory conduction velocity in the girl and positive muscle biopsy. Both were diagnosed as Nemaline Rod myopathy.

**Conclusion:** Nemaline myopathy should be suspected in children with generalized hypotonia and progressive muscle weakness along with delayed motor milestones. This report highlights the importance of EMG & conduction velocity studies along with histo-chemistry & ultrastructural examination in diagnosis of NM in absence of availability of genetic studies.

Subacute progressive ophthalmoplegia associated with dermatomyositis

S. Kong1, T. Buna1, T. Terada2, B. Konishi2, K. Shirakawa2, H. Miyajima3. 1First Department of Medicine, Hamamatsu University School of Medicine, Hamamatsu, Japan; 2Molecular Imaging Frontier Research Center, Hamamatsu University School of Medicine, Hamamatsu, Japan

**Background:** Dermatomyositis is a systemic autoimmune disorder that primarily affects the skin and the proximal groups of limb muscles. Extraocular muscle involvement is a very rare manifestation of dermatomyositis. 

**Objectives:** Pathogenesis of ophthalmoplegia in the dermatomyositis patient is investigated.

**Patient and method:** The patient was a 53-year-old Japanese male who presented with myalgia and difficulty in climbing stairs. He developed progressive diplopia with eyelid edema and ocular pain two weeks after presentation. A femoral muscle biopsy and MRI scans of extracocular muscle and response of corticosteroid therapy were investigated.

**Results:** The physical examination revealed the presence of Gottron's papules on the dorsal surface of the hands, and a neurological examination showed symmetrical weakness of the proximal muscles, including the upper limbs muscles, and bilateral ophthalmoplegia with total limitations of eye movements. A muscle biopsy showed perifascicular atrophy with CD4 and CD8 positive lymphocyte infiltration into the interfascicular septae and within the fascicles. Orbital MRI scans revealed an increased thickness and high intensity signals of the extracranial muscles on T2-weighted images suggesting myositis. Corticosteroid therapy improved the muscle weakness, ophthalmoplegia and abnormal MRI findings. No myositis-specific autoantibodies, including anti-endothelial, -tRNA synthetases or anti-signal recognition particles were detected in the serum.

**Conclusion:** The pathogenesis of ophthalmoplegia in the patient may be associated with inflammatory process of orbital muscles because of the orbital MRI images showing increased muscle thickness with abnormal intensity signal and dramatic efficacy of the steroid therapy on the ophthalmoplegia and abnormal MRI images.

Guillain–Barré-like syndrome, as a rare presentation of adult T-cell leukemia-lymphoma: A case report

A. Moghadam-Ahmadia, B. Sasannejad, M. Azarpazhooh, A. Mellat-Ardekani. 1Neurology Department, Clinical Research Development Centre, Rafsanjan University of Medical Sciences, Rafsanjan, Iran; 2Neurology Department, Mashhad University of Medical Sciences, Mashhad, Iran; 3Neurology Department, Yazd University of Medical Sciences, Yazd, Iran

**Background:** Guillain–Barré syndrome is an acute symmetric inflammatory polyradiculoneuropathy which commonly begins after an acute infectious process, immunization, or surgery. It has also been reported in association with some malignancies including lymphoma, small cell lung cancer and leukemia, but not as the primary presentation of Adult T-cell Leukemia/Lymphoma (ATLL) that is a non-Hodgkin T-cell Lymphoma linked to infection by the human T-cell lymphotropic virus type 1 (HTLV-1). The HTLV-1 has been endemic to certain parts of Iran like Khorasan province in the northeast since 1985 with 2.3% prevalence rate of infection. Thus, some rare neurologic complications due to this infection occasionally occur in this area that is worth to be reported.

**Case report:** In March 2009, a 21-year-old woman was admitted to Qa'em Hospital neurology ward in Mashhad having unilateral facial paresis and then developed progressive ascending flaccid tetraparesis with generalized areflexia. Electrodiagnostic studies revealed acute motor axonal polyradiculoneuropathy (variant of Guillain–Barré syndrome). Further evaluations revealed severe leukocytosis, increased erythrocyte sedimentation rate, increased protein content and presence of several lymphocytes in cerebrospinal fluid, and then the presence of HTLV-I in serum and cerebrospinal fluid. Finally, biopsy of the enlarged lymph nodes resulted in the diagnosis of ATLL.

**Conclusion:** This case describes an extremely rare presentation of ATLL with a Guillain–Barré-like syndrome. Thus, in patients with manifestations resembling Guillain–Barré syndrome, it is important to consider...
all the possible etiologies that can lead to this syndrome, and especially this is of value for diseases that are rare, but endemic, in specific geographic regions.

Dilated cardiomyopathy in Becker muscular dystrophy
P.C. Ijes, A. Aquino, M. Ronald, J.D. Magno. 4Department of Adult Cardiology, Philippine Heart Center, Quezon City, Philippines; 5Department of Neurology, Philippine Heart Center, Quezon City, Philippines; 6Department of Adult Cardiology, Invasive Cardiology, Philippine Heart Center, Quezon City, Philippines; 7Non-Invasive Cardiology, Philippine Heart Center, Quezon City, Philippines

Background: Becker Muscular Dystrophy (BMD) was first described in 1955 by a German Neurologist and Geneticist, Peter Emil Becker (1908–2000). The incidence of this rare X-linked muscular dystrophy is 3 in 100,000 live male births. The most common cardiac presentation is cardiomyopathy (occurs in 50% of cases) and conduction disorders. In the archives of the Philippine Heart Center, the most common etiology of dilated cardiomyopathy was found to be ischemic (59% of cases). In the same study, a non-ischemic cause of dilated cardiomyopathy was found in 41% of cases with following etiologies: idiopathic (77%), alcoholic (13%), myocarditis (2%) and peripartum (4%). Cardiomyopathy from BMD was rarely encountered.

Case: This is a case of a 27 year-old male who was diagnosed with BMD during his childhood. He developed gradual progressive muscle weakness with decrease in basal functional capacity. Diagnosis of dilated cardiomyopathy was based on the clinical and echocardiographic findings. He was later admitted due to ventricular tachycardia.

Diagnositics: The chest X-ray showed cardiomegaly with an increased cardiothoracic ratio. There was markedly elevated CK-MM at 4319 IU/L. Two dimensional echocardiography showed generalized hypokinesia with severely depressed systolic function (EF = 25% by Simpson’s, 22% by Teicholz formula). There was dilated left ventricular cavity (LVMi of 132 g/m2, LVEDD = 6.9 cm) and left atrium (LAVI = 29 ml/m2). The sphericity index was 1.23.

Conclusion: BMD is rare, however the knowledge of the disease progression including the development of cardiomyopathy and conduction disorders (atrial and ventricular arrhythmia) will aid the clinician in the management and enable the anticipation of probable sequelae.

Piriforim syndrome and peroneal H-reflex
C. Kamia, R. Jawish. 4Department of Neurology, Lebanese Hospital Geitawi, Beirut, Lebanon; 5Lebanese University, Sacre Coeur Hospital Baabda, Beirut, Lebanon; 6Orthopedic Department, Sacre Coeur Hospital Baabda, Beirut, Lebanon

Background: The electro-diagnostic studies defining piriformis syndrome was elaborated according to the peroneal H-reflex. The aim is to define electrical criteria with delay in latency and decreased amplitude during stress testing.

Objective: Combined to clinical exam, the peroneal H-reflex at stress testing are considered highly suggestive of piriformis syndrome.

Patients and methods: 19 patients suspected to suffer from piriformis syndrome after ruling out other causes of spinal affection were tested with EMG exam on both sides in neutral and dynamic positions. The amplitude and latency of the H-reflex on the peroneal nerve were studied and compared with the opposite painless side.

Results: The latency of the peroneal H-reflex at the normal side was delayed by 0.7 ms with the stress test. At the painful side, the delay was 5.4 ms, and when we excluded two patients with 2 ms delay confirmed not having piriformis syndrome, the average was 6 ms. The amplitude of the peroneal H-reflex at the normal side was decreased by 14% with the stress test, 70% at the painful side and 74% after excluding patients confirmed not having piriformis syndrome.

Conclusion: Our results confirm the importance of the peroneal H-reflex in diagnosing piriformis syndrome. The delay of latency at stress testing should be considered positive above 3 ms. At the same time the amplitude of the reflex has decreased more than 50% compared with the reflex in neutral position of the limb. Combined to clinical exam, these values are considered highly suggestive of piriformis syndrome.

Correlation between oral corticosteroid therapy and present disease status in myasthenia gravis: A multicenter cross-sectional study in Japan
T. Imai, S. Suzuki, E. Tsuda, Y. Nagane, H. Murai, M. Masuda, S. Kommo, Y. Suzuki, S. Nakane, K. Fujiwara, N. Suzuki, K. Utsugisawa, Japan MG Registry. 4Occupational Therapy, Sapporo Medical University School of Health Science, Sapporo, Japan; 5Neurology, Keio University School of Medicine, Tokyo, Japan; 6Neurology, Sapporo Medical University School of Medicine, Sapporo, Japan; 7Neurology, Hanamaki General Hospital, Hanamaki, Japan; 8Neurology, Graduate School of Medical Sciences, Kyushu University, Fukuoka, Japan; 9Neurology, Tokyo Medical University, Tokyo, Japan; 10Neurology, Toho University Medical Center Oh-hashii Hospital, Tokyo, Japan; 11Neurology, Sendai Medical Center, Sendai, Japan; 12Neurology, Nagasaki Kawai Medical Center, Kawai, Japan; 13Neurology, Tohoku University Graduate School of Medicine, Sendai, Japan

Background: Patients with myasthenia gravis (MG) often do not achieve complete remission without immunotherapy, and many continue to have ADL difficulty due to insufficient improvement and long-term adverse effects of oral corticosteroids.

Objective: The aim of this study was to delineate the status of oral corticosteroid therapy and present MG composite. The aim of this study was to delineate the status of oral corticosteroid therapy and present MG composite.

Methods: We evaluated 676 MG patients from 11 neurological centers. Disease severity was determined according to MGFA, QMG and MG composite. Clinical state following treatment was categorized according to MGFA postintervention status. We also completed the Japanese version of the 15-item MG-specific QOL scale (MG-QOL15-J). Multivariate regression analysis was used to determine the correlation between medication and clinical factors.

Results: Multivariate regression analysis revealed that the worst QMG and MG composite scores for the entire disease period had significant negative effects on the present disease severity. Achievement of minimal manifestation (MM) or better using maximum prednisolone (PSL) dose or reduced PSL dose by 25% or more after adding calcineurin inhibitors had significantly positive effects on the present QMG, MG composite and MG-QOL15-J. The maximum dose and administration period of PSL did not influence present disease severity, but administration period of PSL ≥ 20 mg mg/day had significantly negative effects on the present QOL.

Effect of food on pharmacokinetics of 3,4-Diaminopyridine in rats and healthy volunteers
N. Ishida$^{a,b}$, E. Kobayashi$^c$, R. Matsushita$^b$, K. Komai$^b$.
$^a$Department of Pharmacy, National Hospital Organization Jou Hospital, Kanazawa, Japan; $^b$Graduate School of Natural Science and Technology, Division of Pharmaceutical Sciences, Kanazawa University, Kanazawa, Japan; $^c$Department of Pharmacy, National Hospital Organization Kanazawa Medical Center, Kanazawa, Japan

Background: 3,4-Diaminopyridine (3,4-DAP) is commonly used to treat neuromuscular diseases such as Lambert–Eaton myasthenic syndrome and multiple sclerosis; however, the pharmacokinetics of 3,4-DAP is not well understood.

Objective: We aimed to investigate the effect of food on the pharmacokinetics of 3,4-DAP in rats and humans. In addition, we aimed to study the effect of food on the intestinal absorption of 3,4-DAP in rats.

Material and methods: We administered single 3,4-DAP doses of 10 mg/kg orally or 2 mg/kg intravenously to Wistar male rats ($n=4-7$) and 10 mg 3,4-DAP to healthy volunteers ($n=5$) in the fasting state and after meals. The intestinal absorption rate of 3,4-DAP was estimated by using a in situ closed loop method in rats.

Results: The areas under the serum concentration time curve for 3,4-DAP significantly decrease by food intake, and the corresponding bioavailability values were also significantly decrease from 25.1% ± 4.0% to 12.1% ± 0.8% (mean ± SD; $P<0.01$) in rats. In the healthy volunteers, fasting might have reduced the time to reach the maximum serum concentration ($C_{\text{max}}$) of 3,4-DAP and elevated $C_{\text{max}}$. In situ close loop method, food reduced the intestinal absorption rate of 3,4-DAP by 5–10%.

Conclusion: These studies showed that food intake lowered the absorption of 3,4-DAP. Therefore, the administration of 3,4-DAP without food might be a candidate of improvement of the effect.

Baff (B cell activating factor) can be the clinical marker in myasthenia gravis
W. Sakai$^a$, S. Kanake$^b$, T. Narita$^c$, M. Motomura$^a$, H. Matsuo$^a$, $^a$Department of Neurology, Nagasaki Kawatana Medical Center, Higashisonogi, Japan; $^b$Department of Clinical Research, Nagasaki Kawatana Medical Center, Nagasaki, Japan; $^c$Department of Clinical Neuroscience and Neurology, Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan

Background: Myasthenia gravis (MG) is an antibody mediated disease in which the target autoantigen is the acetylcholine receptor (AChR) at the postsynaptic membrane of the neuromuscular junction. B cell activating factor (BAFF) is the potent B cell survival factor and is necessary for peripheral B cell differentiation and maturation. Excess BAFF promotes the survival and growth of autoreactive B cells. The previous studies have shown that serum BAFF levels in patients with MG are higher than in control subjects. BAFF may play an important role in the pathogenesis of MG.

Objective: To compare serum BAFF levels in patients with AChR antibody positive MG (AChR MG) and muscle specific kinase antibody positive MG (MuSK MG).

Patients and methods: We retrospectively analyzed 14 ocular AChR MG, 31 generalized AChR MG and 25 MuSK MG. We compared the serum BAFF levels with the clinical characteristics among 3 groups.

Results: The serum BAFF levels in generalized AChR MG (1559.6 ± 108.6 pg/mL) were significantly higher than in MuSK MG (568.1 ± 363.3 pg/mL) and ocular AChR MG (598.1 ± 65.9 pg/mL). There was a correlation between the serum BAFF levels and disease severity in AChR MG. The serum BAFF levels of the generalized AChR MG with thymic abnormalities (1536.4 ± 728.8 pg/mL) were statistically higher than the ocular AChR MG.

Conclusion: The serum BAFF levels are increased in patients with generalized AChR MG compared to MuSK MG and ocular AChR MG.

Clinical picture of anti-MuSK-antibody-positive juvenile myasthenia gravis in Japan
R. Nakata$^a$, M. Motomura$^a$, H. Shiraishi$^a$, T. Narita$^a$, T. Yoshimura$^b$, A. Kawakami$^a$, M. Tsujihata$^a$, $^a$Department of Clinical Neuroscience and Neurology, Graduate School of Biomedical Sciences, Nagasaki, Japan; $^b$School of Health Science, Nagasaki University, Nagasaki, Japan

Objective: The present study aimed to determine the characteristics of anti-muscle-specific receptor tyrosine kinase (MuSK)-antibody-positive juvenile myasthenia gravis (JMG) (onset before age 15). Information on JMG is limited, and they are reported to be clinically and immunologically distinct from adult onset myasthenia gravis (MG).

Patients and methods: Four patients were positive for anti-MuSK-antibody among 28 patients collected nationwide from 2006 through 2009 for antibody assay in our institute. We investigated the clinical characteristics and measured IgG subclasses in these patients.

Results: All four patients presented generalized MG with relatively severe clinical course. There were no thymus abnormalities. IgG subclass was dominantly of IgG4 subclass.

Conclusions: The clinical characteristics and clinical course of anti-MuSK-antibody-positive JMG differ from general JMG or adult-onset MG.

Autosomal recessive limb girdle muscular dystrophy: Prospective study and characterisation of 280 cases by immunohistochemistry and immunoblotting
A. Nalini. Department of Neurology, National Institute of Mental Health and Neurosciences, Bengaluru, India

Background: ARLGMD is a common disorder in Southern India due to high consanguinity.

Objective: To study pattern of ARLGMD in India.

Materials and methods: Prospective study of 300 cases seen between February 2010 and October 2012. All suspected cases of ARLGMD

attending the NMD clinic underwent phenotypic characterisation, muscle immunohistochemistry (IHC) and immunoblotting (IB).

Results: 280 cases biopsied, 226 had IHC and 176 of these IB. 54 patients excluded. Consanguinity—45.2%. 200 confirmed to have specific ARLGMD by IHC and/or IB. Commonest form: LGMD2B (82/246—33.3%). Mean age of onset—21.17 ± 6.32 (8–41 years). Mean duration—7.24 ± 5.86 (1–36 years). Mean CK—7966.7 ± 6029.6 IU/L (131–24037). All demonstrated dysferlin deficiency on IHC/IB. Second commonest—LGMD 2I (51/246–20.73%). Mean age of onset—12.64 ± 7.17 (1–29 years). Mean duration—8.54 ± 6.50 (1–27 years) Mean CK—4059.56 ± 3210.8 (211–14667 IU/L). α-DG deficiency by IHC-9, IB-51. Third commonest LGMD2C-F (35/246—14.23%). All confirmed by IHC/IB. Mean age of onset—5.89 ± 3.45 (1–20 years). Mean duration—4.56 ± 2.85 (1–12 years). Mean CK—8888.31 ± 6113.86 IU/L (684–23577). Fourth group—LGMD 2A (25/246—10.16%). Age of onset—15.52 ± 11.18 (2–41 years). Mean duration—9.84 ± 9.33 (2–37 years). Mean CK—2742.58 ± 2144.96 IU/L (286–9018). All confirmed by IB. Fifth group—LGMD 2G (2/246—0.8%). Mean age of onset—12.38 ± 11.35 (5 to 40 years). Mean duration—8.50 ± 6.87 (2–23 years). Mean CK—7189–9253 IU/L (mean ± SD: 2574.4 ± 2847.52). Proximo-distal form with muscle atrophy, calf hypertrophy, foot drop. The course was slow in majority. (mean ± SD: 2574.4 ± 2847.52).

Conclusion: Our study confirms that LGMD 2B is the most common form of ARLGMD among our cohort. Further LGMD21 and 2G have a wider existence and may be among the common ARLGMDs in Indian population.

The importance of follow-up thoracic imaging in myasthenia gravis patients
H. Murai1, K. Utsugisawa2, S. Suzuki3, T. Imai4, Y. Nagane5, M. Masuda6, S. Konno1, Y. Suzuki2, S. Nakane3, J-I. Kirai4, 1Department of Neurology, Kyushu University, Fukuoka, Japan; 2Hanamaki General Hospital, Hanamaki, Japan; 3Keio University School of Medicine, Tokyo, Japan; 4Sapporo Medical University School of Medicine, Sapporo, Japan; 5Tokyo Medical University, Tokyo, Japan; 6Toho University Medical Center Ohashi Hospital, Tokyo, Japan; 7National Hospital Organization Sendai Medical Center, Sendai, Japan; 8National Hospital Organization Nagasaki Kawatana Medical Center, Kawatana, Japan

Background: Approximately 20–30% of myasthenia gravis (MG) patients are accompanied by thymoma. In elderly patients, extra-thymic malignancies are also a matter of concern. Although most MG patients undergo thoracic imaging at the initial diagnosis, the follow-up protocol for thoracic imaging is not clear.

Objective: To elucidate the follow-up status of thoracic imaging in MG.

Patients and methods: From among 676 MG patients in 11 neurological centers, we evaluated 649 patients whose disease duration was over 1 year. The latest thoracic imaging (CT or MRI) after an interval of 1 year or more from the initial scan was evaluated in each case. The rate of abnormal findings and the details of findings in cases without thymoma (group N) and with thymoma (group T) were then investigated.

Results: Thoracic imaging follow-up was performed in 337 (51.9%) of MG patients studied (48.8% in group N, 74.1% in group T). The average interval was 7.3 years in group N and 7.8 years in group T. Abnormal findings were detected in 9.0% in group N and 25.2% in group T. Abnormal findings included breast cancer, swelling of lymph nodes and respiratory system infection in group N, while recurrence or enlargement of thymoma accounted for 76.8% of the abnormal findings in group T.

Conclusion: It is important to keep following up thoracic imaging in MG patients since the rate of abnormal findings is high even 7 years after onset.

The initial electrodiagnostic signs that distinguish acute inflammatory demyelinating polyneuropathy from acute motor axonal neuropathy
C.S.J. Lim1, N. Yuki2, T. Umaphathi4, 1Yang Loo Lin School of Medicine, National University of Singapore, Singapore, Singapore; 2Department of Medicine, Yong Loo Lin School of Medicine, National University of Singapore, Singapore, Singapore; 4Department of Neurology, National Neuroscience Institute, Singapore, Singapore

Background: Guillain–Barré syndrome (GBS) is divided into 2 neurophysiological subtypes, acute inflammatory demyelinating polyneuropathy (AIDP) and acute motor axonal neuropathy (AMAN). The early electrodiagnostic findings of AIDP overlap with AMAN, leading to the latter’s under-diagnosis. Serial nerve conduction studies (NCSs) are more sensitive, but not always feasible.

Objective: To derive diagnostic criteria that distinguish AMAN from AIDP at presentation, by delineating their nascent electrodiagnostic features.

Patients and methods: We used at least 2 serial NCSs to categorise GBS patients into AIDP and AMAN. The initial NCS was scrutinized for features discriminating the 2 subtypes.

Results: Using serial NCSs, 30 GBS patients were divided into 11 AIDP, 14 AMAN, and 5 unclassified cases. The initial NCS, done at median 7 and range 2–14 days, showed prolonged distal motor latency in 7 AIDP and 8 AMAN patients. Six AIDP patients had slowing in non-entrapment sites and 4 had temporal dispersion (TD). Only 1 AMAN patient had these. Slowing at entrapment site was less specific, occurring in 8 AIDP and 3 AMAN patients. Three AIDP patients had conduction block (CB), all with slowing across the block. Seven nerves in 5 AMAN patients had CB, 5 without slowing.

Conclusion: The most specific initial signs of AIDP were slowing in non-entrapment sites and TD. CMAP reduction in at least 2 nerves without TD or slowing at non-entrapment sites and non-slowing CB predict AMAN. Using these features, 22 out of 30 patients were assigned to the right GBS subtypes; current criteria were correct in 14 patients.

LGMD2I: Immunohistochemical and immunoblot technique assisted identification of 51 cases with both duchenne and becker phenotype
S. Modi1, A. Nalini2, N. Gayathri2, M.S. Bharathi2, B. Sunitha2, K. Polavarapu3, 1Department of Neurology, NIMHANS, Bengaluru, India; 2Department of Neuropathology, NIMHANS, Bengaluru, India; 3Department of Neurochemistry, NIMHANS, Bengaluru, India

Background: LGMD2I is caused by mutations in fukutin-related protein gene (FKRP).

Objective: To describe the phenotype and findings of immunohistochemistry (IHC) and immunoblot (IB) in LGMD2I.

Materials and methods: Prospective study of 300 cases of ARLGMD seen at Neuromuscular Disorders clinic between February 2010–
October 2012. All underwent phenotypic characterisation, muscle histopathology, IHC and IB analysis. Age of onset <10 years taken as Duchenne phenotype; >10 years as Becker’s phenotype.

**Conclusion:** Our study confirms that LGMD-2I may be among the more common form AR-LGMD in Indian population. It would be essential to identify them as this carries important implications for management and prognostication.

**Detection of limb girdle muscular dystrophy 2A (calpainopathy) by autocatalytic activity of calpain and by quantification of calpain bands by densitometry**

S. Modí, A. Talini, N. Gayathri, M.S. Bharathi, B. Sunitha, K. Polavarapu.

**Background:** LGMD 2A represents 9–30% of all AR-LGMD’s. We describe clinical and Immunoblot (IB) features in 25 patients from South India with calpainopathy.

**Materials and methods:** This is a prospective case series from the Neuromuscular disorders clinic, NIMHANS, Bengaluru, India. Patients with features of LGMD with autosomal recessive inheritance underwent phenotypic characterisation, muscle histopathology, immunohistochemistry (IHC) and IB.

**Results:** Among 200 patients confirmed to have AR-LGMD by IHC and/or IB there were 25 patients with LGMD2A. Diagnosis of LGMD 2A was confirmed by demonstrating the absence of 94 kDa (full length) and 60 kDa (degradation product) bands on IB in 15 patients, absence of autocatalytic activity of calpain-3 in 7 patients and quantitative reduction of calpain by densitometry in 3 patients. All had predominantly proximal muscle weakness at hips and shoulders. Mean age at onset was 15.5 ± 11.18 (2–41 yr). Mean duration of illness was 9.84 ± 9.33 (2–37). The predominant presenting symptoms were difficulty in rising from floor, difficulty in running fast and tip toe walking. The other features include Scapular winging (72%), Biceps weaker than triceps (44%), Glutei weaker than iliopsoas (52%), Hip abductor sign (32%) and toe walking (52%). Mean CK value was 2742.58 ± 2144.96 (286–9018). Consanguinity was reported in 40%.

**Conclusions:** Calpainopathies formed 12.5% of the AR-LGMD cases in our cohort. IB followed by quantitative estimation of calpain bands on densitometry and/or by demonstrating loss of autocatalytic activity of calpain plays an important role in diagnosing calpainopathy and a subset of patients with normal calpain signal on IB require further analysis by densitometry or by demonstrating loss of autocatalytic activity of calpain.

**doi:** 10.1016/j.jns.2013.07.1541
Background: Difficulty in swallowing and respiratory muscle weakness are the most important factors in prognosis of ALS. We have studied swallowing function in ALS patient during inspiration and expiration separately.

Materials and methods: 25 patients diagnosed with ALS by El Escorial criteria were included in the study. Pulmonary functions were evaluated with sniff nasal pressure test. The presence of aspiration and swallowing dysfunction were checked with video fluoroscopy. Swallowing function of patients was checked with dysphagia limit accompanied by EMG.

Results: 25 patients were included in the study. The average inclusion time after diagnosis were 24.7 ± 27.3 months. 17 cases were in stage 3, 8 cases were in stage 4A and 2 cases were in stage 4B. 25 patients were checked for dysphagia limit and it was normal in 15 patients, abnormal in 10 patients. All cases could swallow 3 cm³ liquid during the expiration. All patients with normal dysphagia limit, 3 patients with >5 dysphagia limit and 1 patient with ≤5 dysphagia limit could swallow during the inspiration. 6 of 7 patients with ≤5 cm³ dysphagia limit could not swallow 3 cm³ liquid during the inspiration.

Discussion: Absence of ability of swallowing in inspiration can use as a threshold in situation of swallowing dysfunction. We think, in which part of respiration patient can swallow is important in terms of dysphagia limit. We think ALS patients with ≤5 cm³ dysphagia limit should be accepted as Stage 4A.

Conclusion: Our genetic investigations in patients with CPEO and detection of GCG expansion in PABPN1.

Complex diagnostics - entrapment neuropathy of the upper limb
F.R. Villar Flores, S. Lobzin, T. Lalaian, E. Maleckiy, N. Alexandrov.
1Department of Neurology, Saint Petersburg, Russia; 2North-West Medical University Named After I.I. Mechnikov, Saint Petersburg, Russia

Background: Entrapment neuropathies of the upper limb are common problems. Despite all the modern diagnostics in rare case it is not possible to identify a clear correlation between clinical data and instrumental studies such as electroneuromyography (EMG), ultrasound (US).

Objective: Improving complex diagnostics with clinical, electrophysiological and US techniques.

Materials and methods: A total of 20 patients were examined with clinical diagnosis of entrapment neuropathy in upper limb, using a combination of EMG and US.

Result: The predominance of pain neuropathic component was observed in all patients. The pain is largely dependent on the psychological condition of the patients, half of patients had motor defect. In 85% of the cases provocative testing (Tinel's, Phalen's) proved positive, the severity of which was confirmed with EMG and US data. In 3 patients with suspected carpal tunnel syndrome (CTS) we have identified tenosynovitis in the thumb tendons, without symptoms of CTS, and one person manifested a combination of tenosynovitis and CTS. It was found that 10% of chronic entrapment neuropathy proved positive during provocative testing, severity of which was not confirmed by the clinical neurophysiological and US diagnosis.

Conclusion: Diagnosis of neuropathies is improved through a combined functional and morphological evaluation of the nerve by using EMG and US. But in rare cases confirmed diagnosis with clinical instrumental methods cannot be obtained at all. And besides neurological examination and modern instrumental methods the physiological condition of the patients should be taken into account for the selection of optimal and appropriate therapy.

doi:10.1016/j.jns.2013.07.1543

doi:10.1016/j.jns.2013.07.1545

Discussions: Previous studies underlined role of heavy metals in neurodegenerative mechanism: lead interferes with calcium metabolism promoting axonal degeneration; manganese chronic exposure can determine manganeseism and parkinsonism; aluminum reduces calcium adsorption promoting demyelination. 

Conclusions: Results suggest presence of heavy metals abnormal blood levels in ALS patients in Campania. We detected manganese increased mainly in ALS patients with late onset and aluminum decreased mainly in farm workers. Significant increase of lead was not found: it might be in agreement with longer survival in SOD1 G93A mutation transgenic mice exposed to lead in low concentrations according to increased VEGF expression in the ventral horn.

Magnetic resonance imaging (MRI) in patients with LGMD 2I confirmed by immunohistochemistry and/or immunoblotting

A. Ramakrishna, A. Nalinia, N. Gayathri, M.M.S. Bharath, B. Sunitha, K. Polavarapu, aDepartment of Neurology, NIMHANS, Bengaluru, India; bDepartment of Neuropathology, NIMHANS, Bengaluru, India; cDepartment of Neurochemistry, NIMHANS, Bengaluru, India

Background: LGMD 2I is caused by mutations in fukutin-related protein gene. Muscle MRI is reported to demonstrate distinct findings.

Objective: To describe the muscle MRI findings in LGMD 2I.

Materials and methods: Prospective case series seen from 2012 to 2012. ARLGMD phenotype patients with absent dystroglycan expression on muscle immunohistochemistry and/or immunoblotting and thus having LGMD2I underwent MRI on 1.5 T machine. Protocol included T1W, T2W, and STIR sequences. Fibrofatty replacement was evaluated on new oedema score. Myoedema evaluated by new oedema score (3 grade scale).

Results: 23 LGMD2I cases. DMD phenotype in 4; BMD in 19. M:F:4.8:1. Mean age-22.13 ± 13.08 years (6–22). Fibrofatty replacement: Gluteus maximus involved in—22 (95.7%); Gluteus medius and minimus—82% (17).Lliopsoas—81.8% (22). Posterior compartment of thigh—22 (95.7%); anterior—19 (87%). Long head of biceps femoris (BF)—22 (95.7%). Short head of BF spared/hyper trophy—15 (65.2%). In anterior compartment of thigh vastus medialis and intermedius more involved than vastus lateralis. Adductor magnus—8 (34.8%). Adductor magnus affected in all, 6–stage 4; 3–stage 3. Spared and hypertrophied: Gracilis—20 (87%); Sartorius—18 (78.3%); Rectus femorus—13 (56.5%). Leg muscles: Tibialis anterior (TA) involved—7 (31.4%); peronei—17 (73.9%); soleus—18 (78.3%); medial gastrocnemius—15 (65.2%); lateral gastrocnemius—9 (39.1%). Tibialis posterior-spared in 22 (95.7%). Oedema assessment: Thigh: Anterior compartment—19 (82.6%); posterior—14 (60.9%); medial—9 (39.1%); Leg: Soleus—21 (87%); medial gastrocnemius—20 (87%); lateral gastrocnemius—17 (73.9%). Anterior compartment and peronei muscles showed less oedema.

Conclusion: Posterior and medial compartments of thigh were affected early and severely. Gracilis, sartorius, rectus femoris spared or hypertrophied. Peronei was more affected than TA. Medial gastrocnemius was more than lateral head. Myoedema was noted predominantly in anterior and posterior thighs, soleus, and gastrocnemii. Thus, muscle MRI a shows distinct pattern in LGMD2I (FKRP) and could be an useful diagnostic tool.

Magnetic resonance imaging findings in immunohistochemically confirmed sarcoglycanopathies

A. Ramakrishna, A. Nalinia, N. Gayathri, M.M.S. Bharath, B. Sunitha, K. Polavarapu, aDepartment of Neurology, NIMHANS, Bengaluru, India; bDepartment of Neuropathology, NIMHANS, Bengaluru, India; cDepartment of Neurochemistry, NIMHANS, Bengaluru, India; dNIMHANS, Bengaluru, India

Background: Sarcoglycanopathies (LGMD2 C,D E,F) are a group of four genetically distinct but clinically similar muscular dystrophies. Scant reports present on MRI of muscle in SG's.

Materials and methods: Muscle MRI was performed in 1.5 T machine on Immunohistochemistry and/or Immunoblot blotted confirmed sarcoglycanopathies (SG's). Protocol included T1W, T2W, and STIR sequences. 37 were muscles studied in each lower limb. Fibrofatty replacement was assessed using Mercuri scoring. Myoedema was evaluated on STIR.

Results: Twelve patients of SGs. M:F—2:1. Mean age—10.91 ± 5.89 years (2–28). Fibrofatty infiltration demonstrated in: Gluteus maximus—12 (100%); Gluteus medius and minimus—9 (75.0%); Tensor fascia lata—10 (83.3%). Spared muscles: Rectus femoris—7 (58.3%); sartorius—6 (66.7%); gracilis—11 (91.7%). Thigh involvement: Posterior compartment—12 (100%); early and severe affection of long head of biceps femoris (BF)—12 (100%); short head in (66.7%); semimembranosus—8 (66.7%); semitendinosus—5 (41.7%). Anterior compartment in 11 (91.7%); vastus medialis—10 (83.3%) more often and severely affected than vastus lateralis and intermedius. Adductor magnus and brevis involvement—12 (100%); adductor longus—7 (58.3%). Leg muscle involvement: Anterior leg compartment—3 (25%). Soleus—7 (58.3%) with mild to moderate fatty infiltration; Medial and lateral gastrocnemius—7 (58.3%). Lateral compartment—10 (83.3%). Asymmetrical involvement in 50. Tibialis posterior spared—11 (91.7%). Myoedema present: Gluteus maximus—2 (16.7%); Gluteus medius and minimus—7 (58.3%); adductor longus—6 (50%); anterior leg compartment—3 (25%) which was segmental; soleus—9 (75%) and was diffuse and global; gastrocnemius—6 (50%). Tibialis posterior(mild)—1 (8.3%). Adductor magnus totally spared in all.

Conclusions: MRI revealed involvement predominantly of hip extensors, adductors and abductors along with severe affection of knee flexors. Vastus medialis more affected than other Vastii. Leg showed more affection of lateraI followed by posterior compartment. Myoedema noted particularly in Gastro–soleus with sparing of Tibialis posterior.

A retrospective review of autonomic screening tests conducted at a tertiary general hospital

O.S.O. Koh, L.B. Tay, M.M. Li, T. Umapathi, aNational University of Singapore, Singapore, Singapore; bNational Neuroscience Institute, Singapore, Singapore

Background: Autonomic screening tests (AST) are commonly employed to assess the integrity of the sympathetic and parasympathetic systems. Objectives: To describe the case mix, findings and usefulness of AST in a tertiary General Hospital setting.

Patients and methods: All AST performed in 2011–2012 were retrospectively reviewed. Referring diagnoses were classified into: orthostatic, neurologic, thermoregulatory and known/suspected disease assessment.
(e.g. Diabetes mellitus, Parkinsonism). Abnormalities and final diagnosis were noted, along with medication and patient cooperation. The relevance of AST to the clinical problem was ranked on a 3-point scale.

**Results:** 162 patients underwent AST. Orthostatic dizziness was the most common referring diagnosis (53.1%) followed by known/suspected disease assessment (33.3%), thermoregulatory (8.6%) and neurological (4.3%). 47.5% of ASTs were abnormal, 40.7% were normal and 11.7% inconclusive. The most frequent abnormal final diagnosis was isolated orthostatic hypotension (OH) (27.3%). 25.5% of diabetics were eventually diagnosed with diabetic autonomic neuropathy. AST was very helpful in 56.2%, somewhat helpful in 32.7% and inconclusive in 11.1%. Among inconclusive ASTs, 61.1% were attributed to poor performance of test maneuvers, 16.7% to medications and 16.7% to both. All patients with irregular heart rhythms had inconclusive results.

**Conclusion:** AST was abnormal in more than half. The most common abnormality was isolated OH. Patients referred for known/suspected disease assessment were most likely to have abnormal AST. Conversely, patients with thermoregulatory problems were most likely to have normal AST. Poor performance of test maneuvers and irregular heart rhythm were confounders in the general population, while medication interfered with AST of Parkinsonism.

**Material and methods:** Observational study of Becker type myotonia genetically diagnosed patients series. We analyzed the age of onset and clinical features.

**Results:** 3 patients (2 males and 1 female) with a mean age of onset of 1, 4 and 3 years old. Only one of them had family disease history. All had weakness at the beginning of the activity but without paralysis and with subsequent warm-up phenomenon. All of them had clinical and electrical myotonia. There was no clinical or EMG signs of muscular dystrophy. CPK levels were normal. Genetic studies identified a homozygous mutation in the male patient with family history, a heterozygous mutation for the female patient and 2 different heterozygous mutations for the gene CLCN1 in the other male.

**Conclusions:** Becker type myotonia congenita may have its onset in adolescence with similar symptoms than those described in earlier ages of onset. Genetic alterations are very variable.

**Late onset post-radiotherapy brachial plexopathy**

F.J. Rodríguez de Rivera, F. Palomo, F. Vivancos, J. Arpa, E. Díez Tejedor, Department of Neurology, Hospital Universitario La Paz, Madrid, Spain

**Introduction:** Risk of developing post-radiotherapy brachial plexopathy from breast cancer is less than 2%. It usually appears around 10.5 months (range 1.5–77) after the start of treatment and only in 25% of cases alterations in EMG are identified. A case of brachial plexopathy developed 13 years after radiotherapy treatment.

**Material and methods:** Female patient, 66 years old with pain and muscle weakness in the distal portion of left arm and hand for 7 months. She had been treated 13 years ago for an infiltrating ductal carcinoma in the left breast with reconstruction and chemotherapy and subsequent radiotherapy.

**Results:** Electromyography: Left brachial plexopathy C7–D1. MRI Cervical: C5–C6 degenerative disc disease without signs of CNS involvement. MRI brachial plexus: Fibrosis post-radiotherapy encompassing left brachial plexus fascicles.

**Laboratory study:** Normal.

**Conclusions:** Post-radiotherapy plexopathy may develop years after completion of treatment probably due to the evolution of tissue fibrosis.

**Juvenile-onset Becker type myotonia congenita**

F.J. Rodríguez de Rivera, I. Sanz, J. Arpa, E. Díez Tejedor, Department of Neurology, Hospital Universitario La Paz, Madrid, Spain

**Introduction:** Becker type myotonia congenita is a very rare (1:100,000) autosomal recessive disease which usually begins between the ages of 4 and 12 years old and its characteristics are defined by small patients series. CLCN1 genetic alterations that occur are multiple and usually heterozygous. We present a juvenile-onset Becker myotonia series.

**Material and methods:** Observational study of Becker type myotonia genetically diagnosed patients series. We analyzed the age of onset and clinical features.

**Results:** 3 patients (2 males and 1 female) with a mean age of onset of 1, 4 and 3 years old. Only one of them had family disease history. All had weakness at the beginning of the activity but without paralysis and with subsequent warm-up phenomenon. All of them had clinical and electrical myotonia. There was no clinical or EMG signs of muscular dystrophy. CPK levels were normal. Genetic studies identified a homozygous mutation in the male patient with family history, a heterozygous mutation for the female patient and 2 different heterozygous mutations for the gene CLCN1 in the other male.

**Conclusions:** Becker type myotonia congenita may have its onset in adolescence with similar symptoms than those described in earlier ages of onset. Genetic alterations are very variable.

**Clinical and immunological predictors of prognosis for Japanese patients with thymoma-associated myasthenia gravis**

S. Suzuki, K. Utsugisawa, Y. Nagane, N. Suzuki, Department of Neurology, Keio University School of Medicine, Tokyo, Japan; Department of Neurology, Hanamaki General Hospital, Iwate, Japan

**Background:** About 30%–50% of patients with thymomas also have autoimmune myasthenia gravis (MG). There are no immunological markers to predict the prognosis of patients with thymoma-associated MG (T-MG). Anti-Kv1.4 antibody, one of the striatal
Abstracts / Journal of the Neurological Sciences 333 (2013) e422–e480
e431

antibodies, is specific for MG and related to severe symptoms and thymomas.

**Objective:** To evaluate the role of anti-Kv1.4 antibody as a predictor of prognosis among various clinical and immunological factors in T-MG.

**Material and methods:** We retrospectively investigated 56 Japanese patients with T-MG. Immunological factors including three autoantibodies and human leukocyte antigen DR alleles were investigated, as well as the clinical features of thymomas and MG. The factors associated with thymoma recurrence or MG relapse were examined by logistic analyses.

**Results:** Anti-Kv1.4 antibodies were detected in 28 patients, and thus the MG patients were divided into two groups: an anti-Kv1.4-positive group and an anti-Kv1.4-negative group. Five patients developed MG after the removal of thymoma. Patients with anti-Kv1.4 antibodies showed higher frequencies of thymoma recurrence and MG relapse compared to those without. The final outcomes of MG were more often unfavorable in the anti-Kv1.4 positive group than the negative group. Eleven patients died, but none died of MG. Anti-Kv1.4 antibody was a factor associated with thymoma recurrence, as well as Masaoka stage 4, World Health Organization type B3, and adjuvant radiotherapy in univariate logistic analyses. Multivariate analyses showed that anti-Kv1.4 antibody was the only independent factor associated with MG relapse.

**Conclusions:** Anti-Kv1.4 antibody is a useful predictor of the prognosis of Japanese patients with T-MG.

**The up-regulation of IL-1β/TGF-β1 and hypoxia induced in immobilization are related to the molecular mechanisms underlying muscle contracture**

Y. Hondaa, Y. Kondob, R. Sasabea, Y. Sekinoc, Y. Morimotod, H. Kataokae, J. Sakamotof, J. Nakanog, M. Okitah, Laboratory of Locomotive Rehabilitation Science, Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan; gDepartment of Rehabilitation, Japanese Red Cross Nagasaki Genbaku Isahaya Hospital, Isahaya, Japan; hDepartment of Rehabilitation, Nagasaki University Hospital, Nagasaki, Japan; iDepartment of Rehabilitation, Nagasaki University Graduate School of Biochemical Sciences, Nagasaki, Japan; jDepartment of Rehabilitation, Japanese Red Cross Nagasaki Genbaku Isahaya Hospital, Isahaya, Japan

**Background/objective:** This investigation was conducted to determine the molecular mechanism governing muscle contracture in immobilized rat soleus muscle.

**Material and methods:** Wistar rats were divided randomly into immobilization and control groups. In the immobilization group, both ankle joints were fixed in full plantar flexion with plaster casts for 1, 2, 4, 8, and 12 weeks. The right soleus muscle was immunostained for type I and III collagen and α-SMA. Additionally, the left soleus muscle was used to detect the expression of type I and III collagen, α-SMA, IL-1β, and TGF-β1 by RT-PCR.

**Results:** Type I and III collagen, α-SMA, IL-1β, and TGF-β1 expression was significantly greater in the immobilization group than in the controls at each time point, whereas HIF-1α expression was significantly greater in the immobilization group than in the controls at 4, 8, and 12 weeks. Furthermore, in the immobilization group, type I collagen, α-SMA, and HIF-1α expression at 4, 8, and 12 weeks was significantly greater than at 1 and 2 weeks.

**Conclusion:** α-SMA, IL-1β, and TGF-β1 expression was significantly higher in the immobilization group than in the controls at 1 week. The up-regulation of IL-1β and TGF-β1 may activate fibroblasts and promote their differentiation into myofibroblasts, and we suggest that these changes are associated with the increased expression of type I and III collagen. Additionally, the soleus muscle became hypoxic after 4 weeks of immobilization. Thus, we suggest hypoxia accelerates fibrosis and these alterations may influence the progression of muscle contracture.

**Effects of heat stress on glucocorticoid-induced myopathy**

Y. Morimotoa, H. Kataoka, Y. Honda, Y. Konbo, J. Sakamoto, R. Kozua, J. Nakano, M. Okita, Laboratory of Locomotive Rehabilitation Science, Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan; bDepartment of Physical Therapy Science, Nagasaki University Hospital, Nagasaki, Japan; cDepartment of Rehabilitation, Japanese Red Cross Nagasaki Genbaku Isahaya Hospital, Isahaya, Japan

**Background:** Glucocorticoids mainly induce atrophy of fast muscles. Heat stress inhibits disuse muscle atrophy by increasing the levels of heat shock protein (Hsp) 72 in fast muscles.

**Objective:** The purpose of this study was to investigate the influence of heat stress on glucocorticoid-induced myopathy.

**Materials and methods:** Eight-week-old Wistar rats were randomly assigned to the control (injected with 2 ml/kg saline 6 d/wk for 2 wk), dex (injected with 2 mg/kg dexamethasone 6 d/wk for 2 wk), and dex and heat (injected with dexamethasone and hindlimbs immersed in water at 42 °C 6 d/wk for 2 wk) groups. At the end of the experimental period, the extensor digitorum longus muscle was extracted. We examined the diameters of muscle fiber types I, IIA, and IIB; the number of myonuclei and capillaries per muscle fiber; expression of Hsp72; and concentration of insulin-like growth factor (IGF)-1.

**Results:** The diameters of all muscle fiber types, the concentration of IGF-1, and the number of capillaries per muscle fiber were significantly lower in the dex group than in the control group. The diameters of all muscle fiber types, the numbers of myonuclei and capillaries per muscle fiber, and the expression of Hsp72 were significantly higher in the dex and heat group than in the dex group.

**Conclusion:** Our results suggest that heat stress inhibits development of glucocorticoid-induced myopathy via inhibiting reduction of the numbers of capillaries and increasing the number of myonuclei and Hsp72 expression.

**Endocrine myopathies**

B.N. Bouzidi, E. Turki, I. Bouchhima, M. Damak, M.J. Miledi, I. Feki, C. Mhiri, Department of Neurology, Hospital Habib Bourguiba, Medical Faculty of Tunisia University, Sfax, Tunisia

**Background:** Most endocrine disorders are now detected and treated at an early stage, and muscle abnormalities are now rare. Endocrine myopathy (EM) is often described in thyroid, parathormone dysfunction and vitamin D deficiency.
Objective: To report clinical, biological and histological findings of Tunisian patient with EM and to discuss diagnostic approach and patient's management.

Patients and methods: Over 20 years (1992–2012), 12 patients were followed up in our department for EM. Clinical, biological, electrophysiological and histological findings are analyzed.

Results: They were 4 males and 8 females (mean age 33 years). All patients presented initially a proximal myopathy. Serum creatine kinase levels, electromyography and muscle biopsy were normal in all patients. Laboratory analysis revealed hyperparathyroidism in the first and second case, hypothyroidism in four cases. Six patients had low serum level of 25 hydroxy Vitamin D. Furthermore, radiological investigations confirmed osteomalacia in these patients. The myopathy improves with restoration of normal PTH levels, thyroidism and vitamin D replacement.

Conclusion: Proximal myopathy may rarely be displayed as the sole manifestation of endocrine disorders. However, it is recommended that endocrine myopathy should be taken into account during differential diagnosis of proximal muscle weakness mainly because they are treatable causes.

Peripheral nerve safety measures in a multicenter, double-blind, randomized, placebo-controlled, dose-ranging study of fulranumab in patients with painful diabetic neuropathy

M. Polydefkis1, G. Wang2, G. Romano3, M.E. Frustaci4, D. Cornblath5, J. Thippawong6, K.M. Kelly4, J. Arezzo5, “Johns Hopkins/EMG Laboratory at Bayview/Cutaneous Neurology Laboratory, Baltimore, MD, USA; 3Janssen Research & Development, LLC, Titusville, NJ, USA; 4Janssen Research & Development, LLC, Spring House, PA, USA; 5Johns Hopkins University School of Medicine, Baltimore, MD, USA; 6Janssen Research & Development, LLC, Fremont, CA, USA; 7Albert Einstein College of Medicine of Yeshiva University, Bronx, NY, USA

Background: Chronic anti-nerve growth factor activity may adversely affect nerve function. To assess progressive neuropathy risk, intraepidermal nerve fiber density (IENFD), nerve conduction velocity (NCV) and quantitative neurologic exam (Total Neuropathy Score-nurse, TNSn) were evaluated in a double-blind, placebo-controlled, phase-2 trial of fulranumab’s efficacy and safety, in patients with diabetic neuropathic pain.

Objective: To evaluate the safety of fulranumab on IENFD and peripheral nerve function.

Patients and methods: Patients were randomized (3:2:2:3) to placebo or fulranumab (1-, 3-, or 10-mg; every 4 weeks subcutaneously).

Results: At the health authority’s request, studies exploring anti-NGF therapy, were terminated early; only 77 patients were randomized. The efficacy and general tolerability of fulranumab from this study were previously reported. Change from baseline (95% CI) for IENFD, NCV and quantitative neurologic exam (Total Neuropathy Score-nurse, TNSn) were evaluated in a double-blind, placebo-controlled, phase-2 trial of fulranumab’s efficacy and safety, in patients with diabetic neuropathic pain.

Conclusions: There is no evidence that, at the doses and for the period studied, fulranumab was associated with decreased nerve function. An adequately powered and longer duration study is required to confirm these observations.

Cerebrospinal fluid biomarkers of neurodegeneration in patients with juvenile and chronic myotonic dystrophy type 1

S. Peric1, G. Mandic Stojmenovic2, I. Markovic3, E. Stefanova2, V. Llic4, A. Parojic3, S. Misirlic Dencic4, M. Ostojic5, V. Rakovec Stojanovic4, V. Kostic4, 6Neurology Clinic, Clinical Center of Serbia, School of Medicine, University of Belgrade, Belgrade, Serbia; 7Institute of Medical and Clinical Biochemistry, School of Medicine, University of Belgrade, Belgrade, Serbia; 8Institute of Ortopedic Surgery and Traumatology, Belgrade, Serbia

Aim: To analyze cerebrospinal fluid (CSF) levels of total tau (T-tau), phosphorylated tau (P-tau) and 42 amino acid form of β-amyloid (Aβ42) in patients with myotonic dystrophy type 1 (DM1), and their possible correlations with cognitive and behavior manifestations in these patients.

Methods: Lumbar puncture was performed in 74 patients with DM1 (27 with childhood/juvenile (jDM1) and 47 with adult form (aDM1) of disease) and 26 control subjects who were subjected to orthopedic surgery. Sandwich enzyme-linked immunosorbent assay (ELISA) was used for measuring the levels of T-tau, P-tau and Aβ42.

Results: CSF level of Aβ42 was the lowest in patients with jDM1 and the highest in controls (p < 0.05). Tendency of T-tau and P-tau increase was observed in aDM1 patients compared to jDM1 and controls (p > 0.05). In both jDM1 and aDM1 patients, significant correlations were found between Aβ42 and T-tau (rho = +0.811 and rho = +0.67 respectively, p < 0.01), as well as between Aβ42 and P-tau (rho = +0.871 and rho = +0.67 respectively, p < 0.01). Aβ42/P-tau ratio decreased with age in aDM1 (rho = −0.30, p < 0.05). Only few correlations were observed between levels of biomarkers and neuropsychological testing.

Conclusion: Further studies with larger cohorts of DM1 patients are necessary. Identification of adequate biomarkers of brain involvement in DM1 is of great importance since central outcome measures are necessary for upcoming gene therapy clinical trials.

Evaluation of Cost Of Illness (COI) and health care burden in Spinal Muscular Atrophies (SMA)

O. Schreiber1, C. Klug2, S. Thiele3, C. Herrmann4, J. Zowe4, P. Reilich5, K. Nagels6, M.C. Walter6, 6Friedrich-Baur-Institute, Dept. of Neurology, Ludwig-Maximilians-University of Munich, Munich, Germany; 4Institute of Management in Medicine and Health Care Sciences, University of Bayreuth, Bayreuth, Germany

Background: SMAs represent a group of fatal inherited disorders leading to progressive disablement with reduced working capacity and high health care utilization. Infantile forms significantly reduce life expectancy. There is no cure but new promising therapies are emerging. Clinical trials in patients are underway.

Objective: Development of these therapies is costly and implementation in SMA care may produce high expenditures. Despite their own cost, the potential contribution of innovative therapies could reduce the COI. In order to forecast the balance from a health economic perspective, our study aimed at assessing the current COI of the most relevant SMA subgroups.

Methods: Patients were questioned using an established German SMA patient registry. In order to determine the COI, a micro-costing method was used to examine the direct and indirect costs measuring the economic burden of SMA on patients, relatives and society.

Results: 300 patients comprising SMA subtypes 1 to 3 aged <0 to 65 years were included. In the light of current standard care the economic burden of patients, relatives and their families was analyzed. Relevant socio-political implications have been identified and compiled.

Conclusion: Our results provide the first step towards a systematic health economic assessment of innovative SMA therapies. They are essential for further cost utility analyses. Particularly, these results enable to speed up the preparation of payer negotiations with regard to pricing and reimbursement. In this context our results contribute to the facilitation of a smooth translation of innovative SMA therapies from their discovery to their implementation into standard care.

Understanding the pathomechanisms of inherited peripheral neuropathies

V. Timmerman, Molecular Genetics Department, VIB and University of Antwerp, Antwerpen, Belgium

Most genes for Charcot-Marie-Tooth (CMT) were identified through positional cloning or via a candidate gene approach. Different CMT phenotypes can be caused by mutations in the same gene, and conversely mutations in different genes may result in the same phenotype. This is further complicated by the fact that some mutations are private and occur in specific subtypes. Mutations in >20 genes cause primary alterations of the myelin sheath. Mutations in genes with a function in the axon however, result in axonal CMT phenotypes. Other mutations have been reported to cause intermediate CMT, with both myelin and axonal phenotypes. Mutations were also found in genes (amino-acyl tRNA synthetases, small heat shock proteins, and enzymes involved in lipid metabolism), where the resulting gene products have housekeeping functions and pleiotropic activities. Therefore, these genes were not the obvious candidates for peripheral nerve degeneration and it remains an enigma why the mutant proteins cause specific length-dependent degeneration of peripheral nerves. To identify peripheral nerve specific molecular pathways we will pinpoint differential protein-protein interaction networks starting from the ubiquitously expressed genes. The identification of interacting molecular partners and higher-order molecular complexes they form part of will provide novel insights in regulatory pathways in health and disease, and contribute to new candidate genes for CMT. Altogether, this will ultimately result in the identification of CMT gene networks which can provide insights in finding molecular targets for therapeutic intervention, not only for one type of CMT, but also for the more rare and/or complex phenotypes.

Preoperative pulmonary function in relation to myasthenic crisis after thymectomy

1Chonnam National University Medical School and Hwasun Hospital, Gwangju, Republic of Korea; 2Chonnam National University Hospital, Gwangju, Republic of Korea; 3Chonnam National University Hospital Medical School, Gwangju, Republic of Korea; 4City Rehabilitation Hospital, Gwangju, Republic of Korea

Background: Postoperative neuromuscular respiratory failure in patients who underwent thymectomy for myasthenia gravis (MG) may be associated with the preoperative pulmonary function (PPF).

Objective: To investigate whether the difference in PPF levels in MG patients who were successfully weaned from a ventilator after thymectomy was associated with myasthenic crisis after thymectomy (MCAT).

Methods: Seventy-one patients were retrospectively enrolled. We explored the relationship of PPF levels with the existence of MCAT occurring several weeks or months after surgery. The factors of PPF were as follows:

a) measured FEV1, mFEV1,
b) measured FVC, mFVC,
c) mFEV1/mFVC,
d) mFEV1/predicted FEV1 (pFEV1),
e) mFVC/predicted FVC (pFVC).

PPF receiver operating characteristic (ROC) analysis to predict the occurrence of MCAT was assessed.

**Results:** MCAT occurred in 17 (23.9%) of MG patients after surgery. mFEV1, mFVC, mFEV1/pFEV1, and mFVC/pFVC were significantly correlated with the occurrence of MCAT, but, mFEV1/mFVC was not. ROC curve area for mFVC/pFVC was 0.902 (95% CI 0.808–0.960, p < 0.0001), with sensitivity, specificity, and negative predictive value (NPV) of 94.1%, 77.8%, and 97.7%, respectively, at a threshold of <80% with 53.3% of 30 patients below this score. During 2 year follow-up, 97.6% of 41 patients with preoperative mFVC/pFVC ≥80% had not experienced MCAT.

**Conclusion:** The PPF receiver operating characteristic (ROC) analysis to predict the occurrence of MCAT was assessed.

**Case report:** A 24-year-old Malian man born from consanguineous parents was referred for the evaluation of a slowly progressive disorder that started five years ago. The disorder was characterized by a facial weakness with bilateral eye closing weakness, dysphonia, dysarthria and dysphagia. He also presented a tongue atrophy, a weakness of the lower jaw muscle that prevented the complete closing of the mouth. Objectively, there is a distal muscular atrophy affecting the hands and legs. Additional signs like vocal paresis, pyramidal signs, facial weakness and diaphragm weakness can be observed. Here we report a Malian family with dHMN that started with cranial nerve palsies.

**Posterior interosseous nerve injury caused by occluded ganglion**

D.H. Kim, S.J. Jung. *Department of Rehabilitation and Research Institute of Rehabilitation, Yonsei University College of Medicine, Seoul, Republic of Korea*

**Background:** Posterior interosseous nerve (PIN) injury can be diagnosed by correlating features typical to it. However, in some cases, dependence in these features may cause one to overlook important factors. Also, many overemphasize on differential diagnosis with lateral epicondylitis, which may lead to a narrow view in diagnosis and a resulting overlook in other causes of pressure increases that may cause PIN injury.

**Case:** A 69-year old right handed male shoeblack came complaining of weakness at his right wrist. He had been carrying shoes with the wrist flexed and pronated for several years, which has caused increased pressure inside the radial tunnel. Physical examination revealed decreased wrist and finger extension strength without any sensory changes. Plain radiography was normal, as well as the ultrasonographic evaluation for extensor tendinopathy. Electromyographic examinations revealed abnormal spontaneous activities in the EIP, EDC, and APL muscles. Combination of clinical presentation and medical evaluations suggested PIN lesion, which correlated with the type of work activity. Physical therapy modalities were applied but symptoms were only aggravated. Finally, an MRI evaluation revealed a 13 × 6 mm sized ganglion at the supinator area with denervation myopathy of supinator and extensor muscles. Excision of ganglion resulted in improvement of symptoms.

**Conclusion:** Ganglion may arise where there is inflammation and damage of tendon and ligamentous structures. As with our case, symptoms of PIN lesions related to occupational activity can be caused by ganglion. MRI may be helpful in finding masses, though ultrasonography may also be useful if held in mind during evaluation.

**Unique MRI brain imaging findings in patient with bulbar onset amyotrophic lateral sclerosis. A case report**

H. Hashim, A. Almadani. *Neurology Department, Rashid Hospital, Dubai, United Arab Emirates*

**Introduction:** Amyotrophic lateral sclerosis is considered as a progressive neurodegenerative illness that causes muscle weakness, disability, and eventually death, with a median survival of 3 to 5 years. Our case is about a young Pakistani male whose clinical presentation, electrophysiological and imaging studies were suggestive of amyotrophic lateral sclerosis.

**Case description:** This case is about a 36 year old Pakistani male who was working as a driver in Dubai for the last 10 years. He presented to the clinic with the history of mild dysarthria started around 6 month back without any other complaint followed by change in the quality of voice and having nasal twang. Now for the last one month he was feeling weakness in arms and legs.

On examination patient was conscious and alert but had severe nasal twang and gag reflex was absent. His tongue was full of fasciculation. His muscle bulk was reduced all over and there was obvious fasciculation on both arms and legs. Reflexes were brisk and planter was up going bilaterally. On MRI brain, T2-weighted sequences showed symmetric bilateral hyper intensities along large myelinated pyramidal tract fibers in the posterior limb of the internal capsule and cerebral peduncle, extending along the corticospinal tract.

**Discussion:** Our case illustrates that amyotrophic lateral sclerosis can start with only bulbar weakness without any other system involvement and simple MRI brain can show finding suggestive of ALS at the start of disease as in our case.

Brain and muscle independent involvement in myotonic dystrophy
C. Ferratiæ, M. Faninaæ, V. Cittonæ, R. Manaraæ, P. Cudiaæ, E. Pegoraroæ, C. Angelinatiæ, 1University of Padova, Padova; 2Hospital of Padova, Padova; 3IRCSS San Camillo, Venice, Italy

Objectives: The aim of this study is to compare the degree of involvement in brain and skeletal muscle in a series of 25 molecularly-defined DM1 patients since there are few reports done in the same patients.

Methods: Twenty five DM1 patients were recruited for our study. Age at study, age at disease onset and disease duration were recorded. CTG(n) expansion was done in genomic DNA. Neuromuscular assessment in DM1 patients was performed by Muscular Impairment Rating Scale (MIRS). A morphometric study of muscle biopsies included the quantitative evaluation of fibre atrophy/hypertrophy factor of both fibre types. MRI imaging was done for White Matter Hyperintense Lesion (WMHL) and Tractography, MRI was also evaluated.

Results: Muscle morphometric analysis showed an increased atrophy factor (AF), AF was increased especially for type I fibres. Most patients had abnormal MRI imaging, showing scattered supratentorial, bilateral, symmetrical focal or diffuse WMHLs, with a typical temporalo-insular diffuse subcortical pattern.

Patients harbouring larger CTG expansion had a more severe muscle involvement at clinical and histopathological level. We found no significant correlation between atrophy factors and MRI total lesion load of WMHL.

Conclusion: We conclude that greater expansion size is a risk factor for more extensive cerebral and muscle impairment, however we found that muscle and brain are independently involved possibly in relation to a different molecular mechanism involving either Muscle Blind-Like Protein 1 or 2 sequestration in respectively muscle and brain tissue.

Objectives: The diagnosis of ALS remains a matter of exclusion. The presentation was spinal in 194 cases (65.5%) and bulbar in 99 (33.5%). The 27 patients meeting a diagnosis of non-ALS MNDs included 13 women and 14 men; the mean age at onset was 54.7 years (men 58.0, women 53.3). The 67 patients affected by other diseases included 42 men and 25 women; the mean age at onset was 53.7 years (men 58.0, women 56.9). The most frequent diagnosis made in men was motor neuropathy and myopathies while in women was myopathies and multiple sclerosis.

Male/female distribution showed no significant difference among the three groups (p = 0.61). Patients not confirmed as affected by SLA were significantly younger and showed generalized asthenia, atypical symptoms, symmetrical disturbances (p < 0.05) as presentation symptoms.

Conclusions: The diagnosis of ALS remains a matter of exclusion. The highest frequency of misdiagnosis was in younger men (26.8%; p < 0.05) and the most common confounding symptom was weakness of lower limb muscles (23.4%).

Isolated acute bilateral ophthalmoplegia as a form of anti-GQ1b syndrome - a case report and differential diagnostic considerations
A. Tóth\textsuperscript{a}, G. Aradi\textsuperscript{b}, I. Vastagh\textsuperscript{b}, K. Pozsgavorszky\textsuperscript{b}, L. Rencz\textsuperscript{d}, D. Bereczki\textsuperscript{d}, Z. Arányi\textsuperscript{d}, D. Baldarana, J. Grassingeb, S. W. Johannesena, U. Bogdahnac.

Background: Isolated acute bilateral ophthalmoplegia is an uncommon occurrence, but it may cause differential diagnostic problems. It may be a manifestation of the Miller Fisher syndrome spectrum, which has been recently referred to as anti-GQ1b syndrome.

Objective: To present a case with acute bilateral ophthalmoplegia associated with anti-GQ1b antibody positivity, but without other typical signs of Miller Fisher syndrome (MFS). Differential diagnostic aspects are highlighted.

Patient: A 57-year-old female patient presented with an acute onset of diplopia, progressing to bilateral ophthalmoplegia within days. These symptoms were preceded by flu-like symptoms. Deep tendon reflexes were diminished, otherwise her neurological status was unremarkable, with normal cell count. Electrophysiological assessment showed normal sensory nerve action potentials, whereas low amplitude or absent sensory nerve action potentials are characteristic findings in MFS. Serological testing confirmed anti-GQ1b class IgG antibody positivity, supporting the diagnosis of MFS spectrum. The patient fully recovered within 3 months, without any specific treatment, showing the benign nature of the condition.

Discussion: Acute ophthalmoparesis may be a restricted form anti-GQ1b syndrome. In addition to classical MFS, further variants include Bickerstaff's brainstem encephalitis, pharyngeal-cervical-brachial paresis, and acute ataxic sensory neuropathy. Although acute ophthalmoparesis as a manifestation of anti-GQ1b syndrome is a benign condition, it may cause differential diagnostic problems with potentially more serious conditions needing prompt treatment, such as Wernicke's encephalopathy, ocular myasthenia, botulism, paraneoplastic brainstem encephalitis, or brainstem stroke.

Safety included abdominal sonography, determination of BW, pulmonary function, clinical chemistry.

Results: Both application modes were safe with no obvious difference in efficacy. Side effects were very mild, tolerance was good. No differences were detected when compared to an ALS population treated with Riluzole only. Clinical outcome revealed some longer stabilisations, unrelated to age or disease dynamics. Median overall survival in application mode 5/28 was 2.9 years. MUNE correlated to disease progression (p < 0.01), and DTI-FAI (p < 0.003), and showed increases in individual patients. DTI-/ FAI-values over time indicated decrease in most patients, in some minor improvement.

Discussion: Prolonged treatment with G-CSF is feasible and safe in ALS patients - prospective study data are needed. MUNE, DTI and BM function parameters are probably very useful biomarkers.

TDP-43 is a highly conserved member of the family of Heterogeneous Nuclear Ribonuclear Proteins (hnRNPs). It is associated with neurodegeneration, constituting the major component found in neuronal cytoplasmic inclusion bodies from patients who suffered from Amyotrophic Lateral Sclerosis (ALS) and Fronto-Temporal Lobar Degeneration with Ubiquitinated Inclusions (FTLD-U/FTLD-TDP). Moreover, dominant missense mutations in TARDBP, the human gene encoding TDP–43, mostly located in its C-terminal, are causative of ALS and FTLD-U. Both the ectopic expression of human wild type TDP-43 and mutant alleles associated with ALS/FTLD-U have been reported to lead to neurotoxicity in different model organisms, including mice. This dose dependent toxicity of wild type and mutant TDP-43 alleles makes the mechanistic dissection of mutant toxicity challenging. Here, we characterize a novel mouse TDP-43 mutant line, carrying an ENU-induced point mutation in the mouse endogenous Tardbp gene. Using a variety of methodologies, including

Idiopathic phrenic neuropathies: A case series and literature review
S. Podnar. Institute of Clinical Neurophysiology, Division of Neurology, University Medical Center Ljubljana, Ljubljana, Slovenia

Background: Phrenic neuropathies are important, and probably underdiagnosed cause of orthopnea, dyspnea and hypercapnic respiratory failure. However, the aetiology, optimal treatment and long term prognosis of "idiopathic" phrenic neuropathies are not known.

Objective: To try establish possible aetiology and long term prognosis of "idiopathic" phrenic neuropathies.

Patients and methods: Patients with "idiopathic" phrenic neuropathies were identified from this authors practice and by the literature search. Their clinical characteristics, treatments and long term outcomes were noted. Compatibility with neuralgic amyotrophy diagnosis was established (typical arm motor nerve lesion findings – definite; trigger event or pain – probable).

Results: Unilateral/bilateral phrenic neuropathy was diagnosed in 10/9 in the authors series and in 18/40 patients from the literature search. In unilateral/bilateral groups 69% and 76% were men (p > 0.05), were 54 ± 12/56 ± 11 years old (p > 0.05), 11%/22% had diabetes (p > 0.05), and 4%/31% hypertension (p < 0.05). Criteria of definite/probable neuralgic amyotrophy were fulfilled by 7%/61% of patients with unilateral, and in 20%/43% of patients with bilateral phrenic neuropathy (p > 0.05). Non-invasive ventilation was used by 22%, IVig by 5%, steroids by 4% and valacyclovir by 4% of patients. Complete resolution occurred in 23%/14% (p > 0.05), and partial improvement in 18%/40% (p < 0.05) of patients with unilateral/bilateral phrenic neuropathy.

Conclusion: About two-thirds of patients with phrenic neuropathies fulfilled some criteria of neuralgic amyotrophy, and about one-half improved at least partially. Only few patients received adequate immunomodulatory and supportive therapy, partially also due to often too late diagnosis.

Possible toxicity of tuberculostatic agents in a patient with a novel TYMP mutation leading to mitochondrial neurogastrointestinal encephalomyopathy
V. Mihaylova1, V. Guergueltcheva2, S. Cherninkova3, L. Penev4, G. Georgiev4, K. Stoyanova4, A. Todorova4, I. Tournev4,5; 1Neurology, Sofia, Bulgaria; 2Radiology, University Hospital 'Alexandrovska', Sofia, Bulgaria; 3Medical Chemistry and Biochemistry, Medical University Sofia, Sofia, Bulgaria; 4Cognitive Science and Psychology, New Bulgarian University, Sofia, Bulgaria

Mitochondrial neurogastrointestinal encephalomyopathy (MNGIE) is a rare autosomal recessive multisystemic disorder caused by TYMP gene mutations. Here, we report on the first MNGIE patient diagnosed in Bulgaria who carries a novel homozygous TYMP mutation (p.Leu347Pro). The patient presented with gastrointestinal complaints, cachexia, hearing loss, ptosis, ophthalmoplegia, cognitive impairment and leukoencephalopathy on MRI examination of the brain. The patient’s motor capacity declined significantly leading to wheelchair dependence several months following the administration of tuberculostatic treatment suggesting mitochondrial toxicity of these agents. The advanced stage of the disease and the poor medical condition prevented us from performing allogenic hematopoietic stem cell transplantation (HSCT). Early diagnosis is important not only for genetic counseling but also in view of the timely treatment with allogenic HSCT.

Neuromuscular sarcoidosis: A retrospective study of 12 cases
M. Namekawa, Y. Hayashi, S. Kondo, T. Mashiko, T. Kameda, S. Asari, Y. Ando, M. Sawada, L. Nakano, A. Neurology, Jichi Medical University, Shimotsuke, Fuchu, Japan; bNeurology, Tokyo Metropolitan Neurological Hospital, Fuchu, Japan

Background: Neuromuscular sarcoidosis accounts for 5–15% of cases of systemic sarcoidosis.
Objective: Determine the clinical characteristics of neuromuscular sarcoidosis.
Patients and method: We enrolled 12 patients with pathologically proven sarcoidosis with neuromuscular symptoms, who were referred to our hospital since 2006. We retrospectively reviewed their clinical records.
Results: Of the 12 patients, 4 had cervical myelopathy (3 intramedullary, 1 extramedullary), 4 had meningeal involvement (2 leptomenigitis, 2 pachymenigitis), 2 had neuropathy (1 spinal mononeuropathy multiplex, 1 recurrent hemifacial palsy), and 2 had chronic myopathy. Bilateral hilar lymphadenopathy and history of the uveitis were observed in 10 and 4 cases, respectively. None of the patients had cardiac involvement. Three had been already been diagnosed pathologically as having sarcoidosis before neuromuscular involvement. Three of the 4 patients with cervical myelopathy were diagnosed by transbronchial lung biopsy, whereas 3 of the 4 cases with meningeal involvement were diagnosed by meningeal biopsy. The mean level of serum angiotensin converting enzyme (ACE) was 23.8 ± 12.9 IU/L, and was not related to disease severity in the myelopathy and meningeal subgroups.
Conclusion: The neuromuscular presentations of neuromuscular sarcoidosis are varied and must be differentiated from other neurological disorders. The diagnosis of “isolated” neuromuscular sarcoidosis is quite difficult and is neglected because the biopsy is difficult to perform. In addition, not all of the neurological symptoms of pathologically proven sarcoidosis might be due to sarcoidosis. It is necessary, therefore, to develop new surrogate markers of the disease, instead pathological examination, for diagnostic purposes.

in Gardner–Medwin–Walton and Vignos scales. A significant correlation (p < 0.05) was detected between the mean MFF of all muscles and Gardner–Meldwin–Walton (r = 0.84) and Vignos (r = 0.60) scale. This correlation was also found separately in the muscles of thigh (anterior r = 0.83, posterior r = 0.75) and calves (anterior r = 0.65, posterior r = 0.82).

**Conclusion:** Muscle fat content measured with 3-point Dixon MRI provides a high correlation with clinical severity of ambulant LGMD2A patients and could be a useful biomarker.

**Rare case of leprosy, where initial presentation is carpal tunnel syndrome**

Y.B. Sharma, Neurology, Vedant Superspeciality Hospital, Vadodara, India

A 33-year-old woman from village area of country, had history of right arm pain with tingling like sensation, especially aggravated in night time. Clinically suspected carpal tunnel syndrome confirmed with nerve conduction study. Apart patient did not have any other symptoms related to skin or other nerve involvement. 9 months post decompression surgery patient had developed hypo pigmented rash on forearm and leg, as well as trophic ulcer in hands. With no apparent exposure to leprosy, clinical and histological evidence of tuberculoid leprosy was found. A particular characteristic of this case was leprous neuritis involving the median nerve which was diagnosed clinically as carpal tunnel syndrome, and scheduled for surgical treatment. Under treatment with dapsone and rifampicin, however, the condition cleared up completely.

**Cholinergic neuromuscular hypersensitivity in musk antibody positive myasthenia gravis**

H.Y. Shin, H.J. Park, Y.C. Choi, I.N. Sunwoo, S.M. Kim, Department of Neurology, Yonsei University College of Medicine, Seoul, Republic of Korea

**Background:** The patients with MuSK antibody (MuSK-Ab) positive myasthenia gravis (MG) show distinct responses to acetylcholinesterase inhibitor (AChEI), such as less effective therapeutic response to AChEI and more frequent nicotinic side effects and negative result of diagnostic AChEI test. Some MuSK-Ab positive MG patients experience overt worsening after AChEI treatment. In addition, the compound muscle action potential with extradischarges (CMAP-EDs), electrophysiologic feature of cholinergic neuromuscular hyperactivity, may develop in the MuSK-Ab positive MG patients with usual therapeutic dose of AChEI.

**Objective:** We investigated the clinical and electrophysiologic features of cholinergic neuromuscular hypersensitivity in MuSK-Ab positive MG patients.

**Patients and methods:** We retrospectively reviewed the medical records and electrodiagnostic findings of seventeen MG patients (MuSK-Ab positive: 10, MuSK-Ab negative: 7) who underwent electrodiagnostic test before and after neostigmine test.

**Results:** The MuSK-Ab positive patients had higher frequency of intolerance to oral pyridostigmine bromide (50 vs 0%, p = 0.044) and lower maximal dose of oral pyridostigmine (90 vs 480 mg/day, p = 0.023) than the MuSK-Ab negative. The frequency of positive results of neostigmine test was significantly lower in the MuSK-Ab positive patient (100 vs 40%, p = 0.035). The nicotinic side effects of neostigmine were more frequent in the MuSK-Ab positive patients (80 vs 14.3%, p = 0.015). The CMAP-EDs were more frequently developed after neostigmine injection in the MuSK-Ab positive patients than the MuSK-Ab negative (90 vs 14.3%, p = 0.004).

**Conclusion:** Cholinergic neuromuscular hypersensitivity is a distinct characteristic of MuSK-Ab positive MG.

**Effect of Alpha-Lipoic Acid on the postural stability of patients with diabetic peripheral neuropathy**

D. Petrova, C. Stambolieva, Department of Neurology, National Transport Hospital “Tsar Boris III”, Bulgaria; D. Petrova, Department of Cognitive Psychophysiology, Institute of Neurobiology, Bulgarian Academy of Sciences, Sofia, Bulgaria

**Background:** Diabetic peripheral neuropathy (DPN) is a common complication of diabetes mellitus, that affects the postural stability.
There are researches about the effect of Alpha-Lipoic Acid (ALA) on the reduction of pain and improvement of neuropathic deficits. **Objective:** This study evaluated the effect of treatment with ALA on the postural stability in patients with type 2 DPN. **Patients and methods:** Sixty patients and 20 healthy age-matched subjects took part in this investigation. All patients had a good gynecic control. The two schemes of treatment were applied: the first — with 600 mg ALA (5 day infusion and 60 day oral dose), and the second — ALA, benfotiamin, pyridoxine and cyanocobalamine together. The postural stability was evaluated using static posturography under two visual conditions (eyes open and eyes closed) on stable and soft surfaces. The investigations were made on the first, 5th and 60th day after the drug therapy. **Results:** Before the treatment with ALA the all posturographic parameters, for both patient groups were significantly higher than in healthy subjects. After treatment the sway velocity and sway path decreased. The most pronounced decrease was observed in sway path during stance on foam support with closed eyes. The changes of the posturographic results after the combined therapy were better than with ALA only. **Conclusion:** Treatment with combined therapy (ALA, benfotiamin, pyridoxine and cyanocobalamine together) showed stabilizing effect on the quiet upright stance, that leads to improvement of the quality of life of patients with type 2 DPN.

**Classification of sporadic lower motor neuron disease in Jeju Island**  
S.-Y. Kang, Neurology, School of Medicine, Jeju National University, Jeju, Republic of Korea

**Objectives:** The sporadic forms of lower motor neuron disease (LMND) constitute a heterogeneous group of diseases with largely unknown pathogenesis. Clinical, genetic, electrophysiological, and immunological findings can help to distinguish patients with LMND who never develop amyotrophic lateral sclerosis (ALS) from patients with typical ALS.  

**Methods:** We studied the clinical and electrophysiological features of 23 patients with sporadic LMND in a cross-sectional study. Disease duration was more than 4 years to exclude the majority of patients with ALS. Based on the pattern of weakness, we classified patients into three groups: with generalized weakness (group 1); with non-generalized asymmetrical weakness of the arms (group 2); with non-generalized asymmetrical weakness of the legs (group 3).  

**Results:** We identified two patients in group 1, eighteen patients in group 2, and three patients in group 3. Distinctive features of group 1 were an older age at onset, more severe weakness and muscle atrophy and more widespread abnormalities on needle EMG. In groups 2 and 3, age at onset was younger than patients in group 1. However, needle EMG findings also suggested a more widespread disease process. Retrospectively, the prognosis of sporadic LMND seems to be relatively good after a median disease duration of 8 years.  

**Conclusion:** The clinical phenotypes of the different subgroups described in this study may help to differentiate the several LMND forms from each other. However, prospective studies are needed to investigate whether specific clinical or pathogenic variables may help to identify patients with a more benign form of LMND.

**Nerve ultrasound score in distinguishing chronic inflammatory demyelinating polyneuropathy from Guillain–Barré syndrome**  
A. Kerasnoudis, K. Pitarokoili, V. Behrendt, R. Gold, M.-S. Yoon,  
Neurological Department, St. Josef Hospital, Ruhr University, Bochum, Germany

**Background:** GBS is defined as an acute-monophasic polyradiculoneuropathy, while CIDP may also present (16% of the cases) with a subacute-monophasic course. Their differential diagnosis is of great importance, as their therapies differ significantly.  

**Objective:** The aim of this study was the development and evaluation of a new ultrasound score to distinguish these two nosologies.  

**Materials/methods:**  
Phase-1 (development):  
20 GBS (mean-age 58.3y, SD ± 13.8; 10 women), 20 CIDP-patients (mean-age 56.7y, SD ± 13.5; 6 women), 75 healthy-subjects (mean-age 53.9y, SD ± 14.8; 30 women) underwent nerve-ultrasound, a mean
of 3.4 years (SD ± 2.91) and 4.55 years (SD ± 3.5) respectively, after onset. Using the acquired ultrasound data we developed a “Bochum-ultrasound-score” (BUS) summarizing:

1) the cross sectional area (CSA) of the ulnar nerve in Guyon’s canal,
2) CSA of the ulnar nerve in upper arm,
3) CSA of the radial nerve in spiral groove,
4) CSA of the sural nerve between gastrocnemius muscle.

The patient received 1 point for every anatomic site of the “BUS”, where he showed pathological CSA enlargement (min = 0, max = 4).

Phase-2 (evaluation):
Further 21 GBS (mean-age 54.2y, SD ± 12.6; 12 women), 10 CIDP-patients (mean-age 55.1, SD ± 9.9; 3 women) underwent blinded for the diagnosis examination with the “BUS”, a mean of 2.3 years (SD ± 1.5) and 3.8 years (SD ± 2.7) respectively, after onset.

Results: The “BUS” showed a sensitivity of 90%, specificity of 90, 4% (PPV81, 8%, NPV = 95%) in distinguishing CIDP from GBS.

Highlight: 6 patients with subacute polyradiculoneuropathy (mean-age 52.6, SD ± 16.47; 2 women), who presented in year 2012 to our department, underwent blinded for the diagnosis examination with the “BUS” a mean of 2.8 weeks (SD ± 2.1) after onset. The “BUS” showed a sensitivity of 75%, specificity of 100% (PPV = 100%, NPV = 66%) in distinguishing subacute-CIDP from GBS.

Conclusion: The “BUS” seems to allow a reliable distinction of CIDP from GBS.

Plasma cortisol levels in amyotrophic lateral sclerosis
R. Spataro, P. Volanti, F. Vitale, T. Colletti, D. De Cicco, F. Meli, V. La Bella, aDepartment of Experimental BioMedicine and Clinical Neurosciences, University of Palermo, Palermo, Italy; bNeurorehabilitation Unit, Salvatore Maugeri Foundation, Mistretta, Italy; cDepartment of Sciences for Health Promotion ‘G. D’Alessandro’, University of Palermo, Palermo, Italy

Background: Amyotrophic lateral sclerosis (ALS) is associated with a significant distress, being possibly linked to changes in hypothalamic–pituitary–adrenal (HPA) axis activity or other stress–response systems.

An early study reported a loss of cortisol circadian rhythmicity in ALS patients (Patacchiali et al, 2003), while more recently it has been shown a blunted cortisol awakening response, which correlated with the clinical status and depressive mood (Rozental et al, 2012).

Objective: To assay the circadian plasma cortisol levels in ALS and to study their relationship with the clinical phenotype and rate of disease progression.

Patients and methods: 122 ALS patients (Bulbar, 30; Spinal, 92; M/F = 1.73) and 103 controls (not affected by neurological or psychiatric disorders, free of drugs; M/F = 1.75) were recruited. Disease progression was scored with ΔFS. Plasma cortisol level (ug/dl) was assayed from fasting patients and controls at 8:00 and 20:00 using Elecsys® Cortisol Immunoassay System. Data were analyzed with the Mann–Whitney U test or, where appropriate, with the Kruskal–Wallis test.

Results: We found higher levels of morning cortisol in ALS patients than controls (morning: ALS, 15.2 [11.5–18.9] vs Controls, 11.4 [8.8–14.3], p < 0.001; evening: ALS, 7.5 [4.7–11.8] vs Controls, 7.9 [5.4–10.0], p = 0.6). The hormone’s morning level was higher in the spinal-onset group (Spinal, 15.9 [11.9–19.0] vs Bulbar, 13.5 [10.1–18.6] vs controls, 11.4 [8.8–14.3], p < 0.001) and in patients with intermediate/rapid disease course.

Conclusions: Morning plasma cortisol level is increased in ALS and correlates with site of onset and rate of disease progression. Thus, a subgroup of ALS patients may have an altered HPA axis activity.

Lateral spread responses on facial motor nucleus suppression using intravenous diazepam in patients with hemifacial spasm
S.I. Choi, D.H. Jang, M.-W. Kim. Rehabilitation Medicine, The Catholic University of Korea, Incheon, Republic of Korea

Introduction: There has been a controversy between two hypotheses for the pathophysiology of hemifacial spasm: peripheral theory and central theory are two candidate. This study sought to investigate the pathophysiologic mechanism of hemifacial spasm.

Materials and methods: A total of 6 patients with hemifacial spasm were recruited. In experimental study, supraorbital nerve stimulation with orbicularis oris muscle recording study and lateral spread test were performed, then we applied intravenous diazepam 10 mg to the patients for facial motor neuronal suppression. Two ‘drug series’ were recorded, 10 min and 20 min after the subject had received a 10 mg diazepam intravenously.

Result: In all patients, orbicularis oris responses were appeared on supraorbital nerve stimulation with orbicularis oris muscle recording study and late responses were appeared on lateral spread test. After diazepam injection, on supraorbital nerve stimulation with orbicularis oris muscle recording study, latencies of orbicularis oris response were showed slowing tendency as time passes in the patients. On lateral spread test, however, in all patient, latencies of direct and late responses were consistent as time passes.

Discussion: In our present study, we inhibited facial motor nucleus using diazepam that is CNS depressant. If the site of abnormal cross transmission is in the facial nucleus, lateral spread response should be recorded with a wave form of delayed latency as our supraorbital nerve stimulation with orbicularis oris muscle recording study. The results suggest peripheral pathway, ectopic excitation–ephaptic transmission as the pathophysiologic mechanism in hemifacial spasm.

Guillain–Barré syndrome in HIV infection — A case report
F.C. Rosca, O. Rosca, L. Chicea, M. Simu, aDepartment of Neurology II, University of Medicine and Pharmacy ‘Victor Babes’, Timisoara, Romania; bDepartment of Neurology II, Clinical Emergency County Hospital, Timisoara, Romania; cDepartment of Infectious Diseases I, University of Medicine and Pharmacy ‘Victor Babes’, Timisoara, Romania

Background: The acute inflammatory demyelinating polyradiculoneuropathy or the Guillain–Barré syndrome (GBS) is rarely described in HIV-infected patients. Recent studies suggest that the treatment with Immunglobulin (IVIG) not only improves the neurologic symptoms, but in addition to ART therapy, it also reduces the HIV reservoir.

Objective: We report the case of a 21-year-old man, with generalized motor deficit that interrupted his ART therapy 3 months ago. Five days before admission, he noted paresthesias in his limbs, followed by pain and progressive weakness.
Patients and methods: On neurological examination, he had 1/5 strength in the lower extremities, 3/5 strength in the upper extremities, diminished tendon reflexes, and decreased sensation in the lower limbs and dysphagia. Examination of the CSF revealed increased protein level and pleocytosis. Electromyographic findings suggested an acute demyelinating process with conduction block. A diagnosis of GBS was made and the patient received treatment with a 5-day course of 0.4 g/kg/d IVIG. He refused the ART therapy.

Results: After the treatment, the neurological status improved (3/5 strength in lower extremities, 4/5 in upper extremities, swallowing problems remitted). Interestingly, his CD4 and CD8 cell counts increased and the plasma viral load decreased.

Conclusion: IVIG has several effects on the immune system but the mechanism of action in HIV infection is unknown; recent studies suggest its utility as adjuvant therapy in HIV infection. The present case brings further evidence in favor of this hypothesis. Furthermore, the patient’s immune status improved and the viral load decreased without any ART therapy.

Autosomal dominant Brown–Vialetto–Van Laere syndrome with UBQLN1 mutation
R. Spataro, F.L. Conforti, R. Mazzei, V. La Bella, \textsuperscript{a}Department of Experimental BioMedicine and Clinical Neurosciences, University of Palermo, Palermo, Italy; \textsuperscript{b}Institute of Neurological Sciences, National Research Council, Mangone, CS, Italy

Background: Brown–Vialetto–Van Laere syndrome (BVVLS) is a rare MND characterized by childhood onset, bulbo-pontine paralysis and neurosensory deafness. Recent genetic studies have demonstrated mutations in c20orf54 riboflavin encoding gene in most familial cases, recessive mutations on Chr. 8q24.3 in a Lebanese family and the UBQLN1 gene mutation E54D in a sporadic BVVLS patient.

Objective: To report the phenotypic and genotypic characteristics of an Italian family with autosomal dominant BVVLS.

Patients and methods: The family studied has two clinically-documented cases. The proband is a 15-year-old girl affected by BVVLS since she was 3. She is now tetraplegic and tracheostomized. The second case is the proband’s maternal aunt. She was diagnosed with BVVLS at 20, but deafness and bulbar weakness started during adolescence. She died at 27 because of respiratory insufficiency. For genetic testing, we obtained an informed consent from the proband’s father. DNA was extracted from blood and the screening of both genes was amplified and directly sequenced.

Results: A heterozygous substitution E54D in exon 1 of the UBQLN1 gene was found in the proband. No mutations in the c20orf54 gene were detected. Screening for UBQLN1 and c20orf54 gene mutations in available asymptomatic living relatives (the father and the brother) was negative.

Conclusions: In this study we describe the first family with an autosomal dominant form of BVVLS linked to a UBQLN1 mutation. The pattern of inheritance is autosomal dominant with incomplete penetrance and with variability of age of onset.

A report of two cases of Guillain Barre syndrome variants post dengue infection
T. Gosavi, C.W. Yip, P. Kumar, Y.L. Lo, \textsuperscript{a}Neurology, National Neuroscience Institute, Singapore, Singapore; \textsuperscript{b}Neurology, Singapore General Hospital, Singapore, Singapore

Background: Various viral infections have been known to precede the development of Guillain Barre Syndrome (GBS). Cytomegalovirus and Epstein Barr virus are commonly implicated. Influenza, para-influenza, adenovirus, herpes simplex and varicella zoster virus have been rarely implicated. Post dengue GBS is an extremely rare neurologic complication of dengue with only few cases reported in literature.

Objective: To report two cases of post dengue GBS and to analyse their clinical presentation, electrophysiologic studies and the outcome.

Patients and methods: Both patients presented with limb weakness and their clinical examination was consistent with hyporeflexic/areflexic quadriaparesis. Patient 1 had history of ongoing fever of 4 day duration with thrombocytopenia and mild hepatitis. His dengue PCR was positive. His weakness recovered fully spontaneously. Patient 2 had history of dengue infection a week ago with dengue IgM positive. She also had autonomic instability and bilateral facial weakness. She was treated with IVIG. She had partial recovery with residual weakness at discharge.

Results: Patient 1 had an acute inflammatory demyelinating polyneuropathy (AIDP/conventional GBS) with good clinical recovery. Patient 2 had an acute motor-sensory axonal polyneuropathy (AMSAN variant of GBS) with partial recovery.

Conclusion: GBS is rare but known neurologic complication of dengue virus infection. It can present as different clinical variants of GBS. GBS should be considered if any patient with recent or ongoing dengue infection presents with weakness. Prognosis can be variable depending upon the pattern of nerve injury.

Cognitive and psychological profile in Tunisian children with Duchenne muscular dystrophy

Background: In Duchenne muscular dystrophy (DMD), mutation of the dystrophin gene has long been recognized as a cause of intellectual impairment. However, underlying etiopathological mechanisms remain unclear.

Objective: To analyze cognitive and psychological profiles in Tunisian children with DMD and their correlation with causal mutations.

Patients and methods: Over 8 years (2005–2013), 18 boys were followed up in our department for a genetically confirmed diagnosis of DMD. Neuropsychological evaluation including full-scale intelligence quotient (IQ), memory assessment, verbal performances, attention processes, executive functions, mood and behavioral patterns. Correlation between dystrophin gene mutation and neuropsychological profile was analyzed.

Results: Mean age of patient was 11.16 years. Causal mutation predicted to lead to a loss of the Dp140 isoform has been found in 13 patients. Mean age at neuropsychological evaluation was 6.9 years. General intelligence assessments showed a mean IQ of 82 (range 50–110). Impairment in working memory was noted in 10 patients. Verbal performances and attention processes were altered in respectively 5 and 3 patients. Executive dysfunction was noted in 3 patients. Cognitive deficits were correlated to the loss of Dp 140 isoform in 9 patients out of 13. There was no evidence of cognitive declining with the progression of muscular deterioration.

Conclusion: Our results support emerging evidence of central nervous system involvement resulting in neuropsychological disorders in DMD. The loss of Dp 140 seems to be involved in the pathological mechanism underlying cognitive impairment. Neuropsychological deficits should be systematically detected in DMD in order to improve patient’s quality of life.

Extracorporeal photopheresis in treatment of myasthenia

Q. Sidorova, A. Kildyushovsky, S. Kotov. Department of Neurology, M.F. Vladimirsky Moscow Regional Clinical and Research Institute, Moscow, Russia

Aim: Estimation of extracorporeal photopheresis (EPT) efficacy in myasthenic patients.

Material and methods: A total of 31 patients with generalized myasthenia were treated beyond exacerbation period. Muscular strength was evaluated according to 5-score scale. EPT method was as follows: patients underwent interrupted leukapheresis procedure, which yielded, out of 1 L of patient blood, approximately 200–250 ml of leukocyte-enriched blood containing, on the average, 2.43–3.6 × 109 mononuclear cells. Prior to reinfusion, leukocyte suspension was UV radiated. Treatment course included 4 expositions (2 times a week with two expositions each time). Each patient received photosensitizing drug before each exposition.
Results: Improvement was noted in 27 of 31 patients (87%). Statistically significant increase of strength was registered in mimic, neck and biceps muscles, musculus deltoideus, musculus gastrocnemius, and musculus iliopsoas (p < 0.05). Clinical effect was retained for 3–4 months. There is a 2-year-follow-up of a patient, admitted to the hospital with bulbar and oculomotor disturbances. During further regular treatment, bulbar disturbances disappeared, and mild eye double-seeing was cured after the first exposition. Lymphocyte subpopulations in general decreased, immune regulatory index CD4/CD8 normalized. Immunoglobulin levels decreased, mainly IgA (by 18%), and less-IgG (by 8.3%) and IgM (by 2%). Decrease of interferon status mean values was statistically insignificant.

Conclusion: Extracorporeal photochemotherapy is an effective and prospective method of myasthenia therapy. EPCT is an alternative method of medicamentous treatment of myasthenia, not requiring glucocorticoids or cytostatic drugs.

Macrophages involvement in neurodegenerative process in motor neuron disease
D. Labunskiy, T. Fedotova. Biomedical Engineering, University of Northern California, Santa Rosa, CA, USA; Tver State Medical Academy, Tver, Russia

Amyotrophic lateral sclerosis (ALS) is incurable neurodegenerative disease characterized by death of upper and lower motor neurons. Neuroinflammation is pathological marker of many neurodegenerative diseases including ALS and is typified by activation and proliferation of microglia and infiltration of T cells into brain and spinal cord. Damaged motor neurons are able to activate complement system microglia and astrocytes, which can contribute to neurodegeneration.Activated microglia and astrocytes are found in close proximity to dying motor neurons. Their activation status and proliferation seemingly increases with disease progression. Aim of our research was to investigate pathologic changes of brain stem (BS) in ALS, we analyzed midsagittal sections of BS from 24 individuals with ALS and 29 controls by using conventional staining and immunohistochemistry with antibodies against CD68 and GFAP. Also we studied macrophagal phagocytosis in 67 patients with different ALS forms. Control group comprised from 122 healthy donors of same gender, age groups. The number of CD68-immunoreactive macrophages/microglia and GFAP-immunoreactive astrocytes were significantly higher in individuals with ALS than in controls in all areas of the BS except rostrum. Among the patients with ALS, the number of macrophages/microglia and astrocytes was significantly higher in isthmus than in rostrum. Multiple immunofluorescence labeling of selected biomarkers revealed different microglial phenotypes during culturing. These findings suggest that pathologic changes in the BS in ALS are present in posterior midbody and isthmus, where callosal motor fibers may traverse between two hemispheres. CD68 and GFAP immunohistochemistry are sensitive methods to detect those pathologic changes in routine paraffin-embedded specimens.

Symptoms and complaints of the patients with dm1 at the early stage
K. Ogata, M. Suzuki, K. Yatabe, T. Shigeyama, Y. Honma, K. Momma, Y. Tanaka, R. Akatani, I. Nonaka, T. Tamura, M. Kawai. Neurology, National Hospital Organization Higashisaitama Hospital, Hasuda, Japan; Cardiology, National Hospital Organization Higashisaitama Hospital, Hasuda, Japan; National Center of Neurology and Psychiatry, Kodaira, Japan

Myotonic dystrophy type 1 (DM1) is an autosomal dominant disorder with dysfunction of multiple systems. Concurrent features of skeletal muscles, myotonia and weakness, do not make difficulties with DM1 patients in early and mild stage, and progress slowly. Consequently, the diagnosis of DM1 at the early stage is difficult and tends to delay. We analyzed main symptoms at onset and chief complaints at the first visit to clinic from the medical records of 67 patients with DM1 (41 males, 26 females). Mean age of their onset was 27.2 ± 14.1. The main symptoms at onset were: weakness, 40; myotonia, 17; mental retardation, 8; dysarthria, 1; lumbago, 1. Mean interval from onset to their first visit to neurological clinics about DM1 was 11.6 ± 9.9 years. The chief complaints at the first visit to clinics were: weakness, 44; myotonia, 7; dysarthria, 2; lumbago, 2; genetic counseling, 2; apathy, 1; syncope, 1; no complaint, 8. Among 17 patients onset with myotonia, only 7 were with also myotonia as the chief complaint at the first visit to clinic. Among 40 patients onset with weakness, 33 were with weakness as the chief complaint at the first visit to clinic. Myotonia is a characteristic and important sign for DM1, which provides early diagnosis. In contrast, myotonia is less likely to be a reason for consultation to physician, suggesting that patients with DM1 are suffering more with weakness than with myotonia.

Clinical and neuroimaging features of familial C9FTD/ALS: A case report
L. Pardo, M. Pardo-Parrado, J. Clarimón, A. García-Redondo, E. Cebrián, I. Jiménez-Martínez, J. Cortés, P. Aguiar, J.A. Castilleiras, T. García-Sobrino, B. Quintáns, M.J. Sobrido, Neurology, Hospital Clinico, Santiago de Compostela, Barcelona, Spain; CIBERNED, Barcelona, Spain; Neurology, ALS Unit, Instituto de Investigación Biomédica Hospital 12 de Octubre, Madrid, Spain; CIBERER, Valencia, Spain; Neurology, Complexo Hospitalario de Pontevedra, Pontevedra, Spain; Nuclear Medicine, Hospital Clinico, Spain; Radiology, Hospital Clinico, Spain; Fundación Pública Galega de Medicina Xenómica-SERGAS, Santiago de Compostela, Spain; Instituto de Investigaciones Biomédicas de Santiago-CIBERER, Santiago de Compostela, Spain

Background: The expansion of an intronic hexanucleotide repeat in chromosome 9 is the most frequent cause of ALS/FTD. Objective: To describe the clinical and neuroimaging features of a patient with familial C9FTD/ALS. Patients and methods: We describe a 45 year old patient with a family history of ALS and FTD (affected father and paternal aunt), in whom the C9ORF72 hexanucleotide expansion was detected. Results: At 26 she started with progressive right hand weakness, followed by weakness of the upper left and, subsequently, lower
right limb. Inability to walk and bulbar symptoms are present since the age of 40. Additionally, personality changes, delusions and progressive cognitive decline started about 12 years after the onset of motor manifestations. Currently she has severe cognitive impairment with a delusional disorder and confabulations. Motor examination revealed tongue atrophy and fasciculations, dysarthria, tetraplegia, upper limb hyporeflexia and lower limb hyperreflexia, as well as marked generalized muscle wasting and diffuse, active denervation in the EMG. While the severe cortical atrophy – especially affecting the left temporal lobe – observed in 3-tesa MRI, was congruent with the predominantly left temporal hypometabolism showed through brain PET scan, the PET–MRI fusion image demonstrated a pattern of generalized cortical hypometabolism.

**Conclusion:** We present the detailed phenotypic characterization of a patient with C9ORF72-associated ALS/FTD. We highlight the potential contribution of PET–MRI fusion image to the understanding of this disorder, since it allows correcting the metabolic activity for the degree of cortical atrophy observed with MRI.

**Anoctamin 5 myopathy: More patients, more phenotypes**

A. Behin1, F. Leturcq2, M. Cossée1, K. Wahbi1, N. Deburggrave3, H.-M. Bécane4, R.-Y. Carlier1, P. Lafont3, T. Stoikovic1, P. Carlier4, B. Eymard4.

1Centre de Reference de Pathologie Neuromusculaire Paris Est, APHP, GH Pitie-Salpetriere, Paris, France; 2Laboratoire de Biologie Moléculaire, Pavillon Cassini, APHP, GH Cochin, Paris, France; 3Service de Neuroradiologie, APHP, GH Raymond Poincaré, Garches, France; 4Laboratoire de RMN, Institut de Myologie, Paris, France

**Background:** Anoctamin 5 myopathies are autosomal recessive disorders resulting from mutations in the ANO5 gene.

**Objective:** To present the expanding spectrum of the disease.

**Patients and methods:** We present here a cohort of patients diagnosed in Paris since 2011, when genetic testing became available in France. Patients tested include known but unexplained cases of muscle dystrophy and new patients diagnosed as possible anoctamin 5 myopathies on clinical grounds.

**Results:** 31 patients, stemming from 26 families, display two mutations of the ANO5 gene, including 24 men and 7 women, the latter being less severely affected in a majority of cases. Mean age of onset was 32 years (range 10–50 years). Clinical pattern was LGMD2L in 22%, Miyoshi-type distal myopathy (MMD3) in 22%, proximo-distal weakness in 4%, exercise intolerance in 22%, isolated high-Cks in 16% of cases. Two further patients presented with a pseudo-Becker dystrophy and 2 female patients developed a severe, calpain-like limb-girdle myopathy. 6 patients presented with cardiac abnormalities on echocardiography, leading to medical treatment in 3 cases. CK levels were usually very high, ranging from 3.5 to 125 times the normal value. Muscle imaging showed a constant involvement of medial gastrocnemii. Most patients harboured heterozygous private mutations, except for the common c.191dupA duplication.

**Conclusion:** Anoctamin 5 myopathy appears as a major cause of muscle dystrophy, sharing similarities with dysferlinopathies. However, later onset, slower course and the presence of dysferlin on muscle immunostainings distinguish anoctamin 5 myopathies, as well as some particular phenotypes and mild heart involvement.

Is tracheostomy still an option in amyotrophic lateral sclerosis? Reflections of a multidisciplinary work group

A.-C. Héroïstère Barras2, R. Iancu Ferfoglia3, J.-P. Janssens6, CeSLA.

1Neurology Clinic, University Hospitals of Geneva, Geneva, Switzerland; 2Division de Pneumologie, University Hospitals of Geneva, Geneva, Switzerland

**Question under study:** Amyotrophic lateral sclerosis (ALS) is a progressive neurogenerative disease with a poor prognosis. Survival and quality of life of ALS patients have improved through the implementation of multidisciplinary approaches, the use of percutaneous gastrostomy and of non-invasive (NIV) or invasive ventilation. The question of whether or not to propose invasive ventilation (by tracheostomy; TPPV) to ALS patients remains a matter of debate.

**Methods:** The present study reviews the medical literature, the practice in Swiss and two large French ALS expert centres, and reports the results of a work group on invasive ventilation in ALS.

**Results:** Improved management of secretions and using different interfaces allows using NIV 24 h a day for prolonged periods and thus avoiding TPPV in many cases. TPPV is frequently initiated in emergency situations with lack of prior informed consent. TPPV appears associated with a lesser quality of life (QoL) and a higher risk of institutionalization than NIV. The high burden placed on caregivers who manage ALS patients is a major problem with a clear impact on their QoL.

**Conclusions:** Current practice in Switzerland and France tends to discourage the use of TPPV in ALS. Fear of a “locked-in syndrome”, high burden placed on caregivers, unmasking cognitive disorders occurring late in the evolution of ALS are some of the caveats when considering TPPV. Most decisions of TPPV are taken in emergency situations in the absence of advanced directives. One exception is that of young motivated patients with predominantly bulbar disease who “fail” NIV.

Spinal cord atrophy correlates with disease severity in amyotrophic lateral sclerosis

**Background:** Biomarkers are needed to help in the diagnosis and long term care of patients with ALS. SC damage is a pathological hallmark of the disease, but there are few studies that investigated quantitative MRI of the SC as a biomarker in ALS.

**Objective:** To investigate spinal cord (SC) atrophy in Amyotrophic lateral sclerosis (ALS), and to determine whether it correlates with clinical parameters.

**Methods:** Forty-three patients with ALS (25 men) and 43 age-and-gender-matched healthy controls underwent MRI on a 3T scanner. We used T1-weighted 3D images covering the whole brain and the cervical SC to estimate cervical SC area and eccentricity at C2/C3 level based on a semi-automatic image segmentation protocol using a validated software (Spineseg). Acquisition parameters: TE = 3.2 ms, TR = 7.1 ms, flip angle = 8°, voxel size = 1.0 mm3 and FOV = 240 × 240. Disease severity was quantified with the ALS functional rating scale. SC areas of patients and controls were compared with Mann–Whitney test. We used linear regression to investigate the association of SC area and clinical parameters.
Results: Mean age of patients and disease duration were 53.1 ± 12.2 years and 34.0 ± 29.8 months, respectively. The two groups were significantly different regarding SC areas (67.8 ± 6.8 mm² vs 59.5 ± 8.4 mm², p < 0.001). However, eccentricity values were similar in both groups (p = 0.394). SC areas presented a significant correlation with disease duration (r = −0.585, p < 0.001) and ALS functional rating scale (r = 0.318, p = 0.037).

Conclusions: Patients with ALS have SC atrophy, but no flattening and SC areas did correlate with disease duration and functional status.

Ultrasonography does not increase sensitivity of the carpal tunnel syndrome electrodiagnosis

G. Omejec, S. Podnar. Institute of Clinical Neurophysiology, University Medical Centre Ljubljana, Ljubljana, Slovenia

Background: Median nerve entrapment at the wrist (i.e., the carpal tunnel syndrome—CTS), is the most common neuropathy. In spite of its high sensitivity, electrodiagnostic (EDx) studies are negative in some patients with typical and bothersome CTS symptoms (i.e., paresthesias in at least 2 of the first 4 fingers pronounced during the night or in the morning).

Objective: To report utility of ultrasonographic (US) examination in this patient population.

Patients and methods: Three groups were studied: (1) patients with typical CTS symptoms and mild EDx abnormalities; (2) patients with typical CTS symptoms, but negative EDx studies; (3) asymptomatic volunteers. The cross-sectional area (CSA) of the median nerve at the pisiform bone and 1 cm proximal (the wrist) and 10 cm proximal (the forearm) were measured by a high-resolution US. The criteria for CTS diagnosis were the median nerve CSA at the wrist > 10 mm², and wrist-to-forearm CSA ratio (WFR) > 1.5.

Results: The median nerve CSA at the wrist was increased in 91% of 58 symptomatic patients with positive EDx, in 38% of 136 symptomatic patients with negative EDx, and in 35% of 48 asymptomatic controls. WFR was increased in 97%, 50%, and 48% of subjects, respectively. No statistical difference in CSA was found between patients with negative EDx and asymptomatic volunteers (p = 0.46).

Conclusion: US is not useful in patients with typical CTS symptoms, but negative EDx studies. EDx or US is equally useful to confirm CTS diagnosis.

Brain involvement in FKRP-related muscular dystrophy

S. Makri-Mokrane¹, P. Richard¹, N. Terki², M. Ait-Kaci Ahmed³, P. Guicheney⁴, ⁵. Neurology, Etablissement Hospitalier Spécialisé Ali Ibn Icid, Benyoucef Benkhedda University, Algiers, Algeria; ⁶Service de Biochimie Métabolique, Ulf Cardiogénétique et Myogénétique, Groupe Hospitalier Pitié-Salpêtrière, Paris, France; ⁷Laboratoire d'Histopathologie, Centre Pierre et Marie Curie, Benyoucef Benkhedda University, Algiers, Algeria; ⁸UMRS 956, Institut de Myologie, Groupe Hospitalier Pitié-Salpêtrière, Inserm/UPMC Groupe Hospitalier Pitié-Salpêtrière, Paris, France

Introduction: FKRP mutations cause a muscular dystrophy which may present in the neonatal period (MDC1C) or later life (LGMD2I). Normal intelligence and brain imaging have been previously reported in FKRP-related muscular dystrophy, except in rare cases presenting with mental retardation associated with structural brain abnormalities.

Patients and results: We studied cerebral MRI in three unrelated children, aged 4–6 years, with FKRP-related muscular dystrophy presenting MDC1C and moderate mental disturbances. Brain MRI in the first patient with moderate muscular phenotype showed structural abnormalities of the posterior fossa with hypoplasia of the vermis and pons, multiple cerebellar hemispheric cysts, and abnormal white matter signal in the cerebellum and periventricular region. Moderate unilateral left vermis hypoplasia, few cerebellar cysts, mild pons hypoplasia, and left temporal atrophy were seen in the second case which had mild clinical picture. The last child had normal neuroimaging and severe phenotype.

Conclusion: MRI abnormalities are common in our patients with FKRP-related muscular dystrophy presenting at birth. They show no correlation with clinical features. Posterior fossa malformation may be associated with mental retardation.

Bent spine syndrome due to myofibrillar myopathy
F. Nadli\textsuperscript{a,b}, M.L. Valentino\textsuperscript{a,b}, M. Columbaro\textsuperscript{c}, P. Avon\textsuperscript{a,b}, F. Bisulli\textsuperscript{a,b}, N.M. Maraldi\textsuperscript{a}, R. Liguori\textsuperscript{a,b}. \textsuperscript{a}Neurology Department, IRCCS Istituto delle Scienze Neurologiche di Bologna, Italy; \textsuperscript{b}Department of Biomedical and NeuroMotor Sciences (DIBINEM), Alma Mater Studiorum - University of Bologna, Italy; \textsuperscript{c}Laboratory of Musculoskeletal Cell Biology, IRCCS Istituto Ortopedico Rizzoli, Bologna, Italy.

Background: Camptocormia, as an isolated sign, could be a diagnostic challenge since it might be caused by several central and peripheral nervous system diseases, including Parkinson disease, dystonia, MSA, Alzheimer disease, ALS, CIDP, myasthenia and myopathies.

Objective: To describe a patient with camptocormia due to a myofibrillar myopathy (MFM) that is, to our knowledge, the second case reported in literature.

Patients and methods: A 75 year-old woman presented progressive trunk forward flexion since the age of 72 as her father, who showed same spine symptoms from the age of 50. The patient underwent clinical examination, laboratory exams, EMG, muscle MRI and biopsy.

Results: Clinical examination revealed camptocormia, mild paraspinal muscles weakness, “compensatory” posture with trunk hyperextension, flexion of legs and arms and tendency to touch lightly her thighs to walk more easily, resembling a “geste antagoniste”. There were no extrapyramidal signs. CPK level was normal and EMG of paraspinal muscles revealed a myopathic pattern. Muscle MRI showed fatty replacement of the paraspinal muscles. Biopsy of D5-D6 paraspinal muscle showed myopathic features with fiber size variability, internal nuclei, slight increase of connective tissue and some vacuoles; the Gomori trichrome staining revealed areas darkly stained within fibers. Immunohistochemistry studies showed an abnormal accumulation of desmin and α-crystallin. Electron microscopy confirmed myofibrillar disruption. A diagnosis of MFM was made.

Conclusion: Bent spine is predominantly described in the later stages of MFM, therefore represents an unusual sign at the disease onset. Among myopathies, MFM should be considered in the differential diagnosis of camptocormia.

Distal myasthenia simulating radial nerve palsy: A case report
J. Pardo\textsuperscript{1}, T. García-Sobrino\textsuperscript{2}, M.P. Vidal\textsuperscript{3}, M. Pardo-Parrado\textsuperscript{4}, G. Fernández-Pajarí\textsuperscript{5}, M. Santamaría-Cadavid\textsuperscript{1}. \textsuperscript{1}Neurology, Hospital Clínico, Santiago de Compostela, Spain; \textsuperscript{2}Clinical Neurophysiology, Hospital Clínico, Santiago de Compostela, Spain.

Background: Distal limb weakness is an uncommon manifestation of myasthenia gravis, although it has been described both as a presenting symptom and during the course of the disease.

Objective: To report a patient previously diagnosed as having ocular myasthenia gravis who was attended because of acute distal weakness in his left hand.

Patients and methods: A 74-year-old male with a history of hypertension, cataract surgery and prostate adenocarcinoma was diagnosed as having seropositive ocular myasthenia gravis in November 2009. He subsequently presented bulbar involvement that required treatment with IV immunoglobulins, corticosteroids and pyridostigmine. Since then, he remained asymptomatic on treatment with pyridostigmine and low doses of prednisone every other day. In September 2012 he developed acute dorsoflexor weakness in his left hand.

Results: Clinically, he had weakness of wrist extension, finger extension and finger abduction in the left hand. All other muscles (extraocular, facial, neck, trunk, upper and lower extremities) as well as the rest of the neurological examination were normal. Three-hertz repetitive stimulation with trains of 10 stimuli of the left radial, ulnar and median nerves demonstrated a significant amplitude decrement. The patient was treated with a gradually increasing daily dose of prednison, with subsequent improvement of the hand weakness.

Conclusion: Although distal weakness is rare in myasthenia, it is recommended that this possibility should be considered in the differential diagnosis of patients presenting focal hand weakness in the absence of sensory symptoms and signs.

Diagnostic usefulness of routine nerve conduction studies for the patients with carpal tunnel syndrome
H. Roh, M.-Y. Ahn, K.-B. Lee, J.-S. Kim. Soonchunhyang University College of Medicine, Seoul Hospital, Seoul, Republic of Korea.

Background: Carpal tunnel syndrome (CTS) is the most common entrapment neuropathy. There are many additional electrophysiologic methods for diagnosis of CTS. We analyze routine nerve conduction studies to improve diagnostic simplification and sensitivity for CTS.

Methods: A total of 70 patients with clinically diagnosed CTS and 207 control subjects were enrolled. All subjects were examined by routine nerve conduction studies. Normal limits were derived by calculating the mean ± 2 standard deviations from the data of the controls. The sensitivity and specificity of each test were calculated.

Results: The difference between median and ulnar sensory peak latency was the most sensitive parameter. The sensitivity and specificity of the median-ulnar sensory latency difference were 58.6% and 96.6% respectively. The sensitivity of other parameters was 55.7% for median nerve sensory peak latency, 55.7% for the median-ulnar motor terminal latency difference, 54.3% for the modified combined sensory index, and 52.9% for the median-ulnar sensory peak latency difference.

Conclusions: In our study, some parameters derived from routine nerve conduction studies, especially difference between median and ulnar sensory latency, could be more sensitive for diagnosis of CTS.

Pan-cord brachial plexus injury after the mirpe for the correction of extreme pectus excavatum

We report a case about brachial plexus injury after MIRPE that was confirmed by electrodiagnostic and imaging study.

Case report: A 23-year-old male patient had MIRPE (minimally invasive repair of pectus excavatum) for extreme pectus excarbatum. To correct the deformity, two metal bars were inserted; the first bar was inserted at the sixth intercostal space, and the second bar was
inserted obliquely from the right fourth intercostal space through the left sixth intercostal space. On postoperative day 1, the patient complained weakness, mainly wrist extensor and numbness at whole right upper extremity. Under the impression of right brachial plexus injury, the patient received steroid therapy. 17 days after surgery, electrodagnostic study showed right brachial plexus injury, involving pan-cord and right long thoracic nerve at clavicle level. MRI findings revealed signal changes of right brachial plexus at costoclavicular level and there was a difference in the space between first rib and clavicle on either side. The patient received physical therapy for 3 months. Strength of his right upper extremity and sensory symptoms was improved but, not fully recovered.

**Conclusion:** The correction mechanism of the MIRPE, deformed costal cartilages and sternum are lifted and transformed forcibly by the correction bar. So the abrupt elevation of sternum and rib cages resulted in altering space between first rib and clavicle and might have injured the brachial plexus. Brachial plexus injury is extremely rare complication of the MIRPE but it can be developed obviously considering anatomic structural alteration.

**TITIN-CAP (TCAP) polymorphisms associated with LGMD2G among Indian patients with ARLGMD**

A. Nalini. Neurology, National Institute of Mental Health and Neurosciences, Bangalore, India

**Background:** This rare form of ARLGMD was first described from Brazil. It is mapped to chromosome 17q11-12. No reports are available from India.

**Objectives:** To perform genetic studies in 4 Immunoblot confirmed cases of LGMD2G.

**Materials and methods:** 300 cases of ARLGMD prospecively studied with phenotypic characterisation, muscle Immunohistochemistry (IHC), Immunoblotting (IB) studies. All the exons of TCAP were sequenced including UTR and flanking regions and sequence analysis performed. 100 age and ethnically matched controls were studied.

**Results:** Of 280 biopsies, 226 had IHC,176- IB. Eight from 7 families had complete absence of 19 kDa band. Four belonging to 2 families revealed two pathogenic variations. Clinically: Mean age of onset was 12.38 ± 11.35(5 – 40 years). Scapular winging was seen in all. Shoulder girdle and arms predominantly affected. Moderate distal weakness in two. In lower limbs: iliopsoas, gluteus medius, maximus preferentially involved. Hip adductors severely weak. Foot drop in all. Mean CK-2574.4 ± 2847.5 IU/L(718 to 9253). Genetically: First family had a novel variation in three affected members, c.32C>T (p.Ser11X), resulting in a premature stop codon. Parents and unaffected siblings were heterozygous for same mutation. Second case had a reported homozygous 6 base pair duplication (c.26,33dupAGGTGTC) resulting in frameshift and truncated protein (p.R126fsX31). All unaffected members were heterozygous for this mutation. These variations not identified in 100 age and ethnically matched controls.

**Conclusion:** This is the first study of TCAP mutations in this large sample size of ARLGMD from India. We have identified one novel and one reported functionally significant mutation, which can be used as diagnostic markers.

**Meralgia paresthetica: Topography of the sensory deficit**

J.D. Stewart. Neurology, University of British Columbia, North Vancouver, BC, Canada

**Background:** Meralgia paresthetica (MP) results from lesions of the lateral cutaneous nerve of the thigh (LCNT). This author observed that the sensory abnormality frequently differs from classical descriptions.

**Objective:** To evaluate the distribution of sensory abnormality in patients with MP.

**Patients and methods:** This was a prospective study. MP was considered present when the sensory loss involved at least part of the lateral thigh, there were no motor or reflex abnormalities in the leg, and electromyography of the quadriceps muscle was normal. The classic sensory distribution was considered to involve at least 50% of the length of thigh (iliac crest to upper patella), and did not extend beyond the anterior midline, nor below the lower edge of the patella. Sensory patterns in affected legs were categorized as: classic, bigger medially (beyond anterior midline), bigger inferiorly (below lower edge of patella), bigger both, or restricted (less than 50% of the length of the thigh).

**Results:** 40 patients (34 males) aged 34–73 years had MP. It was bilateral in 8 patients; total number of legs with MP was 47. Topographic

**Factors affecting ultrasonographic findings of the ulnar nerve in ulnar neuropathy at the elbow**

S. Kang, S.H. Kim, S.N. Yang, S.J. Kim, J.S. Yoon. Physical Medicine and Rehabilitation, Guro Hospital, Korea University, Seoul, Republic of Korea

**Introduction:** High-resolution ultrasound (HRUS) can demonstrate focal nerve enlargement in entrapment neuropathies. We aim to identify the factors affecting ultrasonographic findings of the ulnar nerve in ulnar neuropathy at the elbow (UNE).

**Method:** 54 arms of 49 patients (35 male, 14 female, mean age 48.9 years) with clinical and electrodagnostic evidence of UNE were recruited in this study. 34 arms were electrophysiologically classified as axonal group and 20 arms were classified as demyelinating group. By using HRUS, the arms were also grouped into three categories according to the ulnar nerve movement during elbow flexion:

1) non-displacement (28 arms),
2) subluxation (11 arms),
3) dislocation (15 arms).

We measured cross sectional area (CSA) of the ulnar nerve at maximal swelling point and compared the results among the groups.

**Results:** The CSA of the ulnar nerve at maximal swelling point was significantly larger in displacement group than normal group; dislocation group 17.2 mm², subluxation group 19.1 mm², non-displacement group 12.6 mm² (p < 0.01). However, there was no significant difference in CSA of ulnar nerve between the axonal and the demyelinating group; axonal group 14.3 mm², demyelinating group 16.0 mm². There was no significant correlation between duration of symptom and CSA of the ulnar nerve.

**Conclusion:** As the type of the ulnar nerve displacement (non-displacement vs displacement), the difference of nerve CSA at entrapment neuropathy was existed at our study. Therefore, nerve swelling may be affected by ulnar nerve displacement.

patterns: Classic 10 (21%); bigger medially 25 (53%), bigger inferiorly 5 (11%), bigger both 3 (6%), restricted 11 (23%).

Conclusions: Sensory loss in MP frequently differs from classic descriptions. The area is often larger, sometimes smaller. Explanations may include anatomic variation and the degree of damage of the LCNT.

Electromyography in a small city in Ecuador
F. Estevez, Universidad de Cuenca, Cuenca, Ecuador

Background: EMG studies are helpful in diagnosis for many neuromuscular diseases. There are not enough reports to take care about the necessities for a General Hospital in any region around the World.

Objective: To know the absolute number of patients who can be assessed by a novel EMG laboratory; correlate the true positive relation between the suspected diagnosis and the final report; try to avoid for the future, the excess of demand.

Results: During 2009 we studied a total of 209 patients, mean age 49 years (SD 17), 56.4% women and 43.5% men. Neurosurgery (34.4%), Rheumatology (22%), Traumatology (15%) and Neurology (12%) were the most frequent senders for the studies. The most common diagnosis included: neuropathic pathology (50.7%) in this item, the entrapment neuropathies were the most common diagnosis (carpal tunnel syndrome 34%); root lesions (27.7%) with compromise of the lower back in 58.6% (L4, L5 and S1 roots); and finally 17% of all were normal. 43% of cases had positive relation between the suspected diagnosis and the final report; 40% did not have a presumed diagnosis.

Conclusions: It is important to know the absolute demand for an EMG laboratory, and it is also necessary to establish an educational program for the medical staff in the sense of a better understanding of this kind of tests, the presumed diagnosis as a crucial tool for the electromyographist and of course for the patient because it is not a simple test and to avoid unnecessary discomfort.

Epidemiology of myasthenia gravis in Slovak Republic
I. Martinka, P. Spalek. Department of Neurology, University Hospital Bratislava, Hospital Ruzinov, Bratislava, Slovak Republic

Background: 1785 patients were registered up to December 31, 2012 in the Centre for Myasthenia Gravis (MG) in Slovakia.

Patients and methods: The diagnosis of MG was based on clinical and electrophysiological findings, positive AChR and MuSK autoantibodies.

Sex: 1033 females, 752 males (1.37:1). The median age at MG onset: 54 years, females 48 years, males 62 years. Early-onset MG prior the age of 50 years: 800 patients, 605 females, 195 males (3:1:1). Late-onset MG after the age of 50 years: 985 patients, 428 females, 557 males (1:1.3). Infantile MG prior the age of 15 years: 102 children (5.7%), 77 girls, 25 boys (3:1:1). AChR seropositive MG was diagnosed in 86%, MuSK positive in 3%, seronegative in 11% of MG patients. Ocular MG: 328 (18.4%), generalised MG: 1457 (81.6%) patients. Thymoma was histologically proven in 158 (8.9%) patients.

Conclusion: The prevalence rate of MG has increased over the past 35 years, because the mortality rates declined and MG patients have longer life span due to significant advances in the treatment. Since the 1980s a gradually increased incidence has been evident, mainly due to late-onset MG, giving a significant shift to older age at onset of MG. These findings are relevant for non-thymoma MG. The epidemiological data of thymoma-associated MG were constant.

Development of service for patients with Motor Neuron Disease (MND) in Singapore
K. Anga, C.Y. Cheongb, T. Umaphilt, I.M.H. Woot
National Neuroscience Institute (Tan Tock Seng Hospital), Singapore, Singapore; 2Tan Tock Seng Hospital, Singapore

Background: Observations made in clinical practice suggest that people living with MND need a comprehensive set of services that can meet their bio-psychosocial-spiritual needs. However, there is no known...
literature that can inform the development of services appropriate for patients with MND living in Singapore, a multicultural and family-centered society.

Objective/method: Drawing from findings of our study that explored the needs of patients with MND and observations made in clinical practice, this presentation will attempt to describe services that can meet the needs of patients with MND in Singapore.

Results: Research findings and clinical observations point to the need to develop proactive services that are sensitive to the needs of patients and their caregivers. It was found that “staging” the disease will better meet the needs of the patients as they progress along the disease trajectory.

At the earlier stage of the disease, timely supportive counseling for patients and their caregivers after disclosure of diagnosis is needed to manage impact of the disclosure. Counseling is also required to open up communication between patients and their caregivers. Paced education for patients and their caregivers through verbal communication and audiovisual aids, complemented by support groups, will benefit both patients and their caregivers.

At a later stage of the disease, there is a need to help

1) the patients work towards a respectful death and
2) their caregivers achieve a peaceful farewell.

Advance care planning can be a platform for patients and their caregivers to achieve the closure needed by both parties.

Idiopathic inflammatory myopathies—Potential role of the immunoexpression of interleukin-35 in muscle biopsy

J. Zamecnik a,b, J. Hacek a,b, R.A. Dahmen a,b, H. Mann c, L. Senolt a, J. Vencovsky a, b, "Dept. of Pathology and Molecular Medicine, Charles University Prague, Prague, Czech Republic; bUniversity Hospital Motol, Prague, Czech Republic; cInstitute of Rheumatology, Dept. of Experimental and Clinical Rheumatology, Charles University Prague, 1st Faculty of Medicine, Prague, Czech Republic

Background: Interleukin-35 (IL-35) is a newly described cytokine that belongs to the IL-12 family. Although the experiments in mouse models showed immunosuppressive functions for IL-35, recent papers reported different expression pattern and rather pro-inflammatory properties of IL-35 in humans. Currently available biologic treatment for systemic rheumatic autoimmune diseases including the idiopathic inflammatory myopathies (i.e. polymyositis and dermatomyositis) targets specific cellular and molecular mechanisms; therefore, studies of various molecular pathways of immunopathogenesis in idiopathic inflammatory myopathies are of interest for future therapies.

Objective: To analyze immunoexpression of interleukin-35 in muscle biopsies of inflammatory and non-inflammatory myopathies to assess its pathogenetic and diagnostic value.

Materials and methods: Immunoexpression of IL-35 was studied by primary rabbit anti-human EB13 polyclonal antibody and mouse anti-human IL-12a(p35) monoclonal antibody in a series of 19 muscle biopsy samples of idiopathic inflammatory myopathies (9 polymyositis, 10 polymyositis). Results were compared to those obtained in 10 cases of non-inflammatory myopathies and in 10 control muscles biopsies.

Results: We showed localization of the p35 and EB13 subunits of IL-35 in B cells, T cells and macrophages of the inflammatory infiltrate in idiopathic inflammatory myopathies. No immunoreactivity was observed in healthy controls and in non-inflammatory myopathies.

Conclusion: Our data suggest pro-inflammatory properties of IL-35 in humans and a potential role in the pathogenesis of idiopathic inflammatory myopathies. The immunohistochemical expression of IL-35 might be also of diagnostic help in muscle biopsy.

Supported by: IGA NT/12440-4.

Spinal pain syndromes: Psycho-emotional facets

Y. Goncharova a, N. Bozhenko b, aNeurology Department, State Institution, Institute of Urgent and Recovery Surgery n.a. V.K. Gusak, National Academy of Medical Sciences of Ukraine, Donetsk, Ukraine; bNeurology Department, Lviv National Medical University named after Danylo Galastytsky, Lviv, Ukraine

Background: Low back pain syndromes, especially the chronic ones, are the important link in neurology. Pain as personal experience develops not only due to physical pathology, but as consequence of person’s attitude towards disease, previous experience, described in terms of sensory and emotional disorders.

Material and methods: We studied 23 patients with lumbar-sacral radiculopathies. Features of psycho-emotional state were studied using Hamilton scale and Aysenkov questionnaire. Pain syndrome was assessed using VAS and DN4 scale.

Results: Disorders like depressive syndrome were observed among 58% patients. Pain syndrome according to VAS was 6.5 ± 0.3 in persons with
depressive signs and $5.5 \pm 0.2$ in persons without the latter. Among the persons with duration of the pain syndrome 2 and more months neuropathic elements developed that were assessed according to questionnaire DN4 (35%). Psycho-emotional disorders were very evident among patients with choleric and melancholic type (according to Aysen questionnaire). Among persons with melancholic temperment course of pain syndrome was overlapped with depressive signs in 79%, among patients with sanguin tempoerament it was not the case. Intensity of the pain syndrome was associated with the next trends: it was higher in persons with melancholic and choleric type ($6.7 \pm 0.2$ and $6.3 \pm 0.2$, respectively), and lower among persons with sanguinic and phlegmatic type ($5.9 \pm 0.2$ and $4.8 \pm 0.3$, respectively).

Conclusions: Study of the psycho-emotional features of pain perception, would contribute to optimization of the therapy and rehabilitation among the patients with chronic spinal pain.

Assessing motor units with an improved MUNIX

Objective: Improvement and validation of the new non-invasive neurophysiological method MUNIX (motor unit number index). The reliability, practicability and inter-rater-variability of potential improvements to MUNIX were determined and compared to two established Motor Unit Number Estimation (MUNE) methods.

Methods: 40 healthy subjects and 18 patients with amyotrophic lateral sclerosis (ALS) were studied prospectively at single point or multiple points in time. MUNIX results were compared with incremental stimulation MUNE (IS-MUNE) at abductor digiti minimi muscles (ADM), and with spike-triggered averaging MUNE (STA-MUNE) at trapezius muscles (TRA). In contrast to the original MUNIX method, we recorded a continuous electromyogram during increasing muscle contraction to reduce the influence of both patient's compliance and investigator bias. Moreover, baseline correction for CMAP was implemented and the influence of the parameter settings (filters, number of data points, rectifying) was systematically studied.

Results: The best parameter setting includes high pass-filter 10 Hz, low pass-filter 3000 Hz, number of data points 1000, and rectification of the signals. This leads to an improved correlation between MUNE and MUNIX, up to 0.85 for ADM and 0.7 for TRA. The inter-rater-variability is expected to be considerably better than for IS-MUNE/STA-MUNE.

Conclusion: The improved MUNIX needs minimum patient cooperation, and provides stable results easily and quickly. Improved MUNIX is suggested as an excellent alternative to the established MUNE methods in distal and as well as in proximal muscles.

Lipid storage myopathies: Control of nutrition to prevent whole body catabolism
A. Nascimbenia, M. Fanin. aUniversity of Padova, Padova, Italy; bIRCCS San Camillo, Venice, Italy

Background: Lipid storage myopathies (LSM) represent a complex and potentially treatable group of metabolic myopathies with various etiological mechanisms: defects of carnitine transport, CPT II defects, defects of Beta-oxidation, Riboflavin-Responsive Multiple Acyl-CoA Dehydrogenase (RR-MAD) deficiency due to ETF Dehydrogenase-deficiency and two types of Neutral Lipid Storage Disorder (NLSD-M, NLSD-I).

Objective: The lysosomal-autophagic pathway might be activated by starvation and plays an important role in both cellular and lipid catabolism. This pathway has not been so far studied in LSM.

Patients and methods: We investigated the Transcription Factor EB (TFEB), a master regulator of lysosomal biogenesis and various autophagy markers (LC3 and P62) by immunohistochemistry and Western Blot in six cases of LSM: one case of CPT II deficiency, two cases of ETF-Dehydrogenase deficiency and four cases of Neutral Lipid Storage Disorder (NLSD-M, NLSD-I).

Results: The lysosomal-autophagic pathway might be activated by starvation and plays an important role in both cellular and lipid catabolism. This pathway has not been so far studied in LSM.

Conclusions: The lysosomal-autophagic pathway might be activated by starvation and plays an important role in both cellular and lipid catabolism. This pathway has not been so far studied in LSM.

Clinical, ultrastructural study of traspentinopathy, a new nuclear envelope LGMD
C. Angelini, E. Peterle, M. Fanin, G. Cenacchi, V. Nigro, IRCCS San Camillo, Venice, Italy; University of Padova, Padova, Italy; University of Bologna, Bologna, Italy; TIGEM, Naples, Italy

Background: LGMD are due to heterogeneous causes. Muscle histopathological, ultrastructural features of a large Italian-Spanish family with autosomal dominant LGMD, mapped to 7q32.1-32.2 (LGMD1F) were investigated.

Patients and methods: We collected the clinical history in 19 patients. We observed that the age of onset varied from 2 to 35 years, and occurred either in the upper or in the lower girdle; in 14 cases there was hypotrophy both in the proximal upper and in the lower extremities. The severity was not increased in successive generations. New findings were arachnodactyly, dysphagia and dysarthria; muscle biopsy histopathology was investigated in one pair of affected patients (mother 1 biopsy, her daughter 2 consecutive biopsies at 9 and 22 years).

Results: The daughter has a more severe clinical course, the first biopsy had only type 1 fiber atrophy while increased fiber atrophy was observed in the second biopsy. The mother had a compromised muscle histopathology (more muscle fiber variation, and autophagic changes by acid phosphatase stain). An abnormal sarcomeric assembly is the cause of progressive atrophy and myofiber loss. Electron microscopy revealed accumulation of myofibrillar bodies. Accumulation of myotilin and p62-positive aggregates was observed; autophagosomes were also present.

Conclusions: A defect in transportin-3 gene has been found as the cause of this disease, which represents a new mechanism of limb-girdle myopathy.

Our data seems to suggest a new type of nuclear envelop disease. It is possible that SR protein cannot migrate or be transported-in and -out of the nuclear membrane.

These observations can explain the deterioration of these patients during starvation and suggest control of nutrition to implement therapeutic strategies beside carnitine of riboflavin for disorders of lipid metabolism.

Donadio5, 6Dipartimento di Scienze Biomediche e Neuromotorie, IRCCS Istituto delle Scienze Neurologiche, Italy; 4Dipartimento di Farmacia e Biotecnologie, Dipartimento di Medicina Specialistica, Diagnostica e Sperimentale, Italy; 5Dipartimento di Farmacia e Biotecnologie, University of Bologna, Bologna, Italy; 6UO Neurologia Ospedale San Martino Belluno, Belluno, Italy

Background: Brachial amyotrophic diplegia (BAD) is an adult-onset subtype of lower motor neuron disease mainly affecting men, largely restricted to proximal arm and shoulder girdle muscles without involvement of lower limbs or appearance of pyramidal signs. BAD is considered a sporadic disorder although a SOD1 mutation (L106P) was recently described in a patient with BAD.

Objective: To describe the association between BAD syndrome and a novel SOD1 mutation in a small Italian family.

Patients and methods: A 72 years-old man presented with a 5 years history of weakness and wasting that began in the right arm and slowly progressed to the proximal contralateral arm. His 78 years-old brother complained in the last years a progressive difficulty in precise hand movements. Both patients performed full clinical and neurophysiological examinations and the direct sequencing of the five exons of SOD1 gene. No clinical information concerning their parents were available.

Results: In our family both affected members had clinical and electrophysiological findings of adult onset BAD syndrome with a history of selective involvement of upper limbs without pyramidal tract dysfunction. SOD 1 analysis disclosed in both patients a base substitution of adenine for thymine (GCT > GCA), at codon 140, known as the A140A ‘silent’ mutation since it doesn’t change the correspondent encoded aminoacid (alanine). The same mutation has been previously described in few familial cases and in many sporadic ALS but it wasn’t found in control population, suggesting its pathogenic role.

Conclusion: Our family pointed out the genetic heterogeneity underlying BAD syndrome.

A randomized controlled trial comparing botulinum toxin type A xeomin® and dysport® for treatment of primary axillary hyperhidrosis

F. Pastorelli, R. Plasmati. IRCCS Istituto delle Scienze Neurologiche di Bologna, Bologna, Italy

Two non-bioequivalent toxins: Xeomin® and Dysport® are compared for the treatment of primary axillary hyperhidrosis in a randomized controlled double blind trial.

Methods: Twenty patients with primary axillary hyperhidrosis were treated with 50 units of Xeomin into one axilla and 150 units of Dysport into the other axilla. Both patients and the physician were blinded as to which axilla received which of the two toxins. Pain at the injection site has been evaluated by the VAS scale. The patients will be followed for the next 12 months to evaluate the difference in these two toxins in regard to side effects, time to the onset and the extent of reduction of sweating. All patients have completed the Hyperhidrosis Disease Severity Scale (HDSS) and the Dermatology Life Quality Index (DLQI) before treatment and at each follow up evaluation.

Results: No significant difference was observed between the two toxins regarding pain at the injection site. Preliminary data about side effects, time to the onset of reduction of sweating and amount of sweat reduction, as well as QoL data will be available after the first six months of follow up.

Conclusions: Axillary hyperhidrosis causes considerable emotional and social problems affecting the daily life. Xeomin, a BTX-A without efficacy with end points based on changes in limb-girdle muscles, gait-endurance, and respiratory function, i.e. parameters depending on varying patient-performance. ERT-benefits might be more objectively shown by assessing function of very small muscles, such as the stapedius- and tensor tympani-muscles.

Objective: To assess whether stapedius-reflex-testing shows muscle-function-improvement with ERT in Pompe patients.

Methods: In four Pompe-patients, we determined stapedius-reflex-thresholds ipsilaterally in both ears one and two years after first dosage of biweekly ERT with alglucosidase alfa (Myozyme™, 20 mg/kg KG i.v.). Before ERT-onset, stapedius-reflex-thresholds were assessed in two patients. Muscle tension of stapedius- and tensor tympani-muscles was assessed by measuring acoustic impedance at the tympanic membrane in response to single bursts of 0.5, 1, 2, and 4 kHz tones. Reflex-thresholds above 90 dB indicate impaired reflex-thresholds.

Results:

Patient-1 (female, 46 years) had no responses before ERT-onset, reflex-thresholds of 98.8/87.5 dB (right/left ear) one year, and 91.3/87.5 dB two years after ERT-onset.

Patient-2 (male, 65 years) had reflex-thresholds of 98.8/93.8 dB before, 86.3/91.3 dB one year, and 90.0/91.3 dB two years after ERT-onset.

Patient-3 (female, 53 years) had reflex-thresholds of 93.8 dB (right) and no responses (left) one year, and 96.3/98.8 dB two years after ERT-onset.

Patient-4 (female, 69 years) had reflex-thresholds of 85.0/85.0 dB one year, and 80.0/81.3 dB two years after ERT-onset.

Conclusion: Stapedius-reflex-testing demonstrates impaired small muscle-function in untreated Pompe-patients. After one and two years of ERT, stapedius-reflex-thresholds improved, objectively demonstrating muscle-function-improvement with ERT.

Stapedius reflex testing demonstrates improvement of small muscle function with enzyme replacement therapy

M.J. Hilt,2, 3 U. Hoppe2, J. Koehn3. 2Dept. of Neurology, University of Erlangen-Nuremberg, Erlangen, Germany; 3Depts. of Neurology, Medicine, Psychiatry, New York University Langone Medical Center, New York, NY, USA; 4Dept. of Audiology, University of Erlangen-Nuremberg, Erlangen, Germany

Introduction: Pompe disease primarily affects skeletal and cardiac muscles. It is difficult, assessing enzyme replacement therapy (ERT) threshold, objectively shown by assessing function of very small muscles, such as the stapedius- and tensor tympani-muscles.

Objective: To assess whether stapedius-reflex-testing shows muscle-function-improvement with ERT in Pompe patients.

Methods: In four Pompe-patients, we determined stapedius-reflex-thresholds ipsilaterally in both ears one and two years after first dosage of biweekly ERT with alglucosidase alfa (Myozyme™, 20 mg/kg KG i.v.). Before ERT-onset, stapedius-reflex-thresholds were assessed in two patients. Muscle tension of stapedius- and tensor tympani-muscles was assessed by measuring acoustic impedance at the tympanic membrane in response to single bursts of 0.5, 1, 2, and 4 kHz tones. Reflex-thresholds above 90 dB indicate impaired reflex-thresholds.

Results:

Patient-1 (female, 46 years) had no responses before ERT-onset, reflex-thresholds of 98.8/87.5 dB (right/left ear) one year, and 91.3/87.5 dB two years after ERT-onset.

Patient-2 (male, 65 years) had reflex-thresholds of 98.8/93.8 dB before, 86.3/91.3 dB one year, and 90.0/91.3 dB two years after ERT-onset.

Patient-3 (female, 53 years) had reflex-thresholds of 93.8 dB (right) and no responses (left) one year, and 96.3/98.8 dB two years after ERT-onset.

Patient-4 (female, 69 years) had reflex-thresholds of 85.0/85.0 dB one year, and 80.0/81.3 dB two years after ERT-onset.

Conclusion: Stapedius-reflex-testing demonstrates impaired small muscle-function in untreated Pompe-patients. After one and two years of ERT, stapedius-reflex-thresholds improved, objectively demonstrating muscle-function-improvement with ERT.

Myogenic and endothelial progenitor cells in juvenile dermatomyositis
J. Wanschitz, C. Gumpold, B. Schoser, W. Mueller-Felber, W. Löscher, K. Rostasy, M. Baumann. *Department of Neurology, Innsbruck Medical University, Innsbruck, Austria; †Department of Pediatrics, Innsbruck Medical University, Innsbruck, Austria; †Friedrich-Baur Institute, Ludwig Maximilian University of Munich, Munich, Germany; ‡Department of Pediatric Neurology, Ludwig Maximilian University of Munich, Munich, Germany

Background: Juvenile dermatomyositis (JDM) is a rare immune-mediated microangiopathy characterized by a reduction of endomysial capillaries and perifascicular muscle atrophy. Whether muscle fiber injury induces regenerative processes in JDM muscle remains poorly investigated.

Objective: Our aim was to analyze expression of myogenic transcription factors involved in the regulation of reparative myogenesis as well as the frequency of endothelial progenitor cells in muscle biopsies from JDM patients.

Patients and methods: Markers of satellite cells (Pax7), proliferating (MyoD) or differentiating (Myogenin) myoblasts, and regenerating fibers (developmental Myosin) were studied by immunohistochemistry in patients with JDM (n = 7) compared to controls (n = 4). In addition, capillary density and numbers of endothelial progenitor cells within the endomysium were determined by double-immunofluorescence for CD34 and laminin.

Results: Myogenic regulatory factors (Pax7, MyoD and Myogenin) and developmental Myosin were highly up-regulated in perifascicular regions of JDM (n = 5). Within intrafascicular regions of JDM (n = 7), the number of Pax7+ satellite cells was equivalent to controls. Expression of MyoD, Myogenin and developmental myosin was rarely observed intrafascicularly in JDM and absent in controls. Loss of capillaries was pronounced in perifascicular regions of JDM (n = 5). Quantification of CD34+ endothelial progenitor cells within the endomysium, which are implicated in the process of neovascularisation, revealed no difference between JDM and controls.

Conclusions: Our results indicate induction of regenerative myogenesis in perifascicular regions of JDM, despite pronounced loss of capillaries. No evidence was found for compensatory neovascularisation.

Anterior horn cell and encephalopathic variant of Fabry's disease — The neuro-Fabry
N. Thekkootu Pisharam, N. Solomon, R. Sharma. †Neurology, Hull Royal Infirmary, Hull, UK; ‡Neurology, Walton Centre for Neurology and Neurosurgery, Liverpool, UK; †Adult Inherited Metabolic Diseases, Salford Royal Hospital, Salford, UK

Fabry's disease has always been considered to be predominantly as of cardiac or renal type. Stroke due to vasculopathy and peripheral involvement of A-delta and C fibres with resulting neuropathic pain and autonomic dysfunction has been said to be the neurological involvement.

We report an unrecognised neurological variant of Fabry's disease. A 33 year old, was seen in the neurology clinic with weakness, fasciculation and progressive wasting of initially the right hand and right upper limb over 8 months and progressed to involve the left upper limb. An electrophysiological diagnosis of anterior horn cell disease (motor neuron disease) was made. There is no relevant history other than a past history of encephalitis in his teens with mild cardiac involvement without a cause being found.

He, during the course of investigation developed encephalopathy that recovered in 3 weeks, spontaneously. Atypical demyelinating white matter disease on repeated contrast MRI of the brain and cervical cord without progression and persistently elevated cerebro spinal fluid (CSF) lymphocytes with normal levels of other parameters on repeated lumbar puncture were noted despite clinical recovery from encephalopathy. Extensive investigations were done to identify the cause of atypical central nervous system (CNS) demyelination, anterior horn cell disease with CSF lymphocytosis. A dry blood spot and white cell enzyme studies on separate occasions showed low alpha-galactosidase A levels. Genetic study confirmed Fabry's disease with mutation c.299G>A, p.R100K.

An investigation into the quality of life of patients receiving surgical intervention for the treatment of chronic lower back pain
L. Woerner, R. Cummins, R. Bittar, R. Bittar. †Deakin University, Geelong, Australia; ‡Precision Neurosurgery, Melbourne, Vic, Australia

Background: Lower back pain (LBP) is one of the most prevalent forms of chronic musculoskeletal pain and is the primary cause of disability in persons under the age of 45 years. LBP is a frequently occurring health problem; often associated with substantial personal and community burden. LBP includes many symptoms that have a major adverse impact on individuals' lives, often resulting in a reduction in quality of life.

Objective: The current study aimed to evaluate the subjective wellbeing of patients prior to, and post-surgical intervention for the treatment of chronic LBP.

Patients and methods: The current study employed a longitudinal design. The Australian Unity Personal Wellbeing Index was utilised to assess quality of life in approximately 150 participants who were diagnosed with chronic LBP. All patients received either lumbar interbody fusion or decompressive laminectomy. Assessments were conducted at two time points: prior to surgery and within one week post-surgery.

Results: When compared to an Australian normative population (N = 1980), patients receiving surgical intervention for chronic LBP reported significantly lower quality of life across all domains investigated. Furthermore, patients' quality of life increased dramatically immediately post-surgery. The most dramatic improvement in quality of life was prevalent in relation to the domains of health and future security. Further results will be discussed.

Conclusion: Patients diagnosed with chronic LBP have significantly lower personal wellbeing than the general Australian population. After receiving surgical intervention, patients reported a statistically significant improvement in their quality of life. Further theoretical and clinical implications will also be noted.

Fabry’s disease should be considered in the differential of CNS demyelinating disorders and encephalopathy or motor neuron disease with white matter changes.

Severe myotonia in juvenile myotonic dystrophy type 2 and sodium channel gene mutation

E. Bugiardini1, A. Soriano Camirob, R. Cardanic, A. Bottad, M.P. Wicklundb, G. Meolaac, A. Soriano Camirob, R. Cardanic, A. Bottad, M.P. Wicklundb, G. Meolaac, aNeurology, IRCCS Policlinico San Donato, University of Milan, Milan, Italy; bDepartment of Neurology, Hershey Medical Center, Milton South, PA, USA; cLab of Muscle Histopathology and Molecular Biology, IRCCS Policlinico San Donato, Milan, Italy; dDepartment of Biopathology and Diagnosing Imaging, Tor Vergata University of Rome, Roma, Italy

Background: Myotonic dystrophy type 2 (DM2) is an adult onset muscular dystrophy caused by a dominantly transmitted (CTG)n expansion in intron 1 of the ZFN9 gene. Myotonia generally is mild and inconsistent in DM2. A severe or a juvenile onset myotonia may hide additional genes and/or modifying factors that need to be explored. An association between severe myotonia in DM2 and the presence of recessive chloride channel (CLCN1) mutation has been reported (Cardani R et al. 2012). A similar association with sodium channel gene (SCN4A) mutation has not been described.

Objective: To describe a family with atypical DM2 phenotype characterized by severe myotonia of early onset.

Case description: A 25 year old girl complained of hand cramping and difficulty to relax after activity. Neurological examination showed thenar percussion myotonia and mild distal weakness. EMG showed myotonic discharges in all muscles examined and genetic testing was positive for DM2. Genetic screening for CLCN1 did not identify any alteration in DNA sequence. The analysis of SCN4A gene revealed a SCN4A variant c.215C>T (p.Pro72Leu). Both SIFT and PolyPhen-2.2.2, (HumVar) predicted that this variant is pathogenetic. It may justify the atypical phenotype characterized by severe myotonia of the patient.

Conclusion: A severe and early myotonia in juvenile DM2 suggests the presence of modifying factors contributing to the phenotype. A screening of SCN4A gene is thus recommended in addition to CLCN1.

A novel mitofusin 2 MFN2 gene mutation causing early onset Charcot-Marie-Tooth 2A disease: Genetic, clinical and MR spectroscopy characterization

M. Valva, A. Martinuzzi, M. Domenico, F. Frigia, G. Aghakhanyan, M.L. Mostaccioulo, E. Carraro, V. Casanova, 1Coniglio Research Centre, IRCCS ‘E. Medea’ Conegliano, Italy; 2U.O. Neuroradiology, Fondazione CNR/Regione Toscana G. Monasterio, Italy; 3Institute of Life Sciences, Scuola Superiore Sant’Anna, Pisa, Italy; 4Department of Biology, University of Padova, Conegliano, Italy; 5E ‘E. Medea’ Scientific Institute, Coniglio Research Centre, Conegliano, Italy

Background: Mitofusin 2 (MFN2) mutations are associated with axonal peripheral neuropathies known as Charcot-Marie-Tooth 2A (CMT2A). Even though central nervous system (CNS) involvement has been described in CMT2A, there are as to now no advanced neuroimaging study of patients with MFN2 mutations. We describe a novel MFN2 mutation detailing its clinical presentation, and describing novel neuroimaging findings.

Materials and methods: A 7 yo boy with unremarkable family history underwent neurological assessment and gait analysis. Routine electro-physiological investigation (EMG and ENG) was consistent with axonal polyneuropathy. The MFN2 gene sequence was analyzed. Neuroimaging included standard morphological and spectroscopic (MRS) sampling.

Results: Sequence analysis showed a novel MFN2 mutation (c.2168A>C, T706P). Sequence analysis on the parents confirmed it as a de-novo mutation. The residue is situated between the transmembrane domain and the coiled-coil region close to the C-terminal. The clinical features included early onset with steppage, hyporeflexia and hypopallesthesia. Computerized gait analysis demonstrated primary distal lower limb involvement with club feet and accentuation of the hips and knee flexion. Standard MRI didn’t reveal brain signal alterations. MRS showed an increase of NAA and Cho peaks.

Discussion: This novel mutation (T706P) is associated with early onset CMT2A. The MRI findings, in the absence of macroscopical brain signal alterations, show MRS data suggestive of whole brain biochemical involvement (elevated NAA, increased Cho). These findings, especially in such a young patient, confirm CMT2A as a disease involving both CNS

Frontiers of amyotrophic lateral sclerosis cognitive assessment: The use of Eye-tracking and Brain Computer Interface in the eBrain project
B. Poletti\(^a\), L. Carelli\(^a\), F. Solca\(^a\), P. Meriggia\(^b\), P. Cipresso\(^a\), E. Pedrolì\(^c\), D. Lulè\(^c\), A.C. Ludolph\(^d\), G. Riva\(^c\), V. Silani\(^c\), \(^*\)Department of Neurology and Laboratory of Neuroscience, Dino Ferrari Center, Università degli Studi di Milano, IRCCS Istituto Auxologico Italiano, Italy; \(^b\)ICT & Biomedical Technology Integration Unit, Centre for Innovation and Technology Transfer (CITT), Fondazione Don Carlo Gnocchi Onlus, Italy; \(^c\)Applied Technology for Neuro-Psychology Laboratory, IRCCS Istituto Auxologico Italiano, Milan, Italy; \(^d\)Department of Neurology, University of Ulm, Ulm, Germany

Background: Many patients affected by Amyotrophic Lateral Sclerosis (ALS) show cognitive alterations, especially regarding frontal executive functions. Cognitive assessment is problematic in moderate-severe stages of ALS, due to the presence of motor–verbal impairment. Recently, Eye-tracking (ET) and Brain Computer Interface (BCI) have been preliminarily used in ALS to administrate cognitive testing. However, an extended motor–verbal free neuropsychological (NP) battery is not yet available.

Objective: A recently funded project, “eBrain: BCI-ET for ALS”, aimed to evaluate the use of P300-based BCI and ET technologies to administrate cognitive testing in ALS.

Patients and methods: 28 ALS patients (mean age: 62.6 ± 11.8; mean education: 9.6 ± 3.6) and 30 healthy subjects (mean age: 56.2 ± 11.9; mean education: 13.7 ± 4.2) underwent a comprehensive motor–verbal free NP assessment, administered with both P300-BCI and ET. Moreover, clinical data were collected and usability of both devices was evaluated.

Results: Data showed significant differences between healthy subjects and ALS patients’ performances in BCI and ET adapted measures of frontal abilities (p < 0.05); furthermore, a correlation between traditional NP assessment and BCI-ET one was found (p < 0.05), supporting the concurrent validity of the adapted measures. Finally, even if a higher perceived usability was overall observed for ET compared to BCI (p < 0.05), patients evaluated BCI as a positive and useful tool in order to compensate for the motor–verbal limitations.

Conclusion: These results support the good level of sensitivity and perceived usability of the BCI and ET-based NP assessments, offering promising insights on the use of such devices for the longitudinal cognitive testing in ALS.

Neuroanatomical patterns of central nervous system involvement in myotonic dystrophy type 1 and clinical correlates
F. Casò\(^a\), F. Agosta\(^b\), S. Peric\(^a\), V. Rakovec-Stojanovic\(^c\), L. Sarro\(^c\), V.S. Kostic\(^c\), M. Filippi\(^a\), \(^*\)Neuromaging Research Unit, Institute of Experimental Neurology, San Raffaele Scientific Institute, Vita-Salute San Raffaele University, Milan, Italy; \(^b\)Clinic of Neurology, Faculty of Medicine, University of Belgrade, Belgrade, Serbia; \(^c\)Department of Neurology, San Raffaele Scientific Institute, Vita-Salute San Raffaele University, Milan, Italy

Background: Patients with myotonic dystrophy type 1 (DM1) often show cognitive impairment during the course of disease, beside the motor symptoms.

Objective: To investigate grey matter (GM) and white matter (WM) abnormalities in a large sample of myotonic dystrophy type 1 (DM1) patients and to assess their correlations with clinical findings.

Methods: We enrolled 51 DM1 patients (n = 14 with childhood-juvenile DM1; n = 37 with classic DM1) and 30 healthy controls (HC). Patients underwent clinical and neuropsychological evaluations and brain structural and diffusion tensor (DT) magnetic resonance imaging (MRI). Voxel based morphometry and tract-based spatial statistics were used to evaluate GM atrophy and WM microstructural damage in DM1 patients compared with HC. Regression analyses were performed to correlate GM and WM changes with clinical and cognitive variables.

Results: DM1 patients had moderate muscle impairment, sleepiness and depression as well as attentive-executive and visuo-spatial deficits. Voxel-wise analysis revealed significant and widespread GM atrophy and WM damage in DM1 group (both childhood-juvenile and classic patients) compared with HC. Significant negative correlation was found between Addenbrooke’s Cognitive Assessment-revised orientation and attention sub-scores and MD increase along left corona radiate, internal capsule, inferior fronto-occipital fasciculus and SLF (temporal part) (p < 0.05).

Conclusions: Our data demonstrate the clinical relevance of GM and WM damages in a large sample of DM1 patients. These findings are in line with neuropathological studies showing severe central nervous system involvement in this multisystemic disease.

Therapeutic effects of repetitive transcranial magnetic stimulation on clinical symptoms and signs of patients with HTLV1 myelitis
M. Amiri Andad, S. Nafissi, F. Fatehi, S. Jamal Omidi, M. Amiri. Neurology, Tehran University of Medical Sciences, Tehran, Iran

Background: HTLV1 virus myelitis causes pain and paresthesia of the lower limbs, sphincter function impairment, and most disabling feature of spasticity. Current treatments for this disease have not been effective. Providing the patients with a more effective treatment can improve greatly the quality of life.

Objective: Studying therapeutic effects of repetitive transcranial magnetic stimulation (rTMS) on improvement of pain, spasticity and motor function of people suffering from HTLV1 myelopathy, one month after initiation of treatment.

Materials and methods: In this study 9 patients with confirmed symptomatic HTLV myelitis who had not responded satisfactorily to other treatments (methyl prednisolon, alfa interferone, muscle relaxants) were included. They received 5 sessions of rTMS with a frequency of 5 Hz and 100 times on each side at every session, in five successive days, stimulation sites were bilateral motor cerebral cortex responsible for movement of lower limbs. Spasticity, pain, and motor function were measured by Modified Ashworth Scale, Global Pain Scale, and Medical Research Council Scale, respectively. The data were analyzed by the Wicoxon test.

Results: Spasticity diminished significantly after one month of treatment. Patients showed improvement regarding pain and movement functions, though not statistically significant.

Conclusion: These findings suggest that rTMS can be used to reduce spasticity, as the most disabling feature of HTLV1.

Critical illness myopathy (CIM) is characterized with generalized and respiratory muscle weakness, accompanied with difficulty of weaning from mechanical ventilation and occurs mainly during sepsis after a 1 week intensive care stay. There is no effective treatment. During sepsis, TNF-α causes muscle breakdown, and also influences muscle excitability. This knowledge has led us think that TNF-α might be the critical molecule for CIM and CIM can be prevented by TNF-α decreasing agents pentoxyphylline and etanercept. CIM have been searched with septic rats, induced by cecal ligation and puncture (CLP). TNF-α and IL-1β levels were measured in plasma and muscle at the 2nd hour after operation. Nerve conduction studies (NCS) performed at the 48th hour. In one group Pentoxyphylline was given 1 hour before the operation and for 6 days after. In the other group etanercept was given 1 day before the operation and repeated after 72 hours. Muscle biopsies were performed on the 6th day for histopathologic diagnosis and for detecting myosin level. This research showed that, both pentoxyphylline and etanercept reduced mortality. Increased TNF-α levels of muscle revealed statistically significant difference from other groups in CLP group. NCS investigations revealed an early decrease in CMAP amplitudes in the same group. The main findings were fiber atrophy and basophilic fiber staining mainly in CLP group muscle biopsies. Myosin levels were lowest in CLP and CLP + Pentoxyphylline group and similar with control group in CLP + Etanercept group. This study showed that TNF-α antagonism prevented the development of the neuromuscular changes in septic rats, and did not cause any increase in mortality rate.

Progress report on the development of new classification criteria for adult and juvenile idiopathic inflammatory myopathies

M. de Vissera, A. Tjärnlundb, M. Bottai, L.G. Rider, V.P. Werth, C. Pilkington, L. Alfredsson, A.A. Amato, R.J. Barohn, M.H. Liang, J.A. Singh, F.W. Miller, I.E. Lundberg. *Department of Neurology, Hacettepe University Faculty of Medicine, Ankara, Turkey; †Department of Neurology, Hacettepe University Faculty of Medicine, Ankara, Turkey; ‡Department of Neurology, Hacettepe University Faculty of Medicine, Ankara, Turkey; §Department of Biochemistry, Hacettepe University Faculty of Medicine, Ankara, Turkey; ¶Department of General Surgery, Ankara University Faculty of Medicine, Ankara, Turkey

Background: Inadequate classification criteria for idiopathic inflammatory myopathies (IIM) limit clinical studies in myositis. An international, multidisciplinary collaboration, the International Myositis Classification Criteria Project (IMCCP), was therefore established. Objective: To develop and validate new classification criteria for adult and juvenile IIM and its major subgroups.

Patients and methods: Candidate variables were selected from published criteria and inclusion criteria in controlled trials of myositis. Comparator conditions resembling IIM were defined. Clinical and laboratory data from IIM and comparators were collected from 47 rheumatology, dermatology, neurology and pediatrics clinics worldwide. Crude pair-wise associations among all measured variables and between each variable and clinicians’ diagnoses were assessed. Explored approaches were:

1. Traditional: case defined by specified number of items from a set.
2. Probability score: case assigned a probability score by summing score-points associated with a set of variables.
3. Classification tree: case defined by decision tree.

Internal validation using bootstrap methods was performed. Results: Data from 973 IIM patients and 629 comparators were obtained. Two probability score models were developed: Model 1 comprised clinical variables on muscles, skin, and laboratory measures; and Model 2 additionally comprised muscle biopsy variables. Model 1 performed nearly as well as Model 2 (specificity 87% vs 88%, sensitivity 89% vs 89%, and correctly classified 87% vs 88%). Both models performed equally or better than the classification tree that was developed and published criteria.

Conclusion: New classification criteria for IIM with readily assessable measurements and symptoms have been developed with generally superior performance compared with existing criteria.

HLA associations with mg in Saudi patients

M. Al Jumah, S. Kojan, A. Al Khathaami, F. Sauwidan, A. Jawhary, A. Hajeer. King Abdullah International Medical Research Center, King Saud bin Abdulaziz University for Health Sciences, King Abdulaziz Medical City, National Guard Health Affairs; †Neurology, National Guard Health Affairs, Riyadh, Saudi Arabia; ‡King Abdulaziz Medical City, National Guard Health Affairs, Riyadh, Saudi Arabia

Background: Myasthenia gravis (MG) is a rare autoimmune disease of the neuromuscular junction. MG has been shown to be associated with many HLA antigens in different populations. Recently using low resolution typing technique we found associations with HLA-A*23, B*08, B*18, DRB1*16 and DRB1*13. Objectives: To further describe the association of HLA in Saudi MG patients using SBT.

Methods: We analyzed HLA associations using SBT in 75 Saudi MG patients and 1110 health controls.

Results: Our results supported our previous report with some new findings, B*08:01 (OR 3.58, p = 0.000), DRB1*16:01 (OR 6.82, P = 0.000). A*23:01, B*50:01, C*06:02 & DRB1*0701 were found to form the most common haplotype in our healthy controls. All these alleles were significantly reduced (protective) in the MG patients. No single allele of DRB1*13 was significantly associated with MG, however, collectively 13:01, 13:02 and 13:03 alleles were associated MG (OR 1.47, p = 0.056). Some of our new findings include HLA-C*07:02 and DQB1*05:02 association with MG. It is interesting to note that in CaucasoidsA*01:01–B*08:01–C*07:01–DRB1*03:01haplotype carries the highest risk for MG. Here we showed that a part of
Background: Diagnosis of myasthenia gravis (MG) typically is made based on patient's history and clinical findings. However, the diagnosis must be verified by the electrophysiological investigation of neuro-muscular transmission. The repetitive nerve stimulation (RNS) is an electrodiagnostic technique used to assess the efficacy of neuromuscular transmission.

Objective: The objective of this study was to evaluate combined muscle action potential (CMAP) changes in response to high and low frequency rates of RNS in patients with MG.

Patients and methods: The correlation of muscle strength and CMAP changes were investigated in 104 myasthenic patients. The muscle strength was graded on a scale from 0 to 5. Two stimulating parameters were used throughout the experiments — the low frequency stimulation (LFS) and high frequency stimulation (HFS).

Results: It was found that in 15% of muscles with clinically detectable weakness the CMAP amplitude was decreased, by 21% in area, and by 8% in duration of the negative phase.

The positive correlation was observed between the negative phase of CMAP and the muscle strength and negative correlation was observed between the negative phase duration and the muscle strength.

Conclusion: We used RNS in a large cohort of patients as an additional tool for the confirmation of the MG diagnosis. We registered higher decrement in larger muscle groups which are more commonly affected clinically. However, smaller muscles, such as the abductor digiti quinti muscle are often preferable to investigate, because they create less discomfort for the patient and have fewer artifacts.

Background: In patients suffering from Becker muscular dystrophy (BMD) variable degrees of cognitive impairment have been reported in addition to the well-known muscular and cardiac symptoms. BMD is caused by mutations in the dystrophin gene, changing the cellular dystrophin complex and subsequent muscular blood flow. Few studies have addressed the mechanisms of cognitive impairment. Lack of dystrophin, however, causes secondary loss of vasoactive molecules such as nitric oxide, which is an important player in brain vascular control. We hypothesised that dystrophin can be involved in neurovascular coupling and cerebral reactivity measured by functional MRI and EEG.

Objective: To study the baseline electrophysiological and fMRI BOLD-response to external somatosensory stimulation in BMD patients compared to age and sex-matched healthy controls.

Patients and methods: 17 men (mean age 38.5, range 25–63) with BMD and 8 healthy sex matched controls were included. Functional MRI (fMRI, BOLD) (3T, Philips) and EEG with evoked potentials were performed during a somatosensory stimulation paradigm on the dominant median nerve.

Results: BMD patients showed a significantly (p < 0.02) decreased electrophysiological adaptation together with a decreased (p < 0.01) BOLD-response in the primary somatosensory cortex when compared to healthy controls.

Conclusion: The preliminary results suggest that patients with BMD have a fundamentally altered cerebral neurovascular coupling, which could impact cognitive function in BMD patients.

Background: POEMS syndrome (also known as Crow-Fukase syndrome) is a serious systemic disease characterized by polynuropathy, anasarca, skin lesions and associated with osteoclastic bone lesions and with M-proteinemia. The diagnosis of POEMS syndrome is made robust by finding increased serum vascular endothelial growth factor (VEGF) in addition to the combination of the mentioned characteristic manifestations.

The diagnosis of advanced POEMS syndrome is not difficult when the combinations of characteristic manifestations are fulfilled. However, in the initial stages, only half of POEMS patients start with neuropathy. Neuropathy in POEMS syndrome is characterized by a subacute, progressive sensorimotor type of polynuropathy with mixed features of demyelination and axonal degeneration.

However, nerve conduction study (NCS) results of POEMS syndrome occasionally fulfill the electrophysiological criteria for chronic inflammatory demyelinating polyradiculoneuropathy (CIDP), thus leading to the caveat of an often initial misdiagnosis of CIDP. We herein present two female patients with POEMS syndrome.

Two cases of POEMS syndrome: Initially misdiagnosed as CIDP

O. Watanabe, K. Arimura, N. Arinuma, Y. Akinori, Y. Inamori, Y. Takata, K. Michizono, E. Matsura, H. Takahama. Neurology and Geriatrics, Kagoshima University Graduate School of Medical and Dental Sciences, Kagoshima, Japan

POEMS syndrome (also known as Crow-Fukase syndrome) is a serious systemic disease characterized by polynuropathy, anasarca, skin lesions and associated with osteoclastic bone lesions and with M-proteinemia. The diagnosis of POEMS syndrome is made robust by finding increased serum vascular endothelial growth factor (VEGF) in addition to the combination of the mentioned characteristic manifestations.

The diagnosis of advanced POEMS syndrome is not difficult when the combinations of characteristic manifestations are fulfilled. However, in the initial stages, only half of POEMS patients start with neuropathy. Neuropathy in POEMS syndrome is characterized by a subacute, progressive sensorimotor type of polynuropathy with mixed features of demyelination and axonal degeneration.

However, nerve conduction study (NCS) results of POEMS syndrome occasionally fulfill the electrophysiological criteria for chronic inflammatory demyelinating polyradiculoneuropathy (CIDP), thus leading to the caveat of an often initial misdiagnosis of CIDP. We herein present two female patients with POEMS syndrome.

Case 1: A 67-year-old woman was admitted to one university hospital with a 1.5-year history of progressive weakness and paraesthesia. Her weakness and paraesthesia initially affected his lower limbs, progressing within 2 months to her upper limbs.

Case 2: A 24-year-old woman was admitted to another university hospital with a 2-month history of progressive paraesthesia and muscle weakness affecting her lower limbs. Both cases were electrophysiologically diagnosed as CIDP, then treated with intravenous
immunoglobulin therapy without enough effects. After transfer to our university hospital, we paid attention to both cases of thrombocytosis. Both had hepatosplenomegaly, lambda type M-proteinemia, and significantly elevated serum VEGF.

Etiological consideration of 26 patients with dropped head syndrome
K. Uchino, G. Ogawa, T. Chiba, K. Hokkoku, Y. Hatanaka, M. Sonoo. Department of Neurology, Teikyo University School of Medicine, Itabashi-ku, Japan

Background: The dropped head syndrome (DHS) is caused by a wide variety of neurological disorders ranging from CNS degenerative diseases to peripheral neuromuscular problems. There have been few studies that identified causes of DHS for a large number of patients.

Objective: To elucidate the frequencies of individual causes in a case series of DHS patients.

Materials and methods: Patients presenting with DHS were extracted from the database of our institution for 13 years since 1999. Their medical and EMG records were retrospectively reviewed.

Results: Twenty-six patients were extracted (4 men and 22 women, age 71.1 ± 8.6 years). The final diagnoses were 13 myasthenia gravis (MG), 4 myositis, 1 myopathy of undetermined etiology, 3 amyotrophic lateral sclerosis, 3 Parkinson’s disease, 1 dementia with Lewy body, and 1 with unknown etiology. One MG and 1 myositis patients were associated with Parkinson’s disease, but they were diagnosed as myopathies by EMG. All but one MG patients were negative for AChR antibody, and MuSK antibody was also negative for all of 10 patients examined. They were diagnosed as MG by the abnormal single-fiber EMG (SFEMG) of the splenius muscle, together with lack of profuse fibrillation potentials and positive sharp waves in the concentric needle EMG (CNEMG) of the same muscle. Immunotherapies were attempted in 6 MG patients (5 IVIg and 1 steroid) and were effective at least transiently.

Conclusion: MG was the most frequent cause of DHS, followed by myositis. CNEMG and SFEMG of the splenius muscle were the key to their diagnosis.

26 years’ experience in myasthenia gravis in Iran
A. Soltanzadeh, S. Jamal Omidi, S. Nafissi, F. Fatehi. Neurology, Tehran University of Medical Sciences, Tehran, Iran

Background: Myasthenia gravis is an autoimmune disorder affecting the neuromuscular junction. Signs and symptoms present a wide spectrum ranging from only ocular symptoms to a life-threatening respiratory failure.

Objective: This study was carried out to show the demographic characteristics of myasthenia gravis in Iran. Unusual presenting features of our patients were also taken into account.

Methods: The files of all myasthenia patients arriving to clinic during 26 years were studied on a retrospective basis; their demographic and clinical data were registered and duly analysed. Then, cases of congenital myasthenia were excluded from the study.

Results: Out of the 316 myasthenia gravis patients included in the study, 58.55% were female and 41.45% male. 272 patients suffered from the generalized form of myasthenia while the remaining 51 patients had only ocular presentations. 6 patients had atypical presenting features as the first manifestation (jaw-hanging, cervical weakness, dyspnea). Among those with the generalized type, 11% had suffered crisis and 13.6% experienced at least 1 episode of disease exacerbation. Interestingly the youngest and oldest ages of onset were 8 and 70 years, respectively. Out of the 128 patients who underwent thymectomy, 21.05% and 48.43% had pathology reports of thymoma and hyperplasia, respectively. Unfortunately 6 ladies and 12 men were taken by deaths, two of which died with pneumospeis.

Conclusion: Epidemiologic findings of Myasthenia Gravis in Iran are more or less similar to those of other countries, but it is very important to bear in mind the atypical presenting features of this disease that can otherwise be misleading.

Sporadic Amyotrophic Lateral Sclerosis (SALS) and environment  

H.A. Idrisoglu. Neurology, Istanbul University Faculty of Medicine, Istanbul, Turkey  

Background: The cause of Sporadic Amyotrophic Lateral Sclerosis (ALS) is not known. Studies associate toxic, dietary, infectious, neoplastic, and physical factors as underlying, predisposing or pathogenic influences.  

Methods: 131 SALS patients are followed prospectively all of the patients investigated SOD1 mutation and blood and urine lead level. Also environmental exposure was assessed, in sporadic ALS patients.  

Results: All of the patients are diagnosed definite ALS according to El-Escorial criteria.  

81 of 131 patients who are diagnosed with definite ALS according to El-Escorial criteria are men. The others are women. Men—women ratio is 1.5/1. The age of onset of 131 definite ALS cases is between 15 and 73. The average age is 48.7. The beginning of age in men is 40.1. It is 49.7 in women. The average examination age in men is 49.1. It is 51.1 in women. 131 patients are separated to the specific types based on examination findings during examination. 16 of them are progressive bulbar paralysis (PBP), 72 of them are in PBP + spinal form, and 43 of them are in spinal form.  

When we search blood and urine lead levels in all 131 patients and when we take family individuals. Of this patients as central group and compare them Blood and urine lead levels of this group are statistically and significantly found high. Blood lead level is p < 0.001, urine lead level is p < 0.01. We don’t encounter abnormal (toxic) levels (0.80 mg/dl) in one of the cases.  

All patients are followed prospectively.  

Conclusions: We found blood and lead levels of SALS patients statistically and significantly high.

Parkinson, pesticides and environment  

H.A. Idrisoglu. Neurology, Istanbul University Faculty of Medicine, Istanbul, Turkey  

Background: Parkinson’s disease (PD) is the most common neurodegenerative movement disorder that is a consequence of premature death of dopamine-containing neurons in the substantia nigra. A number of observations have led to the hypothesis that environmental factors, including pesticides, play a significant role in the development of PD.  

Method: 350 Parkinson patients applied to our clinic between the years 2008 and 2012. We achieved prospective follow up of these patients. In the result of this follow-up we determined that 35 patients were exposed to pesticide intoxication.  

Result: Age interval of 35 patients was between 23 and 90. Mean age was 61.7. 33 of them were male and the other patients were female. We determined that 10% of 350 patients were exposed to toxic substances. The first sign of 8 patients was bradykinesias and the first sign of 27 patients was tremor. We determined pesticide intoxication in 19 patients, CO2 intoxication in 2 patients, heavy metal exposure in 10 patients, CO2 intoxication in 2 patients and electrical charging in 2 patients. Finally, we thought 10% toxic etiology risk factor. The other characteristics that we were interested in were male patients. The patients were male and PH signs were in association with tremor.  

Conclusions: Pesticides and environmental factors and gene interactions seem to act together to increase PD risk.

Initial dip and bilobed N21 peak in the tibial nerve SEPs suggest predominant demyelination in the nerve root  

T. Chiba1, M. Sonoo2, C. Oishi3, K. Uchino4, H. Okuma4, H. Kurono4, K. Hokkoku5, Y. Hatanaka4, 1Department of Neurology, Teikyo University School of Medicine, Itabashi-ku, Japan; 2Department of Neurology, Kyorin University School of Medicine, Mitaka, Japan  

Background: Sensory GBS or CIDP may be difficult to diagnose, especially when routine nerve conduction studies show unremarkable findings. Tibial nerve SEPs are useful because they can evaluate the proximal portions of the peripheral nerve. We noticed a previously-undescribed characteristic pattern in tibial nerve SEPs of such patients.  

Objective: To document the significance of the “initial dip and bilobed N21 peak” pattern in the tibial nerve SEPs.  

Material and methods: Subjects consisted of 4 patients presenting with this pattern. Their clinical and electrophysiological records were retrospectively reviewed.  

Results: All patients presented with pure sensory or sensory-dominant symptoms. Routine nerve conduction studies did not show any sign of demyelination for all patients, except for the slightly reduced amplitude of the sensory nerve action potentials. The final diagnoses were sensory GBS in 2 patients, sensory CIDP in 1 patient, and sensory-dominant MADSAM in 1 patient. Tibial nerve SEPs revealed slightly delayed N8 and P15 components. The L1S-Lc’ (ipsilateral iliac crest) lead registered a positive dip 2 to 3 ms later than the P15 latency for all patients, and the N21 peak was either lost (1 patient) or showed a characteristic bilobed pattern (3 patients) with the later peak at a markedly delayed latency.  

Conclusion: The positive peak must correspond to the “killed-end potential” suggesting the near interruption of the sensory conduction. The mechanism of bilobed N21 potential is unknown, but the recognition of this characteristic pattern will help to identify demyelination of the sensory nerve predominant at the root level.

Ultrasound diagnostics and amyotrophic lateral sclerosis  

Y. Rushkevich, G. Zabrodets, S. Likhachev. Republican Research and Clinical Center of Neurology and Neurosurgery, Minsk, Belarus  

Background: Amyotrophic lateral sclerosis (ALS) is a neurodegenerative disease with progressive destruction of the central (upper) and peripheral (lower) motor neurons. One of the specific symptoms of ALS is the appearance of fasciculations, which may precede the development of muscle weakness and atrophy.  

Objective: To explore the possibilities of ultrasound to detect muscle fasciculations in the differential diagnosis of suspected ALS.  

Materials and methods: 150 patients were included (ALS, spinal amyotrophy, cervical myelopathy — 126 (84%), 11 (7%), 13 (8%) patients, respectively). Male/female — 93/37, age (median 25—75%) — 56 (46, 62). The diagnosis of ALS was based on an analysis of clinical data electroneuromyographic El Escorial criteria (Brooks, 1998). All patients underwent electromyography (VikingSelect; Nicolet; USA). Ultrasound

Hereditary sensory neuropathy presenting with only numbness of the extremities
H. Akgun1, M. Yucel2, S. Tasdemir3, S. Alay4, O. Oz5, Z. Odabasli4, S. Demirkaya6, 1Department of Neurology, Etimesgut Military Hospital, Ankara, Turkey; 2Department of Neurology, Kasimpasa Military Hospital, Ankara, Turkey; 3Department of Neurology, Gulhane Military Medical Academy, Ankara, Turkey

Background: Hereditary sensory neuropathy is a slow developing, autosomal dominant disease with sensory loss at the distal parts and autonomic disturbances. The definite prevalence is unknown, but it is estimated to be very low. The first onset is on the 2nd and 5th decades. Autonomic changes like sensory loss on the distal parts of the limbs, loss of muscle strength, skin ulcers and especially perspiration disorders are the clinical manifestations. Future complications that can cause serious morbidities can be prevented with early diagnosis.

Objective: In this report we would like to present a case with hereditary sensory neuropathy.

Patients and methods: A 20-year-old male patient presented to our outpatient clinic with complaints of numbness on the hands and feet. The patient stated 'stocking-glove' pattern of numbness. The complaints had become more evident in the last 2 years. On the neurological examination the patient stated stocking-glove pattern of hypoesthesia, and the DTRs were globally decreased. All other neurological findings were normal.

Results: The biochemistry tests were normal. Bilaterally, sensory nerve action potentials were absent on the electromyography (EMG) of the median, ulnar and sural nerves. The patient was diagnosed with sensory polyneuropathy.

Conclusion: We found this case worth reporting in order to remind the clinicians that hereditary sensory polyneuropathy is a rarely encountered disease that should be considered, with no other objective examination findings other than decreased DTRs.

FGF21: A biomarker of neuromuscular diseases
E. Pál, E. Lovadi, M. Csereklyei, Á. Sebők, S. Komoly. Neurology, University of Pécs, Pécs, Hungary

Background: Human fibroblast growth factor 21 (FGF21) is a 181 amino acid protein that belongs to the human FGF superfamily. The basic biological role of FGF21 is the regulation of the glucose and lipid metabolism.

Objective: Recently two observations were published where they showed elevated circulating FGF21 in human mitochondrial diseases, therefore it was suggested that FGF21 might be a biomarker of mitochondrial diseases.

Patients and methods: The serum level of FGF21 was determined by ELISA in blood samples from 20 healthy subjects, 15 patients with myotonic dystrophy type 1 (MD1) and 25 patients with mitochondrial diseases.

Results: Among healthy subjects serum FGF21 correlated with body mass index (BMI). Mean FGF21 level was significantly raised in MD1 compared to healthy subjects (424 ± 328 and 207 ± 165 pg/ml, respectively, p < 0.05, Mann–Whitney U test). Among mitochondrial patients FGF21 was elevated only in PEO (progressive external ophthalmoplegia) group (589 ± 496 pg/ml, p < 0.05, Mann–Whitney U test), but was not significantly altered in MELAS and myopathy patients. FGF21 correlated with serum creatine kinase (CK) and lactate levels, with clinical severity score as well as some biopsy findings (e.g. ratio of ragged red fibers and mitochondrial inclusions).

Conclusion: Our study implicates that serum FGF21 might be a biomarker for neuromuscular disorders. In contrast to the previous findings our results showed that elevation of FGF21 is not specific and not restricted to mitochondrial disorders. Further research is necessary to find out what neuromuscular disease groups are associated with abnormal FGF metabolism and to investigate the molecular pathomechanism.

Complex chromosomal rearrangements in a patient with oligozoospermia and Charcot–Marie–Tooth disease
G.J. Braathenb, V. Hauganc, A.G.F. Hellandd, K.O. Clauesena. aDepartment of Laboratory Medicine, Section of Medical Genetics, Telemark Hospital, Skien, Norway; bHead and Neck Research Group, Research Centre, Akershus University Hospital, Lørenskog, Norway; cCampus AHUS, Akershus University Hospital, University of Oslo, Lørenskog, Norway

Background: Complex chromosomal rearrangements (CCR) occurring in phenotypically normal persons are rare, about 255 cases have been reported. Most familial cases have a normal phenotype with apparently balanced rearrangements while de novo cases usually are unbalanced or apparently balanced but with associated multiple anomalies as well as mental retardation.

Material and methods: A couple with fertility problems was investigated. He had oligozoospermia and Charcot–Marie–Tooth disease.

Results: Chromosomal analysis and fluorescence in situ hybridization with whole chromosome paint revealed that he had apparently balanced translocation between chromosome 2, 7 and 14. Array comparative genomic hybridization was normal.

Conclusion: To our knowledge, this is a new case of CCR identified in the human population and for the first time a CCR is identified in a patient with CMT.

Global proprioceptive resonance: Effects on neuromuscular and postural systems
U. Garagia, M. Maffei, G. Farronato. Dental and Surgical Biomedical Sciences Department, IRCCS Fondazione Ospedale Maggiore Policlinico, University of Milan, Milan, Italy

Background: The application of mechanical multifocal vibration (MFV) at targeted frequencies and short duration produces positive effects on bone structure, muscles and joints regulating neuromuscular response.

Objective: The purpose of this study was to investigate the effects of the global proprioceptive resonance (GPR) by MFV on muscle performance and body balance in healthy subjects.

Materials and methods: Sixty volunteers (26 males and 24 females, aged 19–25 years) underwent, in a randomized order, both the electromyography–electrogoniography (EMG–EGN) and stabilometry before the GPR and immediately after it. GPR was the ergonomic structure used in this protocol: it gives a psycho-physical release thanks to multifocal vibrations.

Results: The effects of GPR on the surface EMG of masseters and anterior temporalis muscles did not induce any statistically significant change, except for masseter muscles (p < 0.05). The results showed a significant improvement in the neuromuscular activity. Muscular activity mainly decreased, while the Freeway Space increased in 53% of cases: this was the evidence of a muscular release after GPR. From a postural point of view, there was an improvement in the load distribution and in the position of the barycenter according to the ideal axis. There were effects in body balance tests, too (p < 0.05).

Conclusions: In this preliminary study it was concluded that the GPR induced changes both in neuromuscular and in postural tests. Further and future studies should focus on evaluating the effects on orthodontic and temporomandibular disease patients, as well as the long term effects.

Prevalence of neuromuscular disorders in Italian Navy scuba divers: Personalized vs standard mouthpiece
U. Garagia, G. Ruffino, G. Farronato. aDental and Surgical Biomedical Sciences Department, IRCCS Fondazione Ospedale Maggiore Policlinico, University of Milan, Milan, Italy; bCOMSUBIN, Italian Navy, La Spezia, Italy

Background: Scuba divers deal with an extreme psychophysical effort during their activities showing neuromuscular, postural and craniomandibular disorders.

Objective: The aim is to determine the prevalence of temporomandibular disorders and the neuromuscular system variations in scuba divers of the Italian Navy with commercial (CM) and personalized
mouthpiece (PM), and to identify the risk factors for the development of TMD signs and symptoms before and after diving.

**Material and methods:** 40 males (23–30 years) undergone to neuromuscular tests, spirometric and postural exams before and after diving, and MRI and CBCT exams too.

**Results:** The prevalence of TMD symptoms after diving was about 93% with CM and 38% with PM versus a 32% before diving; with CM use the neuromuscular answers after diving (T3) were highly different from rest situation before immersion (T0) (p < 0.001); also postural aspects were different after diving (p < 0.01); with PM use there were no changes.

**Conclusions:** Scuba divers exhibiting TMD-related symptoms have met the greatest risk of developing TMJ dysfunction during and after the dive. Also in asymptomatic divers, before the dive, TMD was a common problem after it. Customized mouthpiece has reduced symptoms, significantly.

**Increased prevalence of malignancy in mitochondrial disorders**

**J. Finsterer, E. Krexner. KAR, Vienna, Austria**

**Objectives:** There are indications that patients with a mitochondrial disorder (MID) develop more frequently malignomas or benign tumours than the general population.

**Aims:** To find out if the prevalence of tumours is increased in MID-patients and which of the malignomas or benign tumours are the most frequent.

**Methods:** Retrospectively evaluated were the charts of MID-patients for the presence of malign or benign tumours. MID was diagnosed according to the modified Walker-criteria.

**Results:** Among 475 MID-patients screened for tumours, at least a single malignoma was found in 65 patients (13.7%), and at least a single benign tumour in 35 patients (7.4%). Among those with malignancy, 22 were male and 43 were female. Among those with a malignancy 1 had definite MID, 9 probable MID, and 54 possible MID. The most common of the malignancies found in MID was breast cancer, followed by dermatological, gynaecological, and gastrointestinal malignancies. The most frequent of the benign tumours found in MID patients was the lipoma, followed by pituitary adenoma, meningiomas, carcinoids, and suprarenal adenomas. Compared to the general population, the prevalence of malignancies and of benign tumours was markedly increased. The female preponderance among those with a malignancy was explained by the frequent maternal inheritance of MIDs.

**Conclusions:** Adult patients with a MID, particularly females, carry an increased risk to develop a malignancy. Since malignancy is an important determinant for their outcome, these patients should be more accurately screened for neoplasms, not to overlook the point, at which an effective treatment can no longer be provided.

**Monoclonal gammopathy of undetermined significance presenting with acute polyneuropathy**

Department of Neurology, Gulhane Military Medical Academy, Ankara, Turkey; Department of Neurology, Etimesgut Military Hospital, Ankara, Turkey; Department of Neurology, Kasimpasa Military Hospital, Istanbul, Turkey

**Background:** Monoclonal gammopathy of undetermined significance (MGUS) is a condition where protein M is generated by abnormal plasma cells. Polyneuropathy is present in 5–28% of the patients diagnosed with MGUS.

**Objective:** Our aim was to present a case with detected IgG paraproteinemia after sudden onset of walking disorder.

**Patients and methods:** A 61-year old female patient presented with difficulty in walking that started 2-months earlier, later developed numbness and loss of strength in her hands. Fifteen days later her walking completely impaired after which she became bedridden. On the blood work her Hgb was 5.5 and 5 units of erythrocyte suspension was administered. On the neurological examination arrival, quadripareisia was present, especially on the extensor muscles of all four limbs, being more severe on the lower limbs. Hypoesthesia on the distal parts of all four limbs was present, DTRs were globally abolic and foot sole responses were bilaterally indifferent.

**Results:** The EMG performed was consistent with acute, severe sensorimotor polyneuropathy, more evident on the lower limbs. On the lumbar puncture, CSF protein level was —27. On the protein electrophoresis gammopathy was detected. On the serum immunofixation electrophoresis IgG-paraproteinemia was detected. The patient was started on IVIG.

**Conclusion:** MGUS is generally considered as a reason for chronic polyneuropathies and it is very rarely seen as an acute polyneuropathy. The possibility of gammopathies should be considered and protein electrophoresis was performed in the acute onset of polyneuropathies in the elderly. These types of symptoms might be the early sign of malignant diseases.

**The attention to Duchenne muscular dystrophy**

F.D. Lima, R.A. Neves, A.J. Godoy. “Universidade do Estado do Pará, Belém, Brazil; Universidade Estadual de Londrina, Londrina, Brazil; Universidade Cidade de São Paulo, São Paulo, Brazil

**Background:** Duchenne muscular dystrophy (DMD) is a major genetic neuromuscular disease in childhood. Death eventuates commonly by the beginning of the third decade of life. Early diagnosis involves mainly a high degree of clinical suspicion, leading to biopsy or genetic assessment for confirmation.

**Objective:** This article provides a brief view on the state of this disease in Brazil, focusing on current diagnostic approach and the main challenges on the attention to patients with neuromuscular disorders.

**Material and methods:** We selected articles indexed in MEDLINE, PubMed, Lilacs, Bireme, Scielo and master degree and doctorate research databases looking for the average age of diagnosis, specialized clinical centrals and the general population knowledge of the disease.

**Results:** There is a severe delay on DMD diagnosis in Brazil, from 4 to 9 years after the first symptoms. In the whole country only two university hospitals had outpatient clinics solely dedicated to the care of DMD and less than 5% of the general population had heard about DMD.

**Conclusion:** The reported situation is caused by poor lay education, lack of genetic counseling services, professional unpreparedness and low investments in researches among others. Generally, such scenario does not differ from worldwide – with some particularities, though – and generates a costly care when DMD patients need respiratory aid. However, important progress is expected as methods of spreading...
essential information and new specialized centers are developed in the country.

Are we really closer to improving the diagnostic certainty in ALS patients with Awaji criteria?
M. Gawel, M. Kuzma-Kozakiewicz, E. Szmidt-Salkowska, A.M. Kaminska. Department of Neurology, Medical University of Warsaw, Warsaw, Poland

Background: Amyotrophic lateral sclerosis (ALS) is a lethal disorder characterized by loss of upper and lower motor neurons. The Awaji criteria equate the diagnostic significance of neurogenic electrophysiological changes to the clinical signs of lower motor neuron dysfunction. They also increase the significance of fasciculation potentials (FPs). The aim of our study was to analyze whether the new criteria improve diagnostic certainty in ALS patients.

Material and methods: Medical records of 160 consecutive ALS patients who underwent electrophysiological examination of at least three anatomical regions were chosen for analyzing. The group consisted of 56.2% patients with classic ALS, 12.5% with progressive bulbar palsy, 3.1% with primary lateral sclerosis, 15.6% with progressive muscle atrophy and 12.5% with flail limb syndrome.

Results: Introduction of the FP aspect of Awaji criteria increased the number of electrophysiological involved muscles in 27.5% of patients and the regions involvement in 21.8% of cases. However, it was only able to improve diagnostic certainty of the ALS diagnosis in 1.25% of patients. The equalization of EMG findings with clinical symptoms increased the level of the diagnosis certainty in 5.6% of cases and decreased it in 3.75% of patients. Altogether, the use of Awaji criteria enabled to change diagnosis certainty in only 9.3% of ALS patients.

Conclusions: Awaji modifications are able to improve the diagnostic certainty in ALS diagnosis in some cases. The ratio for patients with improvement of diagnosis sensitivity depends on the clinical phenotype and is higher in cases with preferential upper motor neuron involvement.

A sporadic case of late-onset familial amyloid polyneuropathy with a monoclonal gammopathy
A.S. Aleixo Correia 1, M. Mendonça 2, A. Caetano 3, E. Medeiros 2, 3, 4. 1Neurology, Hospital Egas Moniz (Centro Hospitalar de Lisboa Ocidental), Universidade Nova de Lisboa, Lisbon, Portugal; 2CEDOC, Faculdade de Ciências Médicas, Universidade Nova de Lisboa, Lisbon, Portugal

Introduction: The Portuguese type of Familial amyloid polyneuropathy (FAP) may present with sensory-motor and autonomic neuropathy, cardiomyopathy, nephropathy and ocular involvement. Disease onset is usually before the age of 40.

Case report: A 77-year-old Portuguese female presented with burning and pain starting in the feet and progressing proximally, fatigue, anorexia, weight loss and diarrhea. These clinical features were gradually progressive since the age of 65. There was no family history of neurological disease. Examination showed sensory loss in a stocking-glove distribution and distal weakness, the tendon reflexes were abolished and the patient had difficulty in walking. Electromyographic testing revealed a severe axonal sensorimotor peripheral neuropathy. A monoclonal protein was identified in serum electrophoresis. The bone scanning showed cardiac uptake of 99 m Tc-HMDP. Ophthalmological examination detected probable amyloid deposits in the right vitreous. The echocardiogram showed severe left ventricular hypertrophy. A diagnosis of primary amyloidosis (AL) was initially considered but the slow progression of the disease prompted screening for a pathologic transthyretin (TTR) mutation. The biopsy of abdominal fat pad did not reveal amyloid deposition and the genetic testing confirmed Val30Met TTR-FAP.

Conclusion: FAP has a clinical heterogeneity with respect to age at symptom onset and penetrance. The diagnosis of late-onset cases with no family history may be challenging. The coexistence of a monoclonal gammopathy with an axonal neuropathy does not necessarily imply a definitive diagnosis of AL amyloidosis as it can occur in a small proportion of patients with FAP.

A clinical analysis of 20 cases of chronic n-hexane intoxication
F. Nebli, R. Beyrouti, S. Ben Sassi, F. Hentati. National Institute of Neurology, Tunis, Tunisia

Background: Chronic n-hexane exposure can result in n-hexane intoxication which is mainly characterized by a series of manifestations of peripheral nerve lesions. The disease was sometimes misdiagnosed as ”unknown multiple peripheral neuropathy”.

Methods: Twenty cases of n-hexane intoxication were colligated between January 2000 and February 2013 in the National Institute of Neurology of Tunis.

Results: The mean age was 22 years (extremes: 11, 54 years), all men. Nineteen were glue-sniffer and one was n-hexane worker. Period of intoxication ranged from 9 months to 22 years. Ten patients suffered from limb weakness. Neurological examination showed peripheral neurogenic syndrome in eight patients associated with hypoesthesia in the lower limb in ten patients or with position errors in two patients. A cerebrospinal analysis was practiced in five cases and was normal in four cases or showed a high level of protein in one case. Electromyogram was practiced on thirteen patients. It showed axonal polyneuropathy in three cases, demyelinic polyneuropathy in two cases and axonal demyelinic polyneuropathy in eight cases. Neuromuscular biopsy was practiced on five patients. It showed giant axone in three cases. Neurogenic muscular affection and demyelinic neuropathy in one case and axonal neuropathy in one case. All patients were treated by vitamins and rehabilitation.

Conclusion: Diagnosis should be made according to the history of n-hexane exposure, the typical clinical manifestations of peripheral neuropathy. Therapeutic measures for peripheral neuropathy of other etiologies may be used and the prognosis is optimistic if correct diagnosis is made and further exposure stopped.

Clinical manifestations of chronic inflammatory demyelinating polyradiculoneuropathies: A retrospective study of forty cases
R. Beyrouti, F. Nabli, S. Ben Sassi, F. Hentati. National Institute of Neurology, Tunis, Tunisia

Introduction: The Portuguese type of Familial amyloid polyneuropathy (FAP) may present with sensory-motor and autonomic neuropathy, cardiomyopathy, nephropathy and ocular involvement. Disease onset is usually before the age of 40.

Case report: A 77-year-old Portuguese female presented with burning and pain starting in the feet and progressing proximally, fatigue, anorexia, weight loss and diarrhea. These clinical features were gradually progressive since the age of 65. There was no family history of neurological disease. Examination showed sensory loss in a stocking-glove distribution and distal weakness, the tendon reflexes were abolished and the patient had difficulty in walking. Electromyographic testing revealed a severe axonal sensorimotor peripheral neuropathy. A monoclonal protein was identified in serum electrophoresis. The bone scanning showed cardiac uptake of 99 m Tc-HMDP. Ophthalmological examination detected probable amyloid deposits in the right vitreous. The echocardiogram showed severe left ventricular hypertrophy. A diagnosis of primary amyloidosis (AL) was initially considered but the slow progression of the disease prompted screening for a pathologic transthyretin (TTR) mutation. The biopsy of abdominal fat pad did not reveal amyloid deposition and the genetic testing confirmed Val30Met TTR-FAP.

Conclusion: FAP has a clinical heterogeneity with respect to age at symptom onset and penetrance. The diagnosis of late-onset cases with no family history may be challenging. The coexistence of a monoclonal gammopathy with an axonal neuropathy does not necessarily imply a definitive diagnosis of AL amyloidosis as it can occur in a small proportion of patients with FAP.
Background: Chronic inflammatory demyelinating polyradiculoneuropathy (CIDP) is a rare peripheral neuropathy often leading to severe neurological disability.

Patients and methods: We conducted a retrospective study in forty patients, hospitalized between 2000 and 2012 at the National Institute of Neurology of Tunis and fulfilling the criteria of definite CIDP.

Results: The age of onset of the disease varied between 5 and 79 years with an average of 47 years. There was a male predominance with a sex-ratio of 2.73. Most patients presented with progressive lower limb weakness. Neurologic examination showed motor deficit in most patients (77.5%) and proxiorceptive ataxia in 15% of patients. Cerebrospinal analysis showed a high level of protein in twenty-five cases (62.5%) and was normal in eight cases (20%). Electroneuromyogram showed a demyelinating neuropathy in 34 cases and a mixed polyneuropathy in six cases. Neuro-muscular biopsy was practiced in eight patients (20%) and showed demyelinating features in six cases (5%). Most patients had a good reponse to corticoids and immunosuppressive agents.

Conclusions: CIDP have various clinical and neurophysiological presentations which are important to recognize as they respond well to treatment.

Motor form of chronic inflammatory demyelinating polyradiculoneuropathy with conduction block: Clinical, electrophysiological and outcome study of 6 cases

B. Benaaboud
N. Birouk
H. Belaidi
B. Kably
S. Aidi
M. El Alaoui Faris
M. Yahyaoui
O. Ouazzani
University Mohamed V Souissi, Rabat, Morocco; Clinical Neurophysiology, University Mohamed V Souissi, Rabat, Morocco

Background: Chronic inflammatory demyelinating polyradiculo-

neuropathy (CIDP) is a progressive or relapsing and remitting paralyzing illness. They are usually characterized by motor weakness of the limbs, sensory disturbances and distal areflexia. The protein concentration level in CSF is often high, neurophysiological and histological study finds signs of segmental demyelination. Besides the classical forms of CIDP, there are other clinical variants. Some of them are purely motor and can be a continuum of the motor neuropathy with conduction block.

Methods: We report 6 cases of mainly motor CIDP with clinical and electrophysiological study. Those 6 patients were recruited from between 1997 and 2011 among 50 patients with CIDP.

Results: There are 4 males and 2 females, of 7 to 50 years old. Within the electrophysiological study, signs of demyelination with conduction blocks were diagnosed in all cases. We noticed a high protein concentration level in CSF among 4 patients. The inflammatory and immunological blood tests were normal for all patients. Under 1 mg/kg/j oral corticosteroids: prednisone or methylprednisolone. Outcome was favorable in all cases. The follow-up duration is between 5 months and 6 years.

Conclusion: Usually in the literature, the first-line treatment for motor form of CIDP would be the IVIG. The particularity among our patients is the positive outcome reached under corticosteroids treatment thus this regime could be the first-line treatment for the motor forms of CIDP.

Neurology, Hospital Británico de Buenos Aires, Buenos Aires, Argentina; Neurology, Hospital Británico de Buenos Aires, Buenos Aires, Argentina; Internal Medicine, Instituto Médico Quilmes, Quilmes, Argentina; Centro Fabry Pinamar, Pinamar, Argentina

Fabry disease (FD) is an X linked lysosomal storage disorder caused by deficiency of the — galactosidase A, affecting frequently the nervous system.

Our aim was to evaluate the frequency and characteristics of neurootologic and peripheral nerve involvement in the same group of patients.

We prospectively examined 36 consecutive adult patients with FD (11 males, mean age 34.7 years old, range 18–60; 25 females, mean age 36.1 years old, range 18–73).

Clinically 78% of patients reported acroparesthesias and 76% neurootological symptoms. In our patients 78% presented abnormal QT; within this subgroup 93% showed increased CDT and 43% had altered WDT.

The inferior division of the vestibular nerve (assessed by VEMPs) was abnormal in 45% of the patients. The superior division of the vestibular nerve (assessed by VNG) was abnormal in 51%. Audiometry showed sensorineural hearing loss in 58%. Neuro-otologically 90% of the patients presented a lack of neural or vascular distribution of their abnormalities known as “no Pattern”.

Conclusions: We identified symptoms of neuropathy in both heterozygous and hemizygous patients. The neuropathy predominantly affects A-delta and C small fibers.

The neuro-otological abnormalities, distributed without a vascular or neural pattern, were not only very common but also highly suggestive of scattered inner ear involvement.

CMAP parameters in the diagnosis of classic form CIDP, MADSAM, and DADS: Usefulness of Erb’s point stimulation

M. Sawada
K. Nakao. Jichi Medical University, Shimotsuke-Shi, Tochigi-Ken Japan

Background: CIDP is currently classified into several subtypes: classical form CIDP, multifocal acquired demyelinating sensory and motor neuropathy (MADSAM), and distal acquired demyelinating symmetric neuropathy (DADS). In detecting these subtypes, it is often challenging for neurologists because motor conduction studies (MCS) are insensitive or nonspecific. Early diagnosis leading to prompt therapy may result in improved patient outcomes.

Objective: To determine the compound muscle action potential (CMAP) parameters along the motor nerve that best reveal the abnormalities in patients with classic form CIDP, MADSAM, and DADS.

Patients and methods: Subjects were 20 patients with classic form CIDP, 18 patients with MADSAM, 6 patients with DADS, and 35 normal controls. MCS of ulnar nerve were performed using standard surface electrodes for stimulation and recording. The ulnar nerve was stimulated on the wrist, below elbow, above elbow, arm, and Erb’s point. Reference values of motor latency, duration, negative area, and negative peak amplitude of CMAP were calculated using 35 control
data. The frequency of an abnormal finding was calculated for the different CMAP parameters for each subtype.

**Results:** In classic form CIDP and MADSAM, CMAP parameters obtained from Erb’s point stimulation were more often abnormal than CMAP parameters obtained from elbow or wrist stimulation. In MADSAM, CMAP parameters in general were less abnormal. In DADS, CMAP parameters revealed abnormality in 100% of the patients.

**Conclusion:** We suggest that CMAP parameters of Erb’s point stimulation should be used to define the conduction along the entire motor nerve in detecting CIDP.

**Topic:** 7 - Neuromuscular disorders

**The follow-up of the patients with GBS treated with plasmapheresis**

**Background:** GBS is an acute polyneuropathy, a disorder affecting the peripheral nervous system. It can cause life-threatening complications, in particular if the respiratory muscles are affected or if there is autonomic nervous system involvement. The disease is usually triggered by an infection. Treatment consists of attempting to reduce autonomic nervous system involvement. The disease is usually in particular if the respiratory muscles are affected or if there is peripheral nervous system. It can cause life-threatening complications, and is usually triggered by an infection. Treatment consists of attempting to reduce the body's attack on the nervous system by plasmapheresis.

**Objective:** To evaluate the efficacy of PEX in GBS patients.

**Methods:** In our prospective study a group of 17 patients with GBS was evaluated before, immediately after PEX and 1 year later. The evaluation was made using the Hughes functional grading scale for GBS (from Hughes et al., Lancet 1978).

**Results:** We have evaluated the 17 patients. We have found an improvement in 14/17 (82.35%) patients immediately after and 1 year after the PEX treatment. We haven’t found an improvement in 3/17 patients. In 4 patients the progression of the neurological signs was stopped immediately after the first PEX procedure and in these patients we have found better results. We have found good results even in patients who require assisted ventilation (score 5 of Hughes functional grading scale for GBS). 3/17 (17.64%) patients had an improvement even they haven’t made all the PEX procedure because of complications.

**Conclusions:** The PEX treatment in GBS patients is efficient. The improvement consisted of good clinical outcome. In some cases the progression of clinical signs was stopped even after only one procedure.

**Autosomal recessive cerebellar ataxia: A clinical and genetic study**

**Background:** Autosomal recessive cerebellar ataxia (ARCA) contains more than 20 clinical entities and an even larger number of associated genes.

**Objectives:** To determine the frequency of the different ARCA forms.

**Patients and methods:** We studied 188 cases belonging to 117 families suspected of ARCA, coming from different regions of Algeria, between 2001 and 2012. Complete clinical examination, laboratory, imaging and electrophysiological investigations allowed us to obtain a detailed phenotype for each patient. The initial molecular investigation was the FRDA GAA expansion test. The non-Friedreich patients were then explored genetically according to their phenotype.

**Result:** The molecular diagnosis could be established in 67% of ARCA patients (126 patients): 52 patients were affected with Friedreich’s ataxia (FRDA), 21 AOA2, 16 AVED, 12 AT, 9 ARSACS, 9 Joubert syndrome, 5 ARCA2, and 2 AOA1. Sixty two patients had no identified mutation.

**Conclusion:** This study in a large Algerian cohort of ARCA patients allowed us to determine the frequency of 8 ARCA entities. Friedreich’s ataxia was the most frequent entity, as found in the majority of studies, followed by AOA2 and AVED. Ataxia with vitamin E deficiency with a founder effect mutation in North-Africa is one of the few ARCA that can be treated and therefore must be looked for in first instance after FRDA in Friedreich-like patients. Two families contributed to identify ARCA2, a new cerebellar ataxia entity. However 32% of ARCA patients remained not linked to known genes, such that new ARCA forms are expected in the near future.

**Temporal cortical damage as a prognostic marker in ALS (amyotrophic lateral sclerosis)**

M. Albuquerque, H.M.T. Andrade, F.P.G. Berg, M.C. França-Junior, A. Nucci. "Neurology, Universidade Estadual de Campinas, Campinas, Brazil; Neurology, Universidade Estadual de Campinas, Campinas, Brazil; Computer Engineering, Universidade Estadual de Campinas, Campinas, Brazil"

**Background:** ALS is a devastating neurodegenerative disorder of motor neurons. Prognostic biomarkers are urgently needed in ALS, and MRI studies are a promising candidate.

**Objective:** To find a MRI-based prognostic marker in ALS.

**Patients and methods:** 35 patients with ALS were evaluated with the ALSFRS-r scale and underwent brain 3T MRI scans. Seventeen patients were clinically reevaluated after 6.6 months. Cortical thickness and gray volume estimation were performed using the Freesurfer image analysis suite (http://surfer.nmr.mgh.harvard.edu/). A control group of 35 matched controls was used for comparison. Statistical analysis was performed using SigmaPlot version 12 (Systat Software, San Jose, CA) (uncorrected p < 0.05) and the Freesurfer suite (uncorrected p < 0.0001). Cortical thickness and gray volumes were compared between groups using ANCOVA, adjusting for subject’s age.

**Results:** Patients presented cortical thinning of the precentral (p = 0.004), superior temporal (p = 0.017) and supramarginal (p = 0.035) cortices of the left hemisphere and paracentral (p = 0.020), precentral (p = 0.001) and supramarginal (p = 0.050) cortices of the right hemisphere. They also presented reduced gray volumes of the middle temporal (p = 0.010), postcentral (p = 0.009) and precentral (p = 0.001) cortices of the left hemisphere and paracentral (p = 0.001), postcentral (p = 0.046) and precentral (p = 0.00032) cortices of the right hemisphere. ALSFRS-r scale variation was associated to cortical thickness at the fusiform, entorhinal, temporal superior, middle and inferior gyri (right hemisphere) and temporal superior and inferior gyri (left hemisphere).

**Conclusion:** Patients with ALS have motor and non-motor cortical damage. Temporal cortex thinning is associated with faster disease progression, and might be a prognostic marker in ALS.

Peripheral neuropathy in neurofibromatoses
M. Poloni1, R. Barbò2, R. Kima, S.-Y. Kwonb, A. Arsovskac.
1Neurosciences, HPG 23, Bergamo, Italy; 2Neurosciences, ICH Gavazzeni, Bergamo, Italy

Neurofibromas are benign tumors which originate from peripheral nerves and are, together with others pathognomonic symptoms, a common finding in Neurofibromatosis 1 (NF1) conversely Neurofibromatosis 2 (NF2) or central neurofibromatosis is characterized by abnormal growth of Schwann cell tumors called schwannomas (SCH) at vestibular nerves, beyond meningiomas, ependimomas and SCHs of other cranial nerves and different Central Nervous System (CNS) tumors. NF1 is a genetic disorder transmitted thorough chromosome 17 due to neurofibromin alterations and abnormal tumors growth with rare Malignant Peripheral Nerve Tumors (MPNT), while NF2 is linked to merlin abnormalities and is at same genetically transmitted but through chromosome 22.

Peripheral neuropathy (PN) appears rarely in NF1, ranging from 0 to 43 % of patients in different casistics, while retains only instrumental abnormalities in NF2 where mononeuropathy, generally as a foot drop or a facial palsy, is relatively common.

Three interesting cases of important and distressing peripheral neuropathy, one affected by NF1 and two brothers affected by NF2, have been seen and studied at the NF Ambulatorial Center of Bergamo: we want to share the clinical and instrumental characteristics of these patients, discussing the differential diagnosis and arguing the different pathogenetic mechanisms.

Facial onset sensory and motor neuronopathy: A neurodegenerative TDP-43 proteinopathy?
E.P. Bosch1, B.P. Goodman2, J.A. Tracyb, P.J.B. Dyckb, C. Gianninnib.
aNeurology, Mayo Clinic Arizona, Scottsdale, AZ, USA; bNeurology, Mayo Clinic Rochester, Rochester, MN, USA; cPathology, Mayo Clinic Rochester, Rochester, MN, USA

Background: Vucic et al. (Brain, 2006) described four adult males with facial sensory loss gradually spreading to cervical and brachial dermatomes associated with LMN weakness of cranio-bulbar and upper extremity (UE) distribution. Autopsy suggested a neurodegenerative process affecting motor neurons and sensory ganglia.

Objective: We report clinical, electrophysiologic and pathologic features of six new cases of facial onset sensory and motor neuronopathy or FOSMN syndrome.

Design and methods: A retrospective review of patients referred to Mayo Clinic from 2004 to 2012 identified six males who met the clinical features of FOSMN.

Results: The age of onset ranged from 55 to 63 years. The presenting symptoms, years after onset, were facial numbness (5), dysphagia (3), and masseter weakness (2). Sensory loss spread to scalp, neck, upper torso and distal UEs. Patients developed facial, masseter, bulbar, neck flexor/extensor and LMN weakness of UEs. Four patients died of complications 6 to 9 years after onset. Electrodiagnostic studies revealed blink reflex abnormalities, reduced sensory nerve action potentials in UEs, and chronic denervation mainly in cranial and cervical regions. Biopsies of greater auricular nerves revealed low grade axonal degeneration. One patient came to autopsy: Neuronal loss and gliosis with TDP-43 positive cytoplasmic neuronal and glial inclusions were present in hypoglossal nucleus and cervical motor neurons.

Conclusion: FOSMN syndrome is a rare, progressive disorder affecting sensory and motor neurons in a cranio-caudal descending distribution. FOSMN syndrome joins sporadic ALS, frontotemporal lobar degeneration (FTLD-U) and other neurodegenerative disorders as a TDP-43 proteinopathy.

Dermatomyositis in elderly, disease that should be recognized — case report
M. Perovska1, K. Majstorovic2, A. Arsovskac.
1University Clinic of Neurology Skopje, Ohrid, The Former Yugoslav Republic of Macedonia; 2Institute of Nephrology Struga, Ohrid, The Former Yugoslav Republic of Macedonia; 3University Clinic of Neurology Skopje, Skopje, FYROM — The Former Yugoslav Republic of Macedonia

Our aim was to present late onset of dermatomyositis as a chronic autoimmune condition, importance in differential diagnosis with other conditions and the possibility of underlying malignancy.
A 70 year old male was presented with history of symmetrical, proximal muscle weakness, muscle pain, cough, reduced appetite, remarkable weight loss, constipation, and erythematous forehead lesion. Clinical symptoms had subsacute course three months prior to hospitalization, initially with erythematous forehead lesion, cough and constipation. The patient had noticed difficulty in climbing the stairs and a month later proximal upper limb weakness in difficulty overhead activities. The muscular weakness was gradually progressive. The patient has uncontrolled diabetes mellitus and he was complaining about hyposthesia in distal parts of lower limbs. Series of tests were carried out prior to hospitalization: complete blood count; EMG; LP; prostigmin test; cervical MRI; SEP; thyroid profile; and PSA. Bedside examination revealed erythematous forehead lesion, inspiratory crackles in the lung bases; proximal, symmetrical muscle weakness, muscle pain on grasping, generalized hypotony, proximal hypotrophy of upper limbs, and generalized areflexia. No fasciculations were seen in any of the muscle. We have made complete blood count; EMG; SEP; oculus fundus exam; chest radiography; and ECG.

With the results our case satisfied all the criteria for the definite diagnosis. Improvement was seen after we began the treatment with high-dose corticosteroids, supportive and symptomatic therapy. It is essential to recognize early manifestations, investigate and differentiate dermatomyositis, initiate the therapy early, and search for malignancy. Further investigation is necessary.

Cryoglobulinaemia and peripheral neuropathy
R. Beyrouti, F. Nabli, S. Ben Sassi, M. Zouari, F. Hentati. Department of Neurology, National Institute Mongi Ben Hamida of Neurology of Tunis, Tunis, Tunisia

Background: Cryoglobulinaemia is a systemic inflammatory condition characterised by immune complex-mediated small-to-medium-sized vasculitis. The most common type described in the literature is secondary to hepatitis C. It has a wide variety of presentations ranging from bruising, neuropathy, and hepatosplenomegaly to acute renal failure.

Objective: Here we described two cases of cryoglobulinaemia and peripheral neuropathy without HCV.

Patients: A 46 year old female and a 29 year old male without pathological history developed paresthesias, painful sensations and progressive distal motor weakness in the lower limbs. Neurological examination of the patients tow showed distal weakness and areflexia in lower limbs associated with superficial and proprioceptive sensory disturbance. Nerve conduction studies were suggestive of axonal sensorimotor neuropathy. Cutaneous muscular nerve biopsy showed a mild axonal neuropathy. Laboratory studies showed a detection of serum mixed (IgG–IgM) cryoglobulins in the first case and the presence of monoclonal cryoglobulins type IgG in the second, and excluded others’ autoimmune and hepatitis markers.

Our patients were treated and subsequently improved with only oral steroids in the second.

Conclusion: Neuropathy in our cases was the initial manifestation of mixed cryoglobulinaemia which was seen in half of the patients in the literature. Previous works reported that the peripheral neuropathy was more common with essential mixed cryoglobulinaemia and was generally of sensory type. Cryoglobulinaemia must be looked for in case of neuropathy.

Agrin–Lrp4–MuSK signaling in passively transferred experimental myasthenia gravis rat
M. Motomura, S. Yoshimura, T. Yoshimura, T. Narita, R. Nakata, A. Mukai, T. Miyazaki, H. Nakajima, A. Kawakami, M. Tsujihata, M. Eguchi, O. Higuchi. Nagasaki University Hospital, Nagasaki, Japan; Nagasaki University, Nagasaki, Japan; Nagasaki Kita Hospital, Nagasaki, Japan; Therapeutic Protein Products Research Department, The Chemo-Sero-Therapeutic Research Institute, Kumamoto, Japan; Nagasaki Kawatana Medical Center, Higashisonogi, Japan

Objective: Passively transferred experimental autoimmune myasthenia gravis (p-EAMG) rats can be induced by injecting serum from an AChR-immunized chronic EAMG rat. The present study aimed to clarify Agrin–Lrp4–MuSK signaling in the neuromuscular junction (NMJ) in vivo using immunohistochemical methods.

Methods: Injection of 250 μL of anti-AChR antibody-positive rat sera into normal female Lewis rats (n = 6) induced severe signs of p-EAMG including weight loss and AChR deficiency in the NMJs. By contrast, injection of 50 μL of the sera into normal rats (n = 6) induced mild signs of p-EAMG with no significant weight loss and AChR deficiency in the NMJs. Using the p-EAMG rats, expression levels of MuSK and Lrp4 proteins at the NMJ were analyzed by an immunohistochemical method.

Results: In the NMJs of p-EAMG rats with mild signs, high signal intensity of MuSK and Lrp4 was detected, but not in p-EAMG rats with severe signs and wild-type of rats.

Conclusions: Our data suggest that expression of Lrp4 and MuSK is up-regulated to oppose a disorder of neuromuscular function caused in rats with mild signs of p-EAMG.

Myasthenia gravis and facioscapulohumeral muscular dystrophy (FSHD) co-existing in one patient — A case report
M. Guger, G. Caravias, W. Struhal, G. Ransmayr. General Hospital Linz, Linz, Austria

Introduction: Some case reports describe co-existence of myasthenia gravis and facioscapulohumeral muscular dystrophy (FSHD) in one patient. It is unclear, if the association is coincidental or not. There is evidence that muscle fibre degeneration can cause innate immune responses and leads to the generation of autoantibodies against muscle proteins.

Case report: We describe a 66-year old male with onset of weakness of the proximal upper limb muscles at age 40. Family history was not available. At this time electrophysiological workup revealed myopathic changes in the upper extremities and muscular biopsy of the left deltoid muscle showed a neurogenic atrophy.

At the age of 45 the patient complained about a ptosis of the right eye and diplopia. A seropositive generalized myasthenia gravis was diagnosed and the patient underwent thymectomy.

On cyclosporine treatment the patient remained symptom free until the age of 61.

At this time neurological examination revealed moderate muscle weakness and atrophy of the scapulothoracic region. Creatine kinase was elevated between 200 and 300 U/L. A myopathic pattern of the muscles of the upper limb was found in electromyography.
Re-biopsy of the right deltoid muscle showed again a neurogenic atrophy.

Genetic testing on FSHD confirmed the diagnosis (10 copies of D4Z4-repeats).

Conclusion: In our case we found a coincidence of two diseases because ptosis and diplopia are not typical for FSHD and we observed an excellent response to immunosuppressive agents for the myasthenia related symptoms.

Mycosis fungoides and CIDP: A case report
M. Moghaddasi, N. Mohebi. 4Neurology, Rasool Akram Hospital, Iran University of Medical Sciences, Tehran, Iran; 5Neurology, Iran University of Medical Sciences, Tehran, Iran

Background: Mycosis fungoides or granuloma fungoides, is the most common form of cutaneous T-cell lymphoma. It generally affects the skin, but may progress internally over time. Symptoms include rash, tumors, skin lesions, and itchy skin. Most cases are sporadic and occur in people over 20 years of age, and it is more common in men than women. Treatment options include sunlight exposure, ultraviolet light, topical steroids, chemotherapy, and radiation.

Case report: A 53 year old male with history of Mycosis fungoides since 10 years PTA, came for his subacute progression of proximal muscle weakness that occurred 2 months before admission. Neurological examination revealed areflexia, proximal and distal muscle weakness, strokes and glove sensory disturbance, and loss of position sense. Electrophysiology study showed sensory motor polyneuropathy with conduction block without spontaneous activity. All lab tests for vasculitis and gangiomaphies were normal. Lp was done that showed elevated protein (90 mg/cc). The patient was diagnosed as CIDP and IVIG therapy was started.

Conclusion: Some complications like skin cancer, melanoma, colon cancer, Hodgkin lymphoma, and non-Hodgkin lymphomas have been reported but if polyneuropathy is a rare complication of disease or it is a concomitant state is still unclear.

Dermatomyositis in a patient with facioscapulohumeral dystrophy

Background: The association of Facioscapulohumeral Dystrophy (FSHD) and Dermatomyositis is not described in the literature.

Objective: Case-report of patient with FSHD and Dermatomyositis.

Material and methods: Review of the clinical record.

Results: Female, 23 year-old, with family history of FSHD (mother, aunt and 2 cousins), apparently healthy until September 2011, when she started to develop a progressive tetraparesis, initially with asymmetry. The genetic testing for FSHD was positive. Five months after the initiation of the muscular weakness she presented a grade 2-3/SMRC tetraparesis, involving cervical involvement and facial weakness, and 2 months later she started with dysphagia for liquids. In May 2012 she was admitted to the Neurology Service because of clinical deterioration with dysphagia and loss of gait. The analytical review performed during this hospital admission showed: CK > 3000 IU, ANA1/1280 mottled pattern, Ac antiMi2+, EMG: findings compatible with necrotizing myopathy. A muscle biopsy showed changes compatible with an inflammatory myopathy. The patient suffered aspiration pneumonia leading to invasive ventilation. Concomitantly heliotropic rash and erythoderma developed at the knees and face with malar rash. Given the clinical picture and the results of diagnostic exams, the diagnosis of Dermatomyositis was proposed. She was treated with methylprednisolone, followed by prednisolone and parallel immune globulin with discreet improvement of motor function. Later, methotrexate was added as well as rescue therapy with 5 plasmapheresis sessions, because of the poor clinical evolution. Currently, she is on spontaneous ventilation, with improved distal muscle strength.

Conclusion: The presence of 2 rare diseases in the same individual hindered the diagnosis and delayed the start of immunosuppressive therapy.

Taurine ameliorates mitochondrial dysfunction and prevents stroke-like episodes in patients with MELAS

Out of the 32 PD had abnormal SWT while 4 out 9 patients with SWT. SWT was performed in 41 patients (32 PD, 9 parkinsonism). 18 radiculopathy and normal SWT and the other normal NCS/EMG and underwent NCS/EMG had axonal sensorimotor PN, 1 had L5 neuromuscular evaluation. NCS/EMG was performed in 12 patients disease (WD), 3 with MSA, 3 with PSP/CBGD] completed clinical

Recent studies have reported that large- and small fiber PN are common in patients with Crohn's disease (CD), 70 patients with ulcerative colitis (UC) and 50 controls (gastritis/dyspepsia/irritable bowel syndrome) were compared. Descriptive statistics and t-test were used to compare the different groups.

Results: In the CD group, 7 patients had small fiber neuropathy (SFN) and 12 large-fiber PN. Sural SNAPs and peroneal CMAPs were lower in the large-fiber PN group: 2.7 ± 1.6 versus 6.2 ± 0.5 (asymptomatic) and versus 24.5 ± 2.7 (SFN) uV (P < 0.05) and 23 ± 1.6 versus 6.2 ± 0.5 (asymptomatic) and 5.1 ± 0.4 (SFN) mV (P < 0.05). Median and ulnar sensory SNAPs and tibial, median and ulnar CMAPs were also decreased (P < 0.05). In the UC group, 8 patients had SFN and 12 large-fiber SM PN. Sural SNAPs and peroneal CMAPs were lower in the large-fiber PN group: 5.9 ± 1.5 versus 7.3 ± 2.3 (asymptomatic) and versus 31.5 ± 3.7 (SFN) uV (P < 0.05) and 3.2 ± 0.6 versus 5.3 ± 0.4 (asymptomatic) and 4.1 ± 0.2 (SFN) mV (P < 0.05). Median SNAPs and tibial, median and ulnar CMAPs were also decreased (P < 0.05). One of the patients also developed myasthenia gravis.

Conclusion: Excluding other contributory factors (medications, low B12, diabetes, hypothyroidism, diabetes or glucose intolerance), 7.1% of the IBD patients had SFN or large-fiber PN probably due to IBD. The most common form of PN in IBD patients is a mild distal symmetric axonal sensorimotor.

Electrodiagnostic findings in a cohort of patients with Inflammatory Bowel Disease (IBD)
F.D.A.A. Gondimc, D.F. Araújodo, B.C. Telesd, L.R. Miranda Pintod, G.R. Oliveiraa, M.H. Souzaa, F.H. Rolabd, L.L. Bragae. 2Internal Medicine—Neurology Division, Fortaleza, Brazil; 3Universidade Federal do Ceará, Fortaleza, Brazil; 4Physiology and Pharmacology, Universidade Federal do Ceará, Fortaleza, Brazil

Background: Patients with IBD may experience a wide range of neuromuscular complications (Gondim, Brain 128:867, 2005).

Objective: To report the electrodiagnostic and clinical findings in a cohort of IBD patients.

Patients and methods: Clinical and electrodiagnostic findings of 51 patients with Crohn's disease (CD), 70 patients with ulcerative colitis (UC) and 50 controls (gastritis/dyspepsia/irritable bowel syndrome) were compared. Descriptive statistics and t-test were used to compare the different groups.

Results: In the CD group, 7 patients had small fiber neuropathy (SFN) and 12 large-fiber PN. Sural SNAPs and peroneal CMAPs were lower in the large-fiber PN group: 2.7 ± 1.6 versus 6.2 ± 0.5 (asymptomatic) and versus 24.5 ± 2.7 (SFN) uV (P < 0.05) and 22 ± 0.6 versus 6.2 ± 0.5 (asymptomatic) and 5.1 ± 0.4 (SFN) mV (P < 0.05). Median and ulnar sensory SNAPs and tibial, median and ulnar CMAPs were also decreased (P < 0.05). In the UC group, 8 patients had SFN and 12 large-fiber SM PN. Sural SNAPs and peroneal CMAPs were lower in the large-fiber PN group: 5.9 ± 1.5 versus 7.3 ± 2.3 (asymptomatic) and versus 31.5 ± 3.7 (SFN) uV (P < 0.05) and 3.2 ± 0.6 versus 5.3 ± 0.4 (asymptomatic) and 4.1 ± 0.2 (SFN) mV (P < 0.05). Median SNAPs and tibial, median and ulnar CMAPs were also decreased (P < 0.05). One of the patients also developed myasthenia gravis.

Conclusion: Excluding other contributory factors (medications, low B12, diabetes, hypothyroidism, diabetes or glucose intolerance), 7.1% of the IBD patients had SFN or large-fiber PN probably due to IBD. The most common form of PN in IBD patients is a mild distal symmetric axonal sensorimotor.

Seed-based and functional connectivity analyses as a tool for evaluating Amyotrophic Lateral Sclerosis (ALS) progression, a pilot study

Background: ALS is a severe neurodegenerative disorder of motor neurons. Candidates for prognostic markers are necessary to follow the course of the disease and possibly guide medical actions.

Conclusions: Large fiber and small fiber PN are common in patients with PD, WD and other forms of parkinsonism. SWT may be used as a useful screening tool for evaluation of small fiber dysfunction in patients with PD.
Objective: Investigate possible fMRI candidates: specific seed-based and functional connectivity analyses from resting state (RS) scanning.

Patients and methods: 30 patients and 24 controls were evaluated with the ALSFRS-r and severity scales. A BOLD signal time series from each RS-scanning of all subjects was obtained using a mask of Brodmann area 4 and the Matlab (MathWorks Natik, Massachusetts) toolbox Pickatlas (Functional MRI Laboratory, Wake Forest University). A correlation map with this signal was calculated for all voxels and all subjects. Correlation maps of control and patient groups were compared by two sample t-test. We also calculated correlation matrices for each subject of every voxel pair of Brodmann area 4. Then we determined a value of connectivity degree. We used General Linear Model to analyze connectivity degree and the clinical variables (ALSFRS-r, severity scale, variation and rate of variation of ALSFRS-r and of severity scale).

Results: We found no significant results in the application of these methods, considering a significance level of 0.01.

Conclusion: Further studies with greater groups may be necessary to confirm if there is no difference between groups analyzed by the cited seed-based and functional connectivity methods. Our results do not support follow-up of patients by the methods we used, nor differentiation between them and individuals from control group.

Subdermal needle electrode facilitates recording of lumbar N22 tibial SEP responses
B.E. Smitha, J.C. Watsonb, B.P. Goodmana, M.A. Rossa, aNeurology, Mayo Clinic Arizona, Scottsdale, AZ, USA; bNeurology, Mayo Clinic Rochester, Rochester, MN, USA

Background: When the tibial SEP shows a delayed scalp response, the N22 lumbar response helps distinguish if the delay is central or peripheral.

Objective: To determine if a subdermal needle electrode enables recording of N22 lumbar posterior tibial SEP responses when the surface recording shows no response.

Materials and methods: Over a two year period twenty-eight patients undergoing tibial SEP testing who had absent or poorly formed N22 lumbar responses using standard surface recording had the SEP study repeated at the same visit replacing the lumbar surface electrode with a subdermal needle electrode. Most of these patients were eventually found to have a variety of CNS, structural intraspinal or other disorders. Each patient consented to have a lumbar subdermal needle placed in an attempt to bring out the N22 lumbar potential.

Results: A reproducible N22 lumbar response was obtained in 14 of 28 subjects. Patients with lumbar responses were of similar age (mean age 62.0 vs. 59.4 years) and had comparable BMI values (mean value 28.0 vs. 30.4) to those without lumbar responses.

Conclusions:

1) A subdermal needle electrode facilitates recording of a reproducible N22 lumbar potential in the posterior tibial SEP study when the surface recording technique shows no convincing lumbar response;
2) Identifying a lumbar potential can help localize delayed conduction.

Lipid and protein oxidative damage in G93A mice, a model of amyotrophic lateral sclerosis
C. Gonzalez Mingota, F.J. Miana Menab, P. Larrodé Pellicerc, J. Garciab, aHospital Universitario Arnau de Vilanova, Lleida, Spain; bUniversidad de Zaragoza, Zaragoza, Spain; cHospital Universitario Clínico Lozano Blesa, Zaragoza, Spain

Background: Amyotrophic lateral sclerosis is a progressive neurodegenerative disorder. Recent studies guide in question, a multisystem disease with a special predisposition for motor neuron. The SOD1 mutation found in some patients with FALS has been shown to result in an increase in free radical production that may cause systemic oxidative injury. In this study, we analyzed the extent of lipid and protein oxidative damages to the brain, heart, liver, muscle and spinal cord of transgenic FALS mice that overexpress the SOD1 mutation.

Material and methods: We used a colony of G93A transgenic mice divided in two groups: control and diseased both with 50 of 40 days and 50 of 100 days of life. We analyzed the concentrations of MDA-4-HDA and carbonyl, indicators of lipid and protein oxidation.

Results: In the preclinical stage (40 days old) no significant differences were found between levels of lipid or protein oxidation when we compared health versus sick animals. In the clinical phase (100 days old), values of lipid and protein oxidative damage in sick animals were higher in all tissues compared with healthy animals. Significant differences were only found in sick spinal cord lipid peroxidation values (diseased spinal cord 1.42 ± 0.24 vs healthy spinal cord 0.62 ± 0.03; Mean ± SEM; p < 0.01).

Conclusions: Our results suggest that overproduction of free radical production caused by the G93A SOD1 mutation leads to extensive lipid and protein systemic damage, above all in spinal cord, that may be involved in neurodegeneration.

Atypical Guillain–Barre syndrome presenting with isolated facial palsy and acral paresthesia
H. Fidancı, A. Yılmaz, S.H. Kaleağası, N. Oksuz, S. Ozal, Z. Demirtas, Mersin University Faculty of Medicine, Mersin, Turkey

Bilateral simultaneous facial paralysis is a rare clinical entity, which unlike the unilateral presentation, is seldom secondary to Bell’s palsy. A 26-year-old-man presented with a one week history of bilateral facial weakness and acral paresthesia. Neurological examination revealed bilateral complete lower motor neuron type of facial palsy, loss of deep tendon reflexes and diminished vibratory sensation. But motor examination was completely normal in both upper and lower extremities. Blood tests for full blood counts, urea and electrolytes, serum angiotensin converting enzyme (ACE) and the vasculitic screen were within normal limits. Tests were negative for Lyme disease, Herpes simplex, Borrelia burgdorferi and Oligoclonal bands. Lumbar puncture revealed albuminocytological dissociation. Enhancement of the left geniculate ganglion was confirmed by cranial MRI. The diagnosis of AIDP was made and he was initiated on a five day course of 30 g of intravenous immuno-globulin infusions from day 8. Incidence of bilateral facial palsy is about 1 per 5,000,000. The etiology of facial paralysis includes many
condition such as congenital, traumatic, infectious, neurological, metabolic, neoplastic, toxic, vascular, and idiopathic. GBS presents as a progressive development of palsy of the voluntary muscles. In 27% to 50% of the cases, the facial nerve is involved. Isolated facial diplegia with no limb weakness has been described as a rare GBS variant. Usually in these cases, areflexia helps in distinguishing GBS as the underlying etiology. Prognosis is rather good and therapy consists of plasma exchanges and administration of IV immunoglobulins.

Objective: Assess ataxia in patients with PEO/KSS, correlating with level of independence and quality of life.

Patients and methods: We evaluated the presence of ataxia in 15 patients with mitochondrial disease in the spectrum PEO/KSS and 38 controls. Ataxia was assessed with Brief Ataxia Rating Scale (BARS), International Cooperative Ataxia Rating Scale (ICARS) and Scale for the Assessment and Rating of Ataxia (SARA). Level of independence was estimated through Barthel index and quality of life with the World Health Organization Quality of Life (WHOQOL-bref).

Results: Scores obtained with the ataxia rating scales demonstrated a significant difference between PEO/KSS patients and controls (p < 0.001; Mann–Whitney test). However, only one patient reached the maximum scores, while the remaining ranged from 3–16 (BARS 0–30); 9–42 (ICARS 0–100) and 2–15 (SARA 0–40), indicating a mild to moderate ataxia. Nevertheless, no patients scored zero, compared to 27 controls. Correlation between ataxia scales demonstrated a positive correlation of moderate to high magnitude (r = 0.60 to 0.94; p < 0.05). There was no correlation between the presence of ataxia and level of independence or quality of life.

Conclusion: Our results suggest that ataxia is a frequent feature in patients with mitochondrial disease within the spectrum PEO/KSS. However, ataxia is only mild to moderate and did not influence the level of independence or the quality of life.

A case of painless ptosis due to isolated levator palpebrae myositis
S.H. Heo1, S.-H. Lee1, S.-S. Yoon1, S.-H. Cho2. 1Neurology, Kyung Hee University, College of Medicine, Seoul, Republic of Korea; 2Neurology, Semyung Christianity Hospital, Pohang, Republic of Korea

Background: Idiopathic orbital myositis is a nonspecific orbital inflammation primarily involving one or several extraocular muscles. The cardinal symptom is orbital pain exacerbated by eye movement accompanied with or without ptosis, diplopia, exophthalmos, and conjunctival injection.

Objective: To present a case of levator palpebrae myositis without any pain or other unpleasant feelings.

Patients and methods: A thirty-eight-year-old man visited our outpatient clinic with left ptosis five days ago. He complained of myalgia and generalized weakness from a week ago, but he did not complain of diurnal variation or progression of symptom. Repetitive nerve stimulation test and thyroid function test were normal. Levels of angiotensin converting enzyme, acetylcholine receptor antibody, and anti-GQ1b antibody were normal. His visual acuity and light reflex was normal. There was no edema, exophthalmos, or orbital bruise. His brain MRI showed the swelling and enhancement of left levator palpebrae muscle. After oral steroid treatment, his ptosis was improving. After a week, his symptom was completely improved.

Results: The patient's neurological symptom could be commonly confused with other neurological disorders such as thyroid eye disease, neuromuscular junction disorder, and other autoimmune disorders. MRI could be the most important radiologic finding for diagnosis.

Conclusion: In this case, brain MRI may play an important role in the diagnosis of levator palpebrae myositis. Unlike the other cases, levator palpebrae myositis could be not painful.

Interferon gamma as a potential therapy for Friedreich ataxia
B. Tomassini1, G. Arcuri1, S. Fortuni1, C. Sandi1, V. Ezatizadeh2, C. Casali1, I. Condor3, F. Malisani4, S. Al-Mahdawi5, M. Pook6, R. Testa6, 1University of Rome Tor Vergata, Rome, Italy; 2Brunel University, Uxbridge, UK; 3University of Rome ‘La Sapienza’, Rome, Italy

Background: Friedreich ataxia (FRDA) is the most common of inherited ataxias, affecting > 20,000 individuals in western countries. It is caused by GAA triplet expansions in the first intron of the frx gene, that result in the insufficient production of the mitochondrial protein frataxin. Patients, usually children, experience progressive loss of motory coordination up to severe disability and premature death. Pathology is dominated by the degeneration and loss of dorsal root ganglia neurons. There is no approved therapy for FRDA.

Objective: We observed that interferon gamma was able to upregulate frataxin levels in cells derived from FRDA patients. We aimed at obtaining preclinical evidence of efficacy in an animal model of FRDA.

Methods: FRDA mice, engineered to express only reduced amounts of frataxin, were treated for several weeks with interferon gamma or vehicle.

Results: Interferon gamma-treated FRDA mice showed improved performance on all the motory coordination tests performed, compared to vehicle-treated FRDA mice. Degeneration and neuronal loss were largely prevented in dorsal root ganglia and this was associated with a recovery in neuronal frataxin levels.

Conclusions: Treatment with interferon gamma, a drug currently approved for pediatric indications, shows potential as a therapy for FRDA. A phase II clinical trial, aimed at assessing tolerability of interferon gamma and the ability of interferon gamma to elevate frataxin levels in FRDA patients, is currently underway. Future clinical trials considering the possibility of a more targeted drug delivery by the use of implantable intrathecal pumps and addressing clinical endpoints, are being planned.

Using sensitivity, specificity and accuracy for detection of axonal neuropathy
A. Prochazkaa, V. Oldrichb, O. Tupa3, M. Valisb, 1Computing and Control Engineering, Institute of Chemical Technology, Prague, Czech Republic; 2Department of Neurology, Charles University, Faculty of Medicine in Hradec Kralove, Prague, Czech Republic

Background: Digital signal processing and general mathematical methods of pattern analysis can be used in needle electromyography to detect motor unit potentials and to recognize various kinds of muscle diseases.

Objective: The goal of the paper is to contribute to various methods enabling discrimination of individuals with axonal neuropathy from normal cases using signals acquired from needle electromyography.

Patients and methods/material and methods: Data from a control set of 104 individuals and a set of 76 patients were used to validate selected methods for their separation and classification. Different kinds of signal features in time as well as frequency domains were studied to obtain the most reliable results.

Results: The proposed features used to detect individuals with axonal neuropathy were analyzed by specificity, sensitivity and accuracy of data obtained using the receiver operating characteristic curves and confusion analysis. Accuracy higher than 95% was achieved for the given sets of individuals and for optimal criterion values proposed.

Conclusion: The proposed modified Willison amplitude together with statistical and spectral properties of signal components can be used to classify individuals into sets of healthy and neuropathic patients with sufficient accuracy.

Sphincter dysfunction in a case of cauda equina disorder: An atypical variant of autoimmune lumbosacral polyradiculoneuropathy
S. Yague¹, A. Aceituno¹, R. Belvisa², N. Mayolas³, B. Sanuy⁴, T. Torres⁴, J. Kulisevsky⁵. ¹Neurology, Grupo Quiron Dexeus, Barcelona, Spain; ²Neuroradiology, Grupo Quiron Dexeus, Barcelona, Spain; ³Internal Medicine, Grupo Quiron Dexeus, Barcelona, Spain; ⁴Intensive Care Unit, Grupo Quiron Dexeus, Barcelona, Spain

Background: Sphincter dysfunction is not included in the diagnostic criteria of autoimmune lumbosacral polyradiculoneuropathy and its infrequent appearance can be attributed to autonomic impairment.

Objective: To describe an atypical variant of autoimmune lumbosacral polyradiculoneuropathy in the form of a cauda equina syndrome.

Patient: A 51-year-old woman presented with a 2 week history of back and leg pain, burning pain in her feet, numbness in her toes and saddle area and sphincter dysfunction. There was no history of diarrhea or surgery.

On examination muscle strength was normal, deep tendon reflexes at the knees and ankles were reduced, over the next few days were lost, and vibration sense in her feet was decreased. The levels of ACE, LDH and beta 2-microglobulin were within normal limits, and tumoral markers were absent.

Results: CSF analysis showed no albuminocytologic dissociation. Serological studies were negative for syphilis, Mycoplasma pneumoniae, Lyme disease and HIV. Coprocultures for Campylobacter jejuni were negative.

The patient was treated with intravenous immunoglobulins, which improved her symptoms.

Conclusion:
- After ruling out tumoral, compressive and infiltrative processes in a cauda equina syndrome we have to consider an inflammatory and autoimmune etiology.
- Spinal MRI is a highly valuable imaging method for the diagnosis, as reliable as nerve conduction studies and CSF analysis.

Genetic analysis of Japanese patients with motor neuron disease
Y. Adachi¹, R. Shimoyama². ¹Clinical Research Institute, Matsue Medical Center, Matsue, Japan; ²Department of Neurology, Matsue Medical Center, Matsue, Japan

Background: Motor neuron disease (MND) is heterogeneous syndrome. Even in the same race and the same nation, there are regional differences in the prevalence and clinical features. Because some ALS patients with SOD1 mutation have only lower motor symptom clinically, we think that it is necessary to examine not only ALS patients but also lower MND patients to reveal the prevalence of the patients with ALS related gene mutations.

Objective: We aimed to reveal the genetic background in patients with MND in San-in district, Western Japan.

Patients and methods: We had clinically examined 32 MND patients in our hospital in 2007–2013. We got informed consent for genetic examination in 16 patients among them. They included five families with familial MND (eight patients). We did genetic test for SOD1, ANG, FUS, TDP-43, OPTN, C9ORF72 and SBMA using auto-sequencer.

Results: Three patients in a family had OPTN G478E mutation. Two of them had homozygous mutation and earlier onset of the disease than the patient with heterozygous. These three patients developed dementia and flexion of limbs. Two patients in another family had SOD1 L126S mutation. One patient with familial ALS...

Preliminary report of Tropals study — A survey of amyotrophic lateral sclerosis in Africa
B. Marin1, M. Diegana2, B. Hamidou3, R. Gouider4, A. Basse Fayed5, A. Balogou6, D. Houinato7, P. Couratier8, P.M. Preux8, TROPALS Collaboration. 1UMR Inserm 1054 NeuroÉpidémiologie Tropicale, Limoges, France; 2Service de Neurologie, Nouakchott, Mauritania; 3Department of Neurology Razi Hospital — La Manouba, Tunis, Tunisia; 4Clinique Neurologique CHU Fann, Fann, Senegal; 5CHU Lome, Lome, Togo; 6CHU Cotonou, Cotonou, Benin

Background: Epidemiological studies of Amyotrophic Lateral Sclerosis (ALS) in the tropics are rare and their methodologies are heterogeneous. Many questions arise as regards the characteristics of this disease in the tropics, especially in Africa.

Objective: Describe sociodemographical and clinical characteristics of ALS patients diagnosed in Africa.

Patients and methods/material and methods: TROPALS (http://www.tropals.unilim.fr/) is a multicentre observational cohort study. A shared methodology and an online data base that allows centers to collect data in a standardized and homogeneous way.

Results: 40 patients have been included to date in 5 centers (Benin, Mauritania, Senegal, Togo, Tunisia), 3 other centers are open (Burkina Faso, Gabon, Mali) and 6 are about to be open. Mean age at diagnosis was 51.9 ± 13.5 years (2 cases less than 25 years), male/female sex ratio was 2.4. First symptoms were mostly spinal (72.5%) and 80% (n = 32/40) of patients had Electroneuromyography for diagnosis purpose. At diagnosis, 97.4% of patients were prescribed an occidental treatment: Rilutek® (n = 12), physiotherapy (n = 17), or symptomatic treatment (n = 12). 21.6% of patients used a traditional treatment based on infusion-decoction for 2 of them and of unknown type for 6 patients.

Conclusion: More inclusions are needed to produce precise estimations. Follow-up data are currently being collected. Tropals study will allow us to improve the description of ALS characteristic prognosis of patients and comprehension of the disease in this continent.

Myasthenic crisis presenting with isolated bilateral partial vocal cord palsy
A. Chaudhuri, M. Krommyda. Neurology, Queen’s Hospital, London, UK

Objective: To present a case of myasthenic crisis with acute upper airway obstruction and severe stridor due to isolated bilateral partial vocal cord palsy.

Case: We report the case of a 65-year-old man with a 3-month-history of acetylcholine receptor antibody positive generalized autoimmune myasthenia gravis (MG), who acutely developed severe stridor and speech difficulty. His medications included pyridostigmine 30 mg once daily, azathioprine 75 mg once daily; the corticosteroids (prednisolone) had been recently increased from 30 mg once daily to 30 mg/60 mg on alternating days. During the preceding days he had developed an upper airway infection. Clinical examination at the time of exacerbation showed normal strength in the neck muscles and no proximal limb weakness. A flexible laryngoscopy was performed and revealed a severe adduction position of the vocal cords with limited movement especially on the right side, without any upper airway edema. The patient remained self-ventilating and was transferred to the neurological intensive treatment unit for airway monitoring. He received a full dose of human IVIg (2 g/kg) over 4 days with significant recovery and clinical stabilization.

Discussion: Acute exacerbation of autoimmune MG can present with great variability and can selectively involve isolated muscles. In the case that we present, a myasthenic crisis emerged with inspiratory stridor due to isolated bilateral partial vocal cord palsy, without any signs of other muscle weakness.

The importance of imaging of the nerves in some cases of mononeuropathy
P. Ranganathan, Neurology, Pazhani Neuro Centre, Chennai, India

Case 1: Forty year old female patient came with h/o pain in the left sciatic nerve distribution of 1 year duration. Her MRI lumbar spine and neurophysiological studies are normal. As the symptoms are continuous and partly responding to neuropathic pain medications, it was decided to do MRI imaging of the left sciatic nerve. The investigation showed neuroma of the sciatic nerve in the left mid thigh region.

Case 2: Fifty year old patient noticed acute finger drop in the right hand after heavy cooking. The MRI cervical spine was normal. As she c/o pain in the right elbow region and clinically there was a lump in the palpation, it was decided to do neuroimaging of the right radial nerve around elbow region focusing on posterior intersosseous nerve. The MRI showed a ganglion compressing the nerve resulted in the finger drop.

Case 3: Twenty eight year old gentleman had a trauma in the left midarm region two years back. He noticed a small swelling in the same region for the past one and half years. He noticed painful tingling sensation in the left ulnar nerve distribution for the past 2 months. His neuroimaging of the left arm showed a hemangioma in close relation to the ulnar nerve.

The neuroimaging of the peripheral nerves may be needed in some of the atypical cases of mononeuropathy to rule out underlying structural cause, which is important for further management.

Novel mutations for SPG 11 in a 25-year old woman with hereditary spastic paraparesis and evidence for upper extremity involvement

K. Lackmayera, C. Baumgartnera, P. Schniderb, S. Niaa, A. Baumgartnera, Myftiua, E. Kocasoy Orhan b, B. Baslo b.

aNeurological Center Rosenbühl, Karl Landsteiner Institute for Clinical Epilepsy Research and Cognitive Neurology, Vienna, Austria; bNeurological Department, Landesklinikum Wiener Neustadt, Wiener Neustadt, Austria; cPraxis for Humangenetik, Vienna, Austria

Introduction: Familial spastic paraplegia with thin corpus callosum is related to mutations in the genes SPG11, 15 and 18. Mutations in the SPG11 gene have also been described in amyotrophic lateral sclerosis with young onset and a relatively benign course.

Objectives: We present a patient with typical spastic paraplegia, with electromyographic evidence for upper extremity involvement.

Case report: A 25-year-old woman was admitted because of progressive gait disturbance and muscle cramps since 5 years. Her mother is healthy; the patient has no contact to her father.

The clinical neurological examination showed spasticity in both lower limbs with hyperactive reflexes and cloni, a bilaterally positive plantar reflex, a beginning pes equinus bilaterally, mild ataxia of both lower limbs and slightly saccadic eye movements. Sensory functions were normal. Neuropsychological testing revealed deficits in attention, memory and executive functions. MRI of the spinal cord was normal. Serologic testing revealed no evidence for HTLV1 or 2 infections. Nerve conduction studies were normal. Electromyography showed fasciculations and giant potentials consistent with denervation of motor units.

Genetic testing for SPG 3 and 4 were negative. Mutations were found in the SPG11 gene, probably consistent with a compound heterozygous state: Three heterozygous mutations were found: c.1621C>T, (known causal mutation) and c.5623C>T and c.6526T>C, which are novel mutations.

Conclusion: Upper extremity involvement and an overlapping phenotype with motor neuron disease may be present in familial paraplegia with thin corpus callosum and two novel SPG11 mutations.

Electrophysiological study of spinocerebellar ataxia and Friedreich ataxia’s patients

B. Myftiu a, E. Kocasoy Orhan b, B. Baslo b.
aNeurology, American Hospital, Prishtina, Kosovo; bNeurology, Istanbul University Faculty of Medicine, Istanbul, Turkey

The aim of our study is to examine the bioelectrical activity of nerves and muscles in spinocerebellar (SCA) and Friedreich's ataxia (FRDA) patients according to a standardized protocol, in order to obtain information about the severity and distribution of peripheral nerve involvement.

We examined 18 genetically diagnosed, older than 18 years of age SCA and FRDA patients. Control group was formed by 31 age-matched healthy individuals. We performed sensory and motor conduction studies, F responses, needle EMG of proximal and distal muscles, and motor unit number estimations (MUNE) of distal muscles to upper and lower extremities of both groups. Descriptive statistics and group comparisons were done for each recorded parameter.

All sensory responses were low in amplitude (p<0.01) in patients as well as sensory conduction velocity was slow (p<0.05) for ulnar nerve. Median and peroneal motor amplitudes were also low (p<0.01). Median, peroneal (p<0.01), ulnar, and tibial (p<0.05) motor conduction velocities were significantly slow. MUNE in m. abductor pollicis brevis and m. tibialis anterior muscles were significantly lower in patient group than healthy individuals (p<0.01). Needle EMG evaluation revealed neurogenic involvement in 1/3 of patients.

Polyneuropathy syndrome is frequent in SCA and FRDA patients. Sensory nerves in lower extremities were predominantly involved however, signs of motor dysfunction were also notable. MUNE can provide quantitative information about motor nerve fiber and/or motor neuron involvement. Clinical and electrophysiological findings of peripheric polyneuropathy syndrome were more striking in atactic patients with proven genetic defect.

HLA-DRB1 and HLA-DQ81 allele association to myasthenia gravis in Sudan; an Arabian-African population
*06 (OR = 7.14, 1.9 b 8.7 and the genotype HLA-DRB1*03, DQB1*02, and HLA-DRB1*1001DQB1*05. The genotype HLA-DRB1*08 was found to be positively associated with MG, OR = 2.65 (1.2 b 5.7, P = 0.001). Two HLA genotypes have shown very strong association to MG; HLA-DRB1*08, *13DQB1*03, *06 was associated with an increased risk of MG; HLA-DQ81*03DQB1*016 (OR = 3.3, 1.6 b 6.5, P < 0.001). Two HLA genotypes were associated with an increased risk in EOMG (P < 0.01 in females, P < 0.05 in males).
Conclusion: We reported a pattern of HLA association unique to the Sudanese population, in which two HLA-DRB1 DQB1 genotypes can be used as susceptibility markers for MG. One of the risk genotypes included HLA-DRB1*03DQB1*02 haplotype that has been constantly reported as a risk haplotype in Caucasian populations. This strong association with certain HLA-DRB1 and DQB1 combinations suggests a role of dominant epitopes, or an effect of a linked recessive non-HLA gene.

Jitter estimation using concentric needle electrode on voluntarily activated orbicularis oculi and frontalis muscles in healthy control and myasthenic patients
A.M. Musaa1, A.E. Ahmed2, M. Elzubie rb, R.M. Badi1, A. Physiolog, Faculty of Medicine, University of Khartoum, Khartoum, Sudan; aPhysiology, Neurology, University of Khartoum, Khartoum, Sudan; cNeurology, Bilim University Medical Faculty, Istanbul, Turkey; dMedicine, Faculty of Medicine, University of Khartoum, Khartoum, Sudan; ePediatrics, Baylor College of Medicine, University of Khartoum, Khartoum, Sudan.
Background: Single fiber electromyography (SFEMG) is the most sensitive clinical neuromusiological test for neuromuscular junction disorders, particularly myasthenia gravis (MG).
Objectives: No available data concerning jitter measurement in Sudan in addition to scarcity of data worldwide. The aim of this study was to estimate normal (reference) & abnormal jitters in voluntarily activated orbicularis oculi (OOc) & frontalis muscles in healthy control and myasthenic patients.
Methods: Prospectively 45 MG patients (21 males & 24 females, mean age 39.1 ± 16.9 years) & 62 controls (20 males & 42 females, mean age 43.2 ± 14.0 years) were included in the study. Jitter values were expressed as the mean consecutive difference (MCD) of 30 potential pairs in μs.
Results: In the control group, the mean MCD, mean MCD for individual potential pairs & mean outlier jitter values (with upper 95% confidence limit-CL) for [OOc] were [26.9 ± 3.3 (32.0), 26.1 ± 8.9 (41.8) & 38.5 ± 5.7 (49.0) μs respectively] & for [frontalis] were [27.1 ± 3.0 (31.3), 26.4 ± 9.4 (42.9) & 39.9 ± 5 (49.2) μs respectively]. In the patient group the mean MCD & mean MCD for individual potential pairs for [OOc] were [50.9 ± 21.8, 48.8 ± 36.8 μs respectively] & for [frontalis] were [47.4 ± 13.9, 45.8 ± 28.7 μs respectively].

An autosomal recessive CMT family with a new mutation in the NDRG1 gene
M.T. Goksunguro, Y. Okamoto1b, D. Pehlivan1b, Z. Maturc, K. Akyüz1, E. Battalolu1, F. Deymeerb, P. Serdaroglua1, J.R. Lupski1,2, Y. Parmanc,1
1Neurology, Istanbul University, Medical Faculty, Istanbul, Turkey; 2Molecular & Human Genetics, Baylor College of Medicine, Houston, TX, USA; 3Neurology, Bilim University Medical Faculty, Istanbul, Turkey; 4Molecular Biology and Genetics, Bogazici University, Istanbul, Turkey; 5Pediatrics, Baylor College of Medicine, Houston, TX, USA; 6Pediatrics, Texas Children’s Hospital, Houston, TX, USA.
Background: HMSN-Lom/CMT4D is very rare, an autosomal recessive (AR) peripheral neuropathy with deafness and unusual neuropathologic features.
Objectives: We report the clinical features of the first AR duplication copy number variation (CNV) of NDRG1 causing HMSN-Lom/CMT4D (MIM#601455) in a large Turkish pedigree. The intragenic duplication CNV included exons 6 to 8 and caused a complete loss of function of NDRG1.
Patients and methods: There were four affected siblings from this consanguineous family. Two of them had the same clinical picture. One of them was different and did not have NDRG1 mutation. The index case was a 30-year-old male, and his 24-year-old sister had delayed motor milestones. Involvement of lower and upper extremities became apparent in the first decade with hearing loss and glaucoma. The third affected member had a history of epilepsy and intellectual disability in addition to her more severe neuropathy phenotype.
Results: Their clinical examination showed typical features of peripheral neuropathy including muscle weakness and wasting, tendon areflexia, and skeletal and foot deformities. Nerve conduction studies (NCSs) showed absent sensory nerve action potentials (SNAPs) in all limbs except the little sister. Compound motor nerve potentials (CMAPs) recorded from distal muscles were also absent.
Conclusion: Clinical findings in our cases were consistent with HMSN-Lom (CMT4D) however further cases are needed to make a better genotype–phenotype correlation. To the best of our knowledge this is the first recessive duplication CNV in the literature and the third mutation in NDRG1.

Neuromuscular junction autoantibodies in seronegative myasthenia gravis patients from Sudan

1Physiology, Faculty of Medicine, University of Khartoum, Khartoum, Sudan; 2Institute of Endemic Diseases, University of Khartoum, Khartoum, Sudan; 3Society of Neurosciences, Faculty of Medicine, University of Khartoum, Khartoum, Sudan; 4Medicine/Neurology, Faculty of Medicine, University of Khartoum, Khartoum, Sudan; 5Medicine, University of Khartoum, Khartoum, Sudan

Background: In myasthenia gravis (MG) autoantibodies target neuromuscular junction (NMJ) proteins leading to a decreased sensitivity to ACh with muscle weakness. 80–88% of MG patients have AChR antibodies (AChR-Ab+) ve patients may have autoantibodies against other NMJ proteins or a more sensitive assay is required to detect AChR-Ab. Hoech et al. (2001) detected muscle specific kinase antibodies (MuSK-Abs) in 70% of AChR-Ab+ ve generalised MG patients (GMG). Leite et al. (2008) detected clustered AChR-Ab+ve by cell based assay (CBA) in 66% of AChR-Ab+ ve patients. A considerable proportion of MG patients remained seronegative (SN-MG).

Objectives: To identify the nature of NMJ autoantibodies in AChR-Ab+ ve patients from Sudan and to relate it to their clinical presentation.

Patients and methods: 96 MG patients (77 GMG and 19 OMG) were randomly recruited from two national MG referral centers in Khartoum during the period 2010–2012. All patients were screened for AChR-Ab and MuSK-Ab by radioimmunoprecipitation assay (RIPA). Negative sera were screened for clustered AChR-Ab by the cell based assay (CBA).

Results: 62.5% (60/96) of patients were AChR-Ab+ ve by RIPA. Of the 36 AChR-Ab+ ve patients, 19.4% (7/36) were MuSK-Ab+ ve, and 22.2% (8/36) were clustered AChR-Ab+ ve. 21.9% (21/96) of patients remained SN-MG. MuSK-Ab+ ve patients (MuSK-MG) represented 25.9% (7/27) of AChR-Ab+ ve GMG with a female: male ratio of 1.3:1 and dominant bulbar symptoms (85.7%, 6/7). Clustered AChR-Ab+ ve patients were all females (n = 8). SN-GMG were predominantly females (92.9%, 13/14) (P = 0.02). The incidence of an associated autoimmune disease (AUID) in SN-GMG females was 53.8% (7/13) compared to 17.6% (6/34) in AChR-Ab+ ve GMG females (P < .013), RR (95% CI) = 3.05 (1.3–7.38).

Conclusion: The incidence of MuSK-MG was within the reported detection rates (0–50%). The association between AUID and SN-GMG females suggests the involvement of sex and predisposition to autoimmune diseases in determining the pathogenicity in MG.

The component of EMG studies to predict outcome after transforaminal epidural steroid injection
S.H. Hong. Rehabilitation Medicine, The Catholic University of Korea, Seoul, Republic of Korea

Objectives: We investigated the predictive value of components of electrodiagnostic studies for outcome after lumbar transforaminal epidural steroid injection in 38 subjects with clinical lumbosacral radiculopathy.

Method: In this retrospective study, visual analog scale (VAS) for evaluation of severity of pain, and Roland Morris Disability Questionnaire (RMDQ) and Oswestry Disability Index (ODI) for evaluation of functional outcome were evaluated in 38 patients.

Result: Among 38 patients who had undergone electrodiagnostic studies before injection, 28 patients were positive for lumbar radiculopathy and 10 patients showed negative results. There were significantly greater improvements of VAS and ODI for patients with a positive lumbar radiculopathy as confirmed by electrodiagnostic study. However, when H-reflex abnormalities, ASA in paraspinal muscle, ASA in limb muscle, and MUAP abnormalities were evaluated separately as an indicator of outcome, all of the individual components of electrodiagnostic studies failed to be the significant predictors of improvement based on outcome measure such as VAS, RMDQ, and ODI.

Conclusion: Based on this study, positive lumbar radiculopathy confirmed by electrodiagnostic study is a predictor of pain reduction and functional improvements after transforaminal epidural steroid injection for lumbar radiculopathy. Patients with positive electrodiagnostic study are more likely to show pain reduction and to show better functional recovery after transforaminal epidural steroid injection. However, H-reflex abnormalities, ASA in paraspinal muscle, ASA in limb muscle, and MUAP abnormalities did not predict pain reduction or functional outcome improvement in patients with lumbar radiculopathy.

**Intracranial hypotension is a rare cause of orthostatic headache: A review of the etiology, treatment and prognosis of 13 cases**

S. Güler 1, B. Çağlı 1, U. Utku 1, E. Ünlü 2, Y. Çelik 1. 1Department of Neurology, Trakya University Faculty of Medicine, Edirne, Turkey; 2Department of Radiology, Trakya University Faculty of Medicine, Edirne, Turkey

The aim of this investigation is to examine the causes, clinical picture, treatment, and prognosis of spontaneous intracranial hypotension, a rare cause of orthostatic headache, among the cases presenting in our clinic.

Thirteen cases (5 males and 8 females), diagnosed with spontaneous intracranial hypotension in our clinic between January 1st, 2009 and October 30th, 2011, were included in this study.

The presenting symptoms, treatment, findings on cranial magnetic resonance imaging, cerebrospinal fluid pressure measured at lumbar puncture (in available patients), and healing period of the patients were recorded. Five patients with orthostatic headache and accompanying symptoms were treated with bed rest, increase in oral fluid intake, intravenous hydration, and caffeine, and experienced a complete recovery. Complete recovery was observed in two patients (15.3%) who received similar treatment, but a mild headache persisted intermittently during follow-up in these individuals.

As the headache had not resolved after 30 days, an epidural blood patch was applied in these four cases (37.6%) significantly regressed within 30 days in four patients (37.6%) who received similar treatment, but a mild headache persisted intermittently during follow-up in these individuals.

Spontaneous intracranial hypotension should primarily be suspected in cases complaining about postural headache and contrast-enhanced cranial imaging should be performed. The presence of cranial nerve paralyses and pyramidal tract signs should be considered. Conservative treatments should be considered initially, however if conservative treatments fail, epidural blood patches must be applied.

**Can vision influence trigeminal nociception? A study of the effect of visual cortex activation on the nociceptive blink reflex**

S.L. Sava, V. de Pasqua, D. Magis, J. Schoenen. Department of Neurology, University of Liège, Liège, Belgium

**Background:** In migraine, the link between cortical phenomena and trigeminovascular activation is not clear and thus, headache as well.

**Objective:** To search in humans for a possible functional connection between the visual cortex and the trigeminal nociceptive system by studying the effect on the nociceptive blink reflex (nBR) of repetitive transcranial magnetic stimulation (rTMS) applied over the visual cortex, and to compare healthy volunteers (HV) and migraine without aura patients (MO).

**Methods:** Fifteen bilateral nBR responses were recorded by stimulating the right supraorbital nerve in 22 HS and 13 MO before and after 1 Hz (15 min train) or 10 Hz (20 trains with a 15 s intertrain interval) rTMS. For comparison, we also performed the same study in HV after an 8 Hz visual flash stimulation.

**Conclusion:** This study is the first to report a more positive association of the C-allele of the CCK-AR gene 984T/C polymorphism in patients with migraine than in control subjects.

**Background:** Cholecystokinin (CCK) is one of the most abundant neurotransmitter peptides in the brain. CCK coexists with dopamine in dopaminergic neurons, and modulates the release of dopamine in the nucleus accumbens. The CCK system is believed to be involved in pain processing. The aim of the study was to investigate the prevalence of -81A/G (rs1799723), -128G/T (rs1800908) and 984T/C (rs1800857) polymorphisms of the CCK-AR gene in migraine patients and controls.

**Method:** 144 migraine patients (ICHD III), mean age = 41.6 ± 12.5 y.o. and 197 healthy controls living in Moscow and the Moscow Region were included. SNPs were genotyped by a PCR-RLFP technique: PCR with “GenPakTM PCR Core” (Isogene Lab., Ltd.) and restriction with HinfI for rs1799723 and rs1800908 and with PstI for rs1800857 (ferments by SibEnzyme Ltd.).

**Results:** C-allele frequency in 984C/T was significantly higher in migraine patients, 0.479 ± 0.030 compared with controls, 0.154 ± 0.026 (χ² = 85.44, p < 0.015 in the controls; -128T = 0.045 ± 0.017 in the migraine group and 0.154 ± 0.015 in the controls; -81G = 0.049 ± 0.018 in the migraine group and 0.045 ± 0.011 in the controls.

**Conclusion:** This study is the first to report a more positive association of the C-allele of the CCK-AR gene 984T/C polymorphism in patients with migraine than in control subjects.

**Background:** Cholecystokinin receptor 1 gene polymorphism and migraine

**Can vision influence trigeminal nociception? A study of the effect of visual cortex activation on the nociceptive blink reflex**

S.L. Sava, V. de Pasqua, D. Magis, J. Schoenen. Department of Neurology, University of Liège, Liège, Belgium

**Background:** In migraine, the link between cortical phenomena and trigeminovascular activation is not clear and thus, headache as well.

**Objective:** To search in humans for a possible functional connection between the visual cortex and the trigeminal nociceptive system by studying the effect on the nociceptive blink reflex (nBR) of repetitive transcranial magnetic stimulation (rTMS) applied over the visual cortex, and to compare healthy volunteers (HV) and migraine without aura patients (MO).

**Methods:** Fifteen bilateral nBR responses were recorded by stimulating the right supraorbital nerve in 22 HS and 13 MO before and after 1 Hz (15 min train) or 10 Hz (20 trains with a 15 s intertrain interval) rTMS. For comparison, we also performed the same study in HV after an 8 Hz visual flash stimulation.
Results: 1 Hz rTMS significantly decreased pain threshold (p = 0.0019, p = 0.046) in HV but not in MO. 1 Hz rTMS increased R2 AUC bilaterally (p = 0.024 and p = 0.036) in HV, but not in MO. The effect of flash stimulation in HV was the opposite of that of 1 Hz rTMS: increase in pain threshold, decrease in R2 AUC.

Conclusions: These results demonstrate for the first time a functional connection between the visual cortex and the trigeminal nociceptive system in humans. Interestingly, the modifications found after 1 Hz rTMS, supposed to inhibit the underlying cortex, are similar to those observed during migraine attack and in line with those described after CSD in animals. Why changes are not significant in MO could be related to the interictal dysexcitability found in migraine.

Does trigeminal nociception influence the visual cortex: A study of the effects of supraorbital electro- or chemo-nociceptive stimulation
S.L. Sava, V. de Pasqua, D. Magis, J. Schoenen. Department of Neurology, University of Liège, Liège, Belgium

Background and aims: In migraine pathophysiology, the link between the visual cortex and the trigeminovascular system might play a pivotal role. In a previous study we showed the top-down relation between the visual cortex and the trigeminovascular system might play a pivotal role. To search for the existence of a bottom-up relationship we studied the effect of electrical stimulation or application of capsaicin in the territory of the 1st division of the trigeminal nerve on pattern-reversal visual evoked potentials (PR-VEP).

Methods: We recorded 600 responses of PR-VEP at 3.1 Hz before and after trigeminal stimulation. The electrical stimuli were delivered over the supraorbital nerve for 20 min at 16 mA and 100 Hz in 7 healthy volunteers (HV). Capsaicin (cream 3%) was applied over the right frontal area for 1 h in 8 HV. We measured PR-VEP N1, P1 and N2 latencies, N1–P1 and P1–N2 amplitudes in six sequential blocks of 100 sweeps and habituation as the change in amplitude over the six blocks.

Results: The electrical stimulation increased the latency of P1 (p = 0.027) and N2 (p = 0.042) but left habituation unchanged. The capsaicin application increased habituation between the 1st and 2nd block of 100 responses (p = 0.049) but had no significant effect on latencies.

Conclusions: These results suggest that a bottom-up relation exists between the trigeminal (V1) afferent nociceptive pathway and the visual cortex. Interestingly, an increase in PR-VEP habituation, such as that found after capsaicin application, also occurs during a migraine attack, where it replaces the interictal deficit of habituation.

Verapamil side effects in our cluster headache population
M. Bernal Sánchez-Arjona, O. Lara, P. Matínez, M. Caceres, C. Gonzalez Oría. Neurosciences, Hospital Virgen del Rocio, Seville, Spain

Background: Verapamil is an effective preventive therapy for cluster headache (CH). Side effects include constipation, nausea, asthenia, edemas, bradycardia and atrioventricular block.

Objective: Evaluate verapamil side effects, mainly cardiac, in CH patients.

Patients and method: Retrospective analysis of 84 patients with CH evaluated in the subspecialty Headache Clinic from May 2010 to June 2012. Demographic variables, types of CH (chronic (CCH), episodic (ECH)), acute and preventive therapies, and maximum dose of verapamil achieved, time of use, side effects and EKG characteristics, were reviewed.

Results: A total of 84 patients, 68 men and 16 women, mean age of 46 ± 12 years, were identified. Sixty patients were ECH and twenty four CCH. Seventy eight were treated with verapamil. The maximum daily dose of verapamil achieved was 500 ± 173 mg (mean ± SD) in CCH and 344 ± 139 mg in ECH. Mean time of treatment was 67 ± 72 months and 36 ± 37 months respectively. Only 21 patients treated with verapamil had EKG on records. Eleven patients reported side effects due to verapamil and 7 stopped verapamil treatment, three of those with digestive and four with cardiovascular effects; three patients had hypotension and edema and one patient had a complete heart block which needed a transient pacemaker. Four other patients had asymptomatic bradycardia on EKG. All these patients had CCH.

Conclusions: Patients with CCH had more side effects due to verapamil. Cardiovascular side effects were related to higher doses and lengths of treatment. Although only one patient had a severe arrhythmia, we strongly recommend repeated EKG to avoid fatal complications.

Headache-related disability in patients with systemic lupus erythematosus and primary Sjögren’s syndrome
A.B. Tjensvollb, E. Harboe,c, L.G. Geranssona, J.T. Kvaleyc, R. Omdalb. aStavanger University Hospital, Stavanger, Norway; bUniversity of Stavanger, Stavanger, Norway

Background: Headache in patients with systemic lupus erythematosus (SLE) has been considered common and has a strong weighting in the SLE disease activity index.

Objective: To investigate whether headache has more impact on SLE than on healthy persons, and also to compare headache-related disability in patients with another autoimmune disease, namely primary Sjögren’s syndrome (pSS).

Patients and methods: Fifty-five patients with SLE, 51 pSS patients and 69 healthy subjects, all with primary headache, were included. Headache was classified according to the International Classification of Headache Disorders. The Migraine Disability Assessment Scale (MIDAS) and Headache Impact Test-6 (HIT-6) were used to assess headache-related disability. Depression was measured with the Beck Depression Inventory (BDI).

Results: A total of 84 patients, 68 men and 16 women, mean age of 46 ± 12 years, were identified. Sixty patients were ECH and twenty four CCH. Seventy eight were treated with verapamil. The maximum daily dose of verapamil achieved was 500 ± 173 mg (mean ± SD) in CCH and 344 ± 139 mg in ECH. Mean time of treatment was 67 ± 72 months and 36 ± 37 months respectively. Only 21 patients treated with verapamil had EKG on records. Eleven patients reported side effects due to verapamil and 7 stopped verapamil treatment, three of those with digestive and four with cardiovascular effects; three patients had hypotension and edema and one patient had a complete heart block which needed a transient pacemaker. Four other patients had asymptomatic bradycardia on EKG. All these patients had CCH.

Conclusions: Patients with CCH had more side effects due to verapamil. Cardiovascular side effects were related to higher doses and lengths of treatment. Although only one patient had a severe arrhythmia, we strongly recommend repeated EKG to avoid fatal complications.

Verapamil side effects in our cluster headache population
M. Bernal Sánchez-Arjona, O. Lara, P. Matínez, M. Caceres, C. Gonzalez Oría. Neurosciences, Hospital Virgen del Rocio, Seville, Spain

Background: Verapamil is an effective preventive therapy for cluster headache (CH). Side effects include constipation, nausea, asthenia, edemas, bradycardia and atrioventricular block.

Objective: Evaluate verapamil side effects, mainly cardiac, in CH patients.

Patients and method: Retrospective analysis of 84 patients with CH evaluated in the subspecialty Headache Clinic from May 2010 to June 2012. Demographic variables, types of CH (chronic (CCH), episodic (ECH)), acute and preventive therapies, and maximum dose of verapamil achieved, time of use, side effects and EKG characteristics, were reviewed.

Results: A total of 84 patients, 68 men and 16 women, mean age of 46 ± 12 years, were identified. Sixty patients were ECH and twenty four CCH. Seventy eight were treated with verapamil. The maximum daily dose of verapamil achieved was 500 ± 173 mg (mean ± SD) in CCH and 344 ± 139 mg in ECH. Mean time of treatment was 67 ± 72 months and 36 ± 37 months respectively. Only 21 patients treated with verapamil had EKG on records. Eleven patients reported side effects due to verapamil and 7 stopped verapamil treatment, three of those with digestive and four with cardiovascular effects; three patients had hypotension and edema and one patient had a complete heart block which needed a transient pacemaker. Four other patients had asymptomatic bradycardia on EKG. All these patients had CCH.

Conclusions: Patients with CCH had more side effects due to verapamil. Cardiovascular side effects were related to higher doses and lengths of treatment. Although only one patient had a severe arrhythmia, we strongly recommend repeated EKG to avoid fatal complications.

Conclusion: SLE patients have more severe headache-related disability than healthy persons, but not more than patients with pSS. This may be related to more depression in these patients.

Reduced sleep quality during the active phase of cluster headache

M. Barloese, N. Lund, A. Petersen, R. Jensen. Copenhagen University Hospital, Glostrup, Copenhagen, Denmark

Introduction: Cluster headache (CH) is a severe chronobiological pain-condition with recurring attacks of high-intensity headaches accompanied by autonomic symptoms and agitation. Many attacks occur at night which disrupts sleep but even patients who do not have nightly attacks complain of daytime sleepiness and poor sleep quality. A direct effect on sleep is obvious when attacks occur during the night but how daytime attacks affect sleep is not understood. There is a direct anatomical overlap of regions involved in the pathogenesis of headaches and those involved in the regulation of sleep.

Objective: We aimed to evaluate self-reported sleep quality in CH patients compared to a number of headache-free controls.

Patients and methods: Employing the Pittsburgh Sleep Quality Index we evaluated self-reported sleep quality in 129 patients suffering from CH and 50 headache-free controls.

Results: For all CH patients the average PSQI indicated poor sleep quality compared to healthy controls (p < 0.01). Comparing CH patients in active bout (attack within past month) with those outside of bout, sleep quality was significantly worse in the active group (p < 0.01).

Conclusion: It is possible that headaches occurring strictly during the daytime may affect sleep through an unknown pathway. That CH-patients also report poor quality of sleep in the inactive period of their disease suggests that the mechanisms leading to headache are reversible yet those leading to poor sleep quality are not. Poor sleep may thus be an epiphenomenon or an intrinsic part of the disease mechanism and need further detailed investigations.

Cognitive function patients with idiopathic intracranial hypertension

H. Yri1, B. Fagerlund2, R. Jensen3. 1Dansih Headache Center, Department of Neurology, University of Copenhagen, Glostrup, Denmark; 2Center for Neuropsychiatric Schizophrenia Research, Psychiatric Centre Glostrup, University of Copenhagen, Glostrup, Denmark

Background: Idiopathic intracranial hypertension (IIH) is a condition of raised intracranial pressure without identifiable cause. IIH primarily affects young obese individuals and the incidence is rapidly increasing. In addition to classical symptoms of headache, tinnitus and visual disturbances, patients often report impaired memory and concentration. Despite an obvious and serious threat to visual function; compliance with long-term treatment and instructed weight-loss is remarkably poor which could indicate frontal lobe impairment. However, cognitive impairment in IIH is only infrequently and inconsistently described in literature.

Objective: To investigate the cognitive function in a well-defined group of patients with IIH in a controlled design.

Materials and methods: We compared 31 patients (31.0 ± 11.1 years) with IIH and 31 healthy sex and age-matched (30.7 ± 11.6 years) controls by a comprehensive neuropsychological test battery consisting of validated computerized (CANTAB) and paper tests (Rey–Ostereich complex figure, trail making test A and B; letter and category fluency test; symbol digit modalities test and DART (Danish version of the national adult reading test)). Patients were tested in close relation to diagnosis and before any treatment was initiated.

Results: Patients with IIH performed significantly worse than controls in 8/10 of the initiated tests even though the premorbid intelligence level as measured by DART was similar for both groups. Especially domains controlling verbal fluency, processing speed and set shifting seem to be affected (p ≤ 0.01).

Conclusions: The present case–control study indicates that IIH causes cognitive impairment and that a focused multidisciplinary approach including neuropsychological rehabilitation may supplement the treatment of IIH.

Economic aspects of headaches (HA) in Russia

I. Fokin. Neurology, 64 Moscow Municipal Clinic, Moscow, Russia

Background: Liquor hypotension (LH) is a rare syndrome characterized by positional headache while in vertical posture and decreased CSF opening pressure during LP and characteristic MRI changes. Absence of certain cardinal symptoms however, may occur in some cases or atypical symptoms may appear and dominate the clinical picture, leading to differential diagnostic difficulties and delay in the treatment.

Objectives: To analyze the diagnostic difficulties and complications of LH.

Patients and method: A prospective analysis of LH cases admitted to our department of neurology between 2010 and 2013.

Results: 4 cases of LH were analyzed for their atypical features. In two cases typical clinical manifestations and imaging abnormalities were present. However, CSF opening pressure was normal, questioning the diagnosis. In one patient the CSF pressure was normal despite a documented CSF leakage. In two other cases of LH subdural fluid collections were detected on CT scan. The complications in these cases were severe and misleading. The acute deterioration of the clinical status required urgent neurosurgical intervention.

Conclusions: Normal opening pressure does not exclude LH. LH is generally considered as a benign condition. Although severe complications are rare, subdural effusion or hematoma may indicate worse prognosis, questioning the benign nature of LH.

doi:10.1016/j.jns.2013.07.1714
Background and purpose: Being a major health problem, headache is also associated with a certain financial burden (which was equal to 140 billion rubles in 2011 for migraine alone). The HA management system should be improved and financial losses should be refused to solve the problem.

Material and methods: Data of Federal Service for State Statistics for 2011 and our own questionnaires for migraine patients were used to study the HA management in 6 Moscow and Moscow region outpatient clinics.

Results: The system of HA management was found to be ineffective. Total work input losses related to migraine were 47 million human-days. To solve the problem, a national program for HA management is required including education of the community, foundation of 9 multidisciplinary HA centers, training of physicians and nurses in HA management, education of local healthcare authorities in the field of social and economic aspects of HA with distribution of funds depending on needs of each region and application of effective treatment.

Conclusion: Medical care should consist of three levels: first — general practitioners give primary care to 80–90% of all HA patients; second — neurologists treat 10–15% of patients and the remaining 5–10% of patients will be treated in HA centers. The treatment in such centers is proved to be cost-effective with 10.3% economy of direct medical expenses as compared to the standard therapy. Losses of working days are reduced by half, saving about 10 billion rubles each year for migraine only.

Clinical characteristics of migraine in Sudan
S.M.A. Magzoub1, S.M.H. Ibrahim2, M.E. Ibrahim3, H.M. Salah3, A. Jaber3, 1Physiology Department, Faculty of Medicine, Ribat University, Khartoum, Sudan; 2Physiology Department, Karay University, Khartoum, Sudan; 3Molecular Biology, Institute of Endemic Diseases, Khartoum, Sudan; 4Radiology, Royal Care Hospital, Khartoum, Sudan

Background: The International Headache Society had set certain criteria for the diagnosis and classification of migraine, however some studies reported that migraine has different presentations in different populations.

Objectives: To study the clinical characteristics of migraine in Sudanese families and whether it differs from that set by the International Headache Society.

Material and methods: A cross sectional study that involved 175 subjects from 12 large Sudanese families; Afroasiatics (Ja‘afra, Jaa‘lia, Shawiga, Kwa‘la) and Nilosaharan (Halfaween and Mahhs). 107 migraineurs were included in this study. Diagnosis of migraine was carried out with a validated questionnaire and compared with the most common migraine type being MO (51.4%, N = 55), followed by MA + MO (32.7%, N = 35) and MA (15.9%, N = 17). Unilateral location, presence of nausea, photophobia and aggravation by exercise showed significant results (P value = 0.000).

Conclusions: In the present study the presentation of migraine headache showed results similar to that described by the IHS in most of the criteria and differed in others. Co-morbidity with a number of diseases and migraine coexist.

Abnormal circle of Willis among migraineurs in Sudan
S.M.H. Ibrahim1, A.M. Nour2, S.M.A. Magzoub3, M.E. Ibrahim3, A. Jaber1, 1Physiology Department, Karay University, Sudan; 2Radiology, Ribat University, Sudan; 3Physiology Department, Ribat University, Sudan; 4Molecular Biology, Institute of Endemic Diseases, Sudan; 5Radiology, Royal Care Hospital, Khartoum, Sudan

Background: Several studies have shown a strong relationship between migraine and cerebral ischemia. The circle of Willis (CW) which is the main cerebral collateral pathway that allows flow redistribution in response to low perfusion is reported to be defective during migraine.

Objectives: This study aims to assess the structural characteristics of CW in Sudanese migraineurs.

Material and methods: This is a descriptive study including 54 migraineurs selected from a larger study (Migraine Profile in Sudan; a genetic, EEG and MRI study in 12 Sudanese pedigrees) and 17 apparently healthy volunteers. All subjects underwent three-dimen- sional MRA of the cerebral arterial circle.

Results: Eighty four point four percent (n = 38) of migraineurs have defective CW, while only 15.5% (n = 7) have normal configuration. Sixty point nine percent (n = 28) showed incomplete configuration of CW. Hypoplastic vessels account for 43.4% (n = 20), of these 17.4% (n = 8) have hypoplastic both PcoA. Furthermore, severe migraine is significantly associated with hypoplastic arteries of the posterior circulation (P value = 0.01).
Conclusions: Strong association has been observed between migraine and an abnormal configuration of the circle of Willis with hypoplasia of the both posterior communicating arteries significantly associated with severe migraine. This finding needs further confirmation as it will have an impact on the management and prognosis.

Headaches in public transport drivers
Institute of Occupational Medicine, Lodz, Poland

Background: Headaches are the significant and frequent complaints, caused by many factors, with not always known pathogenesis and different clinical symptoms.

Objective: This work analyses the types and frequency of headaches among public transport drivers and tries to assess the importance of such factors as drivers’ age and time of job.

Patients and methods: The study covered a group of 40 public bus drivers. Their average age was 43.2 (between 31 to 58 years). Their average job time was 11.6 years (between 2 to 33). The history of headaches was completed with the question set to objectify the answers of the examined people. The International Headache Society Classification (1988) was used to diagnose clinical forms of headaches.

Results: In the examined group the 15 (35%) drivers suffered from headaches of different clinical symptoms. Tension-type headaches were diagnosed in 7 (17.5%) examined persons. The other ones — symptomatic (posttraumatic) headaches or connected with vascular diseases (hypertension) or cranial neuralgia were diagnosed. There were no clinical deficits in the neurological examination in the examined group.

Prevalence and characteristics of headaches in Albanian adolescents

S. Grabova, O. Petro, I. Alimehmeti, F. Muslimi, M. Papajani, S. Mijo, M. Kapiszy, J. Kruijts, "Neurology, UHC Mother Theresa, Albania; Regional Health Agency, Tirana, Albania; Endocrinology, UHC Mother Theresa, Tirana, Albania"

Background: Headache is a common disorder in all age groups. No study has been carried out to evaluate headache in Albanian adolescents.

Objective: Assessment of headache prevalence and its characteristics in Albanian adolescents.

Patients and methods: 1380 (820 females, 560 males) high school students aged 16–18 years old (average = 17.1) were interviewed using an eight-item questionnaire for headache evaluation.

Results: 540 students (39.1%) declared headache episodes, females reporting more headache suffering than males. 385 females (47.0%) reported headache versus 155 males (27.7%). 310 students (57.4%) reporting more headache suffering than males. 385 females (47.0%) and 310 students (57.4%) reported headache.

Conclusions: Data show that CM patients report high disability, compared to general population (approximately 18%). Results indicate that CM patients exhibit high disability, with MIDAS (β = 31.5 ± 13.9). Linear regression model explains 34.7% of variance, with MIDAS (β = 31.5 ± 13.9).

Conclusion: Chronic migraine (CM) is an unfavourable outcome of migraine course. It is often associated with lower QoL and increased disability, and may be due to several factors, including comorbidity between depression, genetic terrain, and medication overuse. A personal factor like self-efficacy and an adequate level of social support may act as protective factors towards disability reduction.

Objective: To assess predictors of disability in patients with CM at the time-point of detoxification.

Patients and methods: In this cross-sectional study, disability was measured with the WHO-disability assessment schedule (WHO-DAS), disease activity with the MIDAS, mood state with the Beck depression inventory (BDI-2), self-efficacy with the global self-efficacy scale (GSE), and social support with the MOS-SSS (Social Support Survey).

Linear regression was performed to assess to what extent disease activity, mood state, self-efficacy and social support predict disability.

Results: 189 adult patients were enrolled (82.5% women; mean age = 43.8 ± 12; mean MIDAS = 90.1 ± 69.2); mean WHO-DAS score was 31.5 ± 13.9. Linear regression model explains 34.7% of variance, with MIDAS (β = .228) and BDI-2 (β = .492) being independent predictors.

Conclusion: Data show that CM patients report high disability, compared to general population (approximately five-folds) and to other neurological diseases such as epilepsy (13.6%), myasthenia gravis (18.5), Parkinson’s disease (19.3), episodic migraine (21.3) or stroke (25.9). Disability in CM patients seems to be due to poor personal factors, while mood state had a great impact. These results suggest that treatment programmes should take into account mood states in the daily evaluation of CM patients.

**Valencia, Spain; 4University Duisburg–Essen, Essen, Germany; 5Autonomic Technologies, Inc., Redwood City, CA, USA; Universitäts-Krankenhaus Eppendorf, Hamburg, Germany**

**Background:** A multi-center study of a novel SPG neurostimulation therapy for chronic CH (CCH) has been conducted.

**Objective:** The pain and autonomic symptoms of CH result from activation of the trigeminal parasympathetic reflex, mediated through the SPG. We investigated long-term effectiveness of on-demand SPG stimulation in CCH.

**Patients and methods:** All patients met the ICHD-2 criteria for CCH and were implanted with the miniaturized ATI Neurostimulator. Pain response following SPG stimulation, attack frequency, and Quality of Life (QoL) were analyzed over 18 months. Acute responders achieved relief from ≥ moderate pain, freedom from mild pain in ≥50% of analyzable treatments. Frequency responders achieved a ≥50% reduction in attack frequency for ≥2 months.

**Results:** 43 patients were enrolled, 23 completed follow-up through 18 months following implantation, 10 have not reached 18 months and 10 were terminated (1 – regulatory, 5 – noncompliance, 4 – explanted). Of these 23, 91% responded to SPG stimulation. 81% were frequency responders and 52% were acute responders. 33% were both acute and frequency responders. Frequency responder reduction was 82% (range: 52–95%) from 15 baseline attacks/week (range: 5–25) to 2.8 (range: 0.4–9.7) and the ≥50% continuous frequency reduction lasted 215 days (range: 75–408). 86% of patients experienced clinically significant improvements in QoL (SF-36v2 physical and/or mental scores), 70% experienced clinically significant improvements in headache disability (HIT-6) and 82% rated their overall satisfaction ≥95% from 15 baseline attacks/week (range: 5–25) to 2.8 (range: 0.4–9.7) and the ≥50% continuous frequency reduction lasted 215 days (range: 75–408).

**Conclusion:** On-demand SPG stimulation using the ATI Neurostimulation System provides a lasting, clinically significant response and QoL improvements in CCH patients.

**Topic: 8 — Headache**

**Photophobia is associated with allodynia during migraine attack**

1Department of Clinical and Experimental Medicine, Neurology Unit, University of Pisa, Pisa, Italy; 2Neurology Unit, Hospital of Bergamo, Bergamo, Italy; 3Neurology Unit, Hospital of Viareggio, Viareggio, Italy

**Background:** Alldynia is a phenomenon of central sensitization that may lead to migraine transformation. Alldynia is associated with more functional disability and severity of migraine. It is well known that alldynia is positively related to headache frequency, attack duration, illness duration, and unilateral pain. On the contrary, little is known if some of the common accompanying symptoms of the migraine pain are more present in alldynic migraineurs.

**Objective:** To investigate if some of the common accompanying symptoms of migraine are more frequent in alldynic patients.

**Materials and methods:** We recruited 200 consecutive migraineurs. Other primary headaches, comorbidity and migraine prophylaxis were exclusion criteria. Each patient was interviewed following a structured questionnaire including the presence or not of photophobia, phonophobia, osmophobia, nausea/vomit, throbbing pain, unilateral pain, autonomic signs, and aura. Alldynia during the migraine attack was measured using the alldynia symptoms check-list 12 (ASC-12); χ² test with continuity correction or Fisher’s exact test was used for categorical variables.

**Results:** Forty-two patients (22%) were non-alldynic, 58 (29%) mild-alldynic, 51 (25%) moderate-alldynic, and 49 (24%) severe-alldynic. Photophobia is significantly more frequent in moderate/severe alldynic patients than in non/mild alldynic ones (P = 0.033).

**Conclusion:** Alldynic migraineurs showed a more frequent association with photophobia during migraine attack. We suggest that cortical hyperreactivity and central sensitization may play a role in the light susceptibility of alldynic patients. Other studies are needed to support this hypothesis and clarify the underlying pathophysiological mechanism.

**Dexketoprofen trometamol in the acute treatment of migraine attack: A phase II, randomized, double-blind, crossover, placebo-controlled, dose optimization study**

1Headache Centre, Neurological Division, SS Giovanni e Paolo Hospital, Venice, Italy; 2Headache Centre, Department of Neurosciences, Padua University, Padua, Italy; 3Istituto Luso Farmaco d’Italia, Peschiera Borromeo, Italy

**Background:** Migraine is a disabling disease that can significantly affect the quality of life of the sufferers.

**Objective:** To assess efficacy and tolerability of two doses of dexketoprofen trometamol, 25 mg (DKP25) and 50 mg (DKP50), compared to placebo for migraine acute treatment.

**Material and methods:** This randomized, double-blind, single-centre, cross-over, placebo-controlled study was performed in 93 patients with at least one migraine attack per month in the preceding 6 months. Participants were enrolled and randomized to DKP25, DKP50 and placebo. Primary endpoints were pain-free and pain relief was at 2 h after drug intake. The presence of accompanying symptoms and adverse events were also recorded.

**Results:** 76 patients (mean age = 40.5 ± 10.9 and 61% female) completed the study. At baseline, the mean number of attacks/month was 3.7 ± 1.3, with a mean duration of 15.4 ± 13.5 h. Pain relief at 2 h after drug intake was significantly reduced by DKP50 vs placebo (33.8% vs 14.7%, p = 0.0065). Both DKP25 (57% vs 25%, p = 0.0002) and DKP50 (65% vs 25%, p < 0.0001) improved headache relief compared to placebo. Furthermore, both doses of DKP significantly reduced the functional disability at 2 h after drug intake (DKP25, 40% vs 24%, p = 0.045 and DKP50, 46% vs 24%, p < 0.0004). Both DKP dosages were well tolerated.

**Conclusions:** Both doses of DKP were effective and well tolerated, with no statistically significant differences in adverse events compared to placebo.

**The efficacy of greater occipital nerve blockade in chronic migraine with triptan overuse**

1Department of Neurology, Erzincan Military Hospital, Erzincan, Turkey; 2Department of Neurology, Kartal Education and Research Hospital, Istanbul, Turkey; 3Department of Neurology, Ankara Education and Research Hospital,
**Introduction:** In this study, we evaluate the efficacy of GON blockade in chronic migraine with triptan overuse headache.

**Materials and methods:** 54 patients were included in the study. These patients were divided into 3 groups. Group 1 received no GON blockade, triptans were decreased gradually and hydration was made. Group 2 received 1 session of GON blockade, triptans were decreased gradually and hydration was made. Group 3 received 3 sessions of GON blockade, triptans were decreased gradually and hydration was made. All patients had blockade with 2 ml of 1% lidocaine bilaterally. Severity of headache was evaluated by VAS. Number of days with headache per month and number of triptan use per month were recorded before treatment and 2–4 months after treatment.

**Results:** When we evaluate Group 1 according to the severity of pain, a significant decrease was present at the second month of treatment (p = 0.020) and this decrease continued at the fourth month (p = 0.50). The number of triptan use per month before treatment and after treatment did not show a significant difference. The number of painful days in Group 1 has decreased at the second month after the therapy (p = 0.032) but this decrease had ended at the fourth month (p = 0.098). When we evaluate Group 2 and 3 for all parameters, a statistically significant decrease was detected 2 and 4 months after treatment (p < 0.05 for all parameters).

**Discussion:** 3 sessions of GON blockade are more effective in reducing the pain severity, number of painful days and number of triptan use per month in patients that have chronic migraine with triptan overuse headache.

**Age and pericranial tenderness during headache attacks**

K. Takagi, K. Yamazaki, R. Hishida, M. Arai, S. Nojima, H. Kobayashi. Neurology, Tokyo Medical University Ibaraki Medical Center, Inashiki-gun, Japan

**Background:** Recently it was known that pericranial tenderness (PCT) mechanisms play a role not only in tension-type headache (TH) but also in migraine, whereas we feel muscle fatigability or muscle pain more by aging. In our former study we have paid attention to PCT for migraine patients. According to The International Classification Of Headache II, THs are divided into TH with PCT and TH without PCT. Is migraine with PCT one condition of migraine by aging or a distinguished clinical entity toward migraine without PCT?

**Objectives:** Using our data we reanalyzed the relationship between age and PCT in migraine patients.

**Patients and methods:** We studied PCT during headache attacks using questionnaires given to 363 headache outpatients (153 males, 210 females, with an average age of 47.3 years) from May 2007 to December 2007. All of them completed the questionnaires. We checked distributions of patients with PCT in migraine according to the each generation.

**Results:** Of 363 patient cases 105 had migraine (26 males and 79 females) and 81 had one or more areas of PCT. Each generation has almost the same rate of migraine patients with PCT. (P < 0.01, Mann-Whitney U test).

**Conclusion:** Our result suggests that migraine with PCT does not concern about aging and there is a possibility that migraine with PCT may be one clinical entity.

The efficacy of greater occipital nerve blockade in chronic migraine, chronic tension type headache and patients having both headaches

O. Karadas, H.L. Gul, L. İnan, N. İnan. aDepartment of Neurology, Erzincan Military Hospital, Erzincan, Turkey; bDepartment of Neurology, Kartal Education and Research Hospital, Istanbul, Turkey; cDepartment of Neurology, Ankara Training and Research Hospital, Turkey; dDepartment of Algology, Gazi University Faculty of Medicine, Ankara, Turkey

**Introduction:** In this study, we compare the efficacy of GON blockade in chronic migraine, chronic tension type headache and patients having both headaches.

**Materials and methods:** 61 patients (21 migraine (Group 1), 20 TTH (Group 2), both (Group 3)) were included in the study. All patients have chronic migraine, chronic tension type headache and patients having both headaches.

The severity of pain 6–12 weeks after the treatment has decreased (p: 0.001; p: 0.013 respectively). When we evaluate Group 2 for all parameters, a statistically significant decrease was detected 6–12 weeks after treatment (p < 0.05 for all parameters).

**Discussion:** 3 sessions of GON blockade are more effective in reducing the pain severity and frequency. Additional placebo-controlled studies that include larger study populations are needed to confirm our results.

had 3 sessions of GON (one injection per week for 3 weeks) blockade with 2 ml of 1% lidocaine bilaterally. Severity of headache was evaluated by VAS (Visual Analogue Scale) and number of days with headache per month, number of analgesic use per month and number of triptan use per month were recorded before treatment and 3 months after treatment.

**Results:** When we compare both groups according to gender, age, pre-treatment pain intensity, and frequency, number of analgesic use per month and number of triptan use per month; no significant difference was detected (p > 0.05 for all parameters). When we evaluate Group 1 and 3 for all parameters, a statistically significant decrease was detected 3 months after treatment (p < 0.05 for all parameters). When we evaluate Group 2 according to the frequency of pain, VAS and number of analgesic use per month before treatment and 3 months after treatment, a significant decrease was detected but there was no statistically significant difference in the number of triptan use per month (p > 0.05).

**Discussion:** GON blockade is more effective in patients with chronic migraine and patients with both migraine and chronic tension type headache, but response in TTH is less. Additional placebo-controlled studies that include larger study populations are needed to confirm our results.

**Sinus headache's relationship with primary headaches; clinical and radiological evaluation**

H.L. Gul, O. Karada, S. Firtına, A. Meteoğlu, A.K. Erdemoğlu, A. Özge, L. İnan. 1Department of Neurology, Kartal Education and Research Hospital, Istanbul, Turkey; 2Department of Neurology, Erzincan Military Hospital, Erzincan, Turkey; 3Department of Cardiology, Erzincan Military Hospital, Erzincan, Turkey; 4Department of Ear Throat and Nose, Erzincan Military Hospital, Erzincan, Turkey; 5Department of Neurology, Akbadem Hospital, Ankara, Turkey; 6Department of Neurology, Mersin University, Mersin, Turkey; 7Department of Neurology, Ankara Education and Research Hospital, Ankara, Turkey

**Introduction:** Patients suffering from sinus headache (SH), may be able to meet the criteria for primary headaches (PHs) according to IHS criteria. In this study, we aimed to assess the clinical and radiological findings of sinus headache sufferers that meet the criteria of primary headache.

**Materials and methods:** 39 patients suffering from sinus headache were evaluated clinically and radiologically with paranasal sinus tomography. At CT scans; Lund–Mackay Grading System (LMS) scores, sinus abnormalities and rhinological pathologies were investigated. PHs that also meet the criteria of SH were detected. The study group has a high prevalence of morning headache (frequency greater than in patients with insomnia), suggesting the relevant role of the hypercapnia consequential vasomotor phenomena.

**Results:** The severity of obstructive sleep night apneas is related to the frequency of morning headache (frequency greater than in patients with insomnia), suggesting the relevant role of the hypercapnia consequential vasomotor phenomena.

**Discussion:** The study group has a high prevalence of morning headache confirming results of previous studies concerning both its high frequency and severity in patients with sleep disorders. The strength of our study is the large sample size assessed, and the detailed information collected on sleep disorders and other risk factors for headache.

**Conclusions:** Our study suggests the need for patients with morning headache to undergo careful screening for sleep disturbances related to breathing disorders, for a correct diagnostic and therapeutic approach.

**Contribution of twenty-one epidemiological factors to migraine disability**

A. Mitrovic, S. Sretenovic, A. Stanic. Migraine Center, University Hospital KBC ‘Zvezdara’, Belgrade, Serbia

**Background:** Migraine headache is one of the most important primary headaches. It is associated with a negative impact, reduction of life quality and disability. Epidemiology and impact of migraine on disability are only partially documented in Serbia.

**Objective:** This study is to determine whether socio-epidemiological parameters have an impact on migraine headache and potentially high scores on the MIDAS questionnaire.
Patients and methods: An unsponsored prospective study has lasted for 5 months. A total of the 543 patients who applied for examination at the Migraine Center and who are, according to the IHS criteria (International Classification of Headache Disorders, 2nd ed., 2004), diagnosed with migraine. 108 were included in the study (average age of 39.96 years, F:M = 88:40). The subjects were randomized. Each patient whose illness protocol number ended with number 5 or 0 is included in the study. The survey was conducted using a standardized closed questionnaire containing a set of 21 social and epidemiological questions (age, gender, qualification, employment, hours of work, professional satisfaction, marital status, housing, smoking, alcoholism, drugs, errors in diet, vegetarianism, hobby, family history, etc.) and a MIDAS questionnaire.

Results: By variance analysis, a statistically significant difference has been found in the score of the MIDAS questionnaire among subjects who smoke and non-smokers (p < 0.05). Participants who came into contact, on their workplace, with more than 10 individuals had significantly higher scores on the MIDAS questionnaire (p < 0.05), compared to those who came into contact with less than 10 individuals. Other parameters did not show a statistically significant difference.

Conclusion: This study showed that smoking may have an additional impact on the disability of patients with migraine headache, as well as the number of people whom they may come in contact with at the workplace.

Atypical presentation of Tolosa–Hunt syndrome treated with aggressive immunosuppression and radiotherapy

H. Hamdalla, A. Zermansky. Greater Manchester Neurosciences Centre, Salford, UK

We present an interesting patient with atypical Tolosa–Hunt Syndrome that was refractory to immunosuppression and needed radiotherapy. A 50 year old Caucasian male presented 3 years ago with gradual onset dull headache for 2 months. This evolved into cluster-like attacks with cranial autonomic features which responded to Sumatriptan. He developed diplopia due to a partial R 6th nerve palsy. There were no other visual or neurological symptoms and no systemic manifestations. The ESR was 38, and CRP, haematology, biochemistry, glucose, lipids, TFT, autoimmune profile, vasculitic screen, treponemal serology, HIV, B12, folate and clotting were all normal or negative. CT scan of the brain was normal. CSF showed no cells and normal glucose, that the protein was raised at 0.78 (0.2 – 0.4) and the oligoclonal bands were negative. MRI of the brain showed a Rt cavernous sinus lesion that enhanced with contrast (see picture). MRA was normal as well as CT scans of the chest, abdomen and pelvis. Biopsies from the lesion showed non-specific changes, but no malignancy. His symptoms were steroid responsive with resolution of the 6th nerve palsy, but he continued to have flare ups of severe headaches whenever the steroids were reduced below 50 mg o.d. He tried Cyclophosphamide (for 6 months) with some improvement. Mycophenolate and Methotrexate were tried without benefit. Subsequently, he had radiotherapy with marked improvement. He is back to work now on a small dose of steroids and continues to have occasional migraines.

The MRI lesion resolved (see picture).

Clinic and Doppler ultrasonography correlation of reactivity of cerebral vessels in patients with chronic tension-type headaches

L. Jakubenko, T. Litovchenko, O. Zavalna. Neurology, Kharkiv Medical Academy of Postgraduate Education, Kharkiv, Ukraine

The aim of the research was the investigation of the changes of hemodynamics and reactivity of cerebral vessels among the patients with chronic tension-type headaches by using Doppler ultrasonography with compression tests.

We have examined 39 patients. There were 27 patients with chronic headaches of tension in the first group. The second group consisted of 12 healthy people. While doing research we detected that the patients with chronic tension-type headaches had normal indicators of CO = 1.2 and FAR = 0.79 (in the control group: CO = 1.25, FAR = 0.798). In the compression of carotid the elevation of linear blood flow velocity (LFV) was to 48.2% (to 42.2% in the control group). Postcompression elevation of LFV was in average of 27.3% in comparison to the primary level of LFV (38.2% in the control group). The CO in common arteries was 0.96 ± 0.01 and FAR was 0.6 ± 0.02 and the CO in carotid arteries was 0.72 ± 0.01 and FAR was 0.64 ± 0.22 respectively in the group of patients with chronic headaches of tension. In the control group the CO was 1.25 ± 0.02 and FAR was 0.79 ± 0.01. As a result of our research it was detected that the changers of reactivity of cerebral vessels towards the decline of LFV were observed in the group of patients with chronic tension-type headaches. Paradoxal reaction of vessels was detected in 19 out of 27 patients with chronic headaches of tension. The data obtained testify compensatory derangement of autoregulation of cerebral vessels in chronic tension-type headaches.

in carotid arteries after ACE injection were assessed in relation to serum concentration of estrogen and progesterone on 5th, 13th and 26th days of the cycle, after standardization to a 28-day menstrual period.

**Results:** After ACE administration the flow velocity in the right CCA and ICA increased by 23% and 35% on 5th day, 12% and 31% on 13th day and 30% and 47% on 26th day respectively, and the changes were significantly larger in relation to insignificant changes on the left side (F = 6.793 and F = 4.098 respectively; both P < 0.05). Multivariable regression analysis showed significant associations between changes of blood flow velocity after ACE injection in the right CCA and ICA and ovarian hormones concentrations (F = 3.828, P = 0.028 and F = 3.671, P = 0.032 respectively).

**Conclusion:** Cerebrovascular reactivity changes across the menstrual cycle are associated with ovarian steroid hormones change, and are more pronounced in the right hemisphere.

**Materials and methods:** We performed retrospective case analysis of one hundred patients with CVT, treated at neurology center, Kuwait, from January 2000 to Dec. 2012. The records of patients were retrieved and entered in a data sheet for review.

**Results:** One hundred patients were included in this study, with a male to female ratio of 1:1.7. The main clinical presentations were neurological. Neurological signs and symptoms were headache (90%), focal neurological deficits (62%) and seizures (42%). Papilledema with raised intracranial pressure was recorded in 30 patients (30%). The venous sinuses involved were superior sagittal sinus in 60% (n = 60) and transverse and sigmoid sinuses 63% (n = 63). Hemorrhagic venous infarctions were seen in 24% (n = 24). Sixty percent of patients recovered within 2–4 weeks and 20% of patients required ICU admission.

**Conclusion:** Headache and focal seizures were the common neurological manifestations. Early diagnosis and immediate treatment of idiopathic intracranial hypertension (IIH), may prevent the visual loss. Serum D-dimer level is useful for early diagnosis with sensitivity of 54.5%. Heparin is the gold standard treatment for CVT. Our study supports the use of heparin in all patients, even with intracerebral hemorrhage or hemorrhagic venous infarction. The use of steroids and osmotic diuretics as anti-edema measures were found useful, even though no clear sufficient evidence in the literature.

**Headache prevalence in Uruguay: A general population study**

C. Pérez*, A. Perna*, A. Pernab, Neurology Service, Maciel Hospital, Uruguay; Neurology Institute, Clinical Hospital, Montevideo, Uruguay

Headache is one of the most frequent disorders which lead patients to see a physician; however, there are no prevalence data in Uruguay. The aim of this study was to know the global prevalence per year of headache and migraine in Uruguay. A descriptive cross-sectional study was performed including people age 15 and above who were interviewed over the phone by physicians with a special training in headache issues. The diagnostic criteria of IHS were used for migraine diagnosis. The sample was selected by means of a simple random sampling, using the phone directory. The population's response to the phone interview was very good, with a participation rate of 94.9%. The yearly global prevalence of headache was 58.4% (IC 95% 54.8–62.0), males = 50.8 (IC 95% 43.8–57.8) and females = 65.2 (IC 95% 61.2–69.2). The yearly prevalence of migraine was 6.23% (IC 95% 4.48–7.98), male = 1.5% (IC 95% 0.1–3.11) and female = 10.5% (IC 95% 7.9–13.1). This paper provides the first epidemiological data on headache in Uruguay. Although there are many headache prevalence studies at international level, it is difficult to compare them due to differences in the populations studied, the methodology employed, the case definition and the prevalence period considered. Therefore, from the analysis of the above data, we can conclude that it is still necessary to make comparable epidemiologic headache studies.

**Migraine as the manifestation of acute myocardial ischemia**

**Objectives:** To evaluate migraine (Mg) as a clinical manifestation of acute myocardial ischemia (MI).

**Methods:** Study sample consists of 55 pts. with MI and headache divided in two groups: Gr. I (N = 29) MI with Mg and Gr. II (N = 26) MI with other types of headaches. The data was analyzed using Epi Info.

**Results:** Mean age in Gr. I was 54.06 ± 5.67 and 52.88 ± 4.84 in Gr. II. Headache history was 28.10 ± 12.19 ages in Gr. I vs. 12.55 ± 13.63 in Gr. II (p < 0.05) and severity 7.37 ± 2.59 in Gr. I vs. 3.11 ± 2.72 in Gr. II (p < 0.05). Headache as the clinical manifestation of MI was 55% in Gr. I and 20% in Gr. II (p < 0.05). The severity of headache in the beginning of MI was 5.5 ± 3.55 in Gr. I vs. 1.63 ± 2.97 in Gr. II (p < 0.05). The severity of headache in the beginning of MI was 5.5 ± 3.55 in Gr. I vs. 1.63 ± 2.97 in Gr. II (p < 0.05). During the MI in Gr. I was 6.0 ± 3.33 vs. 1.83 ± 2.98 in Gr. II, and the severity of headache after MI was 4.37 ± 3.43 in Gr. I vs. 1.02 ± 2.38 in Gr. II (p < 0.05). Headache in the beginning of MI was 55% pulsating, 20% throbbing and 25% dull in Gr. I vs. 70% dull and 30% pulsating in Gr. II.

**Conclusion:** Migraine type of headache could be one of the clinical presentations of myocardial infarction suggesting the possible common pathophysiological mechanisms. The clinical presentation of headache associated with acute myocardial infarction was more severe in intensity and pulsating quality. The link between migraine and myocardial infarction needs further investigation.

Dexamethasone multifunctional role in spreading depression
B. Khodaie. Neuroscience, Shefa Neuroscience Research Center, Tehran, Iran

Spreading depression (SD) is a neural hyperexcitability, which spreads to adjoining area of brain cortical; slowly continues through the brain and changes neural electrical and metabolic activity. It has been proved that SD plays a dramatic role in some neurological disorder through the changes it causes. Previous studies applied various types of drugs through diverse pharmacological aspects to relieve SD wave distribution however most have been abort due to their unpleasant side effects. In the present study we seek for dexamethasone’s (Dex) multifunctional properties in order to protect cellular damage and then prevent even other neurological disorder accuracy following SD. Animals were randomly divided into five groups including CTRLs, sham, spreading depression and dexamethasone treatment group. Animals were anesthetized and a cannula as well as an electrode was established above the brain cortex. Intracerebral KCl was used to induce repetitive cortical SD for 4 continuous week. Following each induction memory retrieval tests (T-maze) were done. The brains were removed after 4 weeks. Histopathologically estimation was used to testify dexamethasone effect. In addition dexamethasone effects on blood brain barrier (BBB) to facilitate substance recovery in cerebral fluid were tested by Evans blue. By repetitive SD memory retrieval was impaired due to increase of dark neural seen in several regions of juvenile rat brain. Besides that brain electrical activity determination showed slake of neural activity after SD induction. Neural cell recoveries after SD due to increase of substance passage through BBB were promoted.

Natural experimentation is a poor method for identifying headache triggers
I. Porter a, D.P. Turner b, T. Houle b. aAdvance Neurology & Pain, Cornerstone Healthcare, Advance, USA; bAnesthesiology, Wake Forest School of Medicine, Winston-Salem, NC, USA

Background: Headache patients naturally use the covariation of the presence—absence of triggers with headache attacks to assess the potency of triggers. The validity of this natural experimentation has never been investigated. This study examines this process using real-world conditions.

Objective: In this study we set out to determine whether individual headache sufferser can learn about the potency of their headache triggers (causes) using only natural experimentation.

Methods: The similarity of day-to-day weather conditions over four years, as well as the similarity of ovarian hormones and perceived stress over a median of 89 days in nine regularly cycling headache suffersers were examined. An arbitrary threshold of 90% similarity using Gower’s index identified similar days for comparison.

Results: The day-to-day variability in just three headache triggers is substantial enough that finding two naturally similar days for which to contrast the effect of a different trigger (e.g., drinking wine versus not drinking wine) will only infrequently occur (e.g., 2 similar stressful days/month). If finding comparable days in one trigger is difficult, finding similar days using multiple triggers becomes increasingly difficult. If there were no covariation in 12 different triggers considered together, using a statistical simulation we would expect a similar day occurring only once every 684 days.

Conclusion: Although assessing the personal causes of headache is an age-old endeavor, many candidate triggers exhibit variability that may prevent sound conclusions without assistance from formal experimentation or statistical balancing.

Primary stabbing headache: A new dural sinus stenosis-associated primary headache?
A. Ranieri, S. Montella, R. De Simone. University Federico II, Naples, Italy

Background: Primary stabbing headache (PSH) is a primary syndrome of unknown aetiology characterized by brief stabs felt in orbital, temporal and parietal areas, whose daily frequency largely varies. PSH incidence resulted 33/10000/year in clinical series with a 35.2% prevalence in a population study. Although considered an infrequent condition, a sinus stenosis-associated intracranial hypertension without papilledema (ss-IHWOP) is much more prevalent than believed and may represent a risk-factor for the progression of migraine, tension type headache and exertional, cough and sexual activity-associated headaches.

Objective: Test the hypothesis that PSH is a sinus stenosis-associated primary headache.

Patients and methods: We retrospectively investigated co-occurrence of sinus stenosis by MR-venography (MRV) in patients referring to our headache centre reporting PSH.

Results: Out of 50 consecutive subjects reporting PSH, 8 (6 F, 2 M) underwent MRV. All showed significant unilateral or bilateral sinus stenosis. Mean age at PSH onset was 35.3 ± 18.9 years. Median frequency of attacks/month was 14 (range = 4–30) with a median frequency of attacks/day of 4 (range = 2–20). Attacks lasted 1–2 s in all but one patient (5 s). Six patients described attacks in temporal or parietal areas, one at the top of the head, and one in occipital area. Seven patients were also diagnosed with migraine without aura and one had isolated PSH. Seven patients responded to indomethacin and one to topiramate (both drugs known to lower CSF pressure).

Conclusion: Our findings indicate that PSH is associated with sinus venous stenosis suggesting that an undiagnosed ss-IHWOP might be involved in PSH pathogenesis.
Objective: To test whether detoxification of patients with MOH can improve the clinical characteristics of the patients' headaches and lead to a better QOL as measured by the CHQQ instrument.

Patients and methods: Patients fulfilling the diagnostic criteria of MOH underwent an inpatient detoxification program. Clinical data were collected using a detailed headache diary. CHQQ was completed at the beginning and at the end of the treatment period. We used nonparametric (Wilcoxon) tests while testing for differences between pre- and post-withdrawal variables.

Results: Ten patients (9 females; mean age = 40.5 ± 15.9 years) were enrolled. After detoxification the clinical characteristics (attack frequency, days with headache, duration and intensity of the attacks) improved significantly (p < 0.04). The total score and also the physical, mental and social dimensions of CHQQ showed significant improvements of headache-related QOL (p < 0.01).

Conclusion: In this sample detoxification resulted in the improvement of both the clinical characteristics and QOL of patients. Our data suggest that CHQQ may be useful in monitoring QOL in patients undergoing headache prophylaxis.

Topic: 8 — Headache
Cerebral miliary tuberculosis: A case report
B.B. Maigaa, K. DembeleL, C. Lisse, A. Sissokoa, T. Coulibalya, M. Karembeb, M. Konateb, N. Toloa, C.O. Guintoa, M. Traoreb, aNeurology Teaching Hospital Point G, Mali; bInternal Medicine, University of Bamako, Bamako, Mali

Background: Tuberculosis is one of the most common infectious diseases worldwide, and constitutes a public health issue in the developing countries. The percentage of extrapulmonary seems higher in people of black ancestry, women, and immunodepressed patients. Miliary tuberculosis is due to the lymphohematogenous spread of tuberculous bacillus from focal lesion. Stereotactic biopsy establishes the final diagnosis. In most cases, the diagnosis is presumptive on clinical and biological findings, and the progression under anti-tuberculosis drugs. We report here a case of an immunocompetent patient with cerebral miliary tuberculosis.

Methods: Neurological examination was done by a neurologist; brain CT-scan, blood chemistry and lumbar puncture were performed.

Results: A 29-year-old taxi driver, alcoholic but stopped two months ago, and smoker, came to our clinic for a progressive headache since five months associated with fever, recurrent vomits, and dry cough. He had a deteriorated state without adenopathy and meningal syndrome with a conserved consciousness. Brain CT-scan showed multiple enhanced widespread micronodules with an edema caused by the lesion. Thoracic X-ray identified diffuse micronodular opacities in the two pulmonary fields. Cephalorachidian fluid study showed a pleiocytosis at 50/mm³ with lymphocytes at 85%, total proteins at 2.17 g/l, and a glycorrhachie at 0.5 mmol/l. HIV test was negative.

Anti-tuberculosis treatment associated with corticoids led to progressive clinical and biological improvement.

Conclusion: Although uncommon, cerebral miliary tuberculosis should be considered even in immunocompetent patients before intracranial hypertension symptoms.

Topic: 8 — Headache
Migraine and hypothyroidism: A possible new comorbidity?
G. Zanchia, C. Lisottoa, F. Mainardia, F. Maggioni2. aDepartment of Neurosciences, University of Padua, Padua, Italy; bDepartment of Neurology, Hospital of Venice, Venice, Italy

Background: Migraine patients suffer from a variety of comorbid conditions.

Objective: The International Classification of Headache Disorders (ICHD-II) included in the secondary headache group a form attributed to hypothyroidism (HT). We assessed the prevalence of HT in migraineurs.

Patients and methods: We retrospectively evaluated 3718 patients diagnosed with primary headaches from 2005 to 2012.

Results: Overall, 98 cases (95 females and 3 males) with HT requiring hormone therapy were observed. Ninety of these cases (2 males) were migraineurs and 8 suffered from tension-type headache (TTH). Therefore, the prevalence of HT was 3.0% in migraine and 1.6% in TTH. In population-based studies the prevalence of HT in the general population resulted to be <1%. Interestingly, in our clinic-based survey HT occurred after migraine onset in 87 patients (96.7%), whereas it preceded migraine in 2 migraineurs and in 3 TTH patients. For the latter subjects headache attributed to HT was ruled out, due to headache persistence after levothyroxine treatment. For 52.0% of patients the headache showed a significant worsening after the onset of HT and hormonal replacement therapy. It is challenging to speculate whether the worsening could be attributable to the hormonal disorder, to levothyroxine treatment or both.

Conclusion: We found a high prevalence of HT in migraine, significantly higher than in the general population. HT should be considered as one of the various migraine comorbidities, even if possible pathophysiologic relationships remain unclear. In case of worsening of pre-existing migraine, thyroid function should be investigated to rule out a possible HT.

Topic: 8 — Headache
Third molar tooth in the etiology of cluster type headache: A case report
M. Yucelb, O.M. Akgunc, H. Akgund, S. Alayd, E. Yasinoglue, aDepartment of Neurology, Kasimpasa Military Hospital, Istanbul, Turkey; bDepartment of Pediatric Dentistry, Gulhane Military Medical Academy, Turkey; cDepartment of Neurology, Etimesgut Military Hospital, Turkey; dDepartment of Neurology, Gulhane Military Medical Academy, Ankara, Turkey; eDepartment of Dentistry, Kasimpasa Military Hospital, Istanbul, Turkey

Background: Headaches are one of the most frequently encountered health problems of multifactorial etiology. The fact that the trigeminal nerve has a role in the etiology of migraine and other headaches is being accepted in the recent years.

Objective: We wanted to report a case of unilateral headache accompanied by autonomic findings that meets the diagnostic criteria for cluster headache.

Patients and methods: A 30-year-old male patient complained of headache for about 6 years. His headaches occurred at certain periods of the year and relieved with painkiller but never completely recovered. His headaches were generally localized on the right side of his face, occasionally on the left, generally occurring in the night and sometimes at day time. The pain would start behind his eye and on his forehead lasting for 1–2 h, accompanied by ptosis and rhinorrhea. The patient was previously diagnosed with cluster type of headache and gained benefit from oxygen therapy.

Results: On the panoramic dental x-ray images obtained on his controls, horizontally located third molar teeth were seen bilaterally, compressing the neighboring teeth. Especially on the right side, significant contact with the alveolar nerve and inflammation were detected. The complaints were thought to originate from the wisdom (third molar) teeth so they were bilaterally removed.

Conclusion: In the evaluation and treatment of headache etiologies it is of importance in patients with cluster type of headache to evaluate the alveolar branch of the trigeminal nerve, and not to forget the dental pathologies as a causing factor.

Transient headache and neurological deficits with cerebrospinal fluid lymphocytosis associated with IgM antibodies to the Epstein–Barr virus capsid antigen
K. Apetse, L. Breynaert, C. Butaud, A. Beschet, K. Blanch-Lasserre, L. Ribouillard, V. Chan. Neurology, CHU Campus Lome, Lome, Togo; Neurology, Centre Hospitalier de Valence, Valence, France

Introduction: Some authors have suggested that the syndrome of transient headache and neurological deficits with cerebrospinal fluid lymphocytosis (HaNDL) results from an immunological response directed against a viral agent.

Case report: A 19-year right-hander old male with no previous history of disease, in particular of migraine, was admitted following two episodes of transitory aphasia combined to acute headache and vomiting. Emergency cerebral MR imaging with intracranial and cervical MR angiography did not reveal any vascular or parenchymal lesions. An electroencephalogram revealed the presence of non-epileptiform slowing on the left hemisphere. Examination of the cerebrospinal fluid (CSF) found 250 lymphocytes/ml, normal glucose levels and a minimal increase in protein concentration (0.54 g/l). A PCR performed on CSF with primers specific to HSV and EBV delivered negative results. In contrast, EBV serological test detected isolated IgM viral capsid antigen. Clinical symptoms disappeared within 24 h. EBV serological controls at 4 weeks showed an unchanged profile. Compilation of the clinical and laboratory features led us to pose a diagnosis of HaNDL.

Discussion: Our patient had increased IgM directed against the EBV VCA. These results can be ascribed to an EBV primary infection or to a non-specific reaction. We posit that a virus infection elicits an immune response that includes the production of antibodies.

Conclusion: Throughout this case report, we have argued about a possible abnormal immune reaction elicited by an infection that would trigger the development of this uncommon affection.

The results showed the following possible headache triggers in migraineurs: consumption of certain foods (5.9%), consumption of certain beverages (9.5%), mental strain (58.6%), fatigue (45.6%), strong odors (9.5%), changes in atmospheric pressure (49.1%), menstruation (47.3% of all subjects with migraine, or 54% of women migraineurs), and other triggers (15.4%).

Our results show that mental strain, menstruation, changes in atmospheric pressure and fatigue are the most significant triggers of migraine headache. The effects of food and drink as precipitating factors are present but not significant. These findings are important for planning treatment and educating patients.

Transcranial electro stimulation in the acute treatment of chronic migraine patients with lateral cerebral ventricles asymmetry
L. Rotaru, S. Odobescu, O. Grosu, I. Moldovanu. a,b
aHeadache Center, Institute of Neurology and Neurosurgery, Moldova; bState Medical and Pharmaceutical University ‘Nicolae Testemitanu’, Chisinau, Moldova

Background: Transcranial electro stimulation (TES) is an effective acute treatment for chronic migraine (CM), one of the possible mechanisms being the increase of β-endorphin level. Pharmacologic CM preventive treatment seemed to be less efficient if a “benign” lateral ventricles asymmetry (LVA) was associated. The aim of our study was to estimate the efficiency of TES in the acute treatment of CM with pronounced LVA.

Methods: We conducted a study on 52 patients diagnosed with CM (ICHD-II, revised 2006) treated by TES (39 patients) and by an active placebo (AP) device (15 patients). LVA was graded based on ventricular frontal horns asymmetry index (AI): control group comprised 26 patients with CM + minimal LVA (AI = 1.0–1.24), the study group — 28 patients with CM + pronounced LVA (AI ≥ 2.0). Pre- and post-treatment analyses of serum β-endorphin levels and headache severity on visual analog scale were performed.

Results: There was a significant headache intensity decrease only in the control group (TES — 4.89 ± 2.71 vs. 2.74 ± 3.05, p < 0.01 and AP — 4.71 ± 1.98 vs. 2.43 ± 1.39, p < 0.01). Most of pronounced LVA patients (71.4%) demonstrated a decrease of post-treatment serum β-endorphin level instead of the expected increase (TES — 26.89 ± 12.83 vs. 19.63 ± 11.19, p > 0.05 and AP — 33.45 ± 31.83 vs. 25.82 ± 34.63 pmol/l, p > 0.05).

Conclusions: Our results indicate a lack of efficiency of TES in the acute treatment of CM if a pronounced LVA is associated, that could suggest an eventual dysfunction of the opioid system in LVA patients with an unexpected reaction of diminishing β-endorphin level after TES.

The prevalence of cluster headache in the elderly is higher in women than in men
C. Lisotto, F. Mainardi, F. Maggioni, G. Zanchin. a,b
aDepartment of Neurosciences, University of Padua, Padua, Italy; bDepartment of Neurology, Hospital of Venice, Venice, Italy

Background: Cluster headache (CH) is considered a disorder of young men, peaking at 30 years of age. It is well known that CH affects men more frequently than women, the gender ratio ranging from 4.4:1 to 2.5:1 in various studies.

Objective: We evaluated the patients with CH aged 65 years and older.

Patients and methods: For the last 16 years we have observed 254 patients suffering from CH. Out of these cases, 42 patients (16.5% of the whole population) were older than 65 years.

Results: In this group of elderly patients, 24 were females (57.1%) and 18 were males (42.9%). We diagnosed 4 patients with CH (only one bout, according to the International Classification of Headache Disorders), 24 with episodic CH, and 14 with chronic CH. The onset occurred in ages 35–44 years for 21.4% of cases, in ages 45–54 years for 16.7%, in ages 55–64 years for 28.6% and after the age of 65 years for 33.3%. Notably, in the latter subgroup, the females significantly prevailed, accounting for 78.6% of cases.

Conclusion: In CH patients over the age of 65 years, females represented the great majority of cases, in contrast with the evident male preponderance in the previous ages. Apparently peculiar to the female distribution, an increased frequency of CH appears to occur in middle-age and elderly patients. To our knowledge, we report the patient with the oldest age at onset (a 93-year-old woman) and the largest case series of CH elderly patients published in the literature to date.

Cluster-migraine does exist
Department of Neurosciences, University of Padua, Padua, Italy;
Department of Neurology, Hospital of Venice, Venice, Italy

Background: Cluster headache (CH) is a well defined primary headache. When attacks fulfill all but one of the criteria for CH, established by the International Classification of Headache Disorders (ICHD-II), probable CH should be diagnosed. This entity requires one of the following conditions:

1) attacks lasting >180 min,
2) attacks without local autonomic signs or restlessness,
3) sporadic (less than one every other day) attacks.

Objective: We evaluated the patients previously diagnosed with probable CH.
Patients and methods: For the last 16 years we have observed 254 patients suffering from CH. Out of these cases, 35 (19 males and 16 females) could not fulfill all the criteria for CH.
Results: In this population we could distinguish 4 different subgroups. They could be diagnosed with CH except for:

1) attack duration >180 min, ranging from 4-to-8 h (7 cases),
2) absence of local autonomic signs or restlessness (5 cases),
3) sporadic attacks, with no cluster periodicity (11 cases).

We could also identify a fourth subgroup of 12 patients without cluster pattern and attack duration >180 min, ranging from 3-to-5 h. The first three subgroups meet the criteria for probable CH. The fourth subgroup does not fulfill the criteria either for probable CH or probable migraine without aura (MO).
Conclusion: Patients sometimes present with clinical scenarios having characteristics of both MO and CH, but they do not fully meet ICHD-II criteria for either condition. These occasions provide diagnostic challenges and account for the controversial form of “cluster-migraine”, which was previously considered as a variant of CH.

Sexual headache related to ginkgo glycosides
Department of Neurology, Etimesgut Military Hospital, Ankara, Turkey;
Department of Neurology, Kasimpasa Military Hospital, Istanbul, Turkey;
Department of Neurology, Gulhane Military Medical Academy, Ankara, Turkey

Background: The heart rate and the blood pressure rise during sexual activity. There are two mechanisms in sexual activity causing headache. It is stated that these two mechanisms are related to vascular structure constriction or muscle contractions. Although there are many reasons of sexual headaches it has been stated that they may develop due to medicines. Especially, it has been proved that birth control pills cause sexual headaches.

Objective: In our manuscript we would like to report a sexual headache due to the use of ginkgo glycosides.
Patients and methods: A 29-year-old male patient presented to the neurology outpatient clinic with a complaint of severe headache during sexual intercourse. The patient stated that in order to lessen his forgetfulness and strengthen his memory, upon the recommendation of his friend he used 19.2 mg ginkgo glycosides twice a day for 2 weeks. Two times during orgasm he had suffered severe, bilateral, throbbing headache. He had no headaches other than those two during the orgasm. His neurological examination was normal.

Conclusion: Headache is one of the adverse reactions of ginkgo glycosides. However, being first case presenting as a sexual headache that we know of, we found it worth reporting.

Altered resting state functional connectivity in patients with headache and medication overuse
F. Riederer, S. Kollias, A. Gantenbein, S. Schreglmann, M. Rosenberg-Nordmann, L. Michels.
University Hospital Zurich, Zurich, Switzerland

Background: Medication-overuse headache (MOH) is defined as headache that develops or significantly worsens during medication...
overuse. Functional and structural alterations have been described in MOH, including hypometabolism in orbitofrontal regions (Fumal et al., 2006) and grey matter increases (Riederer et al., 2012) in brainstem regions.

Objective: In episodic migraine, altered functional connectivity (FC) between areas involved in pain modulation and nociceptive processing has been described. It was the aim of the study to investigate potential FC differences in MOH.

Material and methods: We recorded resting state (6 min, eyes closed) functional magnetic resonance imaging data from 17 healthy controls (HC, mean age: 41.6, range: 31–65 years) and 11 age-matched (p = 0.54) patients with MOH according to diagnostic criteria of the International Headache Society (mean age: 43.6, range: 31–61 years). Participants with other neurological- or severe psychiatric disorders were excluded. Voxel-to-voxel functional connectivity (FC) was applied to estimate (whole-brain) spatio-temporal correlations within- and between-groups (p < 0.01, FDR-cluster corrected).

Results: We found exclusively hyperconnectivity in HC in the right insular cortex, middle temporal gyrus, posterior thalamus, premotor cortex, middle cingulate cortex, orbitofrontal cortex, and periaqueductal gray [at p < 0.05, corrected]. In contrast, no hyperconnectivity were observed in patients with MOH at all.

Conclusion: Hypoconnectivity between pain modulating regions, such as insular- and cingulate cortex and posterior thalamus, is consistent with dysfunction of pain modulating systems in MOH patients. Further, the decreased FC in the orbitofrontal cortex might indicate a disturbed reward system or a drug addiction phenomenon.

Trans-cutaneous electric nerve stimulation in chronic migraine patients with tender points

R.M. Amin, T. Emara, N. El Nahas, Ain Shams Faculty of Medicine, Cairo, Egypt; Neurology, Ain Shams Faculty of Medicine, Cairo, Egypt

Background: The therapeutic effect of neuromodulation has been investigated thoroughly in patients with chronic daily headache and has shown promising results.

Objectives: In our case series study, we tried to study the effect of trans-cutaneous electric nerve stimulation (TENS) on the frequency and severity of headache days in patients with chronic migraine with tender points in their scalp.

Methods: Our 5 patients received 3–10 successive TENS sessions on their tender points. They did not change their prophylactic medications during the study period. Patients maintained a headache diary for one month before and after the stimulation sessions. Our primary outcome was reduction in headache days, while our secondary outcomes were reduction in severity, headache index and in the number of rescue medications.

Results: There were significant reductions in the number of headache days (p = 0.043), headache intensity (p = 0.038) and headache index (p = 0.043) with nearly significant reduction in number of abortive bills (p = 0.068) yet with insignificant reduction in attack duration (p = 0.498).

Conclusion: The use of tender nerves as a clinical determinant of the subsequent efficacy of peripheral neuromodulation seems to be a reasonable strategy to manage selected cases of chronic migraine.

Efficacy of Map0004 in treating subjects with severe migraine pain: A subpopulation analysis

S. Kori, E. Connors, J. Zhou, B. Lu, S. Borland, MAP Pharmaceuticals, Inc., a Wholly Owned Subsidiary of Allergan, Inc., Mountain View, CA, USA

Background: The treatment needs of patients with severe migraine are often unmet by available therapies. Map0004, an investigational product that delivers dihydroergotamine systemically via oral inhalation, was shown to be superior to placebo for the acute treatment of migraine in a phase 3 clinical trial.

Objective: This post hoc analysis of phase 3 data was performed to assess the efficacy of Map0004 in treating severe migraine pain.

Patients and methods: This analysis included 366 subjects who treated migraine while experiencing severe pain during the double-blind period. Subjects reported pain levels at 10, 30, and 60 min and at 2, 4, 24, and 48 h after treatment.

Results: Subjects with severe migraine pain receiving Map0004 experienced statistically significant pain relief compared with subjects receiving placebo at 10 min and at all subsequent time points. Significantly more subjects were pain free in the Map0004 group than in the placebo group at 60 min and at all subsequent time points. Rates of sustained pain relief and sustained pain free for 2–24 h and 2–48 h

White matter microstructure abnormalities in pediatric migraine patients: In vivo measures of brain hyperexcitability?

Background: Diffusion tensor (DT) magnetic resonance imaging (MRI) provides several quantities with the potential to disclose white matter (WM) microstructure abnormalities. Among these, fractional anisotropy (FA) reflects axonal integrity and fiber organization, mean diffusivity (MD) measures the overall magnitude of diffusion, axial diffusivity (λ||) is associated with fiber density and axon intrinsic characteristics, whereas radial diffusivity (λ⊥) reflects the degree of myelination.

Objective: To explore abnormalities of WM microstructure in pediatric migraine patients using DT MRI and two different methods of analysis.

Patients and methods: Using a 3.0 Tesla scanner, dual-echo and DT MRI scans were acquired from 15 pediatric migraine patients and 15 age-matched controls. Tract-based spatial statistics (TBSS) analysis and a DT probabilistic tractography of the major brain WM tracts were performed.

Results: Both TBSS and DT tractography analysis showed significant lower MD, λ|| and λ⊥ of the brainstem, thalamus, fronto-temporo-occipital lobes (right cingulum, corpus callosum, optic radiation, fronto-occipital fasciculus and corticospinal tract, bilaterally) in migraine patients vs controls. Migraine patients also experienced increased FA of the left optic radiation. Reduced MD of the right cingulum was correlated with disease duration.

Conclusions: Pediatric migraine patients present diffuse WM microstructural abnormalities. Higher FA and lower MD, λ|| and λ⊥ might be explained by repeated neuronal activation, that is likely to lead to cell swelling and might stimulate the activity-dependent myelo-modulation, or by the presence of higher neuronal and synaptic densities in migraine patients compared to controls. Both these mechanisms would reflect a hyperexcitability of the brain in migraine patients.

Is gray matter atrophy a biomarker of migraine? A study in pediatric patients with migraine

Background: Voxel-based morphometry (VBM) studies in adult patients with migraine have consistently demonstrated atrophy of several gray matter (GM) regions involved in pain processing. Whether abnormalities of these areas represent a phenotypic biomarker of this condition, or, are the consequence of the repetition of migraine attacks is still controversial.

Objective: To assess the regional distribution of GM and white matter (WM) abnormalities in pediatric patients with migraine using VBM. The correlations between regional volumetric abnormalities and clinical manifestations of the disease were also investigated.

Patients and methods: Using a 3.0 Tesla scanner, brain T2-weighted and 3D T1-weighted scans were acquired from 12 pediatric migraine patients (seven with visual aura and five without aura) and 15 age-matched controls. Volumetric abnormalities were estimated using VBM.

Results: Compared to controls, pediatric patients with migraine experienced a significant GM atrophy of several regions of the frontal and temporal lobes which are part of the pain-processing network. Increased GM volume was detected in the right putamen in pediatric migraine patients vs. controls. Compared to patients without aura, those with aura had an increased GM volume of the left fusiform...
A case of multiple sclerosis presenting as trigeminal neuralgia

J. Cho, Neurology, National Health Insurance Service Ilsan Hospital, Goyangsi, Gyeonggido, Republic of Korea

Trigeminal neuralgia is characterized by recurring paroxysms and severe pain in the distribution of the trigeminal nerve. In multiple sclerosis it occurs more commonly than in the general population, and it is more likely to be bilateral and to occur at a younger age. In most cases, other symptoms of multiple sclerosis preceded trigeminal neuralgia. A 45-year-old woman presented with sharp and shooting pain on her right face for 2 years. The pain was in the distribution of the third division of right trigeminal nerve and often triggered by light touch. The pain had been initially well controlled with carbamazepine 200 mg bid, but had recently worsened despite increasing the dosage to 300 mg bid. The neurologic examination was normal including facial sensation. The MRI showed a hyperintensive linear lesion along the right intramedullary trigeminal nerve root on T2-weighted image and multiple white matter lesions compatible with dissemination in space of multiple sclerosis. Follow up MRI revealed dissemination in time with new lesions in T2-weighted image. The patient has received interferon beta 1a. We report a rare case of multiple sclerosis presenting as trigeminal neuralgia and review the MRI findings of trigeminal neuralgia in multiple sclerosis.

doi:10.1016/j.jns.2013.07.1769
Objective: To determine CGRP levels outside migraine attacks in peripheral blood as a potential biomarker for CM.

Methods: Women older than 17 and diagnosed as CM were recruited. Matched healthy women with no headache history and women with EM served as control groups, together with a series of patients with episodic cluster headache in a pain-free period. CGRP levels were determined in blood samples obtained from the right antecubital vein by ELISA outside a migraine attack and having taken no symptomatic medication the day before. Due to ethical reasons, preventatives were not stopped.

Results: We assessed plasma samples from 103 women with CM, 31 matched healthy women, 43 matched women with EM and 14 patients with episodic cluster headache matched for age. CGRP levels were significantly increased in CM (74 ± 90 pg/ml) as compared to control healthy women (33 ± 74 pg/ml), females with EM (46 ± 37 pg/ml) and episodic cluster headache patients (45 ± 87 pg/ml). Thresholds of 43 ± 45 and 58 ± 22 pg/ml optimize the sensitivity and specificity to differentiate CM from healthy controls and episodic migraine, respectively. In the CM group, CGRP levels were significantly increased in women with a history of migraine with aura vs. those only experiencing migraine without aura. Variables such as age, analgesic overuse, depression, fibromyalgia, vascular risk factors, history of triptan consumption or kind of preventative treatment did not significantly influence CGRP levels.

Conclusion: Increased CGRP level measured in peripheral blood outside migraine attacks and in the absence of symptomatic medication seems to be a reliable marker for CM.

Frovatriptan in the treatment of menstrually related migraine: Evidence from late trials and current recommendations
A. MacGregor, Barts Health NHS Trust, UK; Centre for Neuroscience & Trauma, Bizard Institute of Cell and Molecular Science, Barts and the London School of Medicine and Dentistry, London, UK

Menstrually-related migraine (MRM) is a subtype of migraine without aura, with attacks occurring on or between 2 days before the onset of menstruation and the first 3 days of bleeding, in at least two out of three menstrual cycles and additionally at other times of the cycle. Menstrual attacks are generally more severe and disabling, last longer, frequently relapse and are less responsive to symptomatic medication than attacks at other times of the cycle. MRM treatment is based on acute or prophylactic strategies, though predictability of menstrual attacks offers the opportunity of effective perimenstrual prevention. Triptans, including one of the latest representatives of this class, frovatriptan, are indicated as first line treatment for moderate-severe migraine attacks, including MRM. Frovatriptan is recommended by guidelines as short-term preventative treatment of menstrual attacks that do not respond adequately to acute treatment. Results of post-hoc analyses of randomized, cross-over, direct comparative trials also reinforce the role of frovatriptan in the acute treatment of MRM. In these studies, including 187 women, frovatriptan showed pain free and pain relief rates similar to those of other triptans (23 vs. 30% and 37 vs. 43%, respectively) but significantly (p < 0.05) lower relapse rates (15 vs. 26%). Frovatriptan was as safe as the other triptans with a frequency of adverse events of 5% (vs. 4% with comparators). In conclusion, among the variety of effective strategies available, frovatriptan, owing to its sustained effect and good tolerability profile, offers specific attributes suited to acute and prophylactic management of MRM.

Hyperexcitability in flash visual evoked potentials of migraine patients
J.H. Han*, D.E. Kim*, J.M. Kim*, "Department of Neurology, Seoul Veterans Hospital, Republic of Korea; "Department of Neurology, National Police Hospital, Seoul, Republic of Korea

Background: Pattern-reversal visual evoked potentials (PRVEPs) in migraine showed variable results, but flash visual evoked potentials (FVEPs) in migraine showed usually in the increased amplitude. We have tried to ascertain whether the amplitude of FVEPs increases and the other abnormality of FVEP present.

Methods: FVEPs were recorded in 25 patients with migraine with aura, 23 patients with migraine without aura during interictal period without specific medications associated with migraine and 48 normal subjects. The migraine groups consisted of 11 men and 14 women in migraine with aura patients aged 20 to 71 years (mean age: 49 years), and 12 men and 11 women in migraine without aura patients aged 27 to 70 years (mean age: 57 years). The normal control group consisted of 23 men and 25 women in healthy volunteers aged 28 to 71 years (mean age: 54 years).

Results: The amplitude of FVEPs in migraine showed significant increase (p < 0.001) compared to normal subject, and only A1(N1–P1) amplitude in migraine without aura showed significant increase (P < 0.05) compared to migraine with aura.

Conclusion: The increased amplitude of FVEPs compared to PRVEPs results in other study suggests that migraine brain is more excitable in flash stimulation associated Y-system than pattern stimulation associated with X-system. These findings are explained by specific cortical distribution of serotonin and noradrenaline in XY-system of the visual cortex.

Frovatriptan versus other triptans in the acute treatment of migraine with aura attacks: Pooled analysis of double-blind, randomized, cross-over, multicenter studies
S. Evers1,2, O. Summ2, M. Ferrari3, L. Savi4, L. Pinessi4, S. Omboni4, C. Lisotto6, G. Zanchin6, D. Zava6, 1Department of Neurology, University of Münster, Münster, Germany; 2Department of Neurology, Krankenhaus Lindenbrunn, Coppenberg, Germany; 3Department of Neurology, University of Leiden, Leiden, The Netherlands; 4Department of Neurology, University of Turin, Turin, Italy; 5Italian Institute of Telemedicine, Varese, Italy; 6Ospedale Civile San Vito al Tagliamento, San Vito al Tagliamento, Italy

Background: Approximately 20–30% of migraineurs experience attacks with aura. Such symptoms may cause anxiety and distress, making headache attacks disabling. Presently no data are available on the efficacy of treating migraine attacks while experiencing signs and symptoms of aura.

Objective: To evaluate the efficacy of frovatriptan vs. other triptans administered at the onset of a migraine attack with aura (IHS criteria) through a retrospective, pooled analysis of data from randomized, double-blind, cross-over, multicenter studies.

Methods: Subjects were randomized to frovatriptan 2.5 mg or comparator (rizatriptan 10 mg, zolmitriptan 2.5 mg, almotriptan 12.5 mg). Patients were asked to treat 1 to 3 attacks with each drug in no more than 3 months, before switching to the other treatment. 117 attacks were treated during occurrence of aura in 56 subjects of the intention-to-treat analysis (mean age ± SD: 40 ± 10 years; 91% females) were considered.

Results: Pain free episodes at 2-h did not significantly differ under frovatriptan and comparators [30% vs. 17%; OR: 0.47 (0.19–1.14), p = 0.091]. Rate of pain free at 4-h was similarly distributed between treatments [frovatriptan: 51% vs. comparators: 40%; OR: 0.64 (0.31–1.34), p = 0.237]. Conversely, relapse at 48-h was significantly less in frovatriptan-treated attacks [67% vs. 90% comparators; OR: 0.22 (0.08–0.61)]. Additionally, at 48-h from drug intake, headache intensity was significantly reduced in frovatriptan-treated attacks [67% vs. 90% comparators; OR: 0.22 (0.08–0.61)].

Conclusions: Frovatriptan seems to have a similar immediate efficacy, but a more sustained effect and a better tolerability than the other triptans in migraine with aura attacks.

Programmable lumboperitoneal shunting (pLPS) in the management of pseudotumor cerebri (PTC)
N. Roosend, K.A. McIntosh. Neurosurgery, Henry Ford Wyandotte Hospital, Wyandotte, MI, USA

Background: Medication-resistant PTC or idiopathic intracranial hypertension (IIH) is typically managed with a cerebrospinal fluid (CSF) diversion procedure in order to prevent severe morbidity such as papilledema-associated blindness or to treat intractable headaches. The recent advent of pLPS devices marked a possible significant improvement in the surgical treatment of PTC.

Objectives: We reviewed our personal cases to evaluate the impact of pLPS on our surgical PTC practice, particularly our operative revision needs.

Methods: Our PTC patient collective was retrospectively reviewed (2002–2013) focusing on revision surgery vs. pLPS adjustment for pressure-related changes.

Results: There were sixteen patients (all female) with a mean age of 40 years (21- to 60-years-old). Follow-up was between 9 months and 8 years. Six patients had a STRATA pLPS (Medtronic, Inc.) placed. Four of these patients required from one to three reprogramming sessions, whereas one patient required numerous reprogramming sessions due to a very variable intractable headache syndrome. Patients with a fixed pressure LPS (N = 10) needed a total of eight revision surgeries, of which three were pressure setting related.

Conclusion: pLPS is a very useful technique for PTC management and avoids pressure-related surgical revisions in a substantial number of patients.

We followed the standard protocol for Botox in migraine, i.e. 155 units on face, head and neck. Various muscles were injected according to the protocol and consisted of both corrugators, procerus, both frontalis, temporalis, occipitalis, paraspinales and trapezius.

After the injections patients were required to keep a diary in which they would write their response on a daily basis pertaining to a number of headaches per month, the intensity and the duration of headaches and any complications following the injection. Patients were followed in 1 or 2 months and repeat injections were given in 3 months.

Forty patients had between 50 and 60% improvement in duration, intensity and the number of headaches per month. Forty eight patients had 80% improvement. Twelve patients did not respond twice within 6 months and were considered treatment failure. Ten patients had transient ptosis without diplopia lasting for 1 to 2 weeks. Four patients had worsening of headaches during the week after the injection but then showed a good outcome. Ten patients had minor bleeding on the face.

In conclusion Botox is refractory chronic migraine patients and should be tried.

Botulinum a toxin (Botox), in chronic migraine: Our experience in 100 patients
N.S. Rao1, M. Verma2, V. Mangeshkumar2, 1Neurology, PNNI, Harritsburgh, USA; 2Neurology, Neurology and Stroke Associates, USA;
2Neurology, NSA, Lancaster, PA, USA

Since Botox was approved to treat chronic migraine in USA in October 2010, we treated 100 patients, who have had chronic migraine and the following.

(A) Severe migraine for at least 2 years.
(B) Minimum 15 days of migraine headache per month.
(C) Headache lasting for 4 or more hours and
(D) failure of response to migraine medications, prophylactic or active, i.e. Triptans.

Results: Migraine prevalence decreased from 58.6% to 14.9% 1 year after clipping (p < 0.001). It was significantly more (p < 0.001) than in controls where the prevalence decreased from 51.1% to 42.4%. The SIA of internal carotid artery (p = 0.04, OR 3.76, 95% CI 1.0–14.1), left sided SIA (p = 0.04, OR 3.86, 95% CI 1.0–14.9), and the presence of cerebral infarct after SAH (p = 0.04, OR 5.19, 95% CI 0.98–27.4) were associated with the presence of migraine after clipping. Prevalence of other headaches (tension type, cluster and posttraumatic) did not change significantly after clipping.

Conclusion: Migraine prevalence in patients with SIA decreases significantly after clipping of SIA. This supports a role of cerebral arteries or their innervation in migraine.

Metabolic syndrome and migraine headache: A case control study
M. Salmasi1, L. Amini2, S.J. Haghjoo2, M. Tajmirriahi3, M. Saadatnia3, E. Asadimobarakeh4, 1Neurosciences Research Center, Isfahan University of Medical Sciences, Iran;
2Physiology Research Center, Neurosciences Research Center, Isfahan University of Medical Sciences, Isfahan, Iran

Introduction: Evaluating the correlation of metabolic syndrome and migraine headache has shown in some previous studies but there is no study that compared the prevalence of metabolic syndrome in the patients with and without migraine. This study was therefore undertaken to compare prevalence of metabolic syndrome in patients with and without migraine headache.

Method: Two hundred patients with migraine, diagnosed according International Headache Society and 200 people without migraine enrolled in this study. Metabolic syndrome was diagnosed according to ATP III criteria in these two groups and compared with each other.

Result: In the present study 34 (17%) of patients with migraine and 30 (15%) of patients without migraine had metabolic syndrome (P value = 0.58), Body mass index (P value = 0.05) and waist circumference (P value = 0.03) were significantly more frequent metabolic syndrome components in patients with migraine headache in comparison with control group.

Conclusion: Our results demonstrate that metabolic syndrome and migraine headache had not significant correlation, however, higher body mass index and waist circumference as metabolic syndrome components had correlated with migraine headache.

Decreased prevalence of migraine after clipping of saccular intracranial aneurysms (SIA)
E.R. Lebedeva1,2, N.M. Gurary3, V.S. Kolotvinov2, V.P. Sakovich4, J. Olesen5, 1Neurology, Ural State Medical Academy, Headache Center ’Europe–Asia’, Russia; 2Neurology, MU ’New Hospital’, Russia; 3Neurosurgery, City Hospital 40, Russia; 4Neurology and Neurosurgery, Ural State Medical Academy, Yekaterinburg, Russia; 5Neurology, Glastrup Hospital, University of Copenhagen, Copenhagen, Denmark

Background: SIA is associated with an increased prevalence of migraine but the effect of surgical treatment remains unclear [1].

Objective: To compare the prevalence of different types of headaches in patients with SIA before and after clipping of SIA and to identify factors associated with migraine remission.

Patients and methods: Out of 199 patients with SIA, 87 patients with SIA (45 men and 42 women, mean age 39.5) had headache before clipping of SIA. They were interviewed before and 1 year after clipping using a semistructured interview. The remission rate of headache in these patients was compared to the rate in 92 clinic patients after 1 year. Diagnoses of headache were made according to the ICHD-2 criteria.
correlated with obesity and other cardiovascular risk factors. We aimed to compare the severity, duration and frequency of migraine headaches in migraine patients with and without metabolic syndrome.

**Methods:** Two hundred migrainous were selected for this study. These patients divided to two groups, with and without metabolic syndrome. Severity, duration and frequency of migraine headaches were compared in two groups in the first visit, 30 and 60 days later.

**Results:** 34 patients (17%) had metabolic syndrome. They were older (p value < 0.001) and mostly female (p value < 0.01). Duration of migraine headaches was also more in metabolic syndrome group (p value = 0.03). The mean frequency of headache (9.1 versus 10.1, p value = 0.54) and mean severity of headache (7.6 versus 7.3, p value = 0.31) did not have impressive difference in both groups. 30 and 60 days after starting the treatment, severity, frequency and duration of headaches were decreased significantly in both groups, but there were no significant difference in the amount of these reductions in two groups.

**Conclusion:** Our study showed that metabolic syndrome is present in 17% of patients with migraine. Metabolic syndrome was correlated with the patient's age and duration of their headache attacks, but had no significant relationship with the frequency and severity of headache.

**Do vestibular migraine patients differ from migraine patients without history of vertigo in anxiety?**

G. Akdal, Ö. Kutay, B.D. Balci, T. Alkan, "Neurology, Health Science Institute, Dokuz Eylül University School of Medicine, Turkey; Neuroscience, Health Science Institute, Dokuz Eylül University School of Medicine, Turkey; School of Physical Therapy and Rehabilitation, Dokuz Eylül University, Turkey; Psychiatry, Dokuz Eylül University School of Medicine, Izmir, Turkey"

**Background:** Studies showed that anxiety and mood disorder were more common in migraine patients than healthy controls.

**Objective:** The aim was to compare vestibular migraine patients, migraine patients without history of vertigo (migraine only) and healthy controls according to their anxiety and depression scores.

**Patients and methods:** 35 definite vestibular migraine patients according to Neuhauser criteria, 30 migraine only patients and 30 healthy controls were included in the study. Hamilton Anxiety Rating Scale (HAMA), The State-Trait Anxiety Inventory (STAI-X1 and STAI-X2), Beck Depression Inventory (BDI), Anxiety Sensitivity Inventory-3 (ASI-3), Panic-Agoraphobic Scale (PAS; assessing panic like symptoms, stress sensitivity, anxious expectation, illusion phobia and hypochondriasis, and reassurance seeking) and Penn State Worry Questionnaire (PENN) were used for assessment. ANOVA test was used in between group comparisons and BONFERRONI test was used for post-hoc analysis.

**Results:** We found that there were significant differences in HAMA (p = 0.050), PENN (p = 0), 43STAI-X2 (p = 0.003) and panic like symptoms (p = 0.001), agoraphobia (p = 0.012) subscales of PAS scores also general score (0.005) between vestibular migraine and control group. There was also significant difference in HAMA (p = 0.016) between migraine only patients and control group. Migraine only and vestibular migraine patients differed in reassurance orientation (p = 0.04) and agoraphobia (p = 0.030) in subscales of PAS.

**Conclusion:** Our results showed that migraine only was related to higher levels of anxiety whereas vestibular migraine was related to both to anxiety and depression symptoms. Psychiatric symptoms may contribute to severity and disability related to migraine only.

**Idiopathic intracranial hypertension: clinical features and prognosis**

A.O. Keskin, F. Idiman, D. Kaya, B. Bircan, E. Idiman. "Neurology, Dokuz Eylül University, Izmir, Turkey"

**Background:** Idiopathic intracranial hypertension (IIH) is a disorder that predominantly affects obese women of childbearing age. The most important finding of elevated intracranial pressure (ICP) is papilledema which may lead to visual loss.

**Objective:** We aim to determine the demographic features, clinical signs and symptoms, radiological findings and investigate if any of initial features and findings are associated with the prognosis.

**Patient and methods:** In this study we included 59 IIH patients followed up in our neuroophthalmology department. We assessed demographic features, clinical signs and symptoms, radiological findings, and ICP. We also investigate the prognosis.

**Results:** 52 patients were female (88.1%), 7 were male (11.9%), mean of ages were 30.25 ± 13.12. The duration of the symptoms was 23.7 ± 32.4 months when they accepted to the department. Reported complaints were headache (78%), visual disturbances (48%), nausea (30.5%), vertigo (18.4%), tinnitus (8.5%), and diplopia (13.2%). Mean visual acuity was 0.78 ± 0.29. Visual field deficits 69% and papilledema occurred in 71% of the patients most of which were bilateral (66.1%). Mean ICP was 308.7 ± 100.2 mm H2O. %19.7 of the patients were obese, 17.2% of patients have endocrinopathy. Empty sella (15.3%), sinus thrombosis (8.5%) and optic hydrops (6.8%) were the most seen pathological MRI findings. The prognosis was good in 64.7% of the patients and 35.3% of patients worsened. Demographic features, initial complaints, mean ICP, pathological MRI findings and neuro-ophthalmological findings except visual field defects were not associated with the prognosis of participants. The prolonged duration of the time passed before patients gets treated and initial visual field defects were associated with the poor prognosis.

**Conclusion:** The prolonged duration of the time passed before patients get treated and initial visual field defects can be associated with the poor prognosis. Therefore, IIH must be diagnosed immediately, treated appropriately and follow up regularly.

**Post-dural puncture headache after spinal anesthesia and perioperative blood pressure**

J.M. Chung, J.K. Kim, J.Y. Kim, K.I. Park, H.A. Yu. "Department of Neurology, Seoul Paik Hospital, Inje University, Seoul, Republic of Korea; Department of Orthopedic Surgery, Seoul Paik Hospital, Inje University, Seoul, Republic of Korea"

**Background:** The pathophysiology of post-dural puncture headache (PDH) is believed to be related to low cerebrospinal fluid (CSF) pressure caused by CSF leak through the puncture site of dura. Considering that the blood pressure (BP) is one of major determinants of CSF pressure, the role of BP on the occurrence of PDH should be elucidated.
Objective: To ascertain the effect of perioperative BP on the development of PDPH in the patients who received surgery under spinal anesthesia.

Patients and methods: We evaluated the presence of PDPH in all consecutive 199 patients (122 males, 77 females, age: 15–76 years) who received elective knee surgery under spinal anesthesia between September 2012 and February 2013. The spinal anesthesia was performed by the same anesthesiologist with 25-G Quincke needle. Data regarding previous history of headache, pre- and post-operative BP, highest and lowest BP during operation as well as demographic features were analysed.

Results: The overall incidence of PDPH was 9.0%. It was higher in female than in male (15.6% vs 4.9%, p = 0.02). Age, history of hypertension or recurrent headache was not different between patients with and without PDPH. The duration of operation or spinal anesthesia was not different between the two groups. BP variables were expressed as pre- and post-operative mean arterial pressure (MAP), the highest and the lowest MAP during operation, and their differences were not different either.

Conclusion: PDPH after knee surgery under spinal anesthesia occurred more frequently in female patients, and was not influenced by their perioperative BP states.

Memory improvement after spreading depression by NMDA blocker as memory deconstructor
B. Khodaie, Neuroscience, Shefa Neuroscience Research Center, Tehran, Iran

Spreading depression (SD) is transient neural hyperexcitability followed by depolarization wave, which propagates through the brain and modulates electrical gradient and synaptic activity. Data have shown that SD wave distributes coincidence between neural activity and behavioral activity. Neural activity and electrical potential effect on memory retrieval have been demonstrated. Inhibitory effect of NMDA receptors in SD procedure can control memory impairment caused by SD. However, the negative effect of NMDA receptor blockage on memory has been proven in previous studies. In the present study the effect of NMDA receptors blockage (MK801) used to evaluate its efficiency in subsiding of SD negative influence on memory. Wistar rats (60–80 g) were randomly chosen in 6 groups and (NMDA blocker 0.63–1 mg/kg) were administrated after 3 mol/L KCl injection for induction of repetitive SD in rat. The groups were evaluated by T-maze test and SD groups were compared with control groups, including (NMDA blocker 1–0.63 mg/kg controls) and sham group. T-maze data have showed that repeated SD could significantly alter memory retrieval performance. However, in the second week memory enhancement was induced by SD induction. Repeated SD induction during other weeks indicated impairment in memory. Application of NMDA blocker showed significantly enhanced memory retrieval and could potentially control memory impairment after SD. The studies indicated that NMDA blocker may decrease memory performance, on the other hand the effect of MK801 on inhibition of SD propagation may somehow weaken memory improvement due to its memory destruction effects.

Prevalence of migraine among medical students in Kuwait University
J.Y. Al-Hashel1,2*, S. Muhammad3, R. Alroughany4,5. *Neurology, Ibn Sina Hospital, Medicine, Kuwait University, Kuwait, Kuwait; *Neurology, Minia University, Minia, Egypt; 4Neurology, Amiri Hospital; *Neurology, Dasman Diabetes Institute, Kuwait, Kuwait

Background: Prevalence of migraine among medical students is of particular interest as they are subjected to lots of tests and stresses that may precipitate migraine attacks.

Objectives: To determine the prevalence of migraine among medical students in Kuwait University.

Methods: This cross-sectional and descriptive study, which included students registered to Medical Faculty at Kuwait University in the academic year of 2012–2013. Out of 808 registrants, 621 students accepted to participate in the study. Participants who had two or more headaches in the last 3 months were subjected to two preliminary questions and participants with at least one positive response were asked to perform the validated ID-Migraine™ test. The frequency of headache per month and severity of headache by Numeric Rating Scale (NRS) were reported.

Results: Migraine was detected in 173 subjects (27.9%) based on the ID-Migraine™ test. The mean age of the migraine students was 20.17 ± 2.29 (16–25 years). Thirty-seven were male (21.4%) and 136 were female (78.6%). Migraine was significantly more frequent in the last 2 grades (35.5% and 44%, p < 0.000). The frequency and the severity of headache were significantly increased during the last 2 grades (5.55 ± 1.34 and 7.23 ± 1.27, p < 0.000) (6.00 ± 0.76 and 6.88 ± 1.25, p = 0.000) respectively. Stress 43 (24.9%), irregular sleep 36 (20.8%), and much reading 32 (18.5%) were the most common triggering factors.

Conclusion: There is a high prevalence of migraine among medical students in Kuwait University. The frequency and severity of headache increase with years of educations.

A randomized doubled blinded trial of treatment with diamino-oxidase (DAO) in patients with migraine and deficit of enzyme’s activity
1Hospital General de Catalunya, Sant Cugat del Vallès, Spain; 2Universitat Internacional de Catalunya, Sant Cugat del Vallès, Spain

Background: Histamine has been considerate as a chemical mediator of migraine. The degradation is done in two different pathways. One of the enzymes that allow this process is the diamino-oxidase (DAO).

Objective: The aim of this study is to identify the prevalence of the deficit in the activity of DAO in patients with migraine, and test the supplementation of this enzyme in a randomized controlled double-blind trial.

Material and methods: This was a randomized parallel-group controlled study. After a 1-month run-in, patients with migraine attacks/month between 4 and 14 were randomized 1:1 to placebo or DAO three times at day during one month. Primary outcome measures were diminution of hours of pain, and the use of antimigraine drugs.

Results: We studied 137 patients with migraine, and find the deficit of DAO activity (<80 HDU/ml) in 119 (87%).

doi:10.1016/j.jns.2013.07.1782
One hundred patients were randomized and included in the intention-to-treat analysis. Between run-in and first month of treatment, the mean number of hours of pain decreases in both groups but with significant difference in the final control in the group treated with DAO compared with placebo (6.3 vs 5.1; p < 0.03).

The use of the acute antimigraine drug was significantly reduced in the DAO but not in placebo group (p > 0.022).

There were no adverse events in either group.

Conclusions: Deficit in the activity of DAO is very prevalent in population with migraine.

The supplementation with the enzyme is effective and safe as a preventive therapy for migraine.

Subdural haematoma as a late complication of spontaneous cerebrospinal fluid hypovolemia (SCH) syndrome: Two case reports

Background: SCH syndrome is relatively common, and a CSF leakage can be occasionally demonstrated. Subdural haematoma (SDH) has been reported in patients with SCH, mainly in older men, or these displaying longer time to diagnosis of SCH.

Objectives: We report two cases that developed SDH after apparent resolution of SCH.

Material and methods: A 41 year old man developed severe orthostatic headache and neck stiffness after repeated sneezing. Lumbar puncture showed an opening pressure of 0 mm H2O. Cisternography demonstrated cervicothoracic CSF leak. A 43 year old man presented sudden headache after sport activity, highly suggestive of SCH, developing unilateral abducens palsy after several days. Cranial tomography (CT) was normal in both cases, with resolution of symptoms after 3 months of conservative therapy.

Results: Three months after the onset, when patients were almost asymptomatic, a control MRI showed subacute bilateral SDH. In both, resolution of the haematomas was verified after some weeks without need of drainage.

Conclusion: SCH is characterized by orthostatic headache, low CSF pressure, and sometimes typical MRI image. The development of SDH, although rare, has been reported. In our cases the late development of SDH is remarkable, perhaps related to the persistence of SCH for a long time. We emphasize the importance of monitoring patients with SCH, and consider conservative measures only in cases with a brief course. Epidural patching or surgical repair may prevent potentially serious complications such as SDH. Moreover, SCH should be excluded as a cause of SDH in young patients without risk factors.

Analysis of the development of allodynia: Correlation between migraine duration and severity
B. Lu, X. Li, E. Connors, S. Kori. MAP Pharmaceuticals, Inc., a Wholly Owned Subsidiary of Allergan, Inc., Mountain View, CA, USA

Background: Allodynia, the perception of pain from non-nociceptive stimuli, is a clinical presentation of central sensitization. Allodynia is reportedly common during migraine attacks. Although factors leading to development of allodynia are not well understood, duration and severity of migraine have been implicated.

Objective: This retrospective analysis evaluated the relationship between alldynia and the duration and severity of migraine to better understand the mechanisms related to migraine-induced central sensitization.

Patients and methods: This analysis included 792 patients from the double-blind period of a phase 3, placebo-controlled, randomized clinical trial of an investigational acute treatment for migraine (MAP0004). Baseline pain levels were recorded by patients using an electronic diary, and baseline allodynia data were obtained using a standard questionnaire. Correlations between percentage of patients reporting alldynia, severity of migraine, and duration of migraine were analyzed by Fisher’s exact test or Chi-square test, as indicated.

Results: At baseline, 53% of patients reported alldynia. The presence of alldynia did not change in relation to the duration of the migraine (Chi-square P = 0.2182), regardless of migraine severity (moderate pain, Chi-square P = 0.1807; severe pain, Chi-square P = 0.5830). Patients reporting severe pain experienced significantly more alldynia (58.4%) than patients with moderate pain (48.2%; Fisher’s exact test P = 0.0053).

Analysis of the development of allodynia: Correlation between menstrually related migraine and other non-menstrually related migraine
S.K. Aurora, B. Lu, E. Connors, X. Li, D. Kellerman, S. Kori.

Background: Menstrually related migraine (MRM), as defined by The International Classification of Headache Disorders, 2nd edition, occurs from days –2 to +3 of menstruation in 2 of 3 menstrual cycles and at other times of the cycle. MRM generally lasts longer and is more severe and difficult to treat than non-MRM. MAP0004 is an investigational product that delivers dihydroergotamine through the lungs via a breath-synchronized metered-dose inhaler.

Objective: This post hoc analysis of phase 3 data evaluated the efficacy and tolerability of MAP0004 in MRM vs non-MRM.

Patients and methods: This analysis included 149 women from a modified intent-to-treat population who treated MRM (n = 45) and non-MRM (n = 104) with MAP0004. The study used the following clinical end points: pain relief and pain free at 2 h and sustained pain relief and sustained pain free at 2–24 h and 2–48 h.

Results: The efficacy of MAP0004 did not differ significantly in MRM vs non-MRM at 2 h (pain relief 62% vs 64%; pain free 36% vs 29%), at 2–24 h (pain relief 53% vs 49%; pain free 31% vs 23%), and at 2–48 h (pain relief 38% vs 38%; pain free 24% vs 15%). No significant differences were found in frequency of adverse events, and no drug-related serious adverse events were reported.

Conclusion: In this post hoc analysis of phase 3 data, MAP0004 was similarly effective and well tolerated in treating both MRM and non-MRM.

Study supported by MAP Pharmaceuticals, Inc., a wholly owned subsidiary of Allergan, Inc.

Conclusion: The presence and development of allodynia is associated with severity but not duration of migraine. This retrospective analysis suggests that migraine severity is a significant factor in central sensitization.

Study supported by MAP Pharmaceuticals, Inc., a wholly owned subsidiary of Allergan, Inc.

Electrophysiological evaluation of headaches associated with temporomandibular dysfunction
F.A. Kuznetsova, Neurology, Neurosurgery and Medical Genetics, Kazan State Medical University, Kazan, Russia

Objective: To study clinical and neurophysiological peculiarities of headaches associated with temporomandibular dysfunction (TMD) and to evaluate involvement of trigemino-cervical system in pathogenesis of TMD headaches.

Methods: 30 patients aged 17–59 years old with headache complaints and TMD, confirmed by clinical and instrumental methods, were included into study. 30 healthy subjects aged 18–54 years old presented control group. Neurophysiological methods included trigeminal evoked potentials (TEP), blink reflex (BR) and EMG of masticatory muscles. Fisher exact test and correlation analysis with Pearson criterion were used for statistical analysis.

Results: The present study showed the trend to TEP latencies decrease, statistically significant latencies decrease of BR components R1 (p < 0.05) and R2 ipsi- and contralaterally (p < 0.001) compared with healthy controls. The analysis of the results of stimulative EMG revealed M-response asymmetry with amplitude decrease on the side of pain (p < 0.05). Correlation analysis showed strong direct correlation between latencies of TEP and M-response of masticatory muscles (r = 0.83) and inverse correlation between latencies of R2 component of BR ipsilaterally and M-response amplitudes (r = −0.91).

Conclusion: The obtained results demonstrated increased reflex irritability of trigeminal system and brainstem structures in patients with headaches associated with TMD. Functional state of trigemino-cervical system determines parameters of M-response of masticatory muscles. Increased irritability of trigeminal system is accompanied by increased muscle tone of masticatory muscles and leads to enhancing of pain syndrome. According to the obtained results, complex therapy of TMD headaches is recommended, including anticonvulsants in case of trigeminal system involvement.

The role of plasma nitrites in diagnosing of migraine severity in children
O. Rakhmanina, E. Levitina, Tyumen Medical Academy, Tyumen, Russia

Objective: Studying of plasma concentration of steady nitrogen oxide metabolite under migraine in children with regard to the type of migraine (with and w/o aura), frequency, rate and duration of a seizure.

Methods: The Study group is comprised of 81 children with migraine (54 boys, 27 girls) at the age from 6 to 18 y.o. Control group is 20 healthy children. Defining of nitrites in blood plasma was being conducted in accordance with methodology by Karpyuk with co-author (2000). The accuracy of differences: t-criterion of Student at p < 0.05.

Results: There's been diagnosed proven increase of plasma nitrite level up to 3.2 ± 0.8 nM/l in the Study group against 2.2 ± 0.9 nM/l in the Control group. The group of patients with frequent seizures (≥2 times per month) is comprised of 61 children with seizure frequency at the rate of 3.3 ± 1.5 per month and pain rate per visual analogue scale is 6.5 ± 2.0 points. The group of children with occasional seizures (<2 times per month) — 20 children with seizure frequency at the rate of 0.25 ± 0.2 per month and pain rate at 7.4 ± 2.0. Frequent seizure group appeared to have increase of nitrite plasma level up to 3.4 ± 0.9 nM/l against the group with occasional seizures (2.7 ± 0.9 nM/l). The study didn't show any dependence of migraine type, pain rate and seizure duration on the level of nitrogen oxide.

Conclusion: The level of plasma nitrites can serve as a laboratory indicator of disease severity and depends on the frequency of migraine seizure.

The primary headache subtypes in Nazareth city; co morbidity potential risk factors and disability rate
A. Mazaib, Clalit Health Services, Nazareth, Zarzir, Israel

Introduction: To investigate the primary headache subtype prevalence and disability rate associated with mood disorders in low socioeconomic status (LSES) may underlie both diseases.

Methods: I identified 276 headache sufferers, drawn from more than 1254 individuals representative of heterogeneous community of Nazareth city, which were referred to our center by family physicians for various neurological disorders, were subdivided subsequently in tension type headache (TTH) and migraine disorders according to IHS criteria and undergone complete work up profile with therapeutic strategies, secondary headaches were excluded. The socioeconomic status (SES) for every individual was considered and meticulously examined according employment, income and educational gradients. Verbal informed consent was obtained during the first round.

Results: The vast majority of those individuals were belonging to LSES (57.3%) and subdivided according IHS and DSM-IV,(for psychiatric illnesses, mood disorders, depressive and anxiety disorders) in 172 (62.3%)sufferers of TTH with 69.3% depressive disorders background and other psychiatric illnesses, 102 (36.96%) migraine(included with/without aura) with30.7% mood disorders, and finally, 2 (0.72%) sufferers of cluster headache.

Conclusions: The main target of this observational study was to verify the relationship between primary headache disorders and potential co morbidity risk factors. Psychiatric co morbidity was assessed by DSM-IV criteria. The LSES was considered as remarkable co morbidity risk factor for both headache subtypes, migraine and tension type headache.

doi:10.1016/j.jns.2013.07.1793
Background: CaMEO, a prospective cohort study, collects longitudinal and cross-sectional data in migraineurs to characterize migraine clinical course, family burden, barriers to care, endophenotypes, and comorbidities. 

Objective: To describe the methodology and characterize the population in CaMEO.

Methods: Migraineurs were recruited from a 2.4 million member web-based panel and demographically matched with the general population. Using ICHD-2 criteria, participants were divided into episodic (EM) or chronic migraine (CM) based on headache days/month. Participants complete surveys every 3 months for 1 year (starting fall 2012) and also recruit spouses/children in the household to assess familial migraine-related burden. Baseline data includes headache features/frequency, comorbid depression/anxiety, medication use, healthcare consultation, disability, and quality of life.

Results: Of 489,537 invitees, 80,783 (16.5%) responded to the screening survey. Eligible respondents (16,789; 3.4%) were invited into the 12-month assessment and were ≥18 years old, spent an appropriate amount of time completing the survey (≥10 min), and had EM (n = 15,313; 91.2%) or CM (n = 1,476; 8.8%). Compared with nonrespondents, respondents were older (P < 0.0001), more likely to be women (P < 0.0001), white (P < 0.0001), or married (P < 0.0001), and less likely to be employed full/part-time (P < 0.0001) or have incomes <$50,000 (P < 0.0001).

Conclusion: CaMEO characterizes the course of EM and CM over 1 year in a community-based web panel of migraineurs. With repeated assessments, CaMEO data will quantify variations in headache frequency, disability, comorbidities, medication use, and familial impact, and can also be used to define migraine endophenotypes for future genetic studies.

The temporal relationship between daily stress and delayed modulation of chronic headache pain
C.B. Clarka, R.J. Allenb. aNeuroscience, University of Puget Sound, Tacoma, WA, USA; bPhysical Therapy/Neuroscience, University of Puget Sound, Tacoma, WA, USA

Background: Although triggers are known for headache pain, many chronic headache patients do not know what causes episodic pain fluctuations. Previous fibromyalgia and complex regional pain syndrome studies report ten-day delays in pain flare onset following stressful events. Delayed neuropathic pain flares are associated with stress-released thyroxine modulation, which has latent effects due to attachments with serum thyroxine-binding globulins.

Objective: The temporal relationship between reported stress levels and episodic headache pain intensity was investigated to determine if chronic headache shows latent stress-related pain modulation.

Patients and methods: Two female subjects diagnosed with chronic migraine completed pain and stress inventories daily across ten weeks. Pain was assessed using the Visual Analog Pain Scale, McGill Pain Questionnaire Short Form, and modified pain-body diagram. The Visual Analog Stress Scale quantified daily stress.

Results: Serial lag correlations revealed the highest correlation between stress and pain to occur after a ten-day lag in subject 1 (r = 0.63, P < 0.005). Subject 2 showed a high negative correlation between stress and pain ten and eleven days later (r = −0.37 and r = −0.46, respectively, P < 0.05).

Conclusions: Patients manifested delayed pain changes following stress in diametrically opposed ways, where headache pain ten days later seemed to increase as a function of stress in one yet decreased in the other. This finding is consistent with existing literature on pain modulating effects from stress-related release of thyroxine, whereby some individuals increase thyroxine output as a result of psychogenic stress and others notably decrease thyroxine output.

Hemicrania epidemic IHS code 7.61
S. Dasyama, Neurology, SKS Neuro Hospital, Hyderabad, India

Chronic headache of over a 3 month duration is a common disorder for which advice from a neurologist is invariably sought. Over 2500 cases of chronic headache seen between March 1998 and 2013 by
men have significant number of cases (600) which had an epileptic background and no seizures. Headache improved in all cases using antiepileptic drugs (AED) only. Three subgroups were observed from these patients:

a) Calcified granuloma – 210 patients 35%.
b) Febrile seizures/childhood seizure – 120 patients 20%.
c) Family h/o seizures with EEG showing intencital finding – 270 patients 45%.

Based on this analysis, it is desirable to keep in mind the epileptic background of some of the chronic headache cases and treat appropriately (with AED).

All cases (600) studied did not have seizures – headache is the only symptom of presentation for consultation, in these cases headache is the manifestation of seizures without loss of consciousness and only responding to AED – CT scan of brain, EEG and history are great importance to clinch the diagnosis and good response to AED. Hemicrania epileptica was coined as a distinct clinical entity in mid-nineteenth century but in 1984 Isler all documented topographic epileptic form activity in unilateral headache for a 10 year duration in young female patients.

IHS classification does show it as one of the minor code (7.61) secondary headaches. It is the next most common form of headache to migraine in over all incidence of headache in the general population.

**Assessment of neurovascular reactivity at posterior cerebral arteries to visual stimulation in migraine headaches**

G. Tekgol Uzuner, N. Uzuner. *Neurology, Eskisehir Osmangazi University, Eskisehir, Turkey*

**Background:** The intracranial vessels have an important role in migraine pathophysiology, although neuronal mechanisms have been disclosed as primary point of interest.

**Objective:** We aimed the evaluation of neurovascular reactivity using transcranial Doppler ultrasonography in patients with migraine with aura and without aura.

**Patients and methods:** Sixty nine patients with migraine without aura, 58 patients with migraine with aura, and 75 healthy subjects served as controls were enrolled in the study. All patients were studied during headache attack and a headache-free period with transcranial Doppler. Reactivity is defined as relative changes between blood flow velocities measured during stimulus and rest.

**Results:** Increased reactivity was found at the headache side in all migraine patients during pain-free period comparing to control group (53% and 46% respectively, p = 0.01). In addition, reactivity was found significantly higher in migraine with aura (60%) than those of both migraine without aura and control groups (p < 0.001) in the headache-free period. Although, all migraine patients showed lower reactivity (headache side 33%, non-headache side 32%) than that of control group (p < 0.001 vs p = 0.002, respectively) during headache attack.

**Conclusion:** Patients with migraine with aura have higher reactivity to visual stimulation than that of control group in attack-free period. This is compatible with increased cortical excitability in patients with migraine with aura. However, reactivity was significantly lower in both migraine groups than control group during headache period. Inflammation and dilatation of dural and meningeal arteries during headache phase are not able to dilate more to visual stimulation resulting lower degree reactivity.

**Optic coherence tomography for optic disc and clinical evaluation in idiopathic intracranial hypertension**

*Neurology, Ministry of Health, Dr. Burhan Nalbantoğlu Government Hospital, Nicosia, Cyprus; Neurology, Ministry of Health, Ankara Education and Research Hospital, Ankara, Turkey; Ophthalmology, Ministry of Health, Ankara Education and Research Hospital, Ankara, Turkey*

Idiopathic intracranial hypertension (IIH) is the clinical syndrome of raised intracranial pressure (ICP), in the absence of space-occupying lesions or vascular lesions, without enlargement of the cerebral ventricles. It occurs commonly in overweight women and is encountered by most neurology departments on a regular basis. Optic coherence tomography (OCT) is a non-invasive imaging technique producing high-resolution cross-sectional images of the retina. Studies indicate that OCT is becoming valuable in various conditions with increased retinal nerve fiber layer (RNFL) but there are very few studies evaluating ability of OCT to identify and quantify papilledema in IIH. Therefore, the aim was to evaluate the applicability of peripapillary OCT evaluation in 57 patients with confirmed IIH according to Modified Dandy Criteria.

Subjects were evaluated by means of direct ophthalmoscopy, peripapillary retinal nerve fiber layer thickness (RNFLT) measurements (OCT 3 Version 4 Carl Zeiss Ophthalmic System Dublin, USA). Measurements of RNFLT were performed at admission and during the follow up periods. At the time of diagnosis, the mean RNFL of the right eye was 111 μm whereas the value for left eye was 113.5 μm. After the treatment and during the following examinations the RNFL reduced to 96 μm for the right eye and 98 for the left eye (p < 0.001). This presents promising findings for the use of OCT for evaluating papilledema in IIH patients during diagnosis and for the further clinical follow-up and management.

**Do migraineurs with vertigo/dizziness display some common characteristics? Results from a population-based study**

*Neurology, Dokuz Eylül University School of Medicine, İzmir, Turkey; Neurology, Istanbul Medical Faculty Çapa Medical School, Turkey; Neurology, Liv Hospital, İstanbul, Turkey*

**Background:** Migraine and vertigo/dizziness are both common, distressing and interrelated. They occur together 3 times more than by chance, and both impact on quality of life.

**Objective:** Our aim was to assess the frequency of vertigo/dizziness and to define the differences between clinical characteristics related to vertigo/dizziness in a community-based study.

**Patients and methods:** We designed a community-based prevalence study in adults, with face-to face interviews by specially trained general practitioners using a structured electronic questionnaire.
Comprehensive interview form included diagnostic questions based on the ICHD-II criteria. The questionnaire assessed all diagnostic headache features, headache related impact, demographics, comorbidities and disability assessed by MIDAS questionnaire. Descriptive statistics were applied and Chi-square test, t test and logistic regression test were used for comparisons.

**Results:** 5323 participants were reviewed. Vertigo/dizziness was significantly higher in migraineurs when compared to tension type headache sufferers. There were 534 migraineurs with vertigo/dizziness (MwVD) and 337 patients without vertigo/dizziness as controls. MwVD patients established 61.3% of definite migraineurs. MwVD patients had significantly more nausea/vomiting, more headache aggravation with head motions and had more visual aura. Frequency of headaches and pain killers used per month was also significantly high in MwVD patients. MwVD patients reported significantly more motion sickness, allergy, alldynia and osmophobia, interestingly. Furthermore MwVD patients had significantly low quality of life.

**Conclusions:** Our findings showed that more than half of the migraineurs have vertigo/dizziness. These patients showed many significant differences in clinical characteristics and have low quality of life when compared to other migraineurs.

**Age of migraine onset in lateral cerebral ventricles asymmetry patients**

L. Rotaru\(^a\), S. Odobescu\(^b\), O. Grosu\(^b\), V. Rotaru\(^b\), I. Moldovanu\(^a,b\).

\(^a\)Headache Center, Institute of Neurology and Neurosurgery, Republic of Moldova; \(^b\)State Medical University, Chisinau, Republic of Moldova

**Background:** Recent neuroimaging studies reveal that 12–60% of chronic migraine (CM) patients elince a “benign” lateral ventricles asymmetry (LVA). Migraine preventive treatment in these cases seems to be less efficient in decreasing migraine attack frequency as a hint of a worse migraine evolution in such patients.

**Material and methods:** We studied 124 same age (mean 36.56 ± 1.09 y.o.) CM patients diagnosed according to ICHD criteria (2nd edition, revised 2006) that performed an MRI 3T examination. The subjects were divided into four groups according to ventricular frontal corns asymmetry index (AI):

- **Group I** (control) — CM + minimal LVA (AI = 1.0–1.24),
- **Group II** — CM + mild LVA (AI = 1.25–1.99),
- **Group III** — CM + moderate LVA (AI = 2.0–2.99) and
- **Group IV** — CM + severe LVA (AI ≥ 3.0).

One of selection criterion for the study was the similar disease duration: 18.11 ± 1.61 y.o. in group I, 18.91 ± 2.39 in group II, (p > 0.05), 18.65 ± 2.09 in group III, (p > 0.05) and 19.60 ± 1.92 in group IV (p > 0.05). All patients underwent a clinical assessment and data were statistically analyzed.

**Results:** We ascertained a younger disease onset in CM patients associated with significant LVA. So, in moderate LVA CM patients, migraine started at the age of 13.65 ± 1.60 (p < 0.01) y.o., in severe LVA CM patients — at 12.35 ± 1.20 y.o. (p < 0.001), in comparison to the control group (20.42 ± 1.09 y.o).

**Conclusions:** According to our results, significant lateral ventricles asymmetry could be considered as an aggravating factor for the chronic migraine, maybe based on the common underlying serotonin deficiency that possibly fasten migraine onset.

**Prospective recordings of the clinical presentation of migraine with typical aura**

J.M. Hansen\(^a\), P.J. Goadsby\(^b\), A. Charles\(^c\), \(^a\)Department of Neurology, Headache Research and Treatment Program, University of California, Los Angeles, CA, USA; \(^b\)Department of Neurology, Headache Group, University of California, San Francisco, CA, USA

**Background:** About a third of migraine patients have attacks with aura, usually one or more neurological symptoms arising from the cortex or brainstem. The clinical presentation of aura can vary considerably and many descriptions of the clinical characteristics are based on purely retrospective studies.

**Objectives:** To describe the clinical presentation of migraine with typical aura in a large group of patients enrolled in a clinical trial, and to compare self-reported migraine symptoms to prospective recordings of attacks in the same patients.

**Methods:** 267 patients with migraine with typical aura were enrolled and provided data on the clinical presentation of migraine aura, headache, and associated symptoms. Baseline characteristics provided by patients on inclusion were compared with migraine symptoms collected prospectively during the study.

**Results:** Visual aura symptoms were reported by all patients, the most prevalent symptoms being dots or flashing lights (70.4%), wavy or jagged lines (46.8%) and blind spots (42.3%). Non-visual aura was less prevalent, reported by around half the patients. Symptom intensity for migraine symptoms (pain, nausea, photo- and phonophobia) was mainly (≥70%) graded moderate to severe. Patient reported data prior to the trial indicated a consistently higher symptom score (more severe phenotype) than in the prospectively collected data, (P < 0.01 for all).

**Conclusion:** Based on this large clinical collection of data exclusively from MA attacks, we show that visual aura symptoms are more prevalent than non-visual aura symptoms. The severity of self-reported migraine symptoms was greater than that recorded in the prospective data set.

**Distinctive anatomical and physiological features of migraine aura revealed by 20 years of patient recording**

J.M. Hansen, S.M. Baca, A. Charles. Department of Neurology, Headache Research and Treatment Program, University of California, Los Angeles, CA, USA

**Background:** Descriptions of the migraine aura have been presented as prospective self-observations by physicians and other professionals who had migraine with aura or migraine aura without headache.

**Objectives:** To present detailed characterization of a large number of visual auras recorded in one patient over two decades.

**Methods:** A patient documented and made detailed drawings of 1000 aura attacks over 20 years. Drawings were made in real time with documentation of the aura wavefront at 1 min time intervals.

**Results:** Consistent patterns of aura initiation, propagation, and termination were observed in both right and left visual fields. Most aura attacks originated centrally (within 10° eccentricity), but there were also other distinct sites of initiation in the visual field. Auras preferentially propagated first through lower nasal field (69–77% of all auras) before travelling to upper and temporal fields, on both sides. Some auras propagated from peripheral to central regions of the visual field — these typically followed the same path as those

Characteristics of migraines during the postpartum period: A long-term prospective study
E. Hoshiyama, M. Tatsumoto, H. Iwanami, A. Saisu, H. Watanabe, N. Inaba, K. Hirata. "Department of Neurology, Dokkyo Medical University, Mibu, Japan; 2Department of Obstetrics and Gynecology, Dokkyo Medical University, Mibu, Japan"

Background: Although there have been many reports regarding the course of migraines during pregnancy, the prevalence and characteristics of migraines during the postpartum period remain unclear.

Objective: To investigate the characteristics of migraines over a long postpartum period.

Patients and methods: We prospectively investigated the course of migraines experienced during the postpartum period by patients in a postnatal ward. The patients were surveyed during the first postpartum week and 1, 3, 6, and 12 months after delivery. The patients were provided a headache diary to assess medication use and migraine attack frequency, severity (the faces pain scale) and duration.

Results: The migraine remission rate was 63%, 83% and 85% during the first, second and third trimesters, respectively. No patient experienced a worsening of headaches during pregnancy. Headache recurrence during the first month after delivery was more frequent in the patients <30 years of age than in those ≥30 years of age (p < 0.05). The percentage of women experiencing recurrence at 1, 3, 6 and 12 months after delivery was 63%, 75%, 78% (n = 60) and 87.5% (n = 40), respectively. In breastfeeding patients, the rates were 50%, 65.8%, 71.1% and 91.7% and in bottle feeding patients, the rates were 86.4%, 90.9%, 95.5% and 81.3%, respectively.

Conclusion: In our study, we found that 85% of the patients with migraines experience remission during pregnancy and that more than 50% experience recurrence during the first month after delivery. Breastfeeding is associated with a lower recurrence rate than bottle feeding until six months after delivery.

Abstract — WCN 2013

Does pramipexole treatment improve headache in patients with concomitant migraine and restless legs syndrome?
S. Suzuki, K. Suzuki, M. Miyamoto, T. Miyamoto, A. Numao, Y. Watanabe, R. Takashima, K. Hirata. "Department of Neurology, Dokkyo Medical University, Mibu, Japan; 2Department of Neurology, Dokkyo Medical University Koshigaya Hospital, Koshigaya, Japan"

Background: Recent studies have suggested a link between migraines and restless legs syndrome (RLS). Although these disorders may share a dopaminergic dysfunction in the hypothalamic A11 nucleus that contributes to this association, there have been no clinical studies evaluating the effect of dopaminergic treatment on migraine symptoms in patients with concomitant migraines and RLS.

Objective: To report an illustrative case and to investigate the effects of immediate-release pramipexole (P-IR) treatment on migraine headaches.

Patients and methods: We retrospectively reviewed the medical records of patients who experienced both migraines and RLS.

Results: Ten patients (9 patients from the previously completed single-center study) received P-IR treatment were included in the study. Five out of the 10 patients (50%) reported subjective and objective improvement according to the Clinical Global Impression rating scale for migraine headaches. Of these 5 patients, 4 (80%) reported morning headaches.

Conclusion: Our results suggest that the identification of RLS in migraine patients is important and that dopaminergic treatment may improve both migraines and RLS symptoms.

Study on mood and anxiety disorders in patients with tensin-type headache

Background: Migraine is a known risk factor for ischemic stroke, especially in young women. Also, cervical artery dissection is the most common single etiology of stroke in young adults. However, the mechanism of migraine-related arterial dissection is still unknown. It is proposed that the repeated attack of migraine would make the involved artery more vulnerable to tearing and lead to dissection.

Patients and methods: (Case) A 34-year-old female was presented with sudden severe headache during 24 h. The patient complained severe headache with nausea and vomiting after awakening. She suffered from migraine for more than 10 years. The throbbing nature headache usually persisted with 1 or 2 days associated with nausea, vomiting, and photophobia. At emergency department, routine laboratory test and brain CT showed normal findings. We started conservative management for decreasing pain. However, headache and vomiting persisted, and dizziness and imbalance were also noted later. After admission, the neurological examination showed dysmetria, gaze-evoked nystagmus, and ataxia. Brain MRI demonstrated a high signal on the diffusion weighted image and low on the apparent diffusion coefficient image in the right cerebellar hemisphere consistent with acute infarction. Cerebral CT angiography revealed the left vertebral artery dissection. The patient was reluctant to use an anticoagulant. Also, topiramate and beta blocker were given to patient for migraine prophylaxis.

Conclusions: The exact mechanism of migraine-related intracranial artery dissection has yet to be proven, we propose that this may be caused by vessel wall edematous changes with repeated migraine attacks resulting in sudden or unusual stretching.

**Background:** Mood and anxiety disorders seem to be closely related to headaches.

**Objective:** The aim of the study was to evaluate the risk of mood and anxiety disorders in patients with tensin-type headache (TTH).

**Patients and method:** We enrolled in the study 68 patients (55 women and 13 men), aged between 23 and 49 years (mean age 37.5 years) who fulfilled the inclusion criteria: diagnosis of TTH according to the International Headache Society criteria, at least 8 years of education, no previous psychiatric illness. Both mood and anxiety disorders were diagnosed according to DSM IV criteria. The patients were divided into 2 groups:

- group A composed of 39 patients (35 women and 4 men) with chronic TTH and
- group B composed of 29 patients (20 women and 9 men) with episodic TTH.

All the patients were assessed by MMSE, Hamilton Depression Scale, Hamilton Anxiety Rating Scale, Hospital Anxiety and Depression Scale, and Headache Pain Scale Interpretation. The results were analysed by Student Test and Chi Square Test.

**Results:** Mood and anxiety disorders appeared in 66% of the patients: 79.4% in group A and 48.2% in group B. The patients had dysthymia (8.8%), unclassified depressive symptoms (26.4%), panic disorders (5.8%), generalized anxiety disorder (8.8%) and association between depression and anxiety (16.1%). None of the patients had major depression. Depressive disorder was found especially in women.

**Conclusion:** The frequency of depressive disorders was statistically significantly higher in women, but there was no significant difference between groups regarding the type of mood and anxiety disorders.

Cluster-like headache associated with symptomatic Chiari type 1 malformation: A case presentation

Y. Kaplan, O. Kamisli, S. Kamisli, Inonu University, Malatya, Turkey

**Background:** Several cases of symptomatic cluster-like headaches (CLH) have been reported such as arteriovenous malformations, medullary infarcts, and aneurysms. However, CLH associated with Chiari 1 malformation (CM-1) has been described in only one case.

**Objectives:** We describe a case considered as CLH associated with symptomatic CM-1.

**Case:** A 28-year-old female patient visited our outpatient clinic because of recurrent headaches since the age of 20 years. She had severe, recurrent, right frontal and periorbital area pain and headache, and lasted about 20–90 min. She suffered from tearing, rhinorrhea and ptosis during headaches. These pain attacks occurred irregularly two to four times per day. Although attack usually appeared spontaneously, it was precipitated by neck movements. In addition, she also suffered occasional pain in occipital–suboccipital area and vertigo, blackout in the eyes, palpitation, and sweating complaints, all of which would disappear in 5–10 min. Cardiologic tests were normal. Cranial/cervical MRI presented CM-1.

**Conclusion:** While CM-1 and CH are clearly different diseases, determining the actual cause of CH when two pathological processes are present is obviously difficult. CM-1 can be an incidental finding when MRI is conducted for other reasons. In CM-1, variable caudal displacement of cerebellar tonsils occurs into the upper cervical canal. These structural abnormalities in CM-1 may include stretching of cranial nerves or direct compression of brain stem nuclei, and compression of the medulla. The pain of CH may be associated with dysfunction in an area of the brain stem and/or craniospinal pressure dissociation, stimulating pain-sensitive structures in patients with CM-1.

Role of the insolvent connective tissue in the development of pathological deformation of cerebral vessels in patients with primary headaches

K. Khalimova, G. Rakhmatullaeva, N. Rashidova. Tashkent Medical Academy, Tashkent, Uzbekistan

**Aim:** Analysis manifestations of connective tissue disease in patients with pathological strain of cerebral vessels.

**Methods:** The study included 60 patients with primary headaches. Patients were divided into 2 groups: 30 patients with and 30 patients
without abnormalities of the brain. The examination included: clinical neurological research, the study of dysplasia on the questionnaire, MRI, MSCT angiography and duplex scanning.

**Results:** In the first group of patients with headaches started in childhood with migraine pain, the presence of signs of insolvency connective tissue, whereas in the group without anomalies at puberty or adulthood. Thus, in the first group, patients had increased extensibility, and hyper elastic skin: take the pleated skin was pulled easily by a few centimeters. There was a slight fragility of the skin, even with minimal trauma to heal slowly, leaving colloid scars. In the chronic arthralgia, there were no signs of inflammation in the joints of 13.7% of patients. Frequent complication in patients with failure of the connective tissue is a bundle of extra- or intracranial segments of the vertebral arteries, which were observed in 5 patients with basilar migraine. In the second group, in the group of patients with no signs of abnormalities of connective tissue disease was found.

**Conclusion:** 1. Revealed diffuse failure of connective tissue in patients with deformities of the brain vessels. 2. It is shown that the systemic connective tissue dysplasia is a risk factor for the development of pathological deformation. 3. To detect pathology of the connective tissue to be included in the survey design of primary headaches screening of connective tissue.

**Topic: 8 — Headache**

**Some features of neuroimaging research methods in the diagnosis of pathological tortuosity of cerebral vessels in patients with primary headaches**

K. Khelimov, M. Yakubova, G. Rakhmatullaeva, N. Rashidova, D. Kushaeva. Tashkent Medical Academy, Tashkent, Uzbekistan

**Aim:** Analysis of the advantages of MSCT angiography and duplex scanning (DS) of extracranial vessels (ECV) in the diagnosis of pathological tortuosity of cerebral vessels.

**Methods:** The analysis of MSCT angiography versus DS of ECV in the diagnosis of pathological tortuosity of cerebral vessels.

**Results:** We observed 100 patients: 60 women and 40 men aged 17–45 years. 81 patients with migraine — 81%, with a cluster headache 4% and tension-type headache 15% (15%). 35 patients were performed MSCT angiography of the brain, which revealed changes observed in 27 patients with migraine and in 1 patient with a cluster headache, in 7 patients with tension headache were detected. The deformation of blood vessels by type kinking and coiling had incidence in women — 53%, compared with men — 47%, in the internal carotid artery (ICA) — 72.3%, in the vertebral arteries (VA) — 28.7%. It was also revealed hypoplasia of the VA: 25.5% of the middle cerebral and in 13.5% of cases in the posterior communicating artery. Pathological tortuosity was presented in the form of C-shaped crimps 12% of patients, S-shaped, 14%, and looped — 8% of cases. Hypoplasias of the ICA and the VA have been observed more in patients with migraine than in patients with cluster headache.

**Conclusion:** The pathological deformation in cerebrovascular vessels has a high incidence in patients with primary headaches, and in their diagnosis invaluable role to play MSCT angiography of the brain, but with constraints, and in view of the high cost of the study is the method of choice for DS of the ECV.

**Clinical analysis of orthostatic headache in Asian patients**

M.-H. Park, D. Oh, D. Kim, Y. Choi, K. Choi, T. Nam, S. Lee, B. Kim, M. Kim. Chonnam National University Hospital, Gwangju, Republic of Korea

**Background:** The major cause of orthostatic headaches is cerebrospinal fluid (CSF) leak. But orthostatic headache also occurs in variable diseases.

**Objective:** We analyzed clinical, radiological, and etiological differences between favorable and non-favorable groups.

**Methods:** We retrospectively reviewed a group of 44 consecutive patients with orthostatic headache between January 1, 2005 and April 30, 2012. All patients underwent MRI with gadolinium enhancement while clinically symptomatic, and performed conservative therapy with analgesics. Autologous epidural blood patching was carried out in patient who did not respond to conservative therapy.

We divided these patients to two groups, favorable and non-favorable groups. More than two weeks of admission day, two more trials of autologous epidural blood patching, or relapse of orthostatic headache defined as non-favorable group.

**Results:** 21 (48%) of 44 patients were classified as a favorable group. Favorable group had short hospitalization period (7.5 days vs. 16.0 days, p = 0.009) and complain of nausea (n = 17 vs. n = 12, p = 0.031). An unfavorable group had lots of abnormal findings in brain MRI (5 vs. 19, p < 0.001). But no significant differences were found between two groups except pachymeningeal enhancement. In unfavorable group, 12 of patients (50%) showed pachymeningeal enhancement in brain MRI (3 patients in favorable group, p < 0.001). 16 of favorable group and 7 of non-favorable group were defined as normal brain MRI patients.

**Conclusions:** Orthostatic headache presenting unfavorable outcome had more brain MRI abnormalities, CSF leakage on upper spinal level. Especially pachymeningeal enhancement could be a sign of unfortunate prognosis.

**A self-help program—PROAA improves the quality of life of patients with migraine and/or tension-type headache. A 7-year follow-up**

M. Seijo-Martinez, M.J. Lozano-Lorenzo, 1Neurology, Xestion Integrada Pontevedra-Hospital do Salnes, Spain; 2Social Work, Xestion Integrada Pontevedra-Complexo Hospitalario de Pontevedra, Pontevedra, Spain

**Background:** Headache is a major medical complaint with considerable functional and economic consequences. Psycho-social factors may play a major role in primary headache. Therapeutic strategies controlling these factors may be valuable in headache therapy.

**Objective:** To evaluate the impact of a self-help program (PROAA) on quality of life (QoL) in patients with refractory migraine and/or tension-type headache.

**Patients and methods:** Prospective study between 2/01/2003 and 2/01/2010. Patients with unacceptable control of headache-symptoms, according to the treating neurologist, were included.

The PROAA program improves stress-control and anxiety. It is based on the Modeling Development Behaviour (DBM®), physical therapy
and relaxation techniques. For QoL, the SF-12 questionnaire/scale was used before and one month after the program.

**Results:** 252 patients (222 F/30 M) were included. Median age: 36.6 years. 45% had tension-type headache, 24% migraine and 15.87% both types. For all headache-types, the perceived physical health score (PPHS) before the program was 38.27 ± 9.93; after 48.94 ± 7.84 (p < 0.001). The perceived mental health score (PMHS) before the program was 31.03 ± 11.68; after 47.71 ± 8.68 (p < 0.001). For migraine: PPHS before 37.4 ± 9.96; after 48.3 ± 8.50 (p < 0.001); PMHS before 33.4 ± 12.97; after 48.4 ± 9.02 (p < 0.001). For tension-type headache: PPHS before 39.1 ± 10.30; after 48.9 ± 7.60 (p < 0.001); PMHS before 31.2 ± 10.61; after 48.2 ± 8.14 (p < 0.001).

**Conclusion:** The self-help program—PROAA significantly improves QoL in patients with migraine and/or tension-type headache and may be useful as non-pharmacological adjunct therapy.

**Topic: 8 — Headache**

**Grey matter in chronic migraine patients**

G. Zanchin, M. Margoni, M. Calabrese, F. Maggioni.

**Headache Centre of Veneto Region, Department of Neurosciences, Padua University Medical School, Padua, Italy**

**Introduction:** Previous studies have reported a thickening of the somatosensory cortex (SSC) and visual motion processing areas (V3A/MT+) in migraine without aura (MO). However, these changes have not been confirmed. In chronic migraine (CM), atrophy/thinning of amygdala, parietal operculum, middle and inferior frontal gyri, insula and anterior cingulate cortex have been observed.

**Objective:** To investigate regional cortical thickness/atrophy in CM (ICHD II, 2004) patients (CMP).

**Patients and Methods:** We compared 23 CMP (age 38.7 ± 11.5, 20 females) vs 21 controls (age 34.9 ± 4.7, 13 females). Cortical thickness was measured in 146 regions using FreeSurfer and volumetric T1 weighted images.

**Results:** Migraineurs presented a mild focal thinning of the grey matter of the right ventral posterior cingulate cortex (vpcCC) (6.4%, p = 0.014) and left pericallosal sulcus (PS) (4.7%, p = 0.046). Thickening of the left occipito-temporal gyrus (12.8%, p = 0.006), right occipito-temporal sulcus (5.7%, p = 0.048), left inferior temporal sulcus (6.0%, p = 0.023), right transversal temporal sulcus (12.4%, p = 0.016), belonging to the V3A/MT + areas, and of the left postcentral gyrus (7.0%, p = 0.034), that is part of the SCC was observed.

**Conclusion:** The thinning of several cortical regions reported in CM was not confirmed; our preliminary result of a cortical thinning of the right vpcCC and left PS, not observed previously, needs to be confirmed. Our finding of a thickening in the SCC and V3A/MT + areas, not reported in the only study performed on CM, but in keeping with previous observations in MO, supports the hypothesis that repetitive attacks could lead to neuroplastic changes in the grey matter.

Di Lorenzo. 1Anestesiology, Università di Napoli SUN, Napoli; 2Villa Florita Caserta, Caserta; ASL CASERTA PO Pietidonte Matese, Pietidonte Matese; 3Neurochirurgia A, Dipartimento di Scienze Neurologiche, Università La Sapienza Roma, Rome, Italy; 4Neuroscience Rehab Unit, A.O. ‘G. RUMMO’ Hospital, Benevento, Italy

**Purpose:** During the early years of botulinum toxin type A (BoNT-A) treatment for motor conditions, investigators noted a significant benefit of BoNT-A on pain that often exceeded the improvement in muscle contractions. Recently BoNT-A received indication for the treatment of chronic migraine (CM). In this report we analyze how ultrasound-guided techniques, allowing the visualization of tissues, potentially improve the accuracy of the needle placement exemplifying BoNT-A procedures also in the treatment of untreatable CM with onabotulinum toxin A.

**Method:** Patients with CM and inadequate response or intolerance to previous two prophylactic treatments and considered “untreatable class I CM” patients were treated with pericranial injections of about 150 UI of BoNT-A every 3 months. The dose could be increased up to 200 U in case of no response. Patients reported headache diary, MIDAS score effect of BTA on the frequency of disabling attacks, and consumption of analgesics.

**Results:** All meet the IHS criteria for analgesic overuse. The number of sessions studied with BTA was 4. Patients achieved reduction >70% in headache frequency and intensity. Those four patients reduced NSAID and analgesic consumption significantly.

**Conclusion:** US guidance provides clear advantages also in CM patient injections because it permits to visualize the spread of BTA from the needle and to validate procedure’s outcome. US guided
BoNT-A injections could be a profitable option both clinically and pharmaco-economically.

Acute administration of 5-HT precursor 5-hydroxytryptophan upregulates constitutive isoform of neuronal nitric oxide synthase activity in the rat brain
A. Sharma1, D.F. Muresanu2, H.S. Sharma1, 3Surgical Sciences, Anesthesiology & Intensive Care Medicine, Uppsala University Hospital, Uppsala, Sweden; 3Clinical Neurosciences, Medicine & Pharmacy Cluj-Napoca, Cluj-Napoca, Romania

The possibility that endogenous elevation of serotonin is influencing blood–brain barrier (BBB) permeability, neuronal nitric oxide synthase activity was examined in the brain and spinal cord of rats. Elevation of endogenous serotonin level was achieved by administration of its precursor, 5-hydroxytryptophan (150 mg/kg, i.p.). The elevation of serotonin level in the brain and spinal cord was confirmed by immunohistochemical demonstration of 5-HT activity. Four hours after administration of 5-HTP, the animals exhibited hyperthermia and other behavioral symptoms. In these animals, ultrastructural studies revealed breakdown of the BBB permeability at this time period. In 5-HTP pretreated rats, there was a marked increase in neuronal NOS labelling in the several brain regions and in the spinal cord. Morphological examination suggests profound cell injury and edema in the regions associated with NOS upregulation. These observations for the first time demonstrate that endogenous elevation of 5-HT is associated with NOS upregulation. Alternatively, 5-HT mediated cell injury, BBB disruptions are regulated by NOS, not reported earlier.

Recent concept in pathophysiology and treatment of pseudotumour cerebri (PTC)
M.H. Ibrahim. Neurology, GMC & GMU University, Ajman, United Arab Emirates

Objectives: Study the role of intracranial venous sinuses in the pathophysiology of pseudotumour cerebri.

Materials and methods: Twenty patients diagnosed as PTC according to Dandy diagnostic criteria underwent general and neurological assessment, ophthalmologic assessment, laboratory investigations were done, radiological assessment included CT scan brain ± MRI brain without contrast, and MRV of the intracranial venous system. Lastly all underwent digital subtraction cerebral angiography (venous phase) to confirm the validity of filling gaps seen at the level of MRV whether they are true stenosis or not.

Results: MRV brain showed that 14 patients (70%) showed filling gaps suggestive of sinus stenosis. However, digital subtraction cerebral angiography (venous phase) gave different data that only 5 patients (25%) had stenosis in their dural sinuses. MRV showed to be a good screening tool since it had 100% sensitivity and negative predictive value. Therefore, if MRV is normal no further investigations are needed. However, since it has a moderate specificity (62%) with a positive predictive value (PPV) of only 35%, then lesions detected should be confirmed with digital subtraction cerebral angiography (venous phase) particularly those involving the transverse and sigmoid sinus.

Conclusions: Studying the intracranial venous system in patients with PTC is an important step in understanding the pathophysiology of the disease. Detection of venous sinus stenosis opens the way to a novel therapeutic option for refractory patients like venous sinus.

Total migraine freedom (TMF) for single pulse transcranial magnetic stimulation (sTMS) versus triptans for the early acute treatment of migraine
A. Starling1, T. Bravo1, R. Chiaccchieri2, R. Lipton3, P. Goadsby4, S. Silberstein4, A. Charles4, S. Aurora4, D. Dodick4, Mayo Clinic, Phoenix, AZ, USA; 2R.P. Chiaccchieri & Associates, Rockville, MD, USA; 3Albert Einstein College of Medicine, Bronx, NY, USA; 4UCSF, San Francisco, CA, USA; 5Thomas Jefferson University Hospitals, Philadelphia, PA, USA; 6UCLA, Los Angeles, USA; 7Stanford University, Stanford, CA, USA

Background: sTMS is effective and well tolerated for the acute treatment of migraine with aura. Triptans are the gold-standard for acute treatment of migraine. No head-to-head studies have compared the efficacy of sTMS to triptans. Total migraine freedom (TMF) at two hours (2 h TMF) is a composite endpoint that incorporates freedom from pain, photophobia, phonophobia, and nausea. It is a sensitive, patient-centric, clinically relevant summary measure which more powerfully measures treatment effects than the four co-primary endpoints it incorporates.

Objective: To compare the magnitude of the treatment effect for sTMS versus triptans in randomized placebo-controlled trials using an early treatment design where treatment was administered while pain was mild.

Methods: The literature was systematically reviewed to identify placebo-controlled mild pain trials of acute migraine treatment with sTMS or triptans. We identified one sTMS study and 3 triptan trials. For each study we computed the absolute risk reductions (ARR) for 2 h TMF (2 h TMF for active, — 2 h TMF for placebo). Data was summarized including all sites and excluding a site which had a high placebo response.

Results: ARR for 2 h TMF for the sTMS study were 12.2% for all sites and 26.3% excluding a single site. For triptan trials, ARR for 2 h TMF were: rizatriptan 10 mg (27.5%), eletriptan 20 mg (10.4%), eletriptan 40 mg (41.0%), sumatriptan 50 mg, (21.4%), and sumatriptan 100 mg (28.1%).

Conclusions: TMF is a patient-centric, clinically relevant, composite endpoint. sTMS demonstrates efficacy in a range that overlaps with the triptans for this robust treatment outcome measure. Head-to-head comparative studies of triptans with sTMS are recommended.

Concomitant administration of alprazolam and ibuprofen in acute migraine headache
M. Baradaran, A. Ahmadi-Ahangar, F. Teimourian, A.-A. Moghadamnia. Babol University of Medical Sciences, Babol, Iran

Background: Migraine is a chronic neurologic disorder which a wide variety of drugs are used for its prevention and treatment. Combination
therapy has shown its efficiency in treating migraine. In this study, we have administered the combination of ibuprofen and alprazolam as a probable efficient compound.

**Material and methods:** In this clinical trial study, 90 migraine patients (with 2–6 attacks per month) were allocated in 3 groups of 30. Patients were treated with single dose of either ibuprofen 200 mg, ibuprofen 400 mg, or ibuprofen 200 mg plus alprazolam 0.5 mg. Headache severity, functional disability, and associated symptoms were recorded and before and 2 h after taking each regimen; and were scored from 0 to 3. Then three groups were compared statistically.

**Results:** There were no significant differences regarding age, gender and drug histories among the 3 groups. The severity of the headache was decreased significantly after drug therapy in all 3 groups (36%, 46%, and 74% respectively; \( P < 0.001 \)) and statistically significant decreases in patient’s pain, nausea/vomiting, photophobia, and phonophobia scores during migraine attack were observed. On the other hand, an improvement in patients’ function was seen in all treatment groups. Ibuprofen 200 mg plus alprazolam was more effective than ibuprofen 200 mg alone.

**Conclusion:** All three drug regimens (ibuprofen 200 mg, ibuprofen 400 mg, and ibuprofen 200 mg plus alprazolam; in single doses) showed efficacy in migraine treatment that are effective in treating migraine attacks. The analgesic effect of ibuprofen in migraine headache is augmented by alprazolam.

---

Migraine is a very common condition being more prevalent in females. Recent advances in medicine have demonstrated the high complexity in the clinical presentations, variable clinical features and diagnosis of this condition. Many studies have shown the overlap of signs and symptoms between migraine and stroke/transient ischaemic attacks. Here, we describe such a complex case with classical migraine headaches associated with global dysphasia. A 65 year old lady presented with unilateral left sided headache and global dysphasia. There was no convincing history of any vascular disease, head trauma or signs of infections. Collateral history from relatives eluded to sudden onset confusion noticed by the family which led to the patient’s attendance at the hospital. There was no history of head trauma, loss of consciousness, decrease in cognition, inattention, slurring of speech, motor weakness or sensory disturbance. Past medical history included previous history of migraine however she was currently not on any medication for migraine. On examination vital signs were stable with no focal neurological deficit except for expressive and receptive dysphasia that started simultaneously with the headache. Fundoscopy was normal. No negative symptoms. Neurological examination did not show any focal neurological deficits apart from global dysphasia. CT head and LP ruled out life threatening conditions. After 18 h, symptoms resolved spontaneously and patient was diagnosed to have migraine with prolonged aura of global dysphasia. We urge a high index of suspicion for atypical presentations of migraine especially with prolonged aura as these may easily be confused with stroke and transient ischaemic attacks.

**Anticephalgic photoprotective premedicated mask: A report of a successful study of a treatment for migraine and/or tension headaches**

M. Hyson. Neurology, University of Nevada School of Medicine, Las Vegas, NV, USA

**Objectives:** This study was performed to determine the efficacy of an anticephalgic photoprotective mask in conjunction with a topical medication containing *Bryonia* and *Rhus toxicodendron* in the treatment of migraine and/or tension headache.

**Background:** Many clinicians are seeking headache treatment modalities with improved safety profiles. A premedicated mask would serve not only as a delivery system for benign topical medication, but simultaneously provide photorelief and exert external pressure which may alleviate vascular headaches by collapsing painfully distended extracranial arteries and reducing peripheral sensitization.

**Methods:** Thirty-three patients were given masks and tubes of topical medication containing the *Bryonia* and *Rhus toxicodendron*. They were instructed to apply the medication to their frontalis and/or temporalis regions in the event they should suffer a headache and apply a photoprotective mask. They subsequently filled out forms rating the degree of relief which they attributed to the topical medication and the mask using a 0–10 scale.

**Results:** Thirty out of 33 patients stated that the medication and the mask were effective over and above the normal degree of relief they were receiving from their oral and/or parenteral medications. This study demonstrated a significant efficacy rate (91%) in the treatment of migraine and/or tension headache with the anticephalgic mask in conjunction with a topical cream containing *Bryonia* and *Rhus toxicodendron*.

**Conclusions:** This study demonstrated a significant efficacy rate in the treatment of migraine and/or tension headache with the anticephalgic...
mask in conjunction with a topical cream containing Bryonia and Rhus toxicodendron.

Chronification of migraineurs presenting various cervical abnormalities
K.H. Park¹, H.W. Kim², T.W. Yoo³, ⁴Neurology, Pusan National University Hospital, Republic of Korea; ⁵Korean Hand Acupuncture, Korean Hand Acupuncture Therapy, Busan, Republic of Korea

Object and Background: Despite of therapeutic approaches, some migraineurs have progression to chronic course. The chronification of migraine disturbs the quality of patient’s life. Chronic migraine headache is an enormous burden. Generally speaking there are no abnormal findings in laboratory tests in migraineurs according to the second edition of the International Classification of Headache Disorders (ICHD-2). In practice chronic migraineurs show some abnormalities in cervical spine. There are no references that chronic migraineurs have any abnormalities in cervical spine.

Subjects and methods: The procedure was performed during the physical examination from Jan. 2009 to Nov. 2012 at Dept. of Neurology, Pusan National University Hospital. The 200 patients with migraine without aura, who complained of chronic headache for more than 3 years, were included.

The exact location may be a good clue or guide to improve diagnostic accuracy, we applied Korean hand therapy method to confirm migraine headache using the location of tender points on the head and neck. Cervical spine study was included during routine laboratory tests.

Results: Among 200 chronic migraineurs, the number of female was 148, that of male was 52. Mean age was 48 years old. The X-ray finding of cervical vertebrae in migraineurs (200 persons) was various.

Conclusion: The chronic migraineurs having chronic progressive course and long periodic cycles for more than 3 years have some abnormalities on the radiological study. It may be helpful to include the cervical spine study in the chronic migraineurs and to consider the correction of cervical abnormalities for prevention of chronic processes.

Aquaporin-4 antibodies in Egyptian patients with idiopathic intracranial hypertension
N. Abokrysha, N. Kishk, L. Rashed. Cairo University, Cairo, Egypt

Background: The aetiology of idiopathic intracranial hypertension (IIH) is not clear. A dysfunction of the water channels could affect the cerebrospinal fluid (CSF) secretion or absorption and potentially contribute to its pathogenesis. Objective: is to assess the possible role of aquaporin (AQP)-4 antibody in the pathogenesis of IIH.

Subjects and methods: Eighteen symptomatic IIH patients who were diagnosed according to the updated modified Dandy criteria were selected from the Neurology Department of Kasr El-Aini Hospital, Cairo University. Detection of anti-aquaporin antibodies in their CSF samples was measured by ELISA based assay.

Results: The CSF samples of IIH patients were positive for the aquaporin (AQP)-4 antibody in 16 (88.9%) of the patients. The CSF level of AQP-4 antibodies was 15.59 ± 8.03 U/ml.

Conclusions: There are two reports investigating the anti-AQP4 antibodies in IIH. Our study contradicted the results of these reports and indicated that AQP4 antibodies have a role in IIH pathogenesis and provided some support for the contribution of inflammatory mechanisms in IIH.

The pain location for diagnosis of primary headache is closely related with Gold Meridian System of Korean Hand Therapy
K.-H.H. Park¹, T.-H.T. Kang², T.-W.T. Yoo³, ⁴Neurology, Pusan National University Hospital, Busan, Republic of Korea; ⁵Korean Hand Acupuncture, Korean Hand Acupuncture Therapy, Seoul, Republic of Korea

Background: The diagnosis of primary headache has not been sufficient for appropriate treatment. We mainly depend on the history taking and criteria of International Headache Classification. The location of headache might be crucial to diagnosis. We emphasized to manage the patient individually as personalized medicine. In Eastern Asian Medicine, there are meridian and acupuncture points on the body including on the head. It is well described but it is complicated to use easily. We need simplified meridian and acupuncture point system. We propose to use Gold Meridian and Acupuncture Points of Korean Hand Therapy to determine the location.

Subjects and methods: This procedure was performed during physical examination based on well performed history taking at Department of Neurology, Pusan National University Hospital from March 2011 to Feb. 2012. The 200 primary headache patients were included. We checked pain location on both sides and sites of head using 20 new modified acupuncture points on gallbladder meridian (CM1–12) and urinary bladder (CI1–8) on each side.

Results: The headache points are grouped such as gallbladder and urinary bladder gold meridian system, the migraine headache patients belonged to gallbladder and tension type headache belonged to urinary bladder meridian, mixed type headache belonged to various combined gallbladder and urinary bladder meridians.

Conclusion: The pain location of intractable headache patients presented as mixed form headache. The location of pains of such headache should be considered for Botox injection. We can inject small dosage of Botox injection depending on right or left exact side and sites.

HaNDL syndrome presenting during pregnancy
Y. Kaplan, S. Kamisli, O. Kamisli, H. Celik. Neurology, Inonu University, Malatya, Turkey

Background: Headache associated with neurological deficits and cerebrospinal fluid lymphocytosis (HaNDL) is a self-limited syndrome characterized by sudden-onset headache with a temporary neurological deficit and cerebrospinal fluid (CSF) lymphocytosis.
Objective: We report a case of HaNDL syndrome presented during pregnancy.

Patient: A 20-year-old female presented with a 5-day history of severe, bilateral throbbing headache accompanied by nausea, vomiting, and phonophobia. Approximately 2 days after the pain developed, she became acutely confused for less than 90 min. There were no symptoms consistent with meningoencephalitis. Her medical and family histories were unremarkable. She was pregnant and at 11 weeks gestation. A fundoscopic examination showed bilateral papilledema with no visual field defects.

The neuroradiological examination was normal. A lumbar puncture was performed. The CSF revealed lymphocytic pleocytosis, mildly elevated protein (57 mg/dL), and increased opening pressure (320 mm H2O). After excluding all other conditions that cause CSF pleocytosis and severe headache, a diagnosis of HaNDL was made.

Conclusion: HaNDL is considered a secondary headache syndrome. The precise etiology is unknown, although an inflammatory or infectious origin and autoimmune factors have been proposed. Moreover, the risk factors and medical conditions associated with HaNDL are unknown. It is obviously difficult to determine whether the pregnancy was coincidental or associated in this case. We believe that comprehensive studies are needed to clarify the risk factors and medical conditions associated with HaNDL.

Venous discirculation

A.V. Tsokolova, V.G. Senchilo, V.A. Tsokolova, A.U. Egorov, M.A. Tsokolova. 1409 Naval Hospital of the Baltic Sea Fleet, Kaliningrad, Russia

Research objective: Assessment of cerebral venous hemodynamics in children and teenagers having cranialgia with updating cause-effect relations of venous discirculation.

According to the data of ultra sonic testing (in C- and PW-modes) 109 patients (at the age from 2 to 18) were studied. It was found that discirculation in the system of vertebral veins is linked with apparent extravasal effects on bloodstream in internal jugular vein (with vessel compression on the side of vasoconstriction registration) \( r = +0.67 \), spams of posterior cerebral artery \( r = +0.63 \), coiling of internal carotid and vertebral artery \( r = +0.20, +0.32 \). In case of discirculation in the system of internal jugular vein, the changes mentioned are interrelated with extravasal compression on the level of internal jugular vein surrounding soft tissues or compression in the bone canal \( r = +0.76 \), anterior cerebral artery spams, hyperperfusion of vertebral and posterior cerebral artery \( p < 0.05 \). Intracranial venous discirculation depends on the straightness of vertebral artery in the bone canal \( r = +0.33 \), discirculation intensity on the level of vertebral vein \( \text{Vmax right} r = +0.73, p > 0.05 \).

Vasoconstriction in the vein of Galen is accompanied by ipsilateral hypersthenia of vertebral, internal carotid and middle cerebral artery (reflexory changes), and is also interrelated with flexures, sigmoid coiling of internal carotid artery.

The link of “headache syndrome” with accelerated venous blood flow along the veins of Galen turned out to be quite low \( r = +0.22 \).

Conclusion: Main causes of children’s vasoconstriction are either congenital pathology of cervical spine (with araucation and tortuosity of bone canal), or “birth injuries with pseudo-luxation of cervical vertebrae”.

Idiopathic hypertrophic cranial pachymeningitis: A rare cause of chronic headache and progressive cranial neuropathies: A case report

M.G.B. Laguerta\(^a\), E. Esposo\(^b\), B. Mariano\(^b\), M.S. Martinez\(^c\).
\(^a\)Internal Medicine, St. Luke’s Medical Center, Quezon City, Philippines; \(^b\)Neuro-Ophthalmology, St. Luke’s Medical Center, Quezon City, Philippines; \(^c\)Neurology, St. Luke’s Medical Center, Quezon City, Philippines

Background and objective: We report a case of a 75-year-old male with chronic daily headache for more than one year and later on developed deafness, vocal cord paralysis, ophthalmoplegia, and loss of vision. On physical examination, there was ptosis and left gaze palsy, pale optic disc, only light perception on both eyes, weak gag reflex and gross hearing loss.

Methods: Work up included cranial MRI that revealed abnormal pachymeningeal enhancement or thickening of the dura in the posterior fossa, cavernous sinus and orbital apex and bilateral mastoiditis. CSF analysis showed elevated CSF protein, negative results for AFB, KOH, VDRL, TB and bacterial culture, and no malignant cells. ANCA, ANA and ESR were negative. Search for occult malignancies was negative. There was elevated ESR, consistent with an inflammatory process.

Idiopathic hypertrophic pachymeningitis is a rare chronic fibrosing inflammatory disease characterized by marked diffuse thickening of the cranial dura that causes progressive neurological deficits by compression of anatomic structures by the meninx, thickened by inflammation.

Results: After initiation of pulse corticosteroid therapy, methotrexate and maintenance oral prednisone, there was remarkable improvement on hearing, swallowing, and ocular muscle movement, less headaches and marked regression of pachymeningeal enhancement on repeat MRI. However, profound vision loss remained unchanged.

Conclusion: A high index of suspicion of this rare disease is important because early institution and long-term maintenance of steroid may result to complete or partial remission of the neurologic deficits and may help prevent irreversible neurologic sequelae, especially blindness.

Life without pain—A family presenting with HSAN type 1 and dementia
M. Shehu\textsuperscript{a}, P. Oflazer\textsuperscript{b}, A. Shala\textsuperscript{b}. \textsuperscript{a}Regional Hospital ‘Prim. Dr. Daut Mustafa’, Prizren, Kosovo, \textsuperscript{b}Clinic of Neurology, University of Istanbul, Istanbul, Turkey

Hereditary sensory autonomic neuropathy type 1 (HSAN I) is a neurological disorder characterized mainly by distal sensory loss and autonomic symptoms. This autosomal dominant inherited disorder manifests typically during the 2nd–4th decades of life. This case report presents four family members who among the classic features of HSAN I also developed deafness and dementia. We had the opportunity to examine only one member, while the data for other three members were taken retrospectively as they were dead at that time. The four of them, father and three sons, presented with similar clinical findings: sensory disturbances in lower extremities which began during their twenties followed by painless ulcerations in these areas. Shortly after, hearing difficulties progressing to deafness appeared and by late thirties their clinical condition deteriorated further with dementia. All patients died before the age of fifty. The absence of sensory nerve action potentials characterized the EMG of the examined patient, while a predominant frontal atrophy was evident on his head MRI. Dementia is a very rare finding in HSAN type I disease course. Currently, only few cases that have occurred in Japan and USA are described in literature.

Differential endogenous pain modulation in patients with neuropathic pain after spinal cord injury correlates with contact heat evoked potential amplitude  
Sensorimotor Function Group, Hospital Nacional de Parapléjicos, Toledo, Spain  
Background: Central neuropathic pain (NP) is associated with change in endogenous pain modulation (EPM) evoked by hetero-topic noxious conditioning stimulation (HNCs).  
Objective: Characterise EPM disruption in patients with NP following spinal cord injury (SCI) and its relationship with contact heat evoked potentials (CHEPs).  
Methods: Ten healthy subjects and 20 patients with SCI (injury level below Th2) were recruited, 10 of which presented non-evoked NP (>5/10 NRS). Cz/Fz-CHEPs with corresponding perception of evoked heat pain (EvHP) from the C6 dermatome were assessed. Test stimulation (TS) was a 30 s tonic heat stimulus with the plateau intensity set individually at the temperature that evoked 3/10 (0–10, NRS, “pain-3”). The HNCs was a 30 s immersion of the contralateral hand in an innocuous (33 °C) or painful (12 °C) water bath. Subjects performed three protocols: non-conditioned TS; innocuous-HNCS TS and noxious-HNCS TS. TS pain intensity was assessed at 10 s (t1), 20 s (t2) and 30 s (t3).  
Results: Significant net t1 EPM of TS intensity was evoked in the healthy (−1.0 ± 0.3; p < 0.01) and SCI-noNP groups (−0.8 ± 0.3; p < 0.05), but not in the SCI-NP group (+0.2 ± 0.3; p > 0.05). Mean net t1–t3 EPM was different between the healthy and SCI-NP groups (p = 0.04). Importantly mean net t1–t3 EPM correlated highly with the CHEP amplitude only in patients with SCI-NP (ρ = 0.8; p = 0.015), suggesting that disruption of EPM following NP may be quantified with this objective biomarker of pain perception.  
Conclusion: Endogenous inhibitory pain modulation is lost in subjects with SCI NP and is reflected by an increase in sensory evoked potentials in response to contact heat stimulation.

Palliative care for HIV/AIDS in Kenya  
R.N. Mbuguaabc, B.A. Elizabetha, d, e Research, Kenya Medical Research Institute, Nairobi, Kenya, b Research, Nairobi University, Nairobi, Kenya, c Clinical Research, Kenyatta National Hospital, Nairobi, Kenya, d Obstetrics and Gynaecology Clinical Research, Nairobi University, Nairobi, Kenya, e Obstetrics and Gynaecology Clinical Research, Family AIDS Care and Education Services (FACES), Nairobi, Kenya  
Background: Patients with HIV/AIDS on Antiretroviral Therapy (ART) suffer from physical pain, psychological and spiritual problems. Despite international policy explicitly stating that a multidimensional approach such as palliative care should be delivered throughout the disease trajectory and alongside treatment, the effectiveness of this approach has not been tested in ART-experienced populations.  
Methods: This mixed methods study uses a Randomised Controlled Trial (RCT) to test the null hypothesis that receipt of palliative care in addition to standard HIV care does not affect pain compared to standard care alone. An additional qualitative component will explore the mechanism of action and participant experience. The sample size is designed to detect a statistically significant decrease in reported pain, determined by a two tailed test and a p value of ≤0.05.  
Results: Recruited patients will be adults on ART for more than one month, who report significant pain or symptoms which have lasted for more than two weeks. The intervention under trial is palliative care delivered by an existing HIV facility nurse trained to a set standard. Following an initial pilot the study will be delivered at Kenya Medical Research Institute, using two parallel independent Phase III clinical RCTs. Qualitative data will be collected from semi structured interviews and documentation from clinical encounters, to explore the experience of receiving palliative care in this context.  
Conclusion: The data provided by this study will provide evidence to inform the improvement of outcomes for people living with HIV and on ART in Africa.

Preoperative intradermal acupuncture reduces postoperative pain, nausea and vomiting, analgesic requirement and sympathoadrenal responses  
E. Philip. University of Ghana, Accra, Ghana  
Background: In a controlled and double-blind study, preoperative insertion of intradermal needles at acupoints 2.5 cm from the spinal vertebrae (bladder meridian) provides satisfactory postoperative analgesia.  
Methods: Enrolled patients scheduled for elective upper and lower abdominal surgery. Before anesthesia, patients undergoing each type of surgery were randomly assigned to one of two groups: acupuncture (n = 50 and n = 39 for upper and lower abdominal surgery, respectively). In the acupuncture group, intradermal needles were inserted to the left and right of bladder meridian 18–24 and 20–26 in upper and lower abdominal surgery before induction of anesthesia, respectively. Postoperative analgesia was maintained with epidural morphine and bolus doses of intravenous morphine. Incisional pain at rest and during coughing and deep visceral pain were recorded during recovery and for 4 days thereafter on a four-point verbal rating scale.  
Results: Starting from the recovery room, intradermal acupuncture increased the fraction of patients with good pain relief as compared with the control (P < 0.05). Consumption of supplemental intravenous morphine was reduced 50%, and the incidence of postoperative nausea was reduced 20–30% in the acupuncture patients who had undergone either upper or lower abdominal surgery (P < 0.01) and epinephrine concentrations were reduced 30–50% in the acupuncture group during recovery and on the first postoperative day (P < 0.01).  
Conclusion: Preoperative insertion of intradermal needles reduces postoperative pain, the analgesic requirement, and opioid-related side effects after both upper and lower abdominal surgery.

Duloxetine-induced life-threatening long QT syndrome
M. Stuhec. Clinical Pharmacy, Psychiatric Hospital Ormoz, Ormoz, Slovenia

Background: There are few reports of cardiovascular adverse effects of DH.

Objective: The present article describes a case of prolonged QTc and life-threatening arrhythmias in patient treated with DH.

Patients and methods: A 52-year-old Slovenian female was admitted in 2012 to hospital, because of resistant major depressive disorder (MDD). Her medications previous to hospitalization included bupropion 300 mg daily (BUP). There was no family history of sudden cardiac death. Treatment with DH titrated from 30 mg to 90 mg daily was introduced in the hospital, which was followed by gradual symptoms improvement (QTc = 388 ms, normal heart rate and blood pressure). After two months of this treatment, palpitations and loss of consciousness were reported with increased heart rate (76 bpm), sinus arrhythmia and prolonged QT (QTc = 460 ms) interval. Clinical pharmacist advised dose reduction to 30 mg of DH daily. After a one-week dose reduction of DH to 30 mg daily, cardiovascular status returned to normal (QTc = 398 ms, 65 bpm). She left hospital 2 weeks later.

Results: These findings were attributed to adverse effect associated with DH use. Symptoms of MDD were treated successfully. CYP2D6 has a major role in the metabolism of BUP, so we believe that pharmacokinetic drug interaction with DH and BUP occurred, which led to toxic concentration of DH.

Conclusion: In conclusion, even though DH is generally known to be a well-tolerated and safe drug, physicians and clinical pharmacists should be aware of the risk of cardiovascular adverse effects.

Material and methods: The von Frey test and plantar test were performed to examine noxious sensitivity of the skin. Sensory nerve fiber densities were assessed in the basal epidermal layer and expression levels of NGF, TRPV1, and P2X3 in the epidermis were examined by immunohistochemical methods.

Results: In the skin of immobilized rats, both myelinated A fibers and unmyelinated C fibers were increased. NGF, TRPV1, and P2X3 expression levels in the epidermis were also increased. Although, the expression levels of NGF did not show a meaningful change through the immobilization periods, other changes became remarkable, depending on the period of immobilization.

Conclusion: Our results suggest that changes in peripheral nerves, NGF, TRPV1 and P2X3 in skin might be partly responsible for immobilization-induced pain.

Three dimensional computerized mobilization of the cervical spine for the treatment of chronic neck pain and associated headache
Y. Rivera1, S. Aharoni2, 3, Physical Therapy, Hillel Yaffe Medical Center, Hadera, Israel, 1Hillel Yaffe Medical Center, Hadera, Israel

Background: Physical therapy has been successfully used for the treatment of chronic neck pain (NP).

Objective: Investigate the safety and efficacy of computerized mobilization of the cervical spine in 3-dimensional space for the treatment of chronic NP.

Methods: Pilot, open, non-controlled, trial utilizing the Occiflex device (Headway Ltd. Misgav, Israel). We recruited patients with chronic NP due to facet joint disorder, myofascial pain syndrome, and whiplash injury. We excluded patients with myelopathy or radiculopathy. Treatment sessions lasted 20 min, twice a week, for 6 weeks. We evaluated patients with weekly visual analog score (VAS), neck disability index (NDI), neck range of motion (CROM), and joint position error (JPE).

Results: We recruited 7 women and 2 men, with a mean age of 50.5 ± 13.5 years. Treatment was not associated with any significant adverse effects. Comparing baseline to the last week of the trial (6), pain scores dropped by 2.9 VAS points (p < 0.01); CROM increased by 11% on the average of the 6 combined movements (p = 0.01); NDI showed significant reduction (p = 0.03); JPE significantly decreased at the end of the study (p < 0.05). Five out of 7 patients with concomitant headache (tension type headache, migraine, and cervicogenic headache) reported that their headache improved during the trial and 2 weeks following treatment completion.

Conclusions: Preliminary results of this trial show that computerized mobilization is safe and potentially effective for the treatment of chronic neck pain and associated headache. The co-occurrence of neck pain and headache and their response to treatment, suggests shared pathophysiological mechanisms.

Analgesic efficacy of fulranumab in patients with painful diabetic peripheral neuropathy in a randomized, placebo-controlled, double-blind study
H. Wang1, 2, G. Romano3, 4, M.E. Frustaci5, P. Sanga6, 3, 7, 8, 9, L. I. Russell1, 2, 4, M. Fedgchina1, K.M. Kelly1, J. Thippawong6, 7, 8, 9, “Janssen Research & Development, LLC, Titusville, NJ, USA,” Janssen Research & Development, LLC, Spring House, PA, USA, 3Janssen Research & Development, LLC, Fremont, CA, USA

Background: Nerve Growth Factor (NGF) antibodies offer a potential treatment option in diabetic peripheral neuropathy (DPN).

Objective: To evaluate analgesic efficacy of fulranumab in patients with painful DPN.

Patients and methods: Phase-2 study with a 12-week double-blind (DB) efficacy-, 40-week DB safety extension-, and 52-week open-label safety extension phase. Patients with moderate-to-severe pain, stratified by concomitant treatment for neuropathic pain (yes/no), randomly (3:2:2:3) received placebo or fulranumab (1 mg-, 3 mg-, or 10 mg; −2.44; 0.06). 30% responder rates at week-12 were: placebo, 21%; 1 mgQ4wk, 44%; 3 mgQ4wk, 43%; and 10 mgQ4wk, 61%. Secondary efficacy endpoints showed dose-
related improvement trends. Most common (≥5 patients) adverse events for total fulranumab-treated patients vs. placebo were: peripheral oedema (11% vs. 0%), arthralgia (11% vs. 13%), and diarrhoea (9% vs. 8%). No cases of joint replacement or deaths were reported.

**Conclusions:** Despite early study termination, fulranumab treatment resulted in dose-dependent efficacy and was generally tolerable.

**Abstract — WCN 2013**

**No:** 1068

**Topic:** 9 — Pain

**Pregabalin beneficial effects on sleep quality or health-related quality of life are poorly correlated with reduction on pain intensity**

**Background:** Pregabalin (PGB) has been shown to improve sleep quality and Health-related Quality of Life (HRQoL) as well as pain intensity in neuropathic patients.

**Objectives:** To explore the magnitude of the correlations between changes in pain intensity, sleep quality and HRQoL after PGB treatment.

**Methods:** 138 patients suffering from neuropathic pain of any origin and without an adequate response to analgesics received an 8-week treatment course of PGB in an open-labeled fashion. Pain intensity, sleep quality and HRQoL outcomes were evaluated at baseline and at week 8 by means of a numerical rating scale (NRS), the Pittsburgh Sleep Quality Index (PSQI) and the EuroQol health-state visuoanalogic (EQ-5D VAS) score, respectively.

**Results:** At week 8, mean PGB dose was 166.7 ± 7.8 mg/day. Pain intensity NRS score, PSQI total score and EQ-5D VAS score were improved by 66.5 ± 1.9%, 40.0 ± 3.6% and 26.4 ± 4.7% (all p < 0.01) respectively. Correlations between percent change from baseline in pain NRS score and PSQI total score or EQ-5D VAS scores were r = 0.36 (p < 0.01, R² = 0.11) and r = −0.20 (p < 0.02, R² = 0.05) respectively. A multivariate logistic regression analysis disclosed that PSQI score change below the median was not (1.58 [0.78–3.23]).

**Conclusion:** Improvement in sleep quality and HRQoL were marginally related to reductions in pain intensity in neuropathic patients. Improvement in sleep quality was significantly lower. This fact leads to the improvement of the quality of PD patient’s life.

**Clinical characteristics of toxin in Japanese poisonous Clitocybe acromelalga mushroom**

S. Okawa, M. Matsuda, M. Sugawara, A. Kitabayashi, J. Kuroki, H. Ohnishi. ¹Neurology, Akita University Graduate School of Medicine, Akita, Japan, ²Internal Medicine, Akita Kumiai General Hospital, Akita, Japan, ³Internal Medicine, Yuru Kumiai General Hospital, Yurihonjo, Japan

**Background:** Erythromelalgia has been reported in cases of mushroom poisoning with Clitocybe acromelalga in Japan and South Korea, and Clitocybe amoenolens in France and Italy; however, the detailed clinical features have not been well described in the English-language literature. The responsible toxin remains undetermined, although acromelic acid isolated from both species is regarded as a candidate.

**Objective:** To find the clinical characteristics of the toxin in C. acromelalga.

**Patients and methods:** We analyzed the clinical course of three patients with the poisoning. Their ingested mushrooms were identified as C. acromelalga, with inspection by specialists and mass spectrometric determination detecting acromelic acid.

**Results:** Intervals between ingestion and onset were 1, 3, and 5 days, respectively. Alldynia was more severe in the fingers and toes, but redness and swelling were absent. Severe arthralgia was provoked by motion in all joints of the extremities, so much so that the patients could hardly move their limbs as if suffering from quadriplegia. Pain occurred also in the neck, auricles, tongue, and pharynx, causing dysphagia in two patients. Three weeks after onset, the alldynia disappeared, but multiple arthralgias persisted, resisting medications in the two patients. Scores on the 100-mm visual analog scale were 52 mm and 73 mm, respectively, 3 months after onset, and then decreased gradually over several months.

**Conclusions:** The toxin in C. acromelalga does not necessarily cause erythema. It can exert its effects several days after being ingested, and affect sensory nervous systems originating from various body parts, characteristically including joints.

**Abstract — WCN 2013**

**No:** 969

**Topic:** 9 — Pain

**One year follow-up study on pain in patients with Parkinson Disease**

**Background:** Pain is recognized as a non-motor symptom in Parkinson Disease (PD). There is musculoskeletal, neuritic, radicular or dystonia-associated pain.

**Patients and method:** We enrolled in our study 72 patients (30 men and 42 women) with idiopathic PD. They were on stages 2 to 4 on Hoehn–Yahr Scale. They had stable dose of l-dopa 3 months prior to study (average dose 875 mg/day) and no other disease responsible for the pain. We assessed the intensity of the pain using the 5-Point Verbal Rating Scale (VRS-5), 6 Point Behavioral Rating Scale (BRS-6) and 11-Point Box Scale (BS-11). Most of our patients suffered from musculoskeletal pain and dystonia-associated pain. We slowly reduced total daily l-dopa dose from average dose of 875 mg/day to average dose of 785 mg and we concomitantly introduced dopamine agonist ropinirole extended release 2 to 16 mg/day (average dose 7.25 mg/day). The intensity of pain was assessed at the beginning of the study after 6 months and one year later. The results were analyzed by Student’s Test.

**Results:** 12% of patients did not present pain, 42% of them had mild pain, 32% discomforting pain and 14% distressing pain. At the beginning of the study we obtained 4.2 BRS6 Score and 7.9 BS11 Score. One year later our PD patients showed 3 BRS6 Score and 4.2 BS 11 Score.

**Conclusion:** By adding dopamine agonist and reducing l-dopa daily dose the intensity of pain in PD patients can be significantly lowered. This fact leads to the improvement of the quality of PD patient’s life.

Reduction of thalamic tremor with deep brain stimulation performed for post stroke chronic central pain
aMedical University of Lublin, Medical University of Lublin, Lublin, Poland, bDepartment of Neurosurgery, Medical University of Lublin, Lublin, Poland, cDepartment of Neurology, Medical University of Lublin, Lublin, Poland

Background: Deep brain stimulation (DBS) for the treatment of medically intractable pain has been in use for nearly 60 years. This experience was supported by later observations that electrical stimulation of the thalamus or thalamotomy could alleviate or arrest limb tremor. Presently DBS of the sensory thalamus and the periventricular/periaqueductal grey area complex may be applied for treatment of intractable neuropathic pain syndrome.

Objective: To present the patient who underwent the DBS surgery for chronic central pain (with stimulation of the periventricular/periaqueductal grey matter and ventropostrolateral thalamic nucleus) and experienced alleviation of thalamic tremor.

Patients and methods: We present a patient who experienced ischemic stroke within the posterolateral part of left thalamus with subsequent severe burning pain localized in right upper limb, predominantly within the hand and thalamic tremor which occurred 4 months after stroke. After 2 years of ineffective treatment the patient was offered implantation of electrodes to the periventricular grey matter (PVG)/periaqueductal grey matter (PAG) as well as implantation an electrode to ventropostrolateral thalamic nucleus (VPL).

Results: Soon after starting simultaneous PAG/PVG and PVL stimulation we observed significant alleviation of the patient’s thalamic tremor in the hand, which persisted over subsequent months. We discuss possible mechanism underlying tremor suppression in our patient, probably at the level of cerebellar outflow pathways.

Conclusions: The study highlights the fact that DBS provide more insight into the functional anatomy of the thalamus, which used to be available from animal studies only.

Control of chronic pain by the ubiquitin proteasome system
T. Yakovleva, M.H. Ossipovb, A.S. Ahmedc, C. Bakalkinb. aDepartment of Pharmaceutical Biosciences, Uppsala University, Uppsala, Sweden, bUniversity of Arizona Health Sciences Center, Tucson, AZ, USA, cKarolinska University Hospital, Stockholm, Sweden

Chronic pain is maintained by long-lasting neuroplastic changes in synapses and several proteins critical for synaptic plasticity are degraded by the ubiquitin–proteasome system (UPS). Here, we show that proteasome inhibitors prevented the development and reversed nerve injury-induced pain behavior. Proteasome inhibitors blocked mechanical allodynia and thermal hyperalgesia in three pain models although they did not modify responses to mechanical stimuli, but partially inhibited responses to thermal stimuli in control rats. The effects of proteasome inhibitors on chronic pain were apparently mediated through several cellular mechanisms indispensable for chronic pain, including those of dynorphin A release and postsynaptic actions, and of CGRP secretion. Levels of several UPS proteins were reduced in animals with neuropathic pain, suggesting that UPS downregulation, like effects of proteasome inhibitors, counteracts the development of chronic pain. The inhibitors did not produce marked or disabling motor disturbances at doses that were used to modify chronic pain. These results suggest that the UPS is a critical intracellular regulator of pathological pain, and that UPS-mediated protein degradation is required for maintenance of chronic pain. Furthermore, in adjuvant-induced arthritis and experimental osteoarthritis models the inhibition of proteasome reversed the pain behavior and also reduced the severity of arthritis and joint destruction. Our findings suggest that nontoxic proteasome inhibitors may represent a novel pharmacotherapy for chronic pain.

Effects of arterial hypertension on the electromyographic data in patients with injuries of nerves
F. Devlikamova, D. Safina, A. Rogozhin. Kazan State Medical Academy, Kazan, Russia

Background: Puncture techniques—nucleoplasty and radio frequency denervation—have recently been widely used for the treatment of pain syndrome caused by intervertebral disc protrusion.

Objective: The purpose of the study was to assess the effectiveness of nucleoplasty and radio frequency denervation of intervertebral joints as advanced minimally invasive surgical techniques for alleviating pain in the case of intervertebral disc disease, spondylarthrosis and other vertebroneurologic diseases accompanying degenerative disc disease.

Materials and methods: All patients had a history of pain syndrome for not less than 3 months and were followed up after undergoing minimally-invasive procedures for a year. To assess the effectiveness the Visual Analogue Scale and Treatment Satisfaction Scale were used. 81 patients, aged between 30 and 57 years, underwent nucleoplasty and radio frequency denervation. 70 patients of control group were treated therapeutically.

Results: No complications were noted. At a 12 month follow-up all operated patients showed the decrease of pain syndrome intensity according to the Visual Analogue Scale (p < 0.0001), and treatment satisfaction scores were higher compared to patients treated therapeutically (p < 0.001).

Conclusions: Minimally invasive electrosurgical techniques appeared to be safe and effective in the treatment of carefully selected patients suffering from low back and leg pains caused by a degenerative-dystrophic process. Nucleoplasty technique is more effective in younger patients. Procedures performed at several levels also resulted in marked clinical improvement. Primary advantages of these techniques were their safety and efficacy, minimal invasiveness and the absence of a peridural scar. They do not complicate further microsurgical intervention.

doi:10.1016/j.jns.2013.07.1848
Introduction: The structural changes in vasa nervorum in hypertensive rates are similar to the changes in vessels of the brain that can lead to ischemia of the peripheral nerves (Sabbatini M, et al., 1996).

Methods and materials: Thirty nine patients (31 men and 8 women, average age—48.1 ± 1.7) with trauma of nerve (in the period from 3 months to 1 year after the injury) and neuropathic pain have been surveyed: 23 patients with arterial hypertension (AH), 16 patients without AH. Nerve conduction study of injured nerves and neuropathic pain scale were assessed in all patients.

Results: Intensity of neuropathic pain in the group with AH was 33.0 ± 2.6, in the group without AH—51.0 ± 1.9 (p < 0.01). Amplitudes of M-response (M ± m, mV) in patients with and without AH were as follows: n. musculocutaneous—21.1 ± 1.2 and 4.6 ± 1.0, n. supraspinal—1.1 ± 0.4 and 1.3 ± 0.1, n. axilaris—1.7 ± 1.2 and 4.9 ± 1.2, n. medianus—1.5 ± 0.4 and 1.9 ± 0.5, n. ulnaris—1.9 ± 0.4 and 1.6 ± 0.5, n. radialis—1.4 ± 0.3 and 1.7 ± 0.3. Motor conduction velocities (M ± m, m/s) in patients with and without AH were as follows: n. medianus—28.9 ± 2.8 and 38.7 ± 1.7, n. ulnaris—28.5 ± 2.3 and 36.5 ± 2.9, n. radialis—24.9 ± 4.3 and 39.4 ± 1.7. Motor conduction velocity was slower in the group of patients with AH (p < 0.01). The amplitude of M-response did not depend on AH (p > 0.05).

Conclusions: Our data suggests that arterial hypertension in patients with traumatic neuropathy can predispose for more severe nerve injuries and more intensive neuropathic pain.

doi:10.1016/j.jns.2013.07.1851
**Objective:** The aim of the presented study was analyzing the forms of epilepsy with algic seizures, its etiology and localization of ictal (seizure) patterns on the EEG.

**Patients and methods:** Among the patients investigated and treated in the Psycho-Neurological Department N2 of RCCH at the period 2006–2012 years were revealed 15 children with algic seizures fixed by video-EEG monitoring.

**Results:** The group of patient (n = 15) consists of 9 girls and 6 boys (age range 11 month–14 years) suffered with algic seizures: somatosensory algic seizures—6 patient, ictal headache—5, somatosensory + headache—2, headache + vomiting + ictal amnesia—1 and ictal abdominal pain—1 girl. The etiology of epilepsy was symptomatic in 10 cases (Kozhevnicov–Rasmussen encephalitis—2 cases, case of Kozhevnicov epilepsy, Sturge–Weber syndrome, dysembryoplastic neuroepithelial tumor (DNET), focal cortical dysplasia (FCD), post-traumatic epilepsy, hippocampal sclerosis and diffuse hypoxic–ischemic encephalopathy), cryptogenic in 3 cases and also in 3 patients—idiopathic (Panayiotopoulos syndrome—2, and migraine–epilepsy). Ictogenic brain regions were temporal in 4 cases, occipito-posteriortemporal—4, occipital—3, parieto-temporal—2 and parieto-central—also in 2 patients.

**Conclusion:** Epileptic seizures of pain are rare but not so casuistic condition. Epileptic cerebral mechanism of pain must be considered by neurologists and other clinicians. This group of patients needs specific therapy with antiepileptic drugs and sometimes in symptomatic cases with pharmacoresistance–epileptic surgery.

**Fibromyalgia: Another clinical feature of generalized pain syndrome?**

A.A. Karapetyan, H. Manvelyan, Family Medicine, Yerevan State Medical University after M. Heratsi, Yerevan, Armenia, Neurology, Yerevan State Medical University, Yerevan, Armenia

**Background:** Fibromyalgia (FM) is underestimated neurological disorder characterized by widespread pain on axial skeleton and body, with typical symmetrical tender points. Considered as a disease or syndrome, FM is estimated to affect 2–4% of the population, although the vast number of patients with FM is being diagnosed by 5th year of suffering.

**Objective:** Our aim was to reveal potential comorbidities in patients with FM.

**Material and methods:** 123 patients with confirmed diagnosis of FM, 70 females and 53 males, age 51 ± 15 years, were evaluated for comorbidities: Hypothyreosis, Tension Type Headaches (TTH), Chronic Fatigue Syndrome (CFS), Irritated Bowel Syndrome (IBS) and Hyperhomocysteinemia.

**Results:** CFS was found in 96 patients (78%), Hyperhomocysteinemia was found in 68 patients (55%), Hypothyreosis (including Hashimoto type) was found in 42 patients (34%), TTH was established in 82 patients (66%) and IBS in 15 (12%). Most of the patients indicated the serious impact of the pain in their quality of life and everyday activities.

**Conclusion:** All patients with FM need thoughtful evaluation for possible comorbidities. Although FM has distinct diagnostic criteria, most of the patients with FM were suffering of other discreet comorbidities, including thyroid dysfunction, elevated level of homocysteine and Tension Type Headaches, some had different combination of several. In our opinion, FM with those comorbidities must be considered as part of Generalized Pain Syndrome, and each patient with TTH must be additionally evaluated for FM also. In-time diagnostics and clinical evaluation for other features of Generalized Pain Syndrome are paramount for successful management.

**Lower trunk brachial plexopathy by lung mass, demonstrated with ultrasound**

H.K. Park, M.-W. Kim, Department of Rehabilitation Medicine, Catholic University of Korea, Catholic Medical Center, Seoul, Republic of Korea, Department of Rehabilitation Medicine, Catholic University of Korea, Catholic Medical Center, Incheon, Republic of Korea

The brachial plexus supplies most of the upper extremity. Due to its large size and superficial location, it is vulnerable to trauma, and it can be influenced secondarily by neighboring structures affected by skeletal, pulmonary, or vascular disease. We report a case of brachial plexopathy caused by a lung mass, discovered by ultrasound. A 45-year old man had complained of right scapular area pain over 6 months, and right hand grasp power weakness developed. He had conservative care including physical therapy, injection and acupuncture, but his symptoms aggravated. To rule out cervical radiculopathy, he was referred to our department for electrodiagnostic test, and the test was performed at 5 months after the onset. The findings of the electrodiagnostic test were compatible with injury of lower trunk of brachial plexus. Ultrasound imaging study revealed collapsed right internal jugular vein by a remarkable mass. Shortly afterward, a head & neck angio (CE) 3D MDCT and MRI were done, and a lung tumor was found in the right lung apex and supraclavicular region, sized 4.5 times 4 cm. The lung mass caused the scapular pain and brachial plexopathy.

Ultrasound is an effective and established technique in musculoskeletal imaging, and by using ultrasound in brachial plexus imaging, we could access each individual components of the brachial plexus continuously by shifting the probe back and forth. Therefore, it will be helpful for physical medicine and rehabilitation specialists to be familiar with brachial plexus, using ultrasound.

**The results of anxiolytic treatment in patients with chronic vertebrogenic low back pain syndrome**

K. Tsurko, V. Chyzhyk, V. Velugina, T. Rudkouskaya, M. Khitrun, P. Buiko, Chair of Neurological and Neurosurgery Diseases, Belarusian State Medical University, Minsk, Belarus

**Background:** Accompanying increase in levels of anxiety and depression in patients with chronic low back pain has negative influence on course of primary disease.

**Objective:** To study effects of anxiolytic therapy in patients with chronic vertebrogenic low back pain syndrome.

**Material and methods:** 30 patients with chronic vertebrogenic low back pain syndrome were divided onto 2 groups:

1st group received standard protocol treatment,
2nd—standard protocol treatment and Tenoten.

During the 60 day observation period patients had four visits (days 0, 7, 30, 60). On each visit patients underwent neurological examination;

Grey matter changes in chronic pain patients with and without unilateral non-dermatomal sensory deficits (NDSDS)
F. Riedere, G. Landmann, A.R. Gantenbein, L. Stockinger, N. Egloff, H. Sprott, W. Schleinzer, S. Kollias, P.S. Sandor, Neurology, Neurological Center Rosenhugel, Vienna, Austria, aUniversity Hospital Zurich, Zurich, Switzerland, bPain Clinic Nottwil, Swiss Paraplegic Centre, Nottwil, Switzerland, cPsychosomatic Division, C.L. Lory-Haus, Department of General Internal Medicine, Inselspital, University Hospital Bern, Bern, Switzerland, dSchmerzzentrum Basel, Basel, Switzerland, eNeuroradiology, University Hospital Zurich, Zurich, Switzerland, fNeurology, RehaClinic, Bad Zurzach, Baden, Switzerland

Background: About 20–40% of chronic pain patients have widespread sensory deficits often in hemisensory distribution ipsilateral to the site of pain, a phenomenon termed non-dermatomal sensory deficits (NDSDs). Patients with NDSDs show no pathological findings in standard investigations, but decreased activity in the sensory system has been found in PET and fMRI studies.

Objectives: Cerebral grey matter changes were investigated in chronic pain patients with and without NDSDs compared to healthy controls (HC) using voxel-based morphometry.

The effect of lithium on painful diabetic neuropathy in streptozotocin-induced diabetic rats
H.R. Banafshe, G.A. Hamidi, M. Brahimi, aDepartment of Pharmacology, Kashan University of Medical Sciences, Kashan, Iran, bPhysiology Research Center, Kashan University of Medical Sciences, Kashan, Iran

Background: Lithium is widely used in treatment of bipolar disorder as a mood stabilizer. Recently, increasing body of evidences report the neuroprotective effects of lithium against cell injuries caused by different noxious stimuli in cultured cells and animal model of neurodegenerative diseases.

Objective: The present study was conducted to determine the effect of acute and chronic administration of lithium on pain-related behavior in a rat model of peripheral diabetic neuropathy.

Material and methods: Animal studies were carried out on male Wistar rats. All experiments followed the guidelines on ethical standard for investigation of experimental pain in animals. Diabetic neuropathy was induced by a single injection of 60 mg/kg streptozotocin. From the seventh day after the induction of neuropathy, the neuropathic rats received lithium intraperitoneally (5, 10 and 15 mg/kg/day) for ten days. The behavioral scores of neuropathic pain were measured on the first day before the induction of neuropathy as control and before and after lithium administration. The radiant heat plantar and von Frey filament test were used for the assessment of heat hyperalgesia and mechanical alldynia as behavioral scores of neuropathic pain.

Results: Chronic administration of lithium decreased mechanical alldynia scores with dose of 10 and 15 mg/kg in diabetic rats significantly but the acute administration of lithium did not change the behavioral scores of neuropathic pain.

Conclusion: Our results suggest that lithium reduces the behavioral scores of diabetic neuropathic pain and can be considered as a new therapeutic potential for painful diabetic neuropathy.

doi:10.1016/j.jns.2013.07.1858
Patients and methods: High resolution structural MRIs of the brain were acquired in 25 chronic pain patients with unilateral NDSDs, 23 chronic pain patients without NDSDs (termed “pain-only”), and 29 HC. Mechanical detection thresholds (MDT) were determined in all patients in the face, dorsum of hand and foot. Results: MDT was significantly lower ipsilaterally to pain only in NDSDs, whereas “pain-only” patients had no significant side differences. In patients with NDSDs grey matter increases were found in primary sensory cortex, parietal regions and thalamus, as well as in lateral temporal regions. “Pain-only” patients showed a grey matter increase in the posterior insula and less pronounced changes in sensorimotor cortex. In all patients, grey matter in the right middle and inferior temporal gyrus was negatively correlated with MDT in the face. Conclusion: These findings suggest that the dysfunctional sensory processing in NDSDs is associated with structural changes in the somatosensory system. Correlations of temporal cortex grey matter with sensory loss suggest a role of this region in altered sensory perception.

Genetics and underlying mechanisms associated with hereditary sensory and autonomic neuropathies
G. Rouleau, Neurology and Neurosurgery, Montreal Neurological Institute—McGill University, Montreal, QC, Canada

Hereditary sensory and autonomic neuropathies (HSAN) are a group of diseases characterized by a reduced sensitivity to pain, which often results in unnoticed burns and mutilation of the fingers and toes. It is not uncommon that affected individuals have to undergo amputations. HSANII are now classified according to their underlying genetic defect. We are studying two of the three forms of HSANII: HSANII-A (WNK1/HSN2) and HSANII-C (KIF1A). Both disorders are autosomal recessive and caused by mutations in an alternatively spliced exon of the gene they belong to. In HSANII-A the mutations are in an exon referred to HSN2 of WNK1 and in HSANII-C they are in an exon referred to as 25b. A conditional mouse model has been generated for HSANII-A and a second one is in preparation for HSANII-C. While these models should provide novel insights about these neuropathies, cellular and in vitro experiments are also conducted to understand the underlying pathogenic mechanisms at play. In parallel, we are also pursuing more genetic studies using an exome sequencing approach to identify other genes which could explain HSAN cases that are not caused by WNK1/HSN2 or KIF1A (exon 25b).

Topic: 9 — Pain
The effectiveness of Onabotulinum Toxin A injection in the treatment of severe shoulder pain

Background: Shoulder pain has three common pain generators: rotator cuff muscles and tendons, bursa and shoulder capsule. Any one of these structures can become a pain generator if they are inflamed or injured. It can be hard to diagnose the pain generator exactly as the symptoms, with these pathologies, are typically very similar to each other. Most of these pathologies will cause symptoms of pain, weakness, and loss of motion. Objective: This study aims to evaluate the effectiveness of 200 U of Onabotulinum Toxin A (Botox®) injection in the management of severe shoulder pain. Patients and methods: Trial was conducted over a period of 9 months at the International Medical Center, KSA. 20 patients with severe shoulder pain and moderate osteoarthritic/inflammatory changes were evaluated, randomly given 200 U of Botox® injection therapy or trigger point injection. Botox® was injected in the trapezius, deltoids, and rotator cuff muscles, as well as intra-articular, in all cases. Inclusive criteria: 8 males, 12 females; ages from 28 to 65, with mean age of 47 years. Exclusive criteria: patients who have infection (where Botox® will be injected), pregnant, patients with neurological disorder (e.g. Myasthenia Gravis), and medicines that may interact with Botox® (e.g. Quinidine).

Results: Average improvement of about 75% was achieved by patients who were treated with 200 U Botox®, and sustained for 8 months. Conclusion: Botox® injection in 200 U dose is more helpful in addressing severe chronic shoulder pain patients than trigger point injection, and also in establishing long sustained efficacy.

FabryScan — A screening tool for Fabry disease  
J. Höper1, D. Naleschinski2, K. Arning1, R. Maag1, M. Biegstraaten3, P. Kropp1, J. Lorenzen1, C.E.M. Hollak3, I.N. van Schaik1, P. Harten4, R.A. Zeuner1, A. Binder5, R. Baron1, 6Division of Neurological Pain Research and Therapy, Department of Neurology, University Hospital Schleswig-Holstein, Campus Kiel, Kiel, Germany, 6Division of Endocrinology and Metabolism, Department of Internal Medicine, Academic Medical Center, Amsterdam, The Netherlands, 7Institute of Medical Psychology and Medical Sociology, Center of Nervous Diseases, Medical Faculty, University of Rostock, Rostock, Germany, 4Department of Neurology, Academic Medical Center, Amsterdam, The Netherlands, 5Center of Internal Rheumatology, University Hospital Schleswig-Holstein, Campus Kiel, Kiel, Germany, 2nd Medical Clinic, Department of Internal Medicine, University Hospital Schleswig-Holstein, Campus Kiel, Kiel, Germany

Background: Fabry disease is an X-linked lipid storage disorder with early onset, morbidity and mortality. As enzyme replacement therapy is available, early detection of Fabry disease is important.

Objective: Our aim was to develop and validate an easy to use questionnaire and a set of bedside-tests distinguishing between Fabry disease and most frequent differential diagnosis.

Methods: A questionnaire inquiring 15 relevant clinical, mainly pain related, characteristics of Fabry disease and three bed-side tests assessing sensory small and large fiber function (temperature discrimination, sensation of light touch, pallesthesia) were compiled by Fabry specialists and pain experts. The provisional version was tested in a prospective multicenter trial with 138 patients suffering from chronic extremity pain due to Fabry disease (n = 55), painful polyneuropathy (n = 40), or rheumatoid arthritis (n = 43).

Results: For all three bed-side test parameters the chi-square test showed statistically significant differences between Fabry patients and controls (p < 0.001). Analysis of variance (ANOVA) showed statistically significant differences for 10 items of the questionnaire between Fabry patients and controls (p < 0.05). Only these 10 questions and the bedside tests where used for calculation of sensitivity and specificity by multivariate analysis. A high proportion of correctly identified patients (76%) with a sensitivity of 88% and a specificity of 87% was achieved with a cut-off score of 12/33 (corresponding to the number of positive points).

Conclusion: Combining a brief questionnaire and three simple bedside tests the FabryScan is a screening tool for Fabry disease with good discriminative value.

Topic: 9 — Pain  
Spinal cord stimulation for neuropathic pain through an open approach without preliminary test: A clinical series  

Background: Spinal cord stimulation (SCS) for intractable neuropathic pain is, nowadays, a well-established method of treatment. Strict indications, thorough clinical-imaging-electrophysiological examination and psychological assessment are the best prognostic factors. In this setting, careful surgical placement of multi-polar paddle-shaped leads warrants excellent results even without preliminary testing.

Objective: To demonstrate the efficacy of SCS through a minimally invasive approach without need of preliminary test.

Material and methods: 26 patients aged 41–73 were treated for neuropathic pain due to Failed Spine Surgery Syndrome (back and neck), peripheral nerve lesion and post-herpetic neuralgia refractory to medical treatment. All patients were clinically assessed for predominantly radicular or neuralgic components of pain and submitted to proper radiological imaging for exclusion of residual compression, spinal instability and medullary lesions. Previous responses to gabapentin treatment and/or improvement after TENS were considered mandatory prerequisites. Furthermore, electrophysiological studies (SSEPs) were performed in spinal cases to confirm the integrity of dorsal column fibers and psychological consultation in certain patients. All patients underwent placement of a multi-electrode (2 × 8 or 2 × 4) paddle lead through an open interlaminar approach with intraoperative radiological confirmation of proper position.

Results: 19 patients confirmed >50% pain reduction after a mean follow-up of 2 years with concomitant medication reduction, 24 patients declared satisfied with the procedure and no post-operative complications were recorded.

Conclusion: Based on current bibliographic data and modern technological advances, we assume that after careful patient selection SCS through an open approach is a minimally invasive procedure which guarantees excellent results even without preliminary percutaneous test.

Topic: 9 — Pain  
The efficacy of using ozone injection for chronic sacroiliac pain  

Background: Sacroiliac (SI) joint, located between the sacrum (tailbone) and ilium (hip bone) in the pelvis, is a common, but frequently overlooked source of low back pain. Pain which is felt at the very bottom of the lower back, described as a band of pain across the whole width of the back is often caused by sacroiliac dysfunction. Although the concept of SIJ causing lower back pain is now better understood, evaluation and treatment of sacroiliac dysfunctions are still debatable because of its complex anatomy and movement patterns at the joints and area in general.

Objective: The purpose of the study is to evaluate the effectiveness of using sacroiliac ozone injection in the treatment of chronic sacroiliac pain.

Patients and methods: 60 patients with chronic and radicular pain were evaluated at the Pain & Headache Center, International Medical Center, KSA, and were diagnosed clinically and by imaging, as chronic sacroiliac pain. They all have received sacroiliac injection with ozone 20 cm³, 30%. Inclusive criteria: 38 males, 22 females, ages ranging from 44 to 82; mean age is 63. Exclusive criteria: pregnant women, children, anyone who is allergic to any of the medication ingredients, history of low blood pressure, and patients who have liver or kidney disease.

Results: Average improvement of 68% was appreciated, as per numeric pain scale, within one week and sustained for at least 6 months, with no evidence of major side effects.

Conclusion: Sacroiliac ozone injection helps significantly in the management of chronic sacroiliac pain.

We have done a study investigating the value of some less frequently considered Blink reflex parameters for establishing the diagnosis of idiopathic trigeminal neuralgia. The study was done on 50 patients suffering from idiopathic trigeminal neuralgia, diagnosed according to the guidelines of the International Classification of Headache Disorders, with no other apparent illness. We have stimulated the supraorbital nerve at the forehead (foramen n. supraorbitalis) and recorded the reflex response on both mm. orbiculares oculi. Incidence of following findings was determined:

1. occurrence of ipsilateral R3 component,
2. prolonged duration (>25 ms) of R2 when stimulating the affected side
3. occurrence of R1 component during the stimulation of contralateral supraorbital nerve.

We have compared these findings to those of 50 healthy subjects from the control group (Chi square, p < 0.05). Sensitivity, specificity and diagnostic value for individual parameters were determined. All three parameters tested proved to have a significantly higher incidence in the group of subjects. The occurrence of R3 component on the affected side showed the highest diagnostic value.

Manipulative therapy improves sensorimotor integration in patients with neck pain in combination with thoracic pain

V. Zabarovski, L. Anatskaia, T. Svinikovskaya. Neurology, Republican Research and Practical Center of Neurology and Neurosurgery, Minsk, Belarus

Background: Neck and thoracic pain can cause the cortical neuroplasticity changes. Recent research suggests that these changes may be reduced with cervical spinal manipulation and motor-skill training.

Objective: The objective of this study is to evaluate the sensorimotor neurophysiological effects of cervical and thoracic spine manipulations and training therapy course using somatosensory evoked potentials (SEPs) in patients with subacute neck pain in combination with thoracic pain due to cervical or thoracic movement dysfunction.

Patients and methods: Twenty-nine patients (15 women and 14 men aged 35 to 49) with subacute neck pain in combination with thoracic pain due to movement dysfunction were studied clinically. The SEP values of the N9, N13, N20, N9–N13, and N9–N20 were obtained before the first and after the last session of cervical and thoracic spine manipulations and training therapy.

Results: There was a decrease in latency and amplitude of the spinal N13 and the parietal N20 and interpeak values of the N9–N13 and N9–N20 after the last treatment session compared to pre-manipulative SEP values, p < 0.001.

Conclusion: Course of cervical and thoracic spine manipulations and training therapy in patients with neck pain in combination with thoracic pain due to cervical or thoracic movement dysfunction not only helped reduce pain and restore function, but also improved sensorimotor integration at the spinal and parietal cortical levels thus preventing pain chronicity.

Evaluation of sensory and pain perception and mechanisms of central modulation of pain perception in chronic low back pain

E. Vlčkováab, I. Okacovab, R. Kopacib, M. Hnojicikab, P. Praksovab, B. Micankovadamova, J. Bednarikab. 1Central European Institute of Technology, Masaryk University, Brno, Czech Republic, 2Department of Neurology, Masaryk University and University Hospital Brno, Brno, Czech Republic

Background: Chronic low back pain (LBP) is one of the most common pain conditions. The pain intensity in LBP patients is frequently unrelated to degenerative changes of lumbar spinal cord and possible role of abnormal central processing of pain perception may be hypothesized.

Objective: To evaluate the sensory profile and function of central modulation of pain perception in order to reveal underlying mechanisms of chronic LBP, which are still not fully understood.

Patients and methods: A detailed evaluation of sensory and pain perception and of mechanisms of central modulation of pain perception was performed in 28 patients with chronic LBP (16 men, median age 35 years, no symptoms or signs or risk factors for polyneuropathy, no nerve root lesions) and 22 age-matched healthy volunteers (10 men, median age 29 years). Among others, magnitude of conditioned pain modulation (CPM) and temporal summation (TS) using thermal stimuli were assessed.

Results: Seventy-one percent of LBP patients (and 14% of controls) showed at least one abnormality of thermal perception in lower extremities (elevated thermal perception thresholds or decreased thermal-pain thresholds or most frequently so called “paradoxical heat sensation”, i.e., cold stimuli perceived as a burning hot painful sensation). The differences in CPM and TS between the groups were not significant.

Conclusion: Frequent abnormalities of thermal or thermal-pain perception were found in LBP patients compared to controls, while no significant effect of abnormal CPM or TS on the LBP development was disclosed.

Supported by: MH CZ-DRO (FNBr, 65269705) and IGA CR NT13523-4.

The role of sodium channel Nav1.9 in the activation of visceral afferents by histamine and its contribution to IBD

Introduction: The aim of this study was to investigate the contribution of the sodium channel Nav1.9 to the afferent sensitivity to histamine in the small intestine of mice. Such study could elucidate a potential role of Nav1.9 in the visceral hypersensitivity that has been linked to pain in inflammatory bowel disorders and irritable bowel syndrome.

Materials and methods: An in vitro preparation was used to make electrophysiological whole-nerve recordings of multiunit activity in mesenteric afferents supplying segments of the small intestine in Nav1.9 wild-type (WT), heterozygote (hets) and knock out (KO) mice.

Results: In WT preparations, histamine elicited a dose-dependent increase in afferent nerve discharge that was typically biphasic following higher doses of the mediator. Histamine perfused into the tissue bath evoked a robust, and in some cases a biphasic increase in afferent nerve discharge activity. The afferent responses to histamine in hets and KO mice were not significantly different (p > 0.05) from that of WT mice. Although the preliminary findings suggest that Nav1.9 may not have a role in mediating the afferent responses to histamine, further experiments that will utilize higher n values with more thorough investigations are needed.

Conclusion: Future experiments will look to establish a more superior analysis of the histamine response profile in WT mice in order to carry out an adequate, multifaceted comparison with the response in Nav1.9 deficient mice. In the anticipation of such experiments, the contribution of Nav1.9 cannot be as yet ruled out entirely.

Clinical and neurophysiological analysis of pain in vibration-induced hand disorders
L.P. Krivtsova, V.A. Shirokov. Federal State Scientific Institutional Ekaterinburg Medical Research Center for Prophylaxis and Health Protection in Industrial Workers’, Ekaterinburg, Russia

For patients with Hand–Arm Vibration Syndrome (HAVS) the most common complaints are pain, tingling or numbness of fingers and heightened sensibility to cold or fingers of hands alibration. The perception of pain is always subjective. The research of the character and the neurophysiological mechanisms of pain syndrome, including occupational diseases, is an actual problem nowadays.

The aim of the present study was to investigate correlation between electrophysiological methods and pain questionnaires.

26 working miners (48.3 ± 0.9 years old) with upper limb disorders filled in the screening questionnaires for neuropathic pain: DN4 and Pain Detect (PD) and were examined with electroneuromography (ENMG), quantitative sensory testing (QST).

High values of DN4 and PD point to a high probability of presence of neuropathic pain component. The results of ENMG which detects symptoms of axonal-demyelization process (polyneuropathy) and QST (changing of temperature thresholds of four submodalities and the vibration sensitivity) indicates the presence of signs of injury somatosensory nervous system.

Statistically significant Spearman correlation was revealed between questionnaires VAS and PD; questionnaires (PD) and QST (CS) or (WS); questionnaires (DN 4) and ENMG (SNAP). Between ENMG (sensory NCV) and QST (WS) r = −0.719*, p = 0.045; ENMG (sensory NCV) and QST (VT) r = −0.409*, p = 0.038; ENMG (SNAP) and QST (CP) r = −0.400*, p = 0.043; ENMG (SNAP) and QST (HP) r = −0.401*, p = 0.042.

During the analysis of QST between ENMG data we have received correlation dependencies. It may indicate injury of C-warm-fiber, C- or A-delta nociceptors and A-beta fibers. Complex usage of pain questionnaires and QST can contribute to optimization of therapeutic tactics.

Pattern of abnormalities of quantitative sudomotor axon retest in complex regional pain syndrome
J. Jung, J. Oh. Department of Neurology, Konkuk University Medical Center, Seoul, Republic of Korea

Background: Complex regional pain syndrome (CRPS) is complex to diagnose, since it is based on the clinical symptoms and signs without specific laboratory or radiologic findings. Though, quantitative sudomotor axon reflex test (QSART) is introduced to examine the sweating disturbance objectively, its pattern and characteristics in the CRPS patients have been seldom reported. We aimed to know if there was any correlation with the severity of QSART abnormality and disease duration.

Methods: We analyzed the records of the CRPS patients who met the Budapest criteria and underwent QSART during a year period. QSART was regarded abnormal when total sweat volume was reduced or it showed ultrashort latency or persistent sweat activity. We scaled the CRPS grade from 0 to 3 by the number of limbs showing abnormal QSART findings.

**Results:** Forty-nine CRPS patients were included in this study. Thirty of them were male and median age was 44 (from the age of 20 to 72 years). Median duration of symptom was 16 months, ranged from 2 months to 120 months. All the patients showed abnormal QSART findings regardless of the clinical symptoms and disease duration. Most common abnormality was absent or reduced sweat volume. There was no correlation between QSART abnormal degree and morbidity period or age.

**Conclusion:** QSART abnormal degree, referred to as the spatial progression of sudomotor dysfunction, did not reflect the morbidity duration or severity of CRPS. QSART alone should not be interpreted as an objective diagnostic tool for accessing the severity and disease progression of the CRPS.

**Involvement of the middle short gyrus of the insula in pain processing: Intracerebral electric stimulation of epileptic patients**

A. Afifi, D. Hoffmann, L. Minotti, P. Kahane. 1Neurosurgery Department, Neurological Hospital, University Lyon 1, Lyon, France, 2Neurosurgery Department, Grenoble University Hospital, Grenoble, France, 3Neurology Department, Grenoble University Hospital, Grenoble, France

**Objectives:** The data of this study suggests the involvement of the upper middle short gyrus in the procedures of pain.

**Materials and methods:** For this study, we included 25 patients suffering from severe drug refractory partial peripheral pain investigated by stereo-electroencephalography (SEEG). At least one electrode was used to explore the insular cortex using an oblique approach (transfrontal or trans-parietal). 313 stimulations were performed in 27 insula. 83 responses induced by insular electrical stimulation, eight (9.6%) were reported by five patients as painful sensations. The stereotactic approach allows us to identify the stimulation sites within the insular cortex in terms of its gyri and sulci. Also, the stimulation sites were anatomically localized via image fusion between pre-implantation 3D MRI and post-implantation 3D CT scans revealing the electrode contacts.

**Results:** We could obtain pain responses to direct ES of a small anatomical region. We discuss our results in terms of anatomical localization in gyral substructures of the insular cortex. The findings suggest that middle short gyrus is involved in the processing of pain producing stimuli. These sensations were evoked ipsilaterally or bilaterally to stimulation. The data provide evidence of a highly restricted anatomical region. We discuss our results in terms of anatomical processing: Intracerebral electric stimulation of epileptic patients

**Conclusion:** The region of the head is more posterior than the trunk and limbs. The area of the insular cortex inducing painful sensation in response to direct ES. The region of the head is more posterior than the trunk and limbs.

**Materials and methods:** We discuss our results in terms of anatomical processing: Intracerebral electric stimulation of epileptic patients

**Conclusion:** The region of the head is more posterior than the trunk and limbs.

**Materials and methods:** We discuss our results in terms of anatomical processing: Intracerebral electric stimulation of epileptic patients

**Conclusion:** The region of the head is more posterior than the trunk and limbs.

**Single versus repetitive injection of lidocaine HCl in management of carpal tunnel syndrome**

O. Karadaş, H.L. Gül, S. Akarsu, S. Tok, S. Firtına. 1Department of Neurology, Erzincan Military Hospital, Erzincan, Turkey, 2Department of Neurology, Kartal Education and Research Hospital, Istanbul, Turkey, 3Department of Physical Therapy and Rehabilitation, Gulhane Military Medical Academy, Istanbul, Turkey, 4Department of Physical Therapy and Rehabilitation, Iskenderun Military Hospital, Iskenderun, Turkey, 5Department of Cardiology, Erzincan Military Hospital, Erzincan, Turkey

**Objective:** The aim of the present study is to determine the efficacy of single versus repetitive injection of lidocaine HCl into carpal tunnel in management of carpal tunnel syndrome (CTS).

**Methods:** This prospective, randomized trial included 42 patients (42 median nerves) with clinical and electrophysiological evidence of CTS. The 42 patients were randomly assigned to 1 of 2 groups: group 1 was injected with 4 cm³ 1% lidocaine HCl for once and group 2 was injected 4 cm³ 1% lidocaine HCl twice a week for two weeks. Clinical and electrophysiological evaluations were performed at the study onset, 6 and 12 weeks post treatment.

**Results:** At the study onset significant differences were not observed between the groups with respect to DML (distal motor latency), CMAP (compound motor action potential) amplitude, CSAP (compound sensory action potential) amplitude, SNCV (sensory nerve conduction velocity), and VAS (visual analog scale); however all the parameters in group 2 improved 6 weeks after treatment (all P < 0.05), and these parameters persisted at 12 weeks after treatment (all P < 0.05). VAS scores improved significantly in group 1 at 6 weeks after treatment and this improvement persisted at 12 weeks after treatment. Group 2 had better scores in CMAP amplitude and VAS at 6 and 12 weeks after treatment (all P < 0.05).

**A case with generalized anhidrosis and limb pain**

C.-H. Kim, H.-Y. Jung, M.-O. Kim, K.-L. Joa, J.-Y. Oh, J.-H. Shin. 1Physical Medicine & Rehabilitation, Inha University Hospital, Incheon, Republic of Korea, 2Neurology, Konkuk University Hospital, Seoul, Republic of Korea, 3Dermatology, Inha University Hospital, Incheon, Republic of Korea

**Introduction:** A forty year old man has been suffering cholinergic urticaria. He has been treated with systemic steroid. But this symptom didn't recovered fully. 2 months later, he also noted some change of sense and severe lancinating pain in both legs with loss of sweating. In dermatologic evaluation, face showed dry erythematous patches, and in both axillae and periumbilical area, erythematous patches noted.

**Materials and methods:** Under the impression polyneuropathy, we have studied large and small fibers with nerve conduction study (NCS), sympathetic skin response (SSR), heart rate variability test with deep breathing, Valsalva maneuver (HRT), Quantitative axon reflex test (QSART) and thermoregulatory sweat test (TST). Blood chemistry, serologic evaluations, and skeletal surveys were done.

**Conclusion:** The skeletal survey, blood chemistry (glucose, Hba1c, liver, kidney function tests), serologic evaluations, and α-galactosidase were normal. IgE elevation was noted without significance. NCS with F waves was normal but SSR showed reduced amplitude in hands and absent response in feet. HRTs were normal. There were generalized loss of sweating on whole body area, and small sweating was noted on both toes and fingers only in TST. QSART revealed generalized absence of response to acetylcholine, compatible with postganglionic sympathetic dysfunction. For evaluation on the loss of sweat skin biopsy was done on upper back (non-sweating area) and scalp (sweating area). Biopsy result was perivascular and pericollum ductal mild lymphocytic infiltration without significance. He has been diagnosed with non-length dependent pattern, small fiber neuropathy clinically AIGA.

doi:10.1016/j.jns.2013.07.1873
Conclusion: Repetitive local lidocaine HCl injection was effective in reducing the symptoms of CTS and improving electrophysiologic findings.

Modulation of oxido-nitrosative stress induced neuro-inflammatory cascade & monoaminergic pathway by resveratrol in reserpine induced pain depression dyad in rats
V. Arora, K. Chopra. Panjab University, University Institute of Pharmaceutical Sciences, Chandigarh, India

Background: The emerging concept for pain-depression pathogenesis includes dysfunction of biogenic amine-mediated CNS pain control and antioxidant potential in reserpine-induced pain-depression in rats.

Methods and results: Administration of resveratrol (1 mg/kg; sc) for three consecutive days in male Wistar rats led to a significant decrease in nociceptive threshold as evident from reduced paw withdrawal threshold in Randall Sellitto and von-Frey hair test and a marked increase in immobility time. This behavioral deficit was integrated with decrease in the biogenic amine (dopamine, norepinephrine and serotonin) levels along with increased substance-P concentration, nerve growth factor, oxido-nitrosative stress, inflammatory cytokines (TNF-α & IL-1β), NF-κβ and caspase-3 levels in different brain regions of the reserpinised rats.

Conclusion: These results reveal that common mechanisms appear plausible as co-activating factors which result in neurophysiological overlap between pain and depression. Furthermore, the study demonstrates the effectiveness of resveratrol in ameliorating the behavioral deficits associated with pain and depression by restoring behavioral, biochemical, neurochemical and molecular alterations against reserpine-induced pain depression dyad.

¹Department of Radiation Oncology, Kartal Education and Research Hospital, Istanbul, Turkey, ²Department of Neurology, Kartal Education and Research Hospital, Istanbul, Turkey, ³Department of Neurology, Erzincan Military Hospital, Istanbul, Turkey

Objective: Vertebral hemangiomas are common benign vascular lesions. They are often asymptomatic. Pain is the most common symptom. Treatment options are: surgery, intraskeletal injection of alcohol, vertebroplasty with methyl methacrylate, embolisation, and radiotherapy. We present the results of radiotherapy in symptomatic vertebral hemangiomas treated in our clinic.

Methods: 34 patients (24 female, 10 male; mean age 52; range 30 to 65 years) with symptomatic vertebral hemangiomas were treated with external radiotherapy at a dose of 24–40 Gy. All patients had pain and one patient had paraplegia at presentation. Results in terms of pain and pain relief were assessed before and after therapy and during follow-up.

Results: After radiotherapy, 6 patients had less than 50% response to treatment, 10 patients had more than 50%, and 18 patients had a complete response with a median follow-up of 48 months.

Conclusion: Radiotherapy is a non-invasive, safe, and effective treatment option for symptomatic vertebral hemangiomas, especially those cases in which pain is the main symptom.

Leukocytoclastic vasculitis due to duloxetine
G. Erfan¹, R. Alp², Ş. Kaya², K. Oğuz², S. Kalayci³, M. Kulaç⁴, M. Özner⁵.
¹Dermatology, Namik Kemal University, Tekirdag, Turkey, ²Neurology, Namik Kemal University, Tekirdag, Turkey, ³Pathology, Namik Kemal University, Tekirdag, Turkey

We report on a 54-year-old woman, previously in good health, who had syncope, loss of consciousness and neuropathic pain hospitalized for one day and discharged with pregabalin 150 mg/day and duloxetine 60 mg/day. After 2 weeks of this treatment, she developed multiple palpable purpura lesions on her feet and exacerbated in 5 days in lower extremities. The skin biopsy revealed leukocytoclastic vasculitis and direct immunofluorescent was negative for fibrinogen, IgA and C3. No other organ involvement was diagnosed and ANA, ANCA, Anti-CCP were negative. Duloxetine treatment was stopped and she was started on oral prednisone 30 mg daily. In 3 weeks she had resolution of the vasculitic skin lesions. Pregabalin is still the only treatment for today and the patient has no skin lesions in one year follow-up after duloxetine treatment.

According to our knowledge, the case that we presented is the first report of leukocytoclastic vasculitis due to duloxetine and neurologists should be aware of this rare but potentially serious, possible adverse effect of duloxetine.

Long-term prognostic factors for microvascular decompression for trigeminal neuralgia
S.T. Jin¹, K. Jo².
¹The Catholic University of Korea, Bucheon St. Mary’s Hospital, College of Medicine, Catholic University, Bucheon, Republic of Korea, ²Neurosurgery, St. Mary’s Hospital, College of Medicine, Catholic University, Bucheon, Republic of Korea

The purpose of this retrospective study was to identify preoperative imaging characteristics and surgical findings that predict pain relief after microvascular decompression (MVD) for trigeminal neuralgia (TN). This study included 141 patients with follow-up ranging from 6 months to 10 years (mean follow-up = 26.3 months). Preoperative images were assessed in 90 patients who were evaluated with constructive interference in steady-state (CISS) MRI in the last 6 years. These findings were compared with the severity of neurovascular conflict (NVC) found at operation to identify imaging findings useful for prognosis. Using Kaplan–Meier analysis, we found that the success rate of MVD was 91.1 ± 2.5% at 1 year and was 76.3 ± 7.5% after 5 years. A higher degree of NVC at operation (p = 0.000), no vein compression (p = 0.049) and single vessel compression (p = 0.000) were good prognostic factors for pain relief. Two meaningful positive MRI findings, specifically, the “cerebospinal fluid rim sign” and the “deviation sign” were statistically significantly associated with the severity of NVC at operation and MVD success (p = 0.000). In this study, 34 patients (24.1%) complained of facial numbness stoperatively, and the oral herpes simplex virus was

Effect of manipulative therapy in combination with kinesio taping on cervicothoracic pain in highly qualified athletes

V. Zabarovsky, L. Vasilevskaya, L. Anatskaia. Neurology, Republican Research and Practical Center of Neurology and Neurosurgery, Minsk, Belarus

Background: The most effective method for treatment of cervicothoracic pain in highly qualified athletes is manipulative therapy (MT). Kinesio taping (KIT) may be an additional treatment option to MT creating favorable conditions for the activation of local and regional microcirculation in the connective tissue, improving lymphatic flow, encouraging the tissue healing process.

Objective: The aim of the study was to determine the effects of MT in combination with KIT on neck and thoracic pain and skin microhemodynamics (SMHD) in highly skilled athletes with cervicothoracic pain.

Patients and methods: 30 athletes with moderate cervicothoracic pain were treated with MT daily in combination with KIT by intervals of 3 days. Response to treatment was evaluated with a 100-mm visual analog scale and speckle-optical investigation of skin blood flow over a pair of antagonist muscles in a state of imbalance. SMHD was evaluated with average fluctuation frequency (<F>), the spectral power (SP) and asymmetry factors (As).

Results: The statistically significant pain severity decrease was determined after the course of combined treatment of MT and KIT, p < 0.05. The SMHD values of <F> and SP were higher as compared with data before treatment by 11% (p < 0.05) and 27% (p < 0.05) respectively indicating the increase of skin blood flow velocity.

Conclusion: MT in combination with KIT has been found to be an effective treatment for highly skilled athletes with cervicothoracic pain due to local or regional perfusion improving by increasing blood flow and accelerated elimination of pain neurotransmitters and nociceptor stabilization.

Pharmacological, pharmacokinetics and safety profiles of DS-5565, a novel α₂δ ligand  
T. Yokoyama¹, N. Arakawa², Y. Domon², F. Matsuda³, T. Inoue⁴, Y. Kitano⁴, M. Takahashi⁴, N. Yamamura⁴, K. Kai⁴, ¹Biological Res. Labs., Daiichi Sankyo Co., Ltd., Tokyo, Japan, ²Frontier Res. Labs., Daiichi Sankyo Co., Ltd., Tokyo, Japan, ³Drug Metab. Pharmacokinetic Res. Labs., Daiichi Sankyo Co., Ltd., Tokyo, Japan, ⁴Med. Safety Res. Labs., Daiichi Sankyo Co., Ltd., Tokyo, Japan

DS-5565 is an analgesic drug that binds to the α₂δ subunit (α₂δ-1 and α₂δ-2) of voltage-dependent Ca²⁺ channels. The α₂δ-1 is the main target for the analgesic effect of α₂δ ligands. The contribution of the α₂δ-2 to the CNS side effects of α₂δ ligands still remains to be elucidated. To clarify the characteristics of DS-5565, we conducted the experiments using pregabalin (PGB) as a reference. The binding affinity and dissociation rate were investigated with rat α₂δ-1 and α₂δ-2 transfected cells. The analogic effect was investigated with a von Frey test in streptozotocin (STZ)-induced diabetic rats. The CNS side effects were investigated with rota-rod performance (RR) and locomotor activity (LA) in rats. The plasma drug concentration was measured by LC–MS/MS. The binding affinities of DS-5565 for α₂δ-1 and α₂δ-2 were comparable to those of PGB. Interestingly DS-5565 showed a slower dissociation rate from α₂δ-1 than α₂δ-2, in particular α₂δ-1 compared to PGB. DS-5565 showed potent and sustained analgesic effects and the ED₅₀ was ca. 2.5 mg/kg (ED₅₀ for PGB: 29.3 mg/kg). The plasma concentration of DS-5565 in the STZ rats, however, was about 65-fold less than PGB. DS-5565 inhibited RR (ID₅₀: 9.4 mg/kg) and LA (ID₅₀: 43.9 mg/kg) and the ratios ID₅₀/ED₅₀ (CNS safety margin) were ca. 38 in RR and ca. 18 in LA. The ratios for PGB were 0.4 and 3.9, respectively. DS-5565 has superior analgesic effects with a wider CNS safety margin relative to PGB. These profiles of DS-5565 are possibly due to its unique binding characteristics to α₂δ-1 and α₂δ-2.

Neuropathic pain and neuromodulation techniques

B. Fan, China–Japan Friendship Hospital, Beijing, China

Neuropathic pain is a common chronic intractable pain syndrome in clinical setting. It arises as a consequence of a lesion or disease affecting the somatosensory system [1] and may be associated with abnormal sensations called dysesthesia, pain produced by normally non-painful stimuli called allodynia and spontaneous pain. The mechanism of neuropathic pain remains unclear so far, and the management of patients with chronic neuropathic pain is challenging [2–6]. In this paper, I will discuss in brief the etiology, physiopathology and clinical management of neuropathic pain.

First, in etiology and physiopathology, I will discuss about cranio-rectal injury, spinal cord injury, peripheral nerve injury, and come to a conclusion that a correct understanding of the neuropathic pain, especially its etiology and pathology, is extremely important to the prevention and treatment of it. Second, in clinical manifestations, I will discuss about relationship between injury and pain, pain duration, features of pain, thalamic pain, nutritional disorders, and motor dysfunction, which shows that more than 25% of patients may suffer from central pain within 1 week to 1 month after central nervous system damage. But in some other patients, central pain may occur after a few months or even years, and Pain occurs in somatic sensory impairments or deletion regions. Thalamic pain is a typical central pain known as hypothalamic syndrome. Third, in treatment, I will discuss about pharmacological therapy, Reducing sympathetic nervous stimulation, neuromodulation techniques, and get the result for spinal cord stimulation (SCS) (the National Pain Management & Research Center firstly performed SCS in China). From 2003, we have performed 202 SCS procedures (Fig. 1) and there are over 80% of patients who obtained pain relief successfully.

doi:10.1016/j.jns.2013.07.1884
diagnosed [5], an easy reliable tool for screening localized NP (LNP) patients is lacking.

**Methods:** A screening tool for diagnosing LNP proposed by international experts was tested by GPs (Badalona-Municipal-Hospital/Spain; Nov ’12–Mar ’13), and validated against pain specialist diagnosis as reference. Grading system principles proposed for NP [6] by IASP were basis for development, focusing on medical history and distribution of painful symptoms and sensory signs. Positive predictive value (PPV) and negative predictive value (NPV) were calculated.

**Results:** 2079 patients with chronic pain were consecutively screened by 31 GPs (Age: 60.7 ± 11.1 years; female = 69.9%). LNP was diagnosed in 394 patients. Screening, including patient examination, took 7mn (mean). GPs rated the tool as useful (24/31) or very useful (7/31) and facilitating practice (30/31). PPV/NPV was 41%/89%.

**Discussion:** An easy reliable tool for screening LNP by GPs is proposed, that could facilitate targeted treatment. The screening tool narrowly adheres to the NP algorithm proposed by IASP, being the first attempt to validate it in a general population of chronic pain patients on GP level. In contrast, established screening tools used strict inclusion criteria which eliminated unclear pain conditions. Thus, spectrum of disease, most relevant bias in diagnostic studies, is not biased in our real-life study, e.g. "gray zone" is not excluded. Hence, diagnostic accuracy of the tool is realistic.

Meeting and study were sponsored by Grünenthal.

**The mechanism of occurrence of the endoneural edema induced by histamine**

*E. Casimov¹, L. Jamarlova⁵, T. Nadjafova⁴, R. Ghaffarzadagan¹. ¹Hystology, Azerbaijan Medical University, Baku, Azerbaijan, ²City of Zurich Medical Services, Zurich, Switzerland*

The effect of intravenous injection of histamine hydrochloride ($10^{-4}$ M) on endoneural microvessels of white rat sciatic nerve was investigated at the light and ultrastructural levels. Endoneural edema characteristics appeared after 5 min of histamine injection. The presence of pores or transendothelial channels in endothelial layer of endoneural microvessels has not been revealed. The occurrence of edema liquid and the absence of convective ways of transport through the endothelial layer of microvessels indicate the increase of hydraulic permeability of their walls. The lumen expansion of all types of endoneural microvessels, especially arteriole and precapillaries, was observed after analyzing the occurrence of the endoneural edema after injection of histamine. The lumen expansion ostensibly reduces peripheral vascular resistance, and promotes blood intake with elevated hydrostatic pressure in the lumen of endoneural capillaries and postcapillary venule. This explains to be the cause of the appearance of edematous fluid in the endoneural space of the sciatic nerve. Thus, the increase of endoneural liquids stretches the perineural sheath and affects the lumen of venules allowing transit passage through it. Finally, the drastic increase of postcapillary resistance strengthens the filtration through the wall not only in capillaries, but also in arteriolar microvessels, and in extreme cases leads to infringement of the perineural sheath integrity. Based on collected data, the cause of degenerative changes of nervous fibers of peripheral nerves not only affects the increase of pressure of endoneural liquid but also the infringement of perineural sheath integrity. The role of shear stress in the expansion of lumens of endoneural microvessels is being considered.

doi:10.1016/j.jns.2013.07.1887
Background: Neurodegenerative diseases present high prevalence over 50 years and geometrical progression over 60 years. Evidence shows cognitive impairment is preventable by cognitive stimulation. “Remembrance Workshop” is a cognitive stimulation and rehabilitation program based on computers and internet use.

Objective: The objective of this study is to determine whether a cognitive stimulation and rehabilitation program based in computers and internet use can prevent cognitive impairment measured by MMSE.

Material and methods: Intervention controlled cohort study, quasi experimental, was approved by Brazilian National Health Council. All participants were 50 or older, had memory complaints and had normal initial MMSE. Hypertension was significant variable with an independent protective factor of 0.42 (95% CI 0.35–0.90, p < 0.029), NNT = 6.5.

Results: Intervention group 112, 99 (88.4%) remained having no cognitive impairment and 13 (11.6%) showed having cognitive worsening. Control group, 96, 70 (72.9%) had no cognitive impairment and 13 (11.6%) showed having cognitive worsening. Control variables: gender, age, education, marital status, social status, physical activity, obesity, depression, cardiovascular disease, cerebrovascular disease, hyperthyroidism, polypharmacy, dyslipidemia, smoking, use of benzodiazepines, diabetes, functional capacity, time between the first and second interviews, and initial MMSE. Hypertension was significant only in the bivariate analysis (p = 0.031, RR = 2.18 95% CI 1.02 to 4.65). Intervention was the only significant variable with an independent protective factor of 0.42 (95% CI 0.35–0.90, p < 0.029), NNT = 6.5.

Conclusion: The intervention was associated with prevention of cognitive impairment.

Questionnaires underestimate sleep disorders and daytime complaints in neurorehabilitation
K. Bohr, O. Milovanivic, R. Arneja, G. Freier. MediClin Rehazentrum, Plau am See, Germany

Background: Sleep disorders, mainly SRBD and PLMS typically lead to complaints. Questionnaires like the Epworth Sleepiness Scale (ESS) and the Pittsburgh Sleep Quality Index (PSQI) normally are sensitive selection criteria for sleep screening.

Objective: Disturbed sleep will delay the rehabilitation progress, especially poststroke. The predictive value of ESS and PSQI in such patients was evaluated.

Patients and methods: 378 patients, 213 of them after stroke, underwent sleep polygraphy with an ambulatory device (SOMNOscreen, Fa. SOMNOmedics GE). Inclusion criteria were normal speech and communication and sufficient mobility. In the afternoon of the screening the patients filled themselves the ESS and PSQI. The answers of the ESS and PSQI were evaluated thereafter. Independent raters scored the questionnaires and screenings.

Results: ESS was not completed in 36% females and 35% males after stroke without correlation with SRBD (AH1) or PLMS. ESS > 10 was found in 31% females but only in 17% males poststroke. AHI > 10/h was found in 38% females and 79% males poststroke. ESS, PSQI, BMI and age did not correlate with AHI or PLMS in individuals poststroke nor in the other 165 patients (MS, other neurological disorders, orthopedic disease).
Discussion: ESS and PSQI do not correlate with type or amount of sleep disorders in rehabilitation patients. ESS and PSQI are not predictive and therefore should not be used as selection criteria for sleep screening or treatment indication. Nevertheless ESS and PSQI remain important tools for individualized patient education.

The relationship between students’ bonding to school and multiple health risk behaviors among high school students in south-east of Iran
A. Hashdoost, A. Abasszadeh, F. Abazari, Kerman University of Medical Sciences, Kerman, Iran; Shahid Beheshti, Kerman, Iran; Razi Nursing Faculty, Kerman, Iran

Background: School is the first social institution that affects adolescents’ lives and determines their opportunities, life qualities and behaviors. Thus, the aim of this study is to determine the relationship between bonding to school and multiple (problem) behaviors among high school students in Kerman.

Methods: The present study is a descriptive cross-sectional research carried out on students of all levels in high schools in Kerman during the 2010–2011 academic year. The research sample included 1024 students (588 females and 436 males) aged 15 to 19 years. The Multi-stage Cluster sampling method was used to collect data. Using A CTC (Communities That Care Youth Survey) questionnaire, which was designed by Using an standard questioner, the profile of risk behaviors of students were collected.

Results: In the final multivariate logistic regression, two variables including age (ORa = 1.15, p = 0.02) and gender (ORa = 2.14, p = 0.001) had a significant positive association with Multiple Health Risk Behaviors (MHRB). School commitment (ORa = 0.38, p value = 0.001) and school rewards for involvement (ORa = 0.80, p = value = 0.21) had significant negative association with MHRB.

Conclusion: This research also demonstrated that students who were strongly influenced by school commitment and school reward for involvement are less likely to engage in risky behavior. The role of gender and age in these behaviors must also be taken highly into consideration.

Functional electrical stimulation in combination with robotic mechanic in patients with acute ischemic stroke
O. Uvarova, V. Daminov, A. Kuznetsov. National Medical Pirogov Center, Moscow, Russia

Objective: The aim of our research was to evaluate the efficacy and safety of functional electrical stimulation, combined with a robotic mechanical therapy in patients with central hemiparesis in acute ischemic stroke.

Material and methods: 104 patients with acute ischemic stroke in middle cerebral artery were divided into 2 groups. Group I included 58 patients who received a course of rehabilitation therapy with the inclusion of training on robotic system Erigo and synchronized with functional electrical stimulation. Patients with group II (46) received treatment without FES. To assess the rehabilitation measures, we used a 6-point scale paresis and electrophysiological examination (impedance cardiography, Doppler ultrasound of the affected middle cerebral artery, evoked potentials) before, during and after the sessions of robotic mecanotherapy.

Results: In all patients, there was a decrease in the degree of paresis of 1.4 points in group 1 and at 0.54 in group 2. Hemodynamic abnormalities during robotic therapy in combination with FES were not revealed. At 20 days of rehabilitation, there was a decrease of the segmental latency response in both groups of patients, which was more pronounced in patients of group 1.

Conclusion: It was found that the use of functional electrical stimulation is safe in acute stroke, and the effect of the combination of FES with robotized mechanical therapy is higher than in conventional kinezioterapi.

Robotic technology in rehabilitation of patients after surgical revascularization of brain
V. Daminov, O. Uvarova, A. Kuznetsov, S. Kucherenko. National Medical Pirogov Center, Moscow, Russia

Objective: The aim of our study was to evaluate the effect of robotic mechno motoring deficiency in patients after surgical revascularization of the brain on the symptomatic stenosis of the internal carotid artery.
Material and methods: The patients were examined and divided into 2 groups: Group 1 — 95 patients after carotid endarterectomy and Group 2 — 39 patients after balloon angioplasty with stenting. Age stroke was from 17 to 523 days; prescription transactions from 1 to 3 months; and the degree of paresis of the lower extremity from 3 to 4 points. To assess the rehabilitation measures we used: a 6-point scale paresis, Stroke Scale NIHSS, Barthel ADL Index, Hauser Gate Index and electrophysiological examination. Patients received Lokomat training once a day for 6 days a week for 3 weeks. Discharge weight was on average no more than 25% of body weight, and treadmill speed was 1.5–2.5 km/h.

In two groups of patients there was a significant (p < 0.05) decrease in the degree of paresis in the lower limb and a significant increase in absolute and percentage figures in index walk Hauser. Barthel ADL Index increased in group 1 — with up to 46.0 ± 1.4 75.6 ± 1.2 (p < = 0.001), and in group 2 — from 47.0 ± 1.4 to 74.4 ± 0.7 (p < = 0.001) points. In this case, significant differences between the groups were not registered.

Conclusions: It was found that locomotor training with the help of Lokomat improves motor function and quality of life and that it doesn’t depend on the type of surgery.

Transcranial direct current stimulation (tDCS) and vision restoration training (VRT) in post-acute stroke rehabilitation — Implications for further investigations
R. Alberab, D. Moserb, B.A. Sabeb, C. Gallb. aNeurologisches Therapiezentrum Gmundenberg, Altmünster, Austria; bInstitute of Medical Psychology, Otto-von-Guericke-University, Magdeburg, Germany

Background: Posterior-cerebral-artery stroke usually results in visual field deficits varying in size and extent of the blind field and areas of residual vision (ARV). Vision restoration training (VRT) may reduce visual field impairment. Combined application of transcranial direct current stimulation (tDCS) together with VRT indicates that tDCS may accelerate VRT-effects in the post-acute stage. Feasibility of tDCS-VRT treatment in post-acute stroke was not yet investigated.

Objective: In order to plan a controlled efficacy study of tDCS-VRT in post-acute stroke, we investigated two patients with lesion ages of 2 and 5 months after posterior cerebral artery stroke with different lesion sizes.

Patients and methods: One patient with a small scotoma and ARV and one patient with homonymous clear-cut hemianopia without ARV were treated with 5 tDCS-sessions (2 mA, 15–20 min, cathode: Cz, anode: O1) combined with VRT. Perimetric detection thresholds at post were compared to baseline.

Results: After conducting the same stimulation and training protocol with both patients, we found significant improvement of detection accuracy in both cases. However there was a higher effect size in the patient with presence of ARV.

Conclusion: Our data support the theory that neural plasticity after stroke in the visual cortex can be facilitated by tDCS if there is residual functionality. Further studies investigating the efficacy of tDCS in rehabilitation of stroke should consider the presence of ARV as a predictor for a clinically relevant treatment effect.

Topic: 10—Neurorehabilitation
Neurorehabilitation for amelioration of the quality of life of multiple sclerosis patients
L. Kolevaab, D. Stoilova, P. Shotekov. aClinic of Physical and Rehabilitation Medicine, Medical University of Sofia, Medical Faculty, University Hospital ‘St Ivan Rilsky’, Bulgaria; bDept of Medical Rehabilitation and Occupational Therapy, Medical Faculty, Medical University Sofia, Bulgaria; cClinic of Neurology, University Hospital ‘St Ivan Rilsky’, Sofia, Bulgaria

Aim: Structuration of a neurorehabilitation algorithm in MS and clinical approval of our physiotherapy programme and comparative evaluation of the effect of the application of different rehabilitation complexes — by a synergic combination of natural and preformed physical modalities: physiotherapy, kryotherapy, ergotherapy, pulsed magnetic field, electrostimulations, education of MS patients in activities of daily living.

Material and methods: During the period 1996–2012 in three Bulgarian Neurorehabilitation Clinics we effectuate observations on an experimental group of 189 patients with cerebro-spinal form of MS, in remission phase, with a clinically manifested quadripyramidal syndrome with hemiparesis or inferior paraparesis, discoordination syndrome, urinary incontinence, emotional disbalance. We divided experimental group in six therapeutic groups with rehabilitation complexes, including physiotherapeutic programme and different pre-formed modalities. The control group was formed by 49 in-patients, with standard rehabilitation programme. We observed MS patients — before and after physical therapy and one month later. All patients signed informed consent for rehabilitation and investigations. For statistical analysis we used the statistic package SPSS — options t-test (analysis of variances ANOVA) and Wilcoxon rank test (non-parametrical distribution analysis).

Results: During prospective observations we noted a significant effect on spasticity, balance, stability of gait, autonomy in activities of daily living — self service (movement in the bed, toilet, dressing, mobility, eating), test of 20 m walking, depressivity, and autonomy in ADL (ICF). The effect is stable — with duration of one month after the end of rehabilitation.

In conclusion we underline the favourable effect of neurorehabilitation on patient’s quality of life.

doi:10.1016/j.jns.2013.07.1897
activities of daily living of patients suffering from central post-stroke hemiparesis and hemiparetic shoulder.

**Material and methods:** A total of 388 post-stroke in-patients were observed (1997–2012). The rehabilitation complex includes kryokinesitherapy in all cases; additionally — electrostimulations of hand extensors (in group 2), and occupational therapy (in group 3). The patients were investigated before and after therapy and one month later, according a protocol with all results (including neurological and functional status, evaluation according to international classification of functioning, disability and health — ICF). Statistical evaluation was effectuated with t-test (analysis of variances ANOVA) and Wilcoxon rank test (non-parametrical correlation analysis). Comparative analysis of results proved a statistically significant favorable effect (p < 0.001) on some important parameters: muscle weakness, range of motion and functional capacity of the hand (including grip); stabilization of the balance and locomotion (tests of Brunnstrom, Barthel-index, Michel’s test); reduction of spasticity; autonomy in activities of daily living (ICF). The stability of the results one month after the end of neurorehabilitation is satisfactory. In conclusion we underline clinical efficacy of complex neurorehabilitation program.

**Conclusions:** no gait. The detailed assessment of the functional status allows for proper diagnosis and initiation of early treatment.

**Shoulder pain after stroke: Experience in the University Hospital of Casablanca**

L. Riah, M. Elbouchikhi, F. Lmidmani, A. Elfatimi. *Ibn Rochd University Hospital, Casablanca, Morocco*

**Background:** The prevalence of shoulder pain after hemiplegic stroke is around 70%. A shoulder-hand syndrome, adhesive capsulitis may be the cause, favored by a glenohumeral subluxation or significant spasticity. The etiological diagnosis is mainly clinical. The treatment is mainly based on preventative tapping, correct positioning in bed, prudent mobilization and electrostimulation.

**Objective:** The objective of this study is to recall the different clinical, therapeutic and prognostic elements and to evaluate our results based on data from the literature.

**Material and methods:** Prospective study on the management of shoulder pain in 52 hemiplegic patients seen between October 2008 and March 2013.

**Results:** Age: 61 ± 14 years; post-stroke time: 2 to 29 weeks; sex ratio: 33 F/19 H; hemiplegic side: 41 right/11 left; pain assessed by VAS (initial: 8 ± 1; after treatment: 3 ± 1); etiologies: 46 subluxations/6 complex regional syndrome type I.

**Treatment:** All patients were treated with strapping, sling immobilization when standing or sitting, analgesic medication, TENS, and local infiltration of corticosteroids in cases of complex regional syndrome type I.

**Conclusion:** Shoulder pain is particularly high in hemiplegic particular patients, requiring particular therapeutic attention warranting research. The diagnosis of upper limb pain in the hemiplegic remains a subject of controversy. Its origin is multifactorial dominated by glenohumeral subluxation, complex regional syndrome type I, capsulitis, and spasticity. We must stress the importance of the prevention of decoaptation of glenohumeral by proper installation of the patient, proper diagnosis and initiation of early treatment.

**Background:** The main objective of the undertaken rehabilitation is a complete function playback or the compensation of the functions directly lost.

**Objective:** The aim of this study was to assess the functional status of stroke patients eligible for the early neurological rehabilitation.

**Patients and methods:** The research involved 37 patients, meeting the criteria for inclusion in the research. The assessment of functional status was performed on day 1 of hospitalization and 3 months after rehabilitation. To measure the functional status of a patient we used Lovett’s scale, Brunnstrom’s scale, Jebsen’s test, Rankin’s scale, ADL scale by an average of 6 points. In the assessment of muscle strength improvement was seen in more than half of the patients; in ADL scale by an average of 6 points. In the assessment of muscle strength improvement was seen in more than half of the patients; in

**Results:** The quality of the functional status of patients in the period from day 1 to 3 months after stroke improved according to Barthel’s ADL scale by an average of 6 points. In the assessment of muscle strength improvement was seen in more than half of the patients; in 75.67% of them there was an improvement on the lower limb (LL) by 2.1 points in the Lovett’s scale, which also

**Conclusions:** In the first three months post-stroke functional improvement was achieved in two thirds of patients, the rest of them received no gait. The detailed assessment of the functional status allows for setting the objectives of early taken rehabilitation.

Impact of early versus late treatment on goal areas in patients treated with botulinum-toxin A (BoNT-A) for post-stroke upper-limb-spasticity (ULS) (ULS-2-study)
K. Rheodoroff, J.J. Jacinto, L. Turner-Stokes, Department of Neurorehabilitation, Gailltal-Klinik, Hermagor, Austria; Servicio de Reabilitación de Adultos, Centro de Medicina de Reabilitaçãode Alcoitão, Estoril, Portugal; School of Medicine, King’s College, London, UK

Objective: The objective of this study is to investigate primary goal achievement in patients with ULS based on time between stroke and first BoNT-A treatment for ULS.

Design: Subgroup analysis of 454 adults with post-stroke ULS within an observational, prospective cohort study on current practice in an international, multi-center design in 84 centers in 22 countries (ULS-2-study).

Interventions: One cycle of BoNT-A treatment and concomitant therapies in accordance with routine local clinical practice.

Outcome measures: Primary goal achievement in relation to time after stroke.

Results: 180 patients were treated ≤ 1 year after stroke (early treatment, ET) and 274 > 1 year after stroke (late treatment, LT). If ULS treatment starts ≤ 1 year after stroke, a higher proportion of goals related to pain (88.5%, 95%CI 69.8%, 97.6% ET versus 80.0%, 95%CI 63.1%, 91.6% LT), pROM (81.8%, 95%CI 64.5%, 93.0% ET versus 76.4%, 95%CI 64.9%, 85.6% LT) and active function (76.6%, 95%CI 62.0%, 87.7% ET versus 68.4%, 95%CI 54.8%, 80.1% LT) were achieved. A higher proportion of goals related to ease of care (81.6%, 95%CI 63.7%, 97.0% ET versus 85.7%, 95%CI 63.7%, 97.0% LT), pROM (81.8%, 95%CI 64.5%, 93.0% ET versus 76.4%, 95%CI 64.9%, 85.6% LT) and active function (76.6%, 95%CI 62.0%, 87.7% ET versus 68.4%, 95%CI 54.8%, 80.1% LT) were achieved. A higher proportion of goals related to ease of care (81.6%, 95%CI 63.7%, 97.0% ET versus 85.7%, 95%CI 63.7%, 97.0% LT), pROM (81.8%, 95%CI 64.5%, 93.0% ET versus 76.4%, 95%CI 64.9%, 85.6% LT) and active function (76.6%, 95%CI 62.0%, 87.7% ET versus 68.4%, 95%CI 54.8%, 80.1% LT) were achieved. A higher proportion of goals related to ease of care (81.6%, 95%CI 63.7%, 97.0% ET versus 85.7%, 95%CI 63.7%, 97.0% LT) and reduction of involuntary movements (68.4%, 95%CI 43.4%, 87.4% ET versus 85.7%, 95%CI 63.7%, 97.0% LT) were achieved in the long-term.

Conclusions: Further long-term studies should examine patients characteristics and goal areas to develop recommendations on situations demanding an early treatment and a long-term ULS-management in terms of maintaining/improving functioning.

Therapeutic effects for human umbilical cord blood-derived mesenchymal stem cells with methylprednisolone treatment in the contused rat spinal cord
H.-J. Ham. Institute of Catholic Integrative Medicine, Incheon St. Mary’s Hospital, The Catholic University of Korea College of Medicine, Incheon, Republic of Korea

Methylprednisolone (MP), a glucocorticoid steroid, has an anti-inflammatory action and seems to inhibit the formation of oxygen free radicals produced during lipid peroxidation in a spinal cord injury (SCI). Currently MP is the standard therapy after acute SCI on reported neurological improvements. The combination therapeutic effect of human umbilical cord blood-derived mesenchymal stem cells (hUCB-MSCs) for transplantation time (1 d, 7 d, and 30 d) after MP treatment on the axonal regeneration and on the behavioral improvement in SCI was studied in the rat. The spinal cord was injured by contusion using a weight-drop at the level of T9 and MP (30 mg/kg, i.m, 10 min and 4 h) was acute administered after injury. hUCB-MSCs were labeled GFP and our study was performed the efficacy for transplantation time (1 d, 7 d, and 30 d) of hUCB-MSCs into the boundary zone of injured site. Efficacy was determined by histology, anterograde and retrograde tracing, and behavioral test. We found that hUCB-MSCs with MP treatment exerted a significant beneficial effect by neuroprotection and reducing cavity volume. Also the transplantation of hUCB-MSCs with MP treatment was significantly improved functional recovery. Combined transplantation at 7 d after SCI provided significantly greater efficiency than combined transplantation at 1 d and 30 d. These results suggest that transplantation time window of the hUCB-MSCs with MP treatment give rise to an earlier neuron protection strategy and effect of cell grafting in SCI. Thus our study may be considered as a therapeutic modality for SCI.

Experience of physical medicine and rehabilitation department: Treatment of spasticity by botulinum toxin injection, about 30 cases
S. Lahribi, Y. Abdelfettah, K. Belhaj, F. Lnimdani, A. Elfatimi. Physical Medicine and Rehabilitation Department, UHC Ibn Rochd, Casablanca, Morocco

Introduction: The therapeutic use of botulinum toxin has been an important development in movement disorders.

Materials and methods: This is a retrospective study from 1 March 2008 to 30 February 2012 in the Physical Medicine and Rehabilitation department for the treatment of spasticity by botulinum toxin injection, which is indicated for the local treatment of spasticity or dystonia which awkward movement or health of the patient through a central nervous system, an assessment of the severity of the disorder by the Ashworth scale and functional evaluation using generic scales (FIM and Barthel).

Results: 30 patients have benefited from the injection of TB. The average was 27 years (3–75 years). Etiologies were vascular accident (51%), cerebral motor infarct (29%), head injury (13%), tuberculous myelitis (4%), spinal cord injury (4%) and parkinsonism syndrome with dystonia (4%). The severity of spasticity was between 2 and 4 on the Ashworth scale, the injection objectives were variables: functional improvement of the members and hygiene of life and the prevention of joint deformations. Clinical and functional results were satisfied with a reduction in spasticity and an improvement in functional scores.

Discussion and conclusion: The injection of botulinum toxin is the treatment of choice for focal spasticity, and several studies confirm the very satisfied results and significant improvement in quality of life of patients and their functional recovery.

Cerebellar ataxia: Contribution of rehabilitation: 15 cases
S. Lahrabli, A. Khadir, S. Meftah, F. Linidmani, A. Elfatimi. Physical Medicine and Rehabilitation Department, UHC Ibn Rochd, Casablanca, Morocco

Introduction: Cerebellar ataxia is a disorder that affects motor complex planning and execution of movements and reduces the precision and coordination.

Purpose: The purpose of this study is to assess the impact of rehabilitation on cerebellar ataxia in CHU Ibn Rochd Casablanca.

Method: A retrospective study of 15 cases of cerebellar ataxia received a rehabilitation program.

Results: The majority of patients were men (60%), the average age is 19 years (4–54), and etiologies found were dominated by multiple sclerosis (40%), and head trauma (33.5%). Evaluation of balance and walking according to Tinetti showed 73.5% of patients with high risk of falling, the Barthel scale evaluation found 13% had severe dependency, 53% had moderate dependence and 33.5% had a slight dependence. Rehabilitation has improved complete autonomy in activities of daily life in 6.5% of patients and improved level of Tinetti scale in 26.7%.

Discussion and conclusion: Cerebellar ataxia is one of the most characteristics of the cerebellum damage. The beneficial effect of rehabilitation on neurological signs has been proved by several authors; intensive training coordination improves motor performance and reduces ataxia symptoms. Others believe that there is no valid information on the actual value of the physical rehabilitation and psychological support as a treatment for cerebellar ataxia, and that there is a tendency to spontaneous regression of cerebellar syndromes, but it can be slow, incomplete, extending over months or years.

Combining electric brain stimulation and source-based brain-machine interface (BMI) training in neurorehabilitation of chronic stroke
S.R. Soekadar1b, M. Witkowski1b, S.E. Robinson1, N. Birbaume1b, 2, a. Applied Neurotechnology Lab, Department of Psychiatry and Psychotherapy, Germany; b. Institute of Medical Psychology and Behavioral Neurobiology, University of Tubingen, Tubingen, Germany; c. MEG Core Facility, NIMH, NIH, Bethesda, MD, USA; d. IRCCS San Camillo, Venice, Italy

Over the last years, clinical trials indicated that brain-computer or brain-machine interface (BCI/BMI) training coupled with behavioral physiotherapy can facilitate motor recovery after severe stroke. However, results were heterogeneous and training required weeks of daily sessions. Here we introduce a novel BMI-based rehabilitation regime that promises to improve specificity and effectiveness of such training by incorporating the latest methodological advancements, such as area-specific (source-based) real-time reconstruction of brain activity and simultaneous electric brain stimulation during BMI-training to facilitate learning.

Methods: A 48 yo female patient unable to move her right fingers who suffered a subcortical stroke at the age of 25 affecting the left capsule interna, putamen and nucleus caudatus was invited to three consecutive BMI-training sessions. A 275-sensor whole-head magnetoencephalograph (MEG) was used to localize and reconstruct task-related neuromagnetic activity in the left motor cortex (M1) during the attempt to move the affected fingers. Source-based activity was assessed using a LCMV beamformer and translated into online feedback delivered through a hand-exoskeleton opening and closing the paralyzed hand. During the BMI-training, an anodal DC-electric current of 1 mA was delivered to the left M1.

Results: Area-specific real-time reconstruction of motor-related brain activity was reliably possible during electric brain stimulation. The patient achieved good BMI-control across all sessions. Brain stimulation was well tolerated. This is the first report on successful real-time combination of source-based BMI-training and electric brain stimulation in a stroke patient, building the grounds for larger clinical studies further investigating efficacy of such approach in the rehabilitation of severe stroke.

A new onset of Parinaud’s syndrome in a rehabilitation setting
S. Williams1a, S. Vijayarangam Shanmugam1b, M. Sake1c. 1Department of Neurosciences, East Kent University Hospital, Canterbury, UK; 2Department of Neurology, East Kent University Hospital, Canterbury, UK

Background: Parinaud’s syndrome involves supra nuclear vertical gaze palsy due to pathology in dorsal midbrain. There is no specific rehabilitation strategy in literature.

Objective: Through a case story, we assess the clinical and service implications.

Patients and methods: A 35-year old right handed male was diagnosed with cerebellar pilocytic astrocytoma presented with headache and ataxia for 4 months. Post operative complications include hydrocephalus, repeated shunt infections. He was transferred to Neurorehabilitation after clinical stabilisation.

Due to substantial visual impairment, he was re-referred to Neurologists who found severe diplia in all directions but worse horizontally, sluggish pupil with ptosis, absent pupillary reflexes with no near light response, conjugate vertical gaze paralysis with bilateral internuclear ophthalmoplegia, absent vertical and horizontal optic kinetic reflexes. Vertical and Horizontal nystagmus was present with preserved corneal reflex. Eye movements demonstrated convergent nystagmus. In summary there was nuclear 3rd and 6th nerve palsies evident bilaterally, convergent nystagmus and absent near light near reflex with clinical signs in keeping with a Parinaud’s syndrome except eye lid retraction. Repeat neuro-imaging showed subdural bleed but no dorsal midbrain lesion. We speculated that the likely cause of these new onset Parinaud’s stemming from raised intracranial pressure i.e. Pre-tectal syndrome.

He was re-referred to Neurosurgeons.

Conclusion: Apart from the curious clinical presentation, this case raised important issues relating to service reconfigurations e.g. continued engagement with neurologists are needed to guide the rehabilitation programme, prognostication and active interventions. A careful consideration of budgetary implication of neuro-rehabilitation department is needed.

Botulinum toxin (BT) therapy for adult spasticity — A service improvement projects over 9 years
S. Vijayarangam Shanmugam1a, R. Boarda1b, M. Sakel1c. 1Department of Neurology, East Kent University Hospital, Canterbury, UK; 2Department of Neurosciences, East Kent University Hospital, Canterbury, UK

No abstract available.
Modern treatment and rehabilitation strategies reduce the risk of death or dependency after stroke. However, better functional outcome may not always be translated to better quality of life (QoL).

Material and methods: In our department. To assess their QoL we used the Stroke-Specific Quality of Life Scale developed by Williams. Functional outcome was assessed by the modified Rankin scale (mRS).

Results: 19 (13%) patients had died within one year and only 50 patients (mean age 68.5 years; 25 men) delivered answers to all questions from the query. The most affected areas of life, where patients scored <40% of the total score in the selected sub-scale were ‘work’ (54% patients), ‘energy’ (36%) and ‘personality’ (33%). Functional improvement by at least 1 point in the mRS was observed in 72% of patients. There were no differences in any assessed QoL domains.

Conclusion: Such complex service requires co-ordinated care plan by MDT from different organisations within their context. The key gap is ensuring timely post-injection therapy. Identifying a named therapist improved the service. Communication between community & the hospital team deteriorated. This project highlights the value of the iterative process of re-auditing since different challenges will emerge for improvement and sustainability.

Fluoxetine for post stroke depression: Experience of rehabilitation unit in Ibn Rochd University hospital of Casablanca
L. Riah1,2, M. Elbouchikh3, F. Lmidmania4, A. Elfatimia4. 1Ibn Rochd University Hospital, Casablanca, Morocco; 2Rehabilitation Unit, Casablanca, Morocco

Background: Depression after stroke is an obstacle to the rehabilitation which imposes early antidepressant treatment.

Objective: The objective of this study is to evaluate the efficacy of fluoxetine in depression after stroke and its effect on patient response to rehabilitative treatment.

Material and methods: Prospective study over 17 months from September 2011 to February 2013 effecting 41 depressed stroke patients followed in the rehabilitation unit. Onset of stroke had to be less than 30 days, patients with severe aphasia were excluded. The diagnosis of depression after stroke was as defined by the DSM IV, the severity of depression was assessed using the MADRS, and the effectiveness of depression was assessed by the PASS. Treatment with fluoxetine was introduced to all patients at a rate of 20 mg/d. The MADRS and the PASS were reassessed at 1 and 2 months.

Results: Of 56 patients with hemiparesis, 41 patients developed post-stroke depression (73.2%); the mean age was 54.3 years ranging from 31 to 85 years, the sex ratio was 1.7, ischemic stroke accounted for 76.9%, 30 patients (73.1%) had minor depression and 11 patients (26.8%) severe depression. PASS averaged 17.2/36 in early assessment and was 26.9/36 to 2 months of treatment. Fluoxetine was well tolerated, no adverse effects were noted.

Conclusion: In patients with depression after stroke early prescription fluoxetine should be coupled with rehabilitation; this treatment has a dual effect, on depression and on motor recovery as demonstrated by authors reporting the effect of fluoxetine on brain neuroplasticity after stroke.

Vestibular rehabilitation improves postural stability in the degenerative spinocerebellar ataxia patient (DSA): A case report
P. Menune. The Faculty of Physical Therapy, Mahidol University, Salaya, Thailand

Background: DSA is genetically associated with postural instability. The DSA patients usually have gait ataxia, fatigue of falls and decrease balance due to limited activity in daily life. The rehabilitation program of these patients is long term. So, it should be designed for clinical use and home program.

Propose: To determine the effectiveness in increasing the stability after vestibular rehabilitation (VR) in DSA patient and to create the new concept of treatment ataxia patients.

Method: A case report. A 63 years old male with 6 years of DSA symptom who can walk by rolling wheel walker with supervision.
He received the treatment program and the home program that consist of:

1. Cawthorne and Cooksey exercise.
2. Substitution exercise.

The subject was treated at the physical therapy clinic 1 day/week and home program 3 day/week in 6 weeks. The stability test used Time-up and Go test (TUG) before and after treatment at the clinic.

**Result:** After 6 weeks, the TUG score before and after rehabilitation program was decrease from 35.17 ± 15.39 s to 29.17 ± 8.7 s (P = 0.001) and the difference score in each week of treatment program decrease 17, 3, 10, −3.2 and 7 s. The average TUG score before and after program = 6 ± 6.99 s (95%CI = −1.33 to 13.33).

**Conclusion:** Although, the VR can improve the stability of DSA patient, the DSA is a degenerative disease. The patient should keep continuous exercise to maintain the body function, balance and strength.

**Neuromodulation for intractable primary headaches**

M. Mukelabai. Anaesthesia, Critical Care, HIV/AIDS and Pain Mgt. Centre, Mufilira, Zambia

**Objectives:** This review discusses the role of neuromodulation in the management of intractable headaches.

**Discussion:** Although most patients benefit from a range of acute and preventive drugs, a subgroup of patients remain refractory to treatment. For these patients, invasive techniques should be considered. Despite good efficacy in some forms of primary headache, nerve blocks with either local anaesthetics or steroids or combinations thereof, provide only temporary relief in most patients. Neuromodulatory approaches can be pragmatically classified according to implantation site and invasiveness. Given that complex networks of pain processing structures are activated and deactivated upon stimulation of a single target, neuromodulation which interferes activation only. The mode of action differs substantially between different approaches.

**Conclusion:** In clinical practice, delivery of the appropriate neuromodulatory approach remains a challenge. Therefore, an interdisciplinary approach involving a team with expertise in both diagnosis and treatment of headaches and the implantation of invasive neuromodulatory devises are crucial for the success of this promising addition to our armamentarium against intractable primary headaches.

A 22-year follow-up of the incidence of traumatic spinal cord injuries in Western Denmark

E.M. Hagen, R.M. Hansen, I.L. Johanssene. Spinal Cord Injury Centre of Western Denmark, Department of Neurology, Viborg Regional Hospital, Viborg, Denmark

**Background:** Retrospective population-based epidemiological study.

**Objective:** To assess temporal trends in the incidence of traumatic spinal cord injuries (TSCI) and demographic and clinical characteristics of a geographically defined cohort in the period 1990–2011.

**Methods:** Patients were identified from hospital records. Crude rates and age-adjusted rates were calculated for each year. The multivariate relationship between cause of injury, age at injury, time of injury and gender was examined using a Poisson regression model.

**Results:** A total of 669 patients were admitted to the Spinal Cord Injury Centre of Western Denmark. The annual incidence varied between 5.9 and 13.7 per million; men 9.1–23.3 and women 0.7–7.4 per million. Mean age on admission for whole period was 38.6 years. The incidence of TSCI increased among men 60 years.

Motor vehicle accidents (MVA) was the most common cause of injury (50.2%), followed by sports and leisure activities (24.5%). More women were injured during sports and leisure activities (29.8% vs. 23.4%) and more men were injured in MVA (50.4% vs. 47.9%). The lesion level was cervical in 48.6%, and clinically incomplete in 57.2%.

**doi:** 10.1016/j.jns.2013.07.1913
The incidence of incomplete tetraplegia decreased among men <30 years, and increased among men >60 years.

**Conclusion:** The incidence of TSCI has remained stable during the past 22 years. The most frequent causes of TSCI, MVA and sports and leisure activities, are potentially preventable causes.

**The burden of paediatric cerebral palsy on caregiver’s mental health**

H. Hakobyan, H. Manvelyan. Neurology, Yerevan State Medical University after M. Heratsi, Yerevan, Armenia

**Background:** Paediatric Cerebral Palsy (PCP) is the leading cause of childhood disability affecting function and development with huge social burden because of disease both costs of treatment and number of caregivers. It’s well known that PCP affects not only the child, but also their immediate caregivers (usually mothers).

**Aim:** To rule out the level of depression in mothers with PCP child.

**Design:** 96 mothers with PCP kids were evaluated during their children rehabilitation in the city Jermuk, Armenia. Beck Depression Inventory (BDI) was assessed. The level of education was also included.

**Results:** 75 (78.1%) of mothers with kids with PCP had depression. Distribution of depression was 23 (24%) mild, 47 (49%) moderate, and 5 (5.2%) severe. We found strong correlation between severity of depression and education. Mothers with university or higher degree level show most severe level of depression. 40 (88.9%) of mothers with university or higher degree level had depression. Distribution of depression among mothers with university or higher degree level was 11(24.4%) mild, 25(55.6%) moderate, and 4(8.9%) severe.

**Conclusion:** PCP must be considered as disease with huge impact on caregiver’s mental health. Mothers with kids with PCP must be mandatorily evaluated for depression, for a successful management of PCP.

**Functional outcomes after surgery for heterotopic ossifications: 22 cases**

**Introduction:** Heterotopic ossification is a frequent complication in head injury patients. The functional impairment may be severe. The goal of surgery is to improve function. The aim is to determine functional outcomes of patients undergoing surgery for heterotopic ossifications.

**Material and methods:** This was a prospective study of patients who underwent surgery for heterotopic ossifications followed by intensive rehabilitation care in our department from January 2009 to March 2013. The evaluation included a joint assessment and a functional assessment for each affected joint.

**Results:** There were 22 patients (29 operated joints). Predominantly male (82%) and the average age 31.6 years (19–41 years). Operated joints were: knee (n = 11, 38%), elbows (n = 11, 38%), and hips (n = 7, 24%). All patients received physical therapy based mainly on continuous passive mobilization of the elbow or knee in addition to functional work. For operated hips, the Postel Merle d’Aubigné (PMA) score improved from 6.5 to 8. In patients who had knee surgery, the functional status improved: one patient recovered the ability to walk and the others good sitting position. For patients who had elbow surgery, the functional assessment revealed improved possibilities for global nutrition (hand–mouth), hygiene (hand–face) and grooming (hand–neck).

**Discussion and conclusion:** The main objective of surgery for heterotopic ossifications is to restore joint mobility and function. Appropriate rehabilitation in an experienced PRM unit greatly contributes to improved functional capacities.

**Low level laser therapy improves neurological deficits after embolic strokes in rats**

C.-H. Chen<sup>ab</sup>, Y.-H. Wang<sup>c</sup>, M.-H. Huang<sup>d</sup>, <sup>a</sup>Department of Physical and Rehabilitation Medicine, Faculty of Medicine, College of Medicine, Kaohsiung Medical University, Kaohsiung, Taiwan, ROC; <sup>b</sup>Department of Physical and Rehabilitation Medicine, Kaohsiung Municipal Ta-Tung Hospital, Kaohsiung, Taiwan, ROC; <sup>c</sup>School of Dentistry, College of Dental Medicine, Kaohsiung Medical University, Kaohsiung, Taiwan, ROC; <sup>d</sup>Department of Physical and Rehabilitation Medicine, Kaohsiung Medical University Hospital, Kaohsiung, Taiwan, ROC

**Background:** Stroke remains the third leading cause of death. The sequel to stroke leads to disability in daily living activity performance and great economic burden.

**Objective:** Low-level laser therapy (LLLT) has been used a wide range in rehabilitation field. However, few researches have mentioned the effects on stroke. The purpose of this study is to reveal the effects of LLLT on stroke recovery and possible mechanisms involved.

**Material and methods:** Seventy two (300–350 g) Sprague-Dawley rats were divided into the sham (n = 6) and studied groups. The studied rats were applied with a transient occlusion of the middle cerebral artery through internal carotid artery (tMCAO). The studied rats were further divided into 8 subgroups and 6 rats each were irradiated to 0j and 8j of LLLT for 1, 4, 7 and 14 days after tMCAO. Histological studies were performed with triphenyl tetrazolium chloride (TTC) staining to demonstrate the ischemic volume. Behavior patterns could reflect the motor recovery from the impairment. Molecular assays were used to assessed the mechanism.

**Results:** After LLLT on tMCAO tissues, the ischemic volume decreased. Rat movements including front limb symmetry, cylinder test, and swimming task showed much improvement. The mRNA of growth-associated protein-43(GAP-43) and interleukin (IL-1) significantly decreased after LLLT.

**Conclusion:** LLLT could improve rat neural regeneration in the tMCAO tissue and promote motor recovery. LLLT also regulates the nerve related gene expression GAP-43, TNF-α and IL-1. LLLT could offer a non-invasive treatment adjuvant for stroke.

Impact of soft-tissue-shortening on goal achievement in patients treated with botulinum-toxin a (BONT-A) for post-stroke upper-limb-spasticity (ULIS-2 study)
S. Ashford, K. Fheodoroff, J. Jacinto, L. Turner-Stokes, Palliative Care, Policy and Rehabilitation, King’s College London, Northwick Park Hospital, Regional Rehabilitation Unit, London, UK; Gaaital-Klinik, Hermagor, Austria; Centro de Medicina de Reabilitação Alcoitão, Estoril, Portugal; School of Medicine, King’s College, London, UK

Background: Soft-tissue-shortening (STS) is a common long-term sequel of upper-limb spasticity (ULS) affecting different levels of functioning if not treated appropriately.

Objective: To describe the impact of STS on goal achievement in different goal areas in patients after BoNT-A treatment of ULS.

Patients and methods: Analysis of primary goal achievement in relation to STS in adults with post-stroke-ULS within an observational, prospective cohort study on current practice in an international, multicenter design (84 centers in 22 countries: ULIS-2).

Intervention included one cycle of BoNT-A treatment and concomitant therapy in accordance with routine local clinical practice. The presence of soft tissue shortening was defined as severe restriction of passive range of motion (pROM) in at least one segment (shoulder, elbow, wrist, hand).

Results: 340 (74.5%) patients had no STS and 116 (25.5%) presented STS in at least one segment.

If STS was present, goals related to pain control (87.5% with STS versus 81.1% without STS) and ease-of-care (87.5% with STS versus 84.8% without STS) were more often achieved.

A higher proportion of patients without STS achieved goals in active function (73.9% without STS versus 58.3% with STS), maintaining/improving pROM (83.3% without STS versus 63.0% with STS) and reduction of involuntary movements (84.4% without STS versus 55.6% with STS).

Conclusions: Goals related to pain control and ease-of-care were more often achieved in patients with STS, whereas a higher proportion of those without STS achieved goals in active function, improved pROM and reduction of unwanted involuntary movements.

Topic: 10 – Neurorehabilitation
Neuromodulation of the sensorimotor cortex by vibration stimulation of the whole-hand
S.M. Golaszewski, M. Seidt, A.B. Kunz, M. Christova, K. Schwenker, L.-S. Koenig, R. Nardone, E. Trinka, F. Gerstenbrand, Department of Neurology, Paracelsus Medical University, Christian-Doppler-Klinik, Salzburg, Austria; Karl Landsteiner Institute of Neurorehabilitation and Space Neurology, Vienna, Austria; Neuroscience Institute, Salzburg, Austria; Institute of Physiology, Medical University Graz, Graz, Austria; Department of Neurology, Franz Tappeiner Hospital, Merano, Italy

Background: It has been recently shown that 20 min of mechanical flutter stimulation induces lasting motor cortical excitability changes, as assessed by transcranial magnetic stimulation in relaxed hand muscles.

Objective: The present functional magnetic resonance imaging (fMRI) study aims to examine if such neuromodulatory changes are reflected in the BOLD signal during a motor test.

Materials and methods: Two groups were recruited: one group receiving whole-hand flutter stimulation with a frequency of 25 Hz (FSTIM group, n = 22) and a second group receiving no stimulation (NOSTIM group, n = 22). As motor test finger-to-thumb tapping was performed to activate a wide sensorimotor network during the fMRI measurements. Three fMRI measurements were obtained with this test: before stimulation (PRE), after stimulation (POST1), and 1 h after stimulation (POST2). Three regions of interest (ROIs) were defined: primary motor area (M1), primary somatosensory area (S1), and supplementary motor area. In the absence of baseline differences between both groups, the FSTIM group showed increased movement-related brain activations compared with the NOSTIM group, both at POST1 and POST2.

Results: ROI analysis revealed increased blood-oxygenation-level-dependent (BOLD) responses within contralateral S1 (þ20%) and M1 (þ20%) at POST1, which lasted until POST2. These poststimulatory effects within S1 and M1 obviously reflect neuroplastic changes associated with augmented cortical excitability.

Conclusion: We could demonstrate neuromodulation of the sensorimotor cortex by vibration stimulation of the whole-hand that can be
applied as a pre-conditioning of the sensorimotor cortex for a con-
secutive motor therapy to improve outcome in neurorehabilitation.

Modulation of cortical plasticity by whole-hand electrical stimulation in attempt to improve hand motor functions after stroke

L.-S. Koenig*, M. Christova*, K. Schwenker*, H. Bartsch*, G. Luthringhausen*, E. Gallasch*, A.B. Kunz*, M. Seidl*, E. Trinka*, S.M. Golaszewski*, *Department of Neurology, Paracelsus Medical University, Christian-Doppler-Klinik, Salzburg, Austria; †Institute of Physiology, Medical University Graz, Graz, Austria; ‡NeuroCare Rehabilitation Center, Salzburg, Austria

Background: Peripheral electrical stimulation has been proved to modulate cortical plasticity in healthy and in patients. Such effects also occur after application of electrical mesh-glove stimulation (MGS) in our previous studies on healthy subjects.

Objective: The effect of whole-hand electrical stimulation on motor recovery in stroke patients at the subacute stage is examined.

Materials and methods: Patients with cortico-subcortical stroke and predominantly motor hemiparesis of the upper extremity were recruited. MGS was applied on the paretic hand daily for 60 min before the standard rehabilitation training over three weeks. Hand motor and sensory functions were evaluated with Wolf Motor Function test, Fugl-Meyer Assessment score, Nine-hole-peg Test, and Semmes–Weinstein monofilaments. Single and paired-pulse transcranial magnetic stimulation (TMS) were applied to evaluate the corticospinal excitation changes over the treatment period. Further, functional magnetic resonance imaging (fMRI) was conducted to assess the cortical brain reorganization changes after the treatment. Effects of MGS were compared to a control group receiving sham stimulation.

Results: Patients from both groups showed significant functional improvement as assessed with the motor functional tests. The improvement for the MGS group was increased compared to the control group.

Conclusion: Electrical stimulation applied before a physiotherapeutic training raises the motor cortical excitability in the lesioned cortex so that the subsequent training becomes more effective. The obtained results provide better understanding how modulation of central motor controlling structures by somatosensory stimulation correlates with functional motor recovery.

Neurological bladder disorders: Clinical and urodynamic aspects

Introduction: Therapeutic of neurological bladder need an Urodynamic exploration. It’s prevented urinary complications.

Objectives: Our objective was to determine the Urodynamic exploration aspects to patients with neurological bladder.

Patients and methods: We conducted a retrospective study in Rehabilitation department of teacher hospital of Ibn Rochd (Morocco). Patients with neurological bladder who benefited a complete Urodynamic exploration between October–March 2013 were included. Urinary disorders which can be explicaded for organic urinary lesions were excluded. Biographic, urinary symptoms, results of neurological exams and Urodynamic exploration were noted.

Results: We included 55 folders of patients. Patient aged under 15 year at 54, 5% of case. Women represented 56, 4%. Urinary disorders were low voiding jet (30,9%), urinary hesitation (20%), incomplete draining (18,2%), enuresis (7,3%), and urinary incontinence (50, 9%). Other urinary disorders were urge incontinence (18,2%), polakiuria (5,5%). Myelitis (11%), spinal cord tumors (7,3%), multiples sclerosis (5,5%), encephalitis (3,6%), traumatic spinal cord (3, 6%), and spina bifida (3, 6%) were the principal etiologic. Unknown etiologic represented (56,4%). Urodynamic exploration found dysuria (36,4%), vesicospincter dyssnergia (25,5%), high bladder activity (44,9%), low compliance (18,4%), level basic tone (18,4%), high compliance (16,3%), sphincter deficiency (22,4%), and sphincter hypertension (8,2%).

Conclusion: Urodynamic exploration aspects in neurological bladders are multiple. Adequate therapeutic depends on results of this exploration.

The people empowering people (pep) program for stroke patients in Srinagarind hospital

S.S. Ngaosinchai, Khon Kaen University, Khon Kaen, Thailand

Conclusion: Most stroke patients had been continuing home rehabilitation, however home visit by health professional still be necessary.
Background: Stroke patients have impairments and disability. The empowerment is important to enhance the patient wellness.

Material and methods: The 115 stroke patients and 115 caregivers who visited rehabilitation clinic during October 2012–March 2013 were recruited in the program. The PEP program was conducted in small group fashion (5–6 patients/group). The participants were encouraged to express their own issues and discussion. Moreover, essential skills and knowledge for self care activity, and counseling using BATHE technique were instructed by the health professionals.

Results: Most of patients (80%) were able to do self care activity independently. About 30% had complications; joint stiffness, pressure ulcer, aspiration pneumonia and urinary tract infection. All of participants had good knowledge in stroke disease and risk factor. The individual issue mainly focused on emotional problem (depression, anxiety, anger, emotionalism) after stroke, lack of family support, inappropriate environment and being unable to walk.

Conclusion: The PEP program provided an opportunity for patients and their caregiver to share experience with other patients who have had the same experience and health professional as well. This program would be an effective intervention to stimulate patient's well being.

Multifocal tuberculosis revealed by cerebellar ataxia: One case

Introduction: Multifocal tuberculosis is uncommon and is defined by the achievement of two extra-pulmonary sites with or without pulmonary involvement. Multifocal tuberculosis is grave and responsible for 16–25% cases mortality. It is mainly associated with immunocompromised person.

Purpose: To describe the characteristics of multifocal tuberculosis in an immunocompetent.

Case report: 38-year-old woman with history of epilepsy consulted for difficulty in walking, ataxia and weight loss of 10 kg, physical examination found a dyspnea, a normal conscious, a normal voluntary control, a vivacious deep tendon reflexes, balance disorder, enlargement of support polygon, drunken gait, all in a context of apyrexia and impaired general condition. The chest X-ray objectified a miliary tuberculosis, chest CT scan was in favor of pulmonary tuberculosis and lymph nodes, cerebral MRI showed nodular lesions in the left region of occipital lobe with triventricular hydrocephalus in favor of neuromeningeal tuberculosis. The diagnosis of multifocal tuberculosis (pulmonary, cerebral and lymphoid) was retained. Patient received her BCG vaccination without any immunocompromised therapy. Immunocompromised disease was not found. Management was 12 month of antibacillar treatment with rehabilitation. Clinical, laboratory studies and radiological evolution were good.

Discussion: Multifocal tuberculosis is a severe form which can affect even immunocompetent patient particularly in the Moroccan context, hence the need for a systematic dissemination checkup assessment for better management. This treatment should be instituted as soon as possible to avoid the sequelae.

Conclusion: Multifocal tuberculosis is severe, to improve its prognosis, we emphasize the importance of early diagnosis and therefore the treatment.

Atypical evolution of Guillain Barré syndrome: One case

Introduction: The Guillain Barré syndrome is an acute polyradiculoneuritis affection. Involvement of the peripheral nervous system with bladder dysfunction is rare.

Purpose: We describe a case report of uncommon manifestation of GBS with bladder dysfunctions and literature study.

Case report: Mme RA 37 years old, without particular past history, presented an acute polyradiculoneuritis GBS in acute phase with flask tetraparesis, areflexia, facial diplegia, oropharyngeal dysphagia, respiratory difficulty, constipation and urinary retention. The EMG showed a heterogeneous distal and proximal sensory motor function loss with demyelinating stigma, an important axonal injury without any signs of active denervation indicating a severe case. Lumbar puncture revealed an albuminocytologic dissociation. Urodynamic investigations objectivized a dysuria with important post-void residual urines, detrusor was hypoactive, hyposensitive and hypercompliant.

Evolution was a total recuperation of motor function and persistence of urinary retention after 2 months contrary to what has been said in literature. Urinary disorders were managed by an intermittent auto urinary drainage.

Discussion: Bladder dysfunction may be the first manifestation of GBS and urinary retention is the most frequent of these disorders like in the case of our study and is likely secondary to sacral parasympathetic nerve dysfunction, but a detrusor over activity can be observed whose mechanism is unclear. It is important to be aware of these disorders which lead to uro nephrological complications and need a treatment as soon as possible until complete recovery.

Conclusion: Bladder dysfunction prognostic in GBS was good. A total disappearance of symptoms is constant but the period differs in the literature.

Neuromuscular electrical stimulation applied to upper limb flexor muscles of tetraplegics: Interlimb reflex response assessed by electromyography — Pilot study
F. Beinotti, K. Alonso, E. Azevedo, A. Cliquet Junior. State University of Campinas, Campinas, Brazil

Background: Some researchers report that if lower limbs are stimulated, there is a reflex response in the upper limbs, but little research has been done on the inverse response in tetraplegic subjects.

Objective: To observe if there are responses in tetraplegic individuals, analyzing reflex activities when applying neuromuscular electrical stimulation.

Patients and methods: Five patients with chronic tetraplegia were selected and divided in to two groups (Group I; Group II). Electromyographic signals were recorded from surface electrodes placed on the contralateral lower limb muscles: rectus femoris, vastus lateralis, vastus medialis, tibialis anterior, gastrocnemius medialis, soleus, fibularis longus and extensor digitorium longus when neuromuscular electrical stimulation was applied to the flexor digitorium profundus and opponens pollicis.
This stimulation was repeated five times in order to calculate Root Mean Square (RMS) averages.

**Results:** The groups were composed of, AIS-B (n = 2) and patients, AIS-A (n = 3). Group I did not present any signals and group II showed signal in the lower limb muscles. When the muscles were stimulated, in group II, the first subject presented responses in muscles: RF (mean RMS = 93.58mv ± SD = 5.1), TA (164.36 ± 6.1) and S (100.55 ± 1.89). The second patient presented in all muscles: RF (90.64 ± 3.37), VM (63.91 ± 15.27), VL (136.66 ± 2.61), TA (106.89 ± 6.2), GM 87.06 ± 6.2), S (88.27 ± 3.06) FL (129.38 ± 5.67) and EDL (91.16 ± 3.59).

**Conclusion:** The presence of electromyographic signals suggests a possible interaction between upper and lower limbs when applying neuromuscular electrical stimulation in upper limbs. However more studies are needed to confirm this theory.

**Conceptualizing war-induced neurological trauma through personalized psychosocial approach**

A.V. Libin a, T. Hart a, M. Schladen a, J. Scholten a, A.W. Dromerick a, M. Llorente a, M. Blackman a, b Mental Health Service, DC Veteran Affairs Medical Center, Washington, DC, USA; bPsychology, Moss Rehabilitation Research Institute, Elkins Park, PA, USA; cNational Rehabilitation Hospital, Medstar Health, DC Veteran Affairs Medical Center, Washington, DC, USA; dPolytrauma Clinic, DC Veteran Affairs Medical Center, Washington, DC, USA; eResearch Services, DC Veteran Affairs Medical Center, Washington, DC, USA

**Background:** Traumatic brain injury (TBI) is a major war-related health problem that leads to deficits in executive function, a term used for the cognitive operations responsible for decision making and goal management. This, along with emotional and behavioral deficits that follow TBI, contributes to injured Veterans’ reduced ability to return to work or school and to regain satisfactory personal lives.

**Objective:** The COMPASS (Community Participation through Self-Efficacy Skills Development) program aims at testing a patient-centered intervention framework that can be utilized as a platform for VA community re-integration comparative effectiveness research.

**Patients and methods:** The COMPASS intervention integrates principles of goal self-management, emphasizing its positive effect on self-efficacy mediating a neurologic trauma consequences. Veterans with mild TBI will be randomized into two groups: the COMPASS group and the supported discharge group.

**Results:** It is expected that personalized conceptualization of the RCT approach based on two consecutive months treatment phase for the Veterans enrolled in the intervention group will result in their greater social re-integration into the society.

**Conclusion:** Goal-setting and goal management concepts are part of the “natural language” of rehabilitation. It might be argued that retraining returning Veterans with TBI how to self-manage their goals, with appropriate help and support, would essentially treat deficits in executive function. A structured approach to goal self-management would foster greater independence and self-efficacy, help clients to gain insight into goals that are realistic for them at a given time, and help clinicians and clients to work more effectively as true collaborators.

**Evaluating efficacy and user’s expectations of a virtual reality training system: A multi-centre randomised controlled trial using mixed methods**

C. Schuster a, b, K. Engel c, d, I. Lehmann e, L. Schmidt a, b, N. Kobashi a, b, I. Thaler a, S. Signer a, M.L. Verra a, A. Hennke a, M. McCaskey a, D. Kiper a, d. d Research Department, Reha Rheinfelden, Rheinfelden, Switzerland; eInstitute for Rehabilitation and Performance Technology, Bern University of Applied Sciences, Burgdorf, Germany; fInstitute for Neuroinformatics, University Zurich, Switzerland; gETH Zurich, Switzerland; hYouRehab Ltd., Zurich, Switzerland; iInstitute for Physiotherapy, University Hospital Bern, Bern, Switzerland; jSchool of Health Sciences, Queen Margaret University, Edinburgh, UK; kDepartment of Health, Bern University of Applied Sciences, Bern, Switzerland; lPhysiotherapy Department, Buergerspital Solothurn, Solothurn, Switzerland

**Background and objective:** Virtual reality (VR), widely used in gaming, has now found its way into neurorehabilitation. The aim of this study is the efficacy evaluation of a VR training system including two nested qualitative evaluations of patients’ and therapists’ perspectives.

**Methods:** Sixty stroke patients will be randomly allocated to an experimental VR (EG) or a control group using conventional physiotherapy or occupational therapy (16 sessions, 45 min each). Using custom data gloves, patients’ finger and arm movements are displayed in real-time on a monitor and move and manipulate objects in various virtual environments. A blinded assessor will test patients’ motor and cognitive performance twice before, once during and twice after the intervention using the Box and Block Test, Chedoke–McMaster stroke assessments (subscale hand, arm should pain), Chedoke–McMaster Arm and Hand Activity Inventory, Line Bisection Test, Stroke Impact Scale, Mini-Mental-State Examination, and Extended Barthel Index. Semi-structured interviews will be conducted with patients in EG after intervention finalisation focussing on the expectations and experiences regarding the VR training. Therapists’ perspective on VR training will be reviewed in focus groups.

**Results:** Therapists in all centres completed the study training. Until now, seven patients were recruited (one female, age 66.6 ± 5.3 y). One patient finished the study and took part in a semi-structured interview. After verbatim transcription the data coding and categorisation based on a phenomenological approach have started.

**Conclusion:** The study protocol including the patients’ interviews seem to be feasible and patients enjoy the VR training. The study is registered with clinicaltrials.gov: NCT01774669.

**Topic: 10 — Neurorehabilitation**

**Outcomes related to mobility in patients treated with botulinum toxin a (BoNT-A) for post-stroke upper-limb spasticity (ULS-2-Study)**

S. Ashford a, L. Turner-Stokes b, J. Jacinto c, K. Theodoroff d, e. aPalliative Care, Policy and Rehabilitation, King’s College London, Regional Rehabilitation Unit, Northwick Park Hospital, UK; bKing’s College London, London, UK; cServiço de Reabilitação de Adultos 3, Alcabideche, Portugal; dGaïtal-Klinik, Herrmgar, Austria; eDanube University Krems, Herrmgar, Austria

**Background:** The impact of upper-limb spasticity (ULS) on mobility is debated.

**Objective:** To describe the characteristics of patients with mobility-related primary goals compared to those with primary goals in other

areas (e.g. passive/active function, pain, impairment). To compare mobility related goal achievement with achievements in these other areas.

**Patients and methods:** Analysis of 456 adults with post-stroke ULS within an observational, prospective cohort study conducted in 84 centers in 22 countries on current practice of ULS treatment (ULS-2-Study).

**Interventions:** One cycle of BoNT-A treatment and concomitant therapy in accordance with routine local clinical practice.

**Outcome measures:** Primary goal achievement; the Neurological Impairment Scale (adapted for spasticity), composite Modified Ashworth Scale (MAS).

**Results:** Of 456 adults with post-stroke ULS presenting for treatment with BoNT-A, 45 (9.9%) had a primary goal related to mobility and 411 patients had primary goals in other areas. Mobility goals were related to involuntary movements during walking (n = 41), balance (n = 3) and transfers (n = 1). Sub-classification of mobility goals also related to speed of walking (n = 3), arm swing (n = 3), independence (n = 1), walking efficiency (n = 4), cosmetic appearance (n = 3) and dressing (n = 1). Baseline demographics and total BoNT-A dose were similar for the two groups. 33/45 (73%) achieved their mobility goal compared with 330/411 (80%) in the group with other goals (Chi-squared p = 0.33).

**Conclusions:** Treatment of ULS with BoNT-A can lead to improved mobility by reducing involuntary movements. Improved understanding of the impact of ULS on mobility might lead to a higher rate of goal achievement.

**“REVIS”: Restoration of vision after stroke using non-invasive alternating and direct current stimulation**

C. Gał³, P.M. Rossini²,4, T. Tatlisumak⁴, W. Waleczczyk⁵, O. Speck¹, H. He⁵, B.A. Sabel⁶, "Institute of Medical Psychology, University of Magdeburg, Medical Faculty, Magdeburg, Germany; ²Department of Neurology, Catholic University of Rome, Roma, Italy; ³RCCS S. Raffaele Pisana, Roma, Italy; ⁴Department of Neurology, Helsinki University Central Hospital (HUCH), Helsinki, Finland; ⁵Department of Neurophysiology, Nencki Institute of Experimental Biology, Polish Academy of Sciences, Warszawa, Poland; ⁶Institute for Experimental Physics (IEP), Department Biomedical Magnetic Resonance (BMMR), University of Magdeburg, Faculty of Natural Sciences, Magdeburg, Germany; ⁷Chinese Academy of Sciences, Institute of Automation, Beijing, China

Non-invasive brain stimulation using alternating current stimulation (ACS) has recently been shown to improve vision after optic nerve damage. It is assumed that transorbital ACS induces neuronal networks to propagate synchronous firing probably activating residual areas surviving the injury. The aim of the ‘Restoration of Vision after Stroke’ (REVIS) network is to determine if bilateral transcranial direct current stimulation (tDCS) and transorbital ACS may also have a positive impact on vision restoration in patients with post-chiasmatic visual pathway lesions. In particular, the potential of non-invasive current stimulation in ameliorating vision impairment following stroke (hemianopia) is the key issue addressed by the REVIS study group.

Within the REVIS network a number of small sample, randomized, controlled, clinical studies including patients with post-chiasmatic lesions due to monohemispheric, ischemic or hemorrhagic stroke were initiated by clinical partners from Germany (Institute of Medical Psychology and Department Biomedical Magnetic Resonance, University of Magdeburg), Italy (Department of Neurology, Catholic University of Rome), and Finland (Department of Neurology, Helsinki University Central Hospital).

The network also includes a basic neuroscience project that studies neuronal network reorganization in the cat visual system after stroke (Department of Neurophysiology, Nencki Institute, Warsaw). Beyond the European network, a collaboration with the Institute of Automation at the Chinese Academy of Science was established.

This contribution presents the overall aims of the network activity, the functional, physiological and imaging parameters to be studied, and the rational of the clinical endpoint selection.

**Spectral brain mapping in children with cerebral palsy treated by the Masgutova Neurosensorimotor Reflex Integration method**

W. Pileckia¹,², L. Kipiñe³, T. Szawrowicz-Pelka⁴, D. Kalka⁵, S. Masgutovad, "Department of Pathophysiology, Wroclaw Medical University, Wroclaw, Poland; ²University of Medical Sciences in Legnica, Legnica, Poland; ³Department of Neurology, Lower Silesia Specialist T. Marciniak Memorial Hospital - Medical Emergency Centre, Wroclaw, Poland; ⁴Svetlana Masgutova International Institute, Warszawa, Poland

**Background:** Rehabilitation in children with neuromotor impairment disorders can be carried out with the use of effective therapeutic methods. The new one is the Masgutova Neurosensorimotor Reflex Integration (MNRI®) method.

**Objectives:** The aim of this study was to determine the efficiency of rehabilitation carried out with the use of MNRI® in children with cerebral palsy using objective electrophysiological tools.

**Patients and methods:** The study involved a group of 15 children with cerebral palsy treated by MNRI®. We measured their brain activity by multichannel EEG and analysed the obtained signals with use of the spectral brain mapping.

**Results:** By analysis of the spectral maps we documented the changes in electric brain activity as an effect of neurorehabilitation.

**Conclusion:** The rehabilitation carried out by the MNRI® method in children with cerebral palsy causes the reorganisation of the electrical activity of central nervous system network. It may be responsible for positive treatment effect of this therapeutic method.

**Disability due to traumatic brain injury in Ukraine (6 years experience)**

V.A. Golyk, A.V. Ipatov, A.P. Guk, O.M. Moroz, A.P. Pivnyk, V.O. Pogorelova, N.E. Madyukova, “Neurology and Border States, Ukrainian State Institute of Medical and Social Problems of Disability, Dnepropetrovsk, Ukraine; ²Neurotrauma, Institute of Neurosurgery, Kiev, Ukraine; ³Neurorehabilitation, Ukrainian State Institute of Medical and Social Problems of Disability, Dnepropetrovsk, Ukraine

Traumatic brain injury (TBI) is one of leading causes of mortality and disability worldwide. In spite of it, no TBI official statistical disability data were collected in Ukraine since 1987.

**Methods:** 6 years (2007–2012) dynamics of TBI disability incidence rates for adult population (per 10,000) was investigated. Disability
grade (“invalidity” status) in Ukraine is set according to the Ministry of Health Order (no. 561, August 05, 2011) based on ICF (2001) principles. We collected primary disability data structure due to TBI and consequences (ICD X codes S00–S04, S06–S09, S06.0 and T90.5) in Ukrainian regions.

**Results:** Panukrainian TBI (S00–S09) disability incidence was decreased: 0.72–0.72–0.64–0.59—accordingly, as well as the index for TBI consequences (T90.5): 0.99–0.97–0.91–0.84–0.47–0.58. Unexpectedly, a disability data for codes S00–S04 were revealed (total rates 0.17–0.13–0.13–0.07–0.05–0.05). Another peculiarity was role of mild TBI (S06.0) in intracranial TBI statistics (incidence rate 0.23–0.24–0.18–0.24–0.24–0.15, stake ranged 42.1–40.4–35.9–46.0–42.1–30.0%).

**Conclusions:** Revealed data are the subject of further disability epidemiological investigation of posttraumatic syndromes diagnostic correctness followed disability determination and proper expert-rehabilitation diagnostics.

**Effects of virtual reality-augmented training on cortical activation in incomplete spinal cord injury patients: An fMRI study**

M. Villigerab, c, d, P. Pyke, c, d, J. Spillmann, c, d, N. Estévez, c, D. Bohli, c, D. Kiper, e, d, M.-C. Hepp-Reymonde, c, d, A. Curt, c, M. Bolliger, a, S.S. Kollrias, b, S. Hotz-Boendermaker, c, K. Engnc, d

**Background:** Interactive, multimodal sensory stimuli and training using virtual reality (VR) allow the investigation of unique neuroscientific questions and clinical applications.

**Objective:** In this study we examined the neural correlates of imagination, imitation and interactive execution (playing) of goal-directed lower limb movements and the effects of a 4-week active therapist-supervised training paradigm on these cortical activation patterns.

**Patients and methods:** Brain activation of incomplete spinal cord injury patients (N = 8) was measured before and after the training period using 1.5 T fMRI. The stimuli were presented in blocks of 30 s. In each block the subject viewed a video (1st-person perspective) of ball juggling with the feet and was instructed to imagine performing the action, imitate the action or play the game. The baseline view was a scrambled version of the videos. The training paradigm consisted of 16–20 interactive training sessions of 45 min each supervised by a therapist.

**Results:** The playing condition produced broader and stronger activation in prefrontal and subcortical areas than imitation and imagination. The activation patterns of the patients were generally reduced in recruiting cortical areas to control lower limb movements.

**Conclusion:** These results may be of significance for VR-augmented lower limb neuromodulation and motor therapy. The fact that the cortical changes resulted from active patient VR interactions, with the therapist in a coaching role, suggests that it may be also possible to achieve similar effects with minimal therapist involvement.

The prognostic value of cognitive domain deficits on functional recovery in stroke patients after acute physical rehabilitation

V. Ginex, a, L. Veronelli, b, N. Vanacore, b, E. Lacorte, c, L. Pisani, a, F. Clerici, c, d, C. Mariani, d, e

**Department of Neurorehabilitation, Casa di Cura del Policlinico, Milan, Italy; fNational Centre for Epidemiology, Surveillance, and Health Promotion, Italian National Institute of Health, Rome, Italy; gCenter for Research and Treatment of Cognitive Dysfunctions, Institute of Clinical Neurology, Luigi Sacco Hospital, University of Milan, Milan, Italy; hInstitute of Clinical Neurology, Luigi Sacco Hospital, University of Milan, Milan, Italy**

**Background:** Few studies investigated what factors may affect functional recovery in post-acute stroke patients treated with a physical rehabilitation program.

**Objective:** To assess the frequency of domain-specific cognitive deficits and their prognostic value, along with neurological, clinical and demographic predictors, for functional recovery in post-acute stroke patients after discharge from a Neurorehabilitation Department.

**Patients and methods:** This outcome research study included 226 stroke patients (M = 121, F = 105; mean age 75.9 ± 10.7 yrs; education 8.1 ± 4.1 yrs). Patients were assessed at admission and at discharge using the Functional Independent Measure (FIM), and through a comprehensive neurological and neuropsychological evaluation (i.e. reasoning ability, attention and executive functions, memory, visuo-spatial abilities, and language). The main outcome considered is functional recovery, defined as change in FIM score from admission to discharge.

**Results:** Total FIM score at baseline was 62.85 ± 25.3, and FIM cognitive and motor sub-scores were respectively 23.89 ± 8.35 and 38.74 ± 19.21. At the time of discharge FIM score and FIM motor and cognitive sub-scores were respectively 84.58 ± 31, 26.67 ± 8.33 and 57.88 ± 24.53. A linear regression model, considering FIM at discharge as the dependent variable, and baseline motor and cognitive FIM sub-scores, premorbid functional independence, and reasoning ability as main independent variables, was used to assess if neurological, clinical and cognitive domains independently affect functional recovery. The regression model produced an R square value of 67%.

**Conclusions:** Baseline motor and cognitive status, premorbid functional independence, and reasoning ability account for 67% of the total FIM score variance at the time of discharge in patients admitted for post-stroke rehabilitation.

The modified modified ashworth scale (MMAS) in the assessment of muscle spasticity: Intra-rater reliability
N. Nakhostine Ansari\textsuperscript{a}, S. Naghdi\textsuperscript{b}, M. Mashayekhi\textsuperscript{a}, S. Hasson\textsuperscript{b}, Z. Fakhari\textsuperscript{a}, S. Jalaie\textsuperscript{a}, \textsuperscript{a}Physiotherapy, Tehran University of Medical Sciences, Tehran, Iran; \textsuperscript{b}Physical Therapy, Georgia Regents University, Augusta, GA, USA

Background: The MMAS is a new clinical scale for measurement of muscle spasticity. There is little information regarding the intra-rater reliability of MMAS.

Objective: The purpose of this study was to determine the intra-rater reliability of the MMAS in the evaluation of upper limb muscle spasticity in adult patients with stroke.

Material and methods: In this study with a clinical measurement design, one rater randomly graded the spasticity of shoulder adductors, elbow flexors, and wrist flexors in the affected upper limb of 24 patients with hemiparesis twice with at least a 1 week interval to establish intra-rater reliability. The intra-rater quadratic weighted kappa was calculated.

Results: The quadratic weighted kappa was very good for elbow flexors and wrist flexors, and good for shoulder adductors.

Conclusion: The intra-rater reliability of the MMAS was acceptable for measuring muscle spasticity in adult patients with stroke.

Background: Autonomic changes can be induced by different stimuli in patients with disorders of consciousness (DOC) and provide clues on their responsiveness.

Aim: To assess the changes in heart rate variability (HRV) induced by auditory/musical stimuli in patients with DOC.

Materials and methods: The HRV of 5 patients with DOC (3 males, age 35.8 ± 15, LCF = 2.4 ± 0.55) was assessed 9 ± 2 months after severe brain injury (SBI). Patients were assessed while they rested in a wheelchair and listened to a neutral story (NN), a series of autobiographical data read with neutral tone (NA), the story of an episode emotionally important for them (EE), him/her favorite song played live (CdC) and the description of the patient written by his/her relatives (DDL) with musical enrichment. The stimulation was preceded by a baseline of 10 min during which the patient heard
only the sound of a stream (baseline). The patients were assessed twice: the first time, the order of stimuli followed an increasing emotional level and complexity; the second time, the order of stimuli was random.

HRV was derived by a 3 lead ECG using autoregressive (AR) algorithm. 

Results: LFnu, HFnu and LF/HF ratio did not differ during baseline, NN, NA, EE, and CdC, irrespectively of the order of stimuli administration. The LF/HF ratio tended to increase during increasing emotional level and complexity stimuli, but was statistically different only during DDL compared to baseline (p = 0.028).

Conclusion: Enriched stimulation in an immersive environment increased the sympatho-vagal balance of DOC patients.

Clinical efficacy of non-invasive transorbital alternating current stimulation in optic neuropathy: A double-blind, randomized, sham-controlled multi-center study

C. Gall1, S. Schmidt1, A. Antal1, W. Paulus1, M. Schirktkowski1, R. Effert1, S. Kropf1, A. Mante1, S. Brandtb, R. Effert1, S. Kropf1, A. Mante1, S. Brandtb, A. Sabelb, aInstitute of Medical Psychology, University of Magdeburg, Medical Faculty, Magdeburg, Germany; bDepartment of Neurology, Universitätssmedizin Charité, Berlin, Germany; cDepartment of Clinical Neurophysiology, Georg-August University Göttingen, Göttingen, Germany; dDepartment of Ophthalmology, Georg-August University Göttingen, Göttingen, Germany; eEye Clinic, Kassel, Germany; fInstitute of Biometry and Medical Informatics, University of Magdeburg, Medical Faculty, Magdeburg, Germany

Introduction: Non-invasive brain stimulation enhances neuronal plasticity in the visual system in normals and patients with visual field loss (Antal et al., RNN 2012; Sabel et al., RNN 2011) with one of the proposed mechanisms being the neuromodulation of oscillatory brain activity (Schmidt et al., Brain Stimul 2013).

Objectives: In order to improve visual functions after pre-chiasmatic damage to the visual pathway due to various reasons including glaucoma and post-neuritic optic atrophy the efficacy of repetitive transorbital alternating current stimulation (rtACS) was evaluated in a randomized, multi-center clinical trial.

Methods: Ninety-eight patients were randomized into rtACS and sham-group both treated with 10-daily sessions (20–40 min). Outcome measures included visual fields and resting-EEG obtained before and after stimulation, and at 2-months follow-up.

Results: Eighty-two patients completed the study. While rtACS-treated patients (n = 45) showed improvements in visual detection rates (Hodges-Lehmann-estimator median increase 6.4%, 95%-CI(2.9%,11.6%);p < 0.001), no change was observed after sham-stimulation (n = 37, 1.1%,95%-CI(-2.0%,4.3%);p = 0.256. The primary endpoint, percentage change of detection, was significantly better in rtACS compared to sham (p = 0.011; one-sided U-test). Secondary analysis revealed pronounced visual field improvement in the central 5° visual field. Visual field improvements were significant at 2-months follow-up. EEG power changes were observed in the alpha band.

Conclusions: RtACS led to visual field improvement in patients with optic neuropathies. Together with EEG powerspectra change this finding indicates that residual vision activation is associated with plastic alterations in neuronal brain networks and that rtACS is a valid method to partially restore vision loss after optic nerve damage.

MR diffusion tensor imaging and fiber tracking in spinal cord lesions

S. Leis1, M. Seidl1, L. Grassner1,2, M. Mccoy2, E. Trinka1,2
F. Klausner1, aDepartment of Neurology, Christian Doppler Klinik, Austria; bSpinal Cord Injury and Tissue Regeneration Center, Austria;
1Institute of Radiology, Division of Neuroradiology, Christian Doppler Klinik, Paracelsus Medical University, Salzburg, Austria

Background: Magnetic resonance diffusion tensor imaging (MR DTI) can be used to visualize neural pathways within white matter (tractography or fiber tracking). While fiber tracking is of increasing importance in the assessment of brain lesions like space-occupying tumors, experience with spinal cord lesions is limited primarily due to technical limitations.

Objective: To evaluate the feasibility of MR fiber tracking to detect spinal cord lesions.

Patients and methods: In four men (58 +/− 17 years) with spinal cord lesions (cervical spinal cord infarction—ASIA D; compressive cervical myelopathy due to epidural abscess—ASIA D; thoracic herpes zoster myelitis—ASIA C; compressive thoracic myelopathy due to disk herniation—ASIA C) and with pathological somatosensory and motor evoked potentials MR-DTI was performed on a Philips Achieva 3T MRI scanner. Furthermore, a 21 year old man with suspected psychogenic paraparesis who had normal MRI of the spinal cord and normal somatosensory and motor evoked potentials was examined.

Results: In one patient DTI data could not be analyzed due to movement artifacts. In the other three patients fibertracking showed rafification or disconnection of fibers at the level of injury. No discontinuity of fibers was found in the patient with psychogenic paraparesis.

Conclusion: MR fiber tracking is capable to detect lesions of neural tracts in spinal white matter. Quantification of lesion extent and correlation with clinical and electrophysiological data is part of ongoing studies.

Stroke and aphasia quality of life scale (saqol-39). Evaluation of acceptability, reliability and validity of Chilean version

Neurology and Neurosurgery, Hospital Clinico Universidad de Chile, Independencia, Chile

Background: 21 to 38% of stroke has aphasia. Quality of life became a useful indicator in rehabilitation in medicine. There are few instruments to evaluate psychosocial aspect in aphasic patients.

Objective: To evaluate acceptability, reliability and validity of SAQOL-39 to Chilean aphasic population.

Method: The cross-cultural adaptation of the SAQOL-39 into Chilean Spanish was making following translation and back translation method. 31 patients were tested with SAQOL-39 using Boston Aphasia test (BAT), General Head questionnaires (GHQ) and Barthel index. Acceptability was evaluated by examining the floor/ceiling effects and the missing data. The reliability was assessed by Cronbach's alpha and intraclass correlation coefficients.

Results: 61.5 % male, 70 % of the patient must to be retired after stroke. 42% has memory loss. They are not difficult to translate in the English version. The median Boston scale was 3, Barthel index 95 and GHQ-12 = 4. The median SAQOL-39 was 3.6. There good acceptability demonstrated by 2.4% of missing data, 66.7% of ceiling effects and
12.8 % of floor effect. Test re-tests reliability for overall score and the sub scales scores was 0.95(0.76 to 0.95). The Internal consistency analysis by Cronbach's was 0.947.

Conclusion: The Chilean version of SAQOL-39 seems appropriate for clinical use with adequate acceptability, reliability and validity.

Task specific, robot-assisted training in patients with impaired upper limb motor functions—A clinical investigation
A. Hennekea, S. Hahnb, O. Rossic, J. Sutterd, D. Vollenweiderd, C. Schusterd. “Research Department, Reha Rheinfelden, Rheinfelden, Switzerland; Occupational Therapy Department, Reha Rheinfelden, Rheinfelden, Switzerland; Institute for Rehabilitation and Performance Technology, Bern University of Applied Sciences, Burgdorf, Switzerland

Background: Literature showed that robot-assisted arm therapy (RAT) is a safe treatment method that improves upper limb motor function in patients after stroke. There is a need to evaluate the importance of therapy structure, content, and individual adaptation for clinical implementation. There is insufficient evidence for the application of RAT for further pathologies, e.g. Parkinson’s disease and multiple sclerosis.

Objective: To conduct arm therapy using the ARMin III robot technology in a clinical setting with patients with various motor impairment diseases. Evaluation of objective motor function and subjective experiences reported by patients and therapists.

Patients and methods: Explorative study investigating RAT in patients with various diagnoses (myopathy, neuropathy, multiple sclerosis, cerebral palsy, Parkinson’s disease, amyotrophic lateral sclerosis, status after stroke, traumatic brain injury, neuro-surgical intervention, spinal cord injury, or fractures of upper limbs after consolidation. RAT intervention applied 1 to 3×/week for 30–45 min. Pre- and posttesting include objective and subjective assessments depending on diagnosis. Data analysis will focus on therapy parameters.

Results: Study was approved by the responsible ethics committee. Occupational therapists are being trained to apply RAT receiving comprehensive training sessions. Three pilot treatments were conducted with patients. Additionally, one patient (70 years old, male) was treated once during a training session; one male (58 years old) received 9 RAT, one female (33 years old) received 10 treatments.

Conclusion: Intensive training of therapists is necessary. Clinical implementation seems feasible. Patients enjoyed RAT. Active range of motion and increased muscle tonus seems to be positively influenced by RAT.

Islands of consciousness in vegetative state or functional locked-in syndrome?
R. Formisanoa, S. Catani, C. Falletta Caravassoc, M. D’Ippolitob, F. de Pasqualec,d, U. Sabatinic. “Research Department, Reha Rheinfelden, Rheinfelden, Switzerland; Occupational Therapy Department, Reha Rheinfelden, Rheinfelden, Switzerland; Institute for Rehabilitation and Performance Technology, Bern University of Applied Sciences, Burgdorf, Switzerland; Department of Radiology, IRCCS Santa Lucia Foundation, Roma, Italy; aPost-Coma Unit, IRCCS Santa Lucia Foundation, Roma, Italy; Multiple Sclerosis Department, IRCCS Santa Lucia Foundation, Roma, Italy; Department of Radiology, IRCCS Santa Lucia Foundation, Roma, Italy; Institute for Advanced Biomedical Technologies, G. D’Annunzio University, Chieti, Italy

Background: In the last five years residual cortical processing in the absence of behavioural signs of consciousness has been demonstrated in some non-communicative severely brain damaged patients, by means of functional neuroimaging and electrophysiology studies. The term “functional locked-in syndrome” has been proposed for patients with a dissociation between extreme motor dysfunction and preserved higher cortical functions, only identified by functional imaging techniques.

Objective: Patients clinically diagnosed as being in the vegetative state who are able to perform mental imagery tasks are still diagnosed as in the vegetative state with preserved islands of consciousness, not as having functional locked-in syndrome. Our proposal is that functional neuroimaging and electrophysiology should be used in doubtful cases of disorder of consciousness (DOC) to rule out tests for the diagnosis of vegetative state in the presence of residual cognitive functions, at least when performance of complex mental imagery tasks and intentional communication ability have been demonstrated.

Material and methods: Some video recordings of cases during recovery from vegetative state who present with eyes-based communication, together with fMRI data during resting state and after emotional stimulation will be discussed.

Conclusion: The scientific community should finally clearly state that clinically “vegetative patients”, in whom complex mental imagery tasks and intentional communication ability have been demonstrated by means of fMRI or neurophysiology, are not vegetative or unresponsive.
but subjects with total functional locked-in syndrome, clinically misdiagnosed as vegetative state.

Psychiatric and cognitive disorders in neurological patients

A. Buettner-Teleaga, Tumorbiology, Albert-Ludwigs-University, Freiburg im Breisgau, Germany; Psychiatry, University Witten- Herdecke, Witten, Germany

Introduction: Apart from a multitude of physical complaints, neurological disorders can also lead to various kinds of psychiatric and cognitive disorders like mental and cognitive changes or reduced Quality of Life (QoL). In such cases, mental health, mood, attention, vigilance and/or memory may be affected as well as the actual mental and/or cognitive processes themselves. Important factors in this can be the severity of the disorder on one hand, and the duration of prior therapy on other hand.

Methods: The study was carried out involving two groups of randomly selected persons, neurology patients and healthy participants. All patients were selected according to their clinical diagnosis (ICD-10).

Findings: Testing of psychiatric, cognitive and QoL achievements revealed highly significant differences between healthy persons and neurological patients (all parameters: \( p < .001 \)). Analysis of the degree of severity showed for neurology patients no significant differences between mild and severe status (\( p > .05 \)).

Discussion: The study revealed that patients with neurological diseases (strokes, cerebrovascular diseases, brain traumas, brain tumors, etc.) show problems, deficits and disorders concerning in different areas of psychiatric/mental and cognitive achievements as well as in multidimensional QoL. In contrast, the degree of severity of the disorders (neurology patients) was not relevant.

A case report: Neurorehabilitation results in a patient suffering from a “lock-in” syndrome

R. Palić Kramarić, T. Gilman Kuric, B. Radanović, M. Mišir. Department of Neurology, University Hospital Centre Osijek, University J J Strossmayer, School of Medicine, Osijek, Croatia

Background: The 44 year old female patient was hospitalized and treated of disseminating encephalomyelitis. Because of the area affected (pons and crus cerebri) she developed a rarely seen syndrome that included difficulty speaking, swallowing, quadriplegia and incontinence while maintaining full time awareness—the “lock-in” syndrome (LIS).

Objective: The goal was to rehabilitate the patient in a way to establish as much as her previous somatic state as possible.

Material and methods: A patient is a 44 year old white female whose therapy consisted of analgetics, antibiotics, antimicotics, gastroprotectives, antiedematose, anticoagulant and antidepressant therapy as well as intravenous potassium replacement, nutrition supplement, a one time blood transfusion and every day physical rehabilitation therapy. Diagnostics included lumbar puncture, spinal tap and hemoculture analysis, heart and lungs Rtg scan, brain MRI, cervical and thoracal spine, transcranial ultrasound, PCR method and hereditary thrombophilia testing. The nature of illness also requested consultation of other medical experts.

Results: Hospitalization lasted three months during which the patient regained speech and communication skills and after additional neurorehabilitation was able to fully take care of herself.

Conclusion: One of the problems with LIS is the lack of literature concerning its course and prognosis. However, the survival rate for LIS found in Doble et al. (2003) study was 83% for 5 and 10 years and 40% for a 20 year survival rate. So far our patient is in the first 83% and we hope she will continue enduring in order to reach the 20 year survival group.

The effect of short-term rehabilitation for patients with spinocerebellar degeneration

Y. Kikuchi1, E. Kodama2, T. Tsukamoto1, A. Saito1, Y. Asakura1, Y. Narita3, A. Nakajima3, H. Ichiba4, M. Waku5, M. Horiguchi6, M. Koike3, K. Uchida, B. Mihara7. "Department of Rehabilitation for Intractable Neurological Disorders, Iiesaki, Japan; 2Department of Neurology, Institute of Brain and Blood Vessels Mihara Memorial Hospital, Iiesaki, Japan

Background: The effect of rehabilitation has not been well analyzed in patient with spinocerebellar degeneration (SCD).

Objectives: The aim of this study is to clarify the effect of short-term intervention of rehabilitation for patients with SCD.

Patients and methods: We enrolled 10 SCD patients (Multiple System Atrophy (MSA) with predominant cerebellar ataxia 8 case, MSA with predominant parkinsonism 1 case, Spinocerebellar ataxia 1 case). The ages at onset and duration of disease were 58.6 ± 11.6 years old and 4.9 ± 1.9 years, respectively. Rehabilitation was carried out for 12.7 ± 4.3 days. The rehabilitation program was composed of multidimensional exercises such as coordination exercise, proprioceptive neuromuscular facilitation, and mental practice. To evaluate the effect of our program, we carried out measurement of the following four scales before and after the program; 1) Scale for the Assessment and Rating of Ataxia (SARA), 2) Functional balance scale (FBS), 3) Ten meter walk test, and 4) MSA quality of life (MSAQOL). 4) Center of mass × direction (COMx) trajectory.

Results: The score of SARA (12.7 ± 5.7) to 10.4 ± 4.2, \( p < 0.05 \)) and FBS (39.3 ± 8.6 to 45.1 ± 6.7, \( p < 0.05 \)) and gait velocity (40.0 ± 17.6 to 48.8 ± 13.7 m/min, \( p < 0.05 \)) and MSAQOL (43.6 ± 26.8 to 35.8 ± 25.3) were improved after rehabilitation. COMx trajectory was improved from 109.5 ± 39.1 to 92.7 ± 41.1 mm (\( p < 0.05 \)).

Conclusion: Short-term rehabilitation shows beneficial effects in motor function and QoL of patients with SCD.

do1:10.1016/j.jns.2013.07.1949
Improved prediction of recovery after stroke has broad implications for clinical decisions on the type, duration and goals of rehabilitation. Increased understanding of prognostic factors may offer new targets for specific interventions. Almost half of surviving stroke patients are left with impaired function of the hand but individual profiles of weakness, spasticity, sensory and bimanual function vary widely. Combining behavioural and imaging measures can improve prediction of motor recovery (Stinear et al, 2012). In this study we use novel quantitative behavioural measures together with structural and functional MRI measures to understand hand function recovery. We hypothesize that the structural and functional brain connectivity in the early phase after stroke can predict (i) the hand function profile in the late phase and (ii) degree of recovery.

One hundred stroke patients with early signs of upper limb hemiparesis will be recruited at our neurorehabilitation clinic. Imaging and behavioural assessments will be performed at 4 weeks, 3 months and 6 months after stroke. MRI includes anatomical sequences for lesion mapping and diffusion tensor imaging and resting-state functional MRI for structural and functional connectivity analyses, respectively. Clinical hand function measures will be combined with novel validated methods to quantify spasticity, grip force control, sensory and bimanual function. The ProHand will provide insights into neural mechanisms related to recovery of hand function after stroke. Imaging and behavioural markers important for recovery will be identified which should enable enhanced prediction of prognosis and development of targeted interventions.

After three and six weeks patients received a letter and a telephone call reminder.

Results: Totally, 13 patients (age 57.9 ± 15.4y, 9 females, 5 stroke patients) were included. ADL reduced about 79 min/week, sporting activity increased about 204 min/week. MoVo-LISA-questionnaires revealed positive trends regarding SEE, GI, P, AS.

Conclusion: The MoVo-LISA-programme was feasible in groups of five or less. Patients needed help to fill in the questionnaires. It might be considered including information on training options and shift the intervention start to 4 weeks after entry.

MoVo-LISA — implementing a short movement coaching programme to establish a physical active life style: A feasibility study
M. Grill1,2, C. Schuster3, a Physiotherapy Department, Reha Rheinfelden, Rheinfelden, Switzerland; 2Institute for Exercise and Health Sciences, University of Basel, Basel, Switzerland; 3Research Department, Reha Rheinfelden, Rheinfelden, Switzerland; 4Institute for Rehabilitation and Performance Technology, Bern University of Applied Sciences, Burgdorf, Switzerland

Background and objectives: For patients after a disease of the central nervous system (CNS) it is difficult to regain an active life style. The short movement coaching programme MoVo-LISA (Motivation Volition-life style integrated sporting activity) has shown beneficial short and long-term effects in patients with osteoarthritis and obesity. The aim of the study was to implement and evaluate MoVo-LISA in patients with a disease of the CNS.

Methods: A case series with a pre-post design was conducted. Before and six weeks after the intervention patients were assessed with the MoVo-LISA-specific questionnaire including subscales for: current complaints, activities of daily living (ADL), positive and negative consequence expectations, self-efficacy expectation (SEE), goal intention (GI), planning (P), perceived barriers, action and relapse strategies (AS + RS), and social support. The MoVo-LISA-programme included three sessions:

1. group session (60 min) to summarise health goals and movement ideas,
2. individual session (10 min) to refine the activity plan,
3. group session (90 min) to discuss barriers and establish an activity protocol for the upcoming six weeks.

Results: Blind patients had lower EEG spectral power (p = 0.005) and decreased short- (p = 0.015) and long-range (p = 0.033) coherence in the high-alpha EEG band (11–14 Hz) and less densely clustered coherence networks (p = 0.025). rtACS strengthened short- and long-range coherence again which correlated with recovery of detection ability (r = 0.57, p = 0.035) and processing speed (r = 0.56, p = 0.049).

Conclusion: Vision loss in the blind is not only caused by primary tissue damage but also by a synchronization breakdown of short- and long-range connections in brain networks. Because re-synchronization of alpha band coherence is associated with visual field improvements, brain connectivity is a key component in restoration of vision in partial blindness.

The second face of blindness: Processing speed deficits in the intact visual field after pre- and post-chiasmatic lesions
M. Bola, C. Gall, B.A. Sabel. Institute of Medical Psychology, Otto von Guericke University of Magdeburg, Magdeburg, Germany

Background: Damage along the visual pathway results in a visual field defect (scotoma) retinotopically corresponding to the damaged tissue. But other parts of the visual field, processed by the uninjured tissue and believed to be intact, suffer from perceptual deficits as well.

Objective: We studied features of the visual field and scotoma in patients to elucidate factors predicting intact field defects.

Methods: Patients with pre- (n = 53) or post-chiasmatic lesions (n = 98) were tested with high resolution perimetry — a method used to map visual fields with supra-threshold light stimuli. Reaction time (RT) of detections in the intact visual field was then analyzed as an indicator of processing speed and correlated with features of the visual field defect.

Results: Patients from both groups exhibited processing speed deficits in their presumably “intact” field when compared to a normative sample (p < 0.001). Further, processing speed was found to be a function of two factors. Firstly, a spatially restricted (retinotopic) influence of the scotoma was seen in longer RT when stimuli were presented in intact field sectors close to the defect. Secondly, patients with larger scotomata had on average longer RT in their intact field indicating a more general (non-retinotopic) influence of the scotoma.

Conclusions: Visual system lesions have more widespread consequences on perception than previously thought. Because dysfunctions of the seeing field are expected to contribute to subjective vision, including visual tests of the presumed “intact” field may help to better understand vision loss and to improve methods of vision rehabilitation.

Care assistant support following specialist rehabilitation for people with Parkinson’s and carers in the community: Findings from the SPIRIT RCT
H. Gage, L.D. Grainger, S. Ting, P. Williams, C. Chorley, G. Carey, N. Borg, K. Bryan, B. Castleton, P. Trend, J. Kaye, S. Khan, D. Wade, School of Economics, University of Surrey, Guildford, UK; 6Department of Mathematics, University of Surrey, Guildford, UK; 7School of Health and Social Care, University of Surrey, Guildford, UK; 8The Runnymede Hospital, Chertsey, UK; 9Department of Neurology, Royal Surrey County Hospital, UK; 10GPDRC, University of Surrey, Guildford, UK; 11Surrey Clinical Research Centre, University of Surrey, Guildford, UK; 12Oxford Centre for Enablement, Oxford, UK

Background: Multidisciplinary rehabilitation gives short term benefits in Parkinson’s but these are not sustained.

Objectives: To assess (1) if ongoing support from trained Parkinson’s care assistants (PCA) is effective at sustaining benefit from time-limited rehabilitation; (2) costs; and (3) acceptability.

Patients and methods: Pragmatic three parallel group randomised controlled trial, Surrey, England; people with Parkinson’s (all stages), and live-in carers. Groups A and B received domiciliary specialist rehabilitation from a multidisciplinary team (MDT), tailored to individual needs (about 9 h per patient). In addition, Group B received ongoing support for a further four months from a PCA, embedded in the MDT (1 h per week). Control group (C) receives care as usual (no coordinated MDT care or ongoing support).

Results: 269 people with Parkinson’s (155 live-in carers) were analysed at baseline [A, n = 88 (52); B, n = 88 (50); C, n = 93 (53)]. Significant improvements for patients arose at the end of the MDT intervention in disability, non-motor symptoms, health related quality of life, psychological wellbeing, and speech. Over 6 months, sustained marginal improvements were recorded in mobility (Group A vs. C, p = .063), psychological wellbeing and speech (Group B vs. Groups A and C, p = .085, .047 respectively). Carers in B recorded reduced strain (B vs. A, p = .005; B vs. C, p = .041), during the PCA intervention. Cost per patient: £833 (MDT); £600 (PCA). Participants welcomed the intervention and reported knowledge gains.

Conclusions: Support from PCA benefits carers. Further research on sustaining benefits from rehabilitation is needed.

Importance of intervention program for the promotion of physical activity in the perception of illness in people with multiple
L. Pedro, J.L. Pais Ribeiro, J. Pascoa Pinheiro. “Rehabilitation, Polytechnic of Lisbon, ESTESL, Lisbon, Portugal; 2Psychology, University of Porto, Porto, Portugal”

Multiple sclerosis (MS) is a chronic neurological disease. The promotion of physical activity can be an important factor on the perception illness of these patients. The aim of this study is to examine the perception of disease of an implementation of a program of physical activity, with patients with MS.

Methods: This is a prospective study. We use the question “Please classify the severity of your disease” The study includes 24 patients with MS diagnosis according to relevant medical criteria, between 20 and 58 years, mean age 44 years, 58.3% women, 37.5% currently married, 67% retired, mean school level of 12.5 years, being diagnosed at least 1 year ago, and EDSS score under 7. Intervention followed the recommendations of Helsinki Declaration.

The program consists of an intervention to promote physical activity in a group of eight people, in once a week sessions of 90 min. The program was held for seven weeks. We use the program statistic SPSS version 18, the General Liner Model, repeated measure.

Results: Comparing the results obtained from the assessment before the intervention program (time A) to promote physical activity and the end of the program (time B), we find that (Time A): M = 5.46, DP = 2.13 (Time B) M = 5.04, DP = 2.01 (F = 8.01; p < 0.009).

Conclusions: There are statistically significant differences between the two moments of assessment, which suggest that physical intervention programs for promotion of physical activity can play an important role in the perception of disease severity, in EM.

Changes in intrathecal baclofen dosage during long-term treatment in patients with spasticity due to traumatic spinal cord injuries
B. Skoog, L. Hylliemark, B. Hedman, L. Rutberg. “Institute of Clinical Neuroscience and Physiology, Gothenburg, Sweden; 2Clinical Neuroscience, Karolinska Institute, Stockholm, Sweden”

The study includes 24 patients with MS diagnosis according to relevant medical criteria, between 20 and 58 years, mean age 44 years, 58.3% women, 37.5% currently married, 67% retired, mean school level of 12.5 years, being diagnosed at least 1 year ago, and EDSS score under 7. Intervention followed the recommendations of Helsinki Declaration.

The program consists of an intervention to promote physical activity in a group of eight people, in once a week sessions of 90 min. The program was held for seven weeks. We use the program statistic SPSS version 18, the General Liner Model, repeated measure.

Results: Comparing the results obtained from the assessment before the intervention program (time A) to promote physical activity and the end of the program (time B), we find that (Time A): M = 5.46, DP = 2.13 (Time B) M = 5.04, DP = 2.01 (F = 8.01; p < 0.009).

Conclusions: There are statistically significant differences between the two moments of assessment, which suggest that physical intervention programs for promotion of physical activity can play an important role in the perception of disease severity, in EM.

Background: Intrathecal baclofen is an effective treatment for severe leg spasticity but tolerance was reported during short term treatment.

Objective: To investigate dosage changes during long-term treatment.

Methods: The 24 patients included in the study had spinal cord injuries and had been treated with an intrathecal baclofen pump (Syncormed) because of severe leg spasticity for at least 7 years. Seven patients were excluded from the study due to factors which aggravated spasticity. Of the remaining 17 patients 13 had cervical and 4 had thoracic spinal cord injury. ASIA A (n = 6), ASIA B (n = 5), ASIA C (n = 3) and ASIA D (n = 3). The effect was estimated by patient/doctor dialogue, usually 4–10 times per year, in order to reduce leg spasticity and at the same time avoid an increase in leg/trunk weakness.

Results: One year after the start of intrathecal baclofen the patients needed a median dose of 264 μg baclofen per 24 h (range 30–383) in order to reach an optimal effect. After an additional year the mean dose had not changed (95% CI +/− 6%). Seven years after the start of baclofen the dose had increased by 9% compared to the first year dose (95% CI +/− 12%), after ten years by 17% (95% CI +/− 15%, n = 14) and after fifteen years by 34% (95% CI +/− 25%, n = 6).

Conclusion: The dose which needed to reach an optimal effect on leg spasticity was not increased significantly after seven years, while it was slightly increased beyond this time.

A standardised motor imagery introduction program (MIIP) for patients with sensorimotor impairments: Development and evaluation

C. Wondruschs, C. Schusters, aDepartment of Health, Zurich University of Applied Sciences, Winterthur, Switzerland; bResearch Department, Reha Rheinfelden, Rheinfelden, Switzerland; cInstitute for Rehabilitation and Performance Technology, Bern University of Applied Sciences, Burgdorf, Switzerland

Background and objective: A solid motor imagery (MI) introduction is crucial to understand and use MI to improve motor performance. The study's aim was to develop and evaluate a standardised MI group introduction program (MIIP) for patients after stroke, multiple sclerosis (MS), Parkinson’s disease (PD), and traumatic brain injury (TBI).

Methods:

Phase 1: Development of a MIIP comprising MI theory (definition, type, mode, perspective, planning) and MI practice (performance, control).

Phase 2: Development of a 27-item self-administered MI questionnaire to evaluate MIIP: MI knowledge (12 items), MI ability self-evaluation (5 items), MIIP satisfaction (10 items).

Phase 3: Evaluation of MIIP and MI questionnaire by 2 independent MI experts based on predefined criteria and 2 patients using semi-structured interviews.

Phase 4: Case series with a pre-post design to evaluate MIIP (3 × 30 min) using the MI questionnaire, Imaprax (IMAvis), Kinaesthetic and Visual Imagery Questionnaire (KVIQvis + kin), and Mental Chronometry (MC).

Results: Eleven patients (5 females; age 62.3 ± 14.1 years; Mini-Mental State Examination score 28.4 ± 1.5; 5 stroke, 4 MS, 1 PD, 1 TBI) were included. MI knowledge improved significantly from 5.4 ± 2.2 to 8.8 ± 2.9 (p = 0.01); Self-evaluated MI ability changed from 16.2 ± 4.3 to 18.5 ± 2.4 (p = 0.47). Patients demonstrated high satisfaction with MIIP (40.3 ± 5.6). MI ability remained high: IMAvis33.3 ± 3.3 to 33.6 ± 3.5 (p = 0.8), KVIQvis36.2 ± 10.5 to 37.0 ± 6.2 (p = 0.2), KVIQvis33.6 ± 9.7 to 29.7 ± 8.2 (p = 0.1). MC revealed ratios between 0.5 to 1.9 pre-test and from 0.5 to 2 (p = 0.9) post-test.

Conclusion: The MIIP seems to be valid and feasible for patients with sensorimotor impairments resulting in improved MI knowledge. MIIP sessions can be held in groups of four or less.

Neuroprotective role of docosahexaenoic acid and gamma-linolenic acid in lead induced neurological deficit in Swiss albino mice

S. Yadavb, V. Sharmaa, aPharmacy, Banasthali University, Newai, India; bBiosciences and Biotechnology, Banasthali University, Newai, India

Lead is virtually toxic to every organ of the body including central nervous system where it may manifest as encephalopathies and neuropathies, but also various behavioral changes indicative of cerebral dysfunction like; periodic convulsions, irritability, hyperactivity, retardation of normal development, emotional instability, behavioral disorders, low attention span, impaired motor development, and antisocial behavior. The purpose of present study was to characterize the putative neuroprotective role of docosahexaenoic acid and gamma-linolenic acid. PRO-PL (British Biologicals, Bangalore) dietary supplement containing docosahexaenoic acid and gamma-linolenic acid was fed in diet to study neuroprotective role using rota rod apparatus. A total number of 46 adult Swiss albino mice of either sex were included in the study consisting of equal numbers (six each) in Standard, Control + Dietary Supplement and Experimental, and Experimental + Dietary Supplement Groups. Experimental groups received 4.5% and 5% Lead Nitrate and Lead Acetate Trihydrate orally alone and with Dietary Supplement for a period of 3 weeks. Diazepam (1 mg/kg i.p.) was used as the standard drug. All the experimental work was approved by the Institutional Animal Ethics Committee (Ref. No. IAEC/257). In rota rod apparatus, there was significant increase in time spent by the animals on revolving rod whereas; in elevated-plus maze there was significant increase in time spent and number of entries into the open arms. Dietary supplement containing docosahexaenoic acid and gamma-linolenic acid showed prominent neuroprotection in lead induced Swiss albino mice.

Targeting sensory and awareness problems in upper limb rehabilitation in chronic stroke. A report of three cases

T. Emara, Neurology, Ain Shams University, Egypt; Taheal Rehabilitation Center, Cairo, Egypt

Background: Regaining normal function of the upper limb after stroke occurs in around 10% of cases. Sensory problems such as proprioceptive deficits, learned non-use, and manifest neglect are among the causes of disability.

Objective: Targeting these frequently overlooked symptoms may boost functional recovery.

Methods: We suggest a treatment protocol consisting of simultaneous bhemispheric TDCS + TENS + mirror therapy followed by ADLs training.
Case 1: 78 years old, had severe left proprioceptive deficit 3 years after her second stroke with intact motor power. She had pseudoathetosis in her left upper limb. Her left hand would get in her way with eyes open. After 24 sessions; enjoys knitting and other bimanual activities.

Case 2: 68 years old, had learned non-use and moderate right hand weakness 6 years after second stroke. He had shortening in long flexors, weak finger/wrist extensors 1–2/5. Amputated distal phalanges in the right hand. Needed help with all ADLs. He presented to us after his family left him. After 30 sessions; managed to live alone.

Case 3: (managing expectations): 65 years old, presented 1.5 years after stroke with inability to move his left arm. He had a fixed flexion deformity in his arm that was painful with manipulation and had averted him from therapy. He had USN causing and visuospatial problems (could not locate or draw the exit door of the room). After 2 months, safe ambulation at home. He declined a tenotomy for his arm.

Conclusions: Targeting sensory and awareness problems in chronic stroke with multimodal sensory stimulation modalities may augment recovery in selected cases.

Postural profile of individuals with HAM/TSP
M.C. Macêdo1, A.F. Baptista2, B.G. Castro-Filho3, E.F. Duarte1, N. Patrício1, R.D.A. Kruschewsky3, K.N. Sá1, A.D.S. Andrade Filho5, Dinâmica do Sistema Neuromusculosquelético. 1Escola Bahiana de Medicina e Saúde Pública, Brazil; 2Universidade Federal da Bahia, Salvador, Brazil

Background: HTLV-1 also has high prevalence in Brazil, especially in the city of Salvador. HTLV-1-associated myelopathy or Tropical Spastic Paraparesis (HAM/TSP) is characterized by a demyelinating, slowly progressive disease, associated with weakness of lower limbs, sphincteric dysfunction, and sensitivity impairment. A computerized postural assessment may help to systematize the clinical practice of physical therapy in the treatment of patients with HAM/TSP and to monitor the results of specific interventions.

Objective: This study sought to delineate the postural profile of these individuals by comparing them with a group of healthy subjects.

Patients and methods: This was cross-sectional research conducted at the HTLV Center of “Escola Bahiana de Medicina e Saúde Pública, Bahia”, Brazil. Subjects who were diagnosed with HTLV-1 by ELISA and confirmed by Western Blot Test, and manifested clinical signs compatible with HAM/TSP were included in the study. Patients suffered from other disorders that compromised the definition of postural profile, patients unable to remain in orthostasis without assistance and those who had cognitive impairment that could compromise the postural assessment, as well as those who were undergoing physiotherapy were excluded from the study. 30 volunteers with HAM/TSP were paired with 30 healthy subjects, who underwent a postural evaluation by means of a Postural Assessment Software (SAPO®).

Results: A trend characterized by postural projection of the trunk forward or backward, forward displacement of the body, bending the knees and ankle angle reduction was noted.

Conclusion: This study demonstrates that there is a posture typical of the HAM/TSP patient which manifests itself with changes in the sagittal plane.

Effects of sitting training on a tilting platform in patients with acute stroke: A randomized control trial
Y. Fujinoe1, K. Amimotos2, K. Fukata2, M. Harimoto3, Y. Togano3, S. Takashit3. 1Tokyo Metropolitan University, Arakawa City, Japan; 2Saitama Medical University International Medical Center, Hidaka City, Japan

Background: It is important to improve lateral trunk control after stroke. However, the effects of sitting training on a tilting platform are still poorly understood.

Objective: To investigate the effects of sitting training on a tilting platform after stroke.

Patients and methods: Thirty stroke patients participated in this study after providing their written informed consent. Patients were randomly allocated to either an experimental group (n = 15) or a control group (n = 15).

Intervention: The experimental group patients sat on a platform tilted 10° to the paretic side in the frontal plane. The control group patients also sat on a horizontal platform. Both groups moved their trunks laterally to the non-paretic side 60 times. The intervention was in addition to conventional therapy, and was performed for 1 week.

Assessment: Subjects sat on a horizontal platform and moved their trunk laterally to the left or right as much as they could. During this task, the trunk angle was recorded by using the 2-dimensional movement analysis system. As a clinical measurement, patients were evaluated with the Stroke Impairment Assessment Set (SIAS) and the Trunk Control Test (TCT).

Results: The experimental group showed a greater increase in lateral bending to the un-affected side than that of the controls. Although SIAS and TCT significantly improved in both groups, we found a significant interaction in TCT of the experimental group that had a higher score.

Conclusion: These results indicate that tilting platform sitting training can improve lateral trunk control and trunk performance of acute hemiparetic patients.

Efficacy of conventional neurorehabilitative therapy using Tc-99m HMPAO single photon emission computed tomography in patients with subacute infarction
H.K. Park1, M.-W. Kim1. 1Department of Rehabilitation Medicine, Catholic University of Korea, Catholic Medical Center, Seoul, Republic of Korea; 2Department of Rehabilitation Medicine, Catholic University of Korea, Catholic Medical Center, Incheon, Republic of Korea

Background: To objectively evaluate the efficacy of neurodevelopmental therapy on rehabilitative unit was difficulty.

Objective: The purpose of this study was to objectively assess the efficacy of neurodevelopmental therapy on rehabilitative unit using Tc-99m HMPAO single photon emission computed tomography (SPECT) in patients with subacute left MCA infarction.

Method: A total of seven subacute stage patients with left MCA infarction were included in this study. These patients received conventional neurorehabilitative therapy including physical and occupational therapy, twice per day for 3–5 weeks on admitted condition. Brain perfusion SPECT images obtained at pre-Tx and post-Tx were reconstructed using statistical parametric mapping in these patients. A voxel with an uncorrected p-value of less than 0.01 was considered to be statistically significant.
**Result:** First SPECT scans were performed at 31 days ± 22 after stroke onset and second SPECT scans were performed at 27 days ± 9 after first study. The overall regional cerebral blood flow (rCBF) in the left cerebral hemisphere was increased on pre-Tx SPECT images in comparison to that observed on the post-Tx SPECT images. The rCBF in the left temporal, parietal, and frontal cortices was increased on the post-Tx SPECT images in comparison to the pre-Tx SPECT images. These findings indicate that mild improvement in the rCBF can be expected after conventional neurorehabilitative therapy.

**Conclusion:** Improvements in rCBF following neurodevelopmental therapy were objectively demonstrated in the patient group through SPM analysis of brain perfusion SPECT images, which also correlated well with the clinical symptoms in these patients.

**Four periodical botulinum toxin type A injections, followed by home-based functional training in poststroke patients with severe upper limb hemiparesis**  
The Jikei University School of Medicine, Tokyo, Japan

**Background and objective:** Botulinum toxin type A (BoNT-A) has been reported to be an effective treatment for limb spasticity after stroke. However, few studies have reported improvements in the active motor function in poststroke patients with spastic upper limb hemiparesis. The aim of this study was to assess the clinical influence of four periodical BoNT-A injections, followed by special instructions for a home-based functional training on not only passive but also active motor functions in poststroke patients with severe upper limb hemiparesis with spasticity.

**Patients and methods:** Of the 295 patients, 41 patients with spastic upper limb hemiparesis were studied. The severity of hemiparesis was categorized as Brunnstrom stage of 3 for hand-fingers in all patients. BoNT-A (maximum dose of 240 U) was injected into the target muscles of the affected upper limb after a clinical evaluation using the modified Ashworth scale, Fugl-Meyer Assessment. Following the injection, occupational therapists provided home-based functional training for each patient on a one-to-one basis. The follow-up evaluation was performed 4 weeks after the four periodical injection.

**Results:** The changes in the Fugl-Meyer Assessment and the modified Ashworth scale indicated a significant improvement in the active motor function of the affected upper limb, compared evaluation after four periodical injection with before injection.

**Conclusion:** Our proposed protocol of the periodical BoNT-A injection, followed by home-based functional training seems to have the potential to improve the active motor function of the affected upper limb after stroke, although the efficacy should be confirmed in a randomized-controlled trial.

**The importance of extracranial carotid stenosis detection after stroke**  
D. Prtina.  
Neurology Rehabilitation, Institute for Rehabilitation, Banja Luka, Bosnia and Herzegovina

**Introduction:** Stroke is the primary cause of permanent disability. It is estimated that 25 to 50% of all strokes were caused by these changes.

**Patients and methods:** The study included patients that suffered a stroke (first or recurrent), 90 days of occurrence, regardless of the degree of neurologic deficit. Both carotids were examined by Doppler ultrasound (DUS), the findings were grouped in multiple groups: up to 50% stenosis, 50–75%, 75–99% stenosis and occlusion. The NIHSS score was used to estimate the severity of stroke while the main risk factors monitored were blood fats, high blood pressure and smoking.

**Results:** During the study, 93 patients underwent DUS screening for carotid stenosis, the mean age of patients was 65.4 years (MD 8.4), 51 (54.83%) were male. 79% of all strokes were ischemic. There was a mean NIHSS score of 7.62, mean total cholesterol 6.48, triglycerides 1.99. 29 patients (31.2%) had normal findings in carotid, 26 had (27.9%) stenosis of 50% (19 on symptomatic, 7 on asymptomatic side), 21 (22.5%) had stenosis of 50–75% (16 on symptomatic, 5 on asymptomatic side), 11 had severe stenoses of 75–99% (9 on symptomatic and 2 on asymptomatic side) and 6 occlusions. There was no statistically significant connection of certain categories of carotid stenosis with NIHSS score and recorded risk factors.

**Conclusion:** Due to prevalence of severe carotid stenoses, the increased availability of DUS examination, different medications and surgical treatments, the DUS should be a mandatory screening method for high-risk categories of patients.

Efficiency of visual biofeedback training for balance correction in neurorehabilitation of the patients with the central hemiparesis syndrome after stroke

V. Ondar, S. Prokopenko, M. Abroskina. Department of Neurology, Krasnoyarsk State Medical University named after Prof. V.F. Vojno-Yasenetsky, Krasnoyarsk, Russia

Background: It’s well known that the balance and gait are being changed by the central hemiparesis syndrome.

Aim: To prove expediency of the use of visual biofeedback training for balance correction in neurorehabilitation of the patients with the central hemiparesis syndrome.

Methods: Research was performed with application of the complex MBN “Biomekanika” (Moscow) and Smart Equitest Balance Manager (USA). The 45 male and 51 female patients were aged between 42 and 70 years with post-stroke central hemiparesis syndrome which had passed 8–10 trainings during 20–30 min. Visual biofeedback trainings included the gradual displacement of the center of gravity towards the hemiparesis of the body side. The estimation of balance condition was performed before and after the trainings with the help of: Berg Balance Scale, Dynamic Gait Index, and also computerized stabilometry, sensory organization test and motor control test.

Results: After the trainings we can observe the progressive displacement of the center of pressure towards the hemiparesis side and the approaching of the actual center of pressure towards “the ideal”. The balance scale indices also had the positive dynamics.

Conclusion: These findings let us to conclude the expediency of use of visual biofeedback programs for balance correction in neurorehabilitation of the patients with the post-stroke central hemiparesis syndrome.

CPD-choline (ceraxon) treatment with hypoxia in the newborn infant

R. Issayeva¹, K. Pushkarev², ¹Nazarbayev University, Astana, Kazakhstan; ²Center for Pediatric Emergency Care, Almaty, Kazakhstan

Long-term observations suggest that infants who have had a severe hypoxia, lead to a wide range of somatic and neuropsychiatric disorders in the future. See the effectiveness of therapy in the rehabilitation period Ceraxon infants with perinatal brain lesions, controlled neurosonography doplerometry with cerebral blood flow, ophthalmoscopy fundus.

Study group were 543 infants who suffered severe hypoxia: 247 full-term and 296 preterm infants who were seen after treatment in catamniss Ceraxon. Catamniss duration ranged from 3 to 12 months. According to neurosonography after initiation of treatment Ceraxon, intraventricular hemorrhage in pseudocyst formed in 42%, complete lysis in 22%, posthypoxic changes were revealed in 26%, and 10% of ventriculomegaly. By the end of the first week of treatment 82% of children had normalized indices in pools of anterior and middle cerebral arteries and blood flow in the vein of Galen. Just at the end of the first week physical activity significantly improved in 46%, muscle tone in 64%, and reflex activity in 62% of children.

The analysis of the fundus newborns had diffuse opacities, limited foci of hemorrhage and pigmentation. After treatment Ceraxon on the second week after the initiation of treatment 32% of children improved picture fundus.

It was thus established that the drug Ceraxon has a positive effect on cerebral hemodynamics of patients: there is rapid correction of neurological disorders by the end of the first week of treatment. This is a positive effect both on the timing, and the final outcome of treatment.

Intracortical GABA is decreased after stroke and further suppressed with successful rehabilitation

J.U. Blicher¹, A. Guzik, M. Druzbiicki, A. Kwolek, G. Przysada, A. Brzozowska-Magoń. Faculty of Medicine, Institute of Physiotherapy, University of Rzeszów, Rzeszów, Poland

Objective: The most important needs of stroke patients are to recover the independent, the efficient and safe gait. The aim of the study is the gait assessment using a treadmill with biofeedback among the patients in the late period after stroke.

Material and method: The study included 50 ischemic stroke patients who were treated after six months from the stroke. The mean age of the patients was 69.1 and mean time from the stroke was 27 months. The patients were randomized into an experimental or control group. The experimental group completed training program on the treadmill with biofeedback. The control group practiced on the treadmill without biofeedback. Gait velocity in the 10-Meter Walking Test, 2-minute walk test, functional evaluation by Barthel index and balance in timed ‘up and go’ test were tested. Spatio-temporal and kinematic gait parameters were also evaluated. Physiotherapy program lasted two weeks.

Results: At baseline, the average walking speed did not differ significantly between the groups (p = 0.7878). The average walking speed in both groups significantly increased after the program of rehabilitation but there was no significant difference between groups. The number of steps per minute significantly increased from 68 to 76 steps, step width decreased but there was no significant difference between the groups.

Conclusions: Among stroke patients in the late period the exercises on a treadmill have an impact on a significant gait improvement. Use of biofeedback did not significantly affect the results.

**Objective:** To relate GABA changes to motor relearning after stroke through the use of j-difference edited Magnetic Resonance Spectroscopy (MRS).

**Methods:** 21 patients (3–12 months post stroke) and 21 healthy, age-matched subjects were recruited. Patients had mild to moderate hand impairment, and fulfilled the criteria for Constraint-Induced Movement Therapy (CIMT). Patients completed two weeks of CIMT, and were scanned before and after training. For MRS a 2 × 2 × 2 cm voxel was placed on the “hand knob” in the affected hemisphere of the patients and in the dominant hemisphere of the healthy subjects. GABA was expressed as a ratio to Creatine (Cr). Motor function was measured using the Wolf Motor Function Test (WMFT).

**Results:** GABA/Cr was significantly lower (p < 0.001) in patients (0.33) at baseline compared to healthy subjects (0.42). After therapy, patients showed a significant improvement in hand function (p < 0.001), which was negatively correlated with GABA/Cr changes (R = −0.57, p = 0.015) — larger improvements in patients were associated with greater reductions in GABA/Cr. Results were also significant after correcting for changes in intracortical grey matter volume.

**Conclusion:** A decrease in GABA appears to facilitate motor recovery after stroke. GABA, as measured non-invasively with MRS, could be a biomarker for neuronal plasticity during recovery and guide rehabilitation interventions.

**Amantadine treatment of aphasia after stroke**

K. Severinsen, A. Pedersen. *Neurology, Hammel Neurorehabilitation and Research Centre, Aarhus University, Hammel, Denmark*

**Background:** Amantadine hydrochloride has been used as a central stimulating pharmacological agent for treatment of disordered consciousness in patients with traumatic injury, but not for stroke patients suffering from aphasia and other cognitive deficits in the domains of execution, attention and processing speed.

**Objective:** To evaluate the effect of short term amantadine treatment on aphasia in subacute stroke patients suffering from aphasia and other cognitive deficits in the domains of execution, attention and processing speed.

**Materials and methods:** Nine subacute stroke patients (age 30–69 years, time since onset 32–150 days) suffering from aphasia and various other stroke sequelae, receiving inpatient neuro-rehabilitation, completed the cohort study. No blinding was attempted and the intervention was not placebo controlled. Participants were treated with amantadine (50 mg x 2 on days 1–2 and 100 mg x 2 on days 3–7) in order to ameliorate cognitive deficits. Participants were evaluated for changes in the severity of aphasia by application of the Western Aphasia Battery (WAB), the WAB Aphasia Quotient (WAB-AQ) being the primary outcome measure.

**Results:** Amantadine treatment improved the verbal performance as measured by the WAB-AQ by 11 points (CBootstrap: 6.7; 15.3), p < 0.0001. The verbal performance after the subsequent three days of amantadine wash-out was decreased by 5.1 (0.6; 9.6), p = 0.028 on the WAB-AQ.

**Conclusion:** Treatment with amantadine seems to improve verbal performance in patients suffering from aphasia after stroke. This is a preliminary pilot trial and interpretation of the results must be made with caution until further studies are performed.

**Topic:** 10—Neurorehabilitation

**The role of energocorrection of asthenoneurotic syndrome in different neurologic disorders**

**Objective:** To evaluate the prevalence of asthenic syndrome in patients with different general medical conditions and neurologic disorders.

**Patients and methods:** 171 patients with different peripheral nervous system disorders receiving inpatient treatment at hospitals were included (mean age 36.9 ± 8.1 years). Screening revealed the presence of asthenoneurotic syndrome (ANS) of different severity in 120 patients (70.6%) aged 25–56 years. To evaluate the dynamics of ANS complex monitoring was performed on days 1 and 25, including analysis of complaints, assessment of physical and neurologic status, and electroencephalography (EEG-neurokartograf MBN-20). The intervention group received conventional therapy plus energocorrector and antioxidant anthopyxanty cofaktinin (n = 63) 2 tabs twice a day for 25 days. The control group received conventional therapy plus placebo (n = 108) according to the same regimen.

**Results:** 28.1% of the patients with ANS demonstrated marked personality accentuation with anxiety and excitable traits. At day 25 in the intervention group 44.4% of the patients demonstrated asthenic symptoms, 31.8%—only mild symptoms, 15.9%—moderate symptoms and 7.9%—severe symptoms (p < 0.001). The control group showed an insignificant improvement (p = 0.257). There was a positive trend in the subscales “anxiety” and “depression” with a strong correlation with asthenia reduction in the intervention group (r > 0.5; p < 0.05). There was also an improvement in EEG indices—an increase in α-rhythm from 23% to 46% at day 25 in the intervention group (p < 0.05). Overall improvement was registered in 88.9% of the patients, in the control group—27.8% (p < 0.05).

**Conclusion:** Energocorrection therapy in ANS results in a significant decrease in asthenic and neurotic symptoms.

**Power effective electrical stimulation of frog’s tibial-gastrocnemius preparation for 200-s continuous maximum contraction**

W.-Y. Ho, H. van der Merwe, Y.-K. Huang, F.-S. Jaw. *Institute of Biomedical Engineering, National Taiwan University, Taipei, Taiwan, ROC*

**Background:** Electrical nerve stimulation (ENS) is not widely adopted in clinical therapy due to a lack of standard and verification of efficacy. A previous study shows that ENS is beneficial to prevent atrophy. Nevertheless, nerve fibrosis might occur if the pulse frequency exceeds 40 Hz. For effective standing, various muscles need to maximally contract for more than 200 s. Therefore, an ENS protocol should be developed for this purpose.

**Materials and methods:** The contraction force (CF) of the gastrocnemius of frogs was measured and digitized for processing. An adjustable pulse was used to achieve a 200-s continuous maximum contraction (CMC) with minimal power delivery. The maximum contraction force was obtained by the interpolated twitch technique.

**Results and discussion:** Our data show that the best ENS protocol for 200-s CMC is 8 Hz, 120 mV, and 35% duty cycle. Compared with

The short-term effects of plantar vibration therapy on the balance of patients after stroke
S. Nashi, N. Nakhhostin Ansari, M. Akbari, S. Jalaie, M. Khalifeloo. Physiotherapy, Tehran University of Medical Sciences, Tehran, Iran

Background: Balance disability is common in patients following stroke. The vibration is one of the physiotherapy modalities used in neurological rehabilitation. The effects of local vibration on balance impairment poststroke have not been investigated.

Objective: The aim of the present study was to investigate the short-term effects of plantar vibration on the balance of patients with stroke.

Material and methods: In this pretest-posttest clinical trial, eighteen patients with stroke participated. Outcome measures were Timed Up and Go test (TUG), Functional Reach test (FR), and posturography to assess balance changes; and the Modified Modified Ashworth Scale (MMAS) for evaluation of ankle plantar flexor spasticity. Vibration with a frequency of 100 Hz was applied to the sole of the affected foot for 5 min. All measurements were taken before and after vibration therapy.

Results: The vibration therapy significantly improved the TUG test (p = 0.03) and the ankle plantar flexor muscle spasticity (p = 0.008). The changes of posturography measures and FR test have not been improved significantly (p > 0.05).

Conclusion: Plantar vibration therapy may have beneficial effects on the balance disability of the patients with stroke.

The effects of mirror therapy on arm and hand function in subacute stroke inpatients
A. Radajewska1, J. Opara2, A. Malecki1, J. Szczygilewicz1. 1Public Higher Medical Professional School, Opole, Poland; 2Jerzy Kukuczka Academy of Physical Education, Katowice, Poland; 3Repty Upper Silesian Centre of Rehabilitation, Tarnowskie Gory, Poland

Aim: The aim of this study was to evaluate the effect of mirror therapy on arm and hand function in subacute stroke inpatients.

Material and methods: The study included 60 hemiparetic right-handed patients, eight to ten weeks after ischemic stroke. They underwent stationary comprehensive rehabilitation in the Rehabilitation Centre. There were two study groups: mirror (n = 30) and control (n = 30) and two subgroups in each: one for people with right arm paresis (n = 15) and the other for those with left arm paresis (n = 15). The mirror group received an additional intervention: 20 min of exercise program with mirror therapy (twice a day for five and a half days a week for 21 days). The control group (n = 30) underwent a conventional rehabilitation program without mirror therapy. To evaluate self-care in performing activities of daily living the Functional Index “Repty” was used. To evaluate hand and arm function the Frenchay Arm Test (FAT) and the Motor Status Score (MSS) were used. Measurements were performed twice: before and after 21 days of applied rehabilitation.

Results: Significant improvement in ability to perform activities of daily living (ADL) in the right arm paresis subgroup of the mirror group has been observed. No significant improvement of hand and arm function in both subgroups in FAT and MSS scales has been observed.

Conclusions: Mirror therapy for arm paresis after stroke is effective in improving independency in activities of daily living.

Background: The aim of the study was to measure the effect of EEG biofeedback therapy on motor and cognitive deficits in children with ADHD or ADD and compare this effect with classical rehabilitation.

Patients and methods: The study included 65 children with mild central motor disorders with ADHD, divided into two subgroups: the first group was composed of 35 children (mean age 9) who underwent EEG biofeedback, and the second group was composed of 30 children (mean age 8.50) who underwent classic neurorehabilitation, with each group undergoing 30 sessions, 2-3 times/week/30-45 min with PANESS/CIT tests before/after procedures.

Results: The mean achieved score of EEG biofeedback was lower (M = 29) compared to the score before the procedure (M = 60). The majority of AEs were considered not related to onabotulinumtoxinA, and treatment-related AEs were consistent with the known mechanism of action of onabotulinumtoxinA.

OnabotulinumtoxinA in lower limb spasticity: Safety results from a pooled analysis

N. Earl, L. James, G. Shi, G. Demos, R. Dimitrova. Allergan, Inc, Irvine, CA, USA

Objective: Evaluate the safety of onabotulinumtoxinA (BOTOX®) in treating adult post-stroke lower limb spasticity (LLS).

Background: Approximately 80% of post-stroke spasticity patients have lower limb involvement and 66% have involvement of ankle joint muscles, the most commonly affected muscle group.

Patients and methods: Results from eight studies in adult patients with LLS were integrated to evaluate the safety profile of 700 patients. Overall safety population was summarized across all onabotulinumtoxinA doses for double-blind placebo-controlled (DBPC) exposure (onabotulinumtoxinA = 415; placebo = 265) and any onabotulinumtoxinA exposure (N = 625; median dose = 300 U).

Results: Overall adverse event (AE) rates during DBPC exposure were 62.2% in the all-onabotulinumtoxinA group, 55.1% in the placebo group, and 68.0% for any onabotulinumtoxinA exposure. During DBPC exposure, AEs ≥ 1% higher in the all-onabotulinumtoxinA group than placebo were fall (7.2%), peripheral edema (4.1%), urinary tract infection (3.9%), headache (3.4%), arthralgia (2.9%), and joint sprain (2.2%). Treatment-related musculoskeletal and administration site AEs were consistent with known onabotulinumtoxinA tolerability. Incidence of serious AEs (SAEs) during DBPC exposure was 11.1% and 8.7% for all-onabotulinumtoxinA placebo groups, respectively. Discontinuation due to AEs was 1.4% in the all-onabotulinumtoxinA group (none in placebo) during DBPC exposure. SAEs and discontinuations due to AEs represented co-morbidities and underlying post-stroke conditions. No reported events were associated with distant spread of toxin and no clinically relevant changes were noted in laboratory tests and physical examinations.

Conclusion: OnabotulinumtoxinA treatment in LLS was well tolerated. The majority of AEs were considered not related to onabotulinumtoxinA, and treatment-related AEs were consistent with the known mechanism of action of onabotulinumtoxinA.

Anatomic localization of motor points in flexor carpi radialis and flexor carpi ulnaris muscles

H. Cheong*, S.H. Hong*, M.E. Chung†. *St. Paul’s University Hospital, The Catholic University of Korea, Seoul, Republic of Korea; †St. Mary’s Hospital, The Catholic University of Korea, Seoul, Republic of Korea

Background: Tetraplegia compromises the upper limb motor function, thus affecting reach, grasp and handling movements.

Objective: To assess and compare the dominant upper limb muscle recruitment of tetraplegic individuals during reach and grasp movements.

Patients and methods: Four subjects with chronic tetraplegia (motor level: C5–C7) were recruited and divided in two groups (Group I: complete injury, AIS A; Group II: incomplete injury, AIS B). Electromyographic signals were recorded at 4000 Hz sampling rate and 15 to 1000 Hz bandpass-filtering from surface electrodes placed on the biceps brachii, triceps brachii, extensor digitorum communis (EDC) and flexor digitorum superficialis (FDS) muscles. The proposed movement was to reach and pick up a cylindrical object (Phase I) and bringing it to the mouth afterwards (Phase II). This cycle was repeated five times in order to calculate phase duration and root mean square (RMS) averages.

Results: Both variables were analyzed for each phase and compared between groups. Data was presented as group I (mean/SD) and group II (mean/SD), respectively. Phase I—duration (s): (1.83/0.50), (1.93/0.89). RMS (mv): biceps (13.74/2.26), (25.09/7.67); triceps (11.55/1.99), (25.21/4.92); EDC (37.17/11.74), (74.05/18.11); FDS (15.81/11.91), (62.69/60.77). Phase II—duration (s): (1.59/0.46), (2.03/1.08). RMS (mv): biceps (18.64/9.83), (34.47/4.60); EDC (26.73/10.95), (43.21/4.92); FDS (9.67/2.14), (no response in the case of group II).

Conclusion: Individuals with incomplete injuries show greater muscle recruitment in both phases compared to those with complete injuries. Furthermore, participants developed rather unique strategies to accomplish all tasks.

Upper limb spasticity usually involves the flexor muscle groups. Flexor carpi radialis (FCR) and flexor carpi ulnaris (FCU) are commonly targeted muscles during neuromuscular blockade in the management of spastic wrist flexors. Precise localization of the motor endplate may enable maximization of the paralytic effect of chemodenervation with botulinum toxin.

The objective of this study was to determine the location of the motor points and intramuscular branches of the FCR and FCU muscles in relation to bony landmarks.

This study was performed on 16 adult cadaveric arms with intramuscular innervation of the flexor carpi radialis and flexor carpi ulnaris muscles.

The site of entry of the motor nerve into the muscle belly was recorded as the motor point in FCR and FCU. We expressed the three parameters (motor points, proximal limit point, distal limit point) in transverse and vertical coordinates in relation to the reference lines.

The mean length of the FCR reference line was 27.2 ± 1.5 cm and that of the FCU reference line was 25.3 ± 1.6 cm. Single motor points in 16 limbs were located for the flexor carpi radialis muscle. On the other hand, one motor point in 6 limbs and two motor points in 10 limbs were identified for the flexor carpi ulnaris muscle.

Based upon these data, we conclude that the optimal area for injection is at a quarter point, for the flexor carpi radialis muscle, and at one-third, for the flexor carpi ulnaris muscle, along each reference line from the medial epicondyle.

of immersive VR games and scenarios, delivered with low-cost equipment. The therapy replicates the conventional exercise and activity sequence recommended for restoring postural and coordination abnormalities after TBI, and can be delivered either in a supervised clinical setting or in a patient’s home.

**Objective:** Therapy efficacy was tested in 15 participants with moderate manifestations of TBI-related postural and coordination deficits, in the framework of a phase II clinical trial. Therapy included 15 sessions, delivered in-clinic, each approximately 50–55 min in duration, scheduled 2–4 times a week over 5 consecutive weeks. Each participant was evaluated with a battery of clinical tests and movement performance parameters at baseline, immediately after the therapy; and 1 month after the completion of training.

**Results:** Upon completion of the therapy most participants improved their postural stability, gait, and upper extremity movements. The effects were maintained fully or partially over the retention interval. Safety criteria were established for practicing in-home.

**Conclusion:** Results will be used to refine the current version of the therapy into a cost-effective, highly-accessible approach, which can be delivered remotely via telerehabilitation.

**Safety criteria of verticalization in acute stroke**

St. Petersburg State I.P. Pavlov Medical University, Saint Petersburg, Russia; Medical Military Academy, Saint Petersburg, Russia; North-Western State Medical University named after I.I. Mechnikov, Saint Petersburg, Russia

**Background:** Traditionally, to assess the safety verticalization of patients with stroke there are tests used with half-orthostasis and hypercapnia. But the majority of these patients are not able to perform them adequately.

**Objective:** To assess the safety of verticalization based on indicators of cerebral blood flow (CBF), and to determine simple functional tests to predict the risk of verticalization.

**Patients and methods:** Fifty patients (63.7 ± 9.3 years old) underwent a series of head-up tilts (HUT) from the 1st to the 5th day after stroke onset. CBF by transcranial Doppler (TCD) and blood pressure (BP) were measured every 3 min during 30 min HUT. Before verticalization was started the overshoot coefficient was determined on the affected side. Outcomes were assessed by NIH scale. Patients were divided into two groups: Group 1 (26) with the full recovery on the 14th day according to NIHSS (Δ6.0 ± 3.2), and Group 2 (24) with lower recovery (Δ4.0 ± 2.1).

**Results:** In Group 1 the overshoot coefficient was higher on the first day (6.4 ± 2.5%) compared to Group 2 (2.1 ± 0.8%, p = 0.034), and it increased at the 14th day by 8.1% in Group 1 and by 6.8% in Group 2.

**Conclusions:** TCD can be used to estimate the risk of complications of early verticalization, thus providing a personalized and intensified approach. Before verticalization a test on reactivity should be performed to determine the overshoot. The higher overshoot coefficient at the start of treatment (>6%) is associated with better recovery.

**Influence of plantar somatosensory input on calorically induced and pathologic vertigo**

R.J. Allen, A.P. Miner. University of Puget Sound, Tacoma, WA, USA; Physical Therapy, University of Puget Sound, Tacoma, WA, USA

**Background:** Active plantar somatosensory stimulation (PSS) via direct pressure has been reported to reduce aspects of induced vertigo in normals. Questions remain whether passive PSS applications also reduce vertigo symptoms and whether the phenomenon has viability for treating patients with pathologic vertigo.

**Objective:** To compare the effects on vertigo of two PSS methods, direct plantar surface pressure versus plantar TENS, and determine if PSS methods are effective for treating episodic symptoms in patients with benign paroxysmal positional vertigo (BPPV).

**Patients and methods:** Caloric vertigo was induced with 5 °C water irrigation to external acoustic meatus in 21 asymptomatic adults. Using within-subjects design, each participant received direct plantar pressure, plantar TENS, and sham “subsenory” stimulation control treatments. Visual-analog intensity ratings and electrooculographic measures of nystagmus intensity and duration assessed influence on vertigo. Seventeen patients with BPPV positionally induced vertigo and were treated with a random presentation of the three treatment conditions across six sessions. Repeated measures ANOVA with multiple contrast analyses compared treatment responses.

**Results:** While not significantly different from each other, the two PSS conditions yielded significant reductions in vertigo intensity compared to control (p = 0.019) in normals. No significant differences in vertigo duration were found between the groups (p = 0.424). Patients with BPPV similarly showed PSS reductions in vertigo intensity (p = 0.037) for treatments over control.

**Conclusions:** Plantar somatosensory stimulation attenuates intensity of vertigo, whether via direct plantar pressure or TENS, for both induced normals and patients with BPPV. Both methods of providing plantar pressure appear similarly efficacious.

**Lateralized response in dynorphin A peptide levels after traumatic brain injury**

T. Yakovleva, S. Fitting, S.W. Scheff, K.F. Hauser, G. Bakalkin. Department of Pharmaceutical Biosciences, Uppsala University, Uppsala, Sweden; Virginia Commonwealth University, Richmond, VA, USA

The dynorphins, endogenous opioid peptides have been implicated in secondary CNS injury and neurodegeneration. To gain better insight into the pathophysiological role of dynorphins in the CNS response to trauma, we analyzed short term (1 day) and long term (7 day) changes in dynorphin A (Dyn A) levels in the frontal cortex, hippocampus and striatum induced by unilateral left-side or right-side cortical TBI in mice. TBI effects were significantly different from those of sham operation (Sham), while the Sham also produced noticeable effects. Both Sham and TBI induced short-lasting changes in peptide levels in the striatum, and long-term changes in all three regions. Two types of responses were generally observed. In the hippocampus, Dyn A levels were predominantly altered ipsilaterally to the injury. In the striatum and frontal cortex, injury to the right (R) hemisphere affected Dyn A levels to a greater extent than on the left side (L). The R-Sham but not L-Sham reduced the
peptide levels in the striatum at the 24 h time point, and R-TBI but not L-TBI produced Dyn A changes in the striatum and frontal cortex at 7 days after the injury. Injury to the R-side induced changes that were similar in both left and right hemispheres. Thus, trauma may uncover an existing laterализation in the mechanism mediating the response of Dyn A-expressing neuronal networks in the brain. These networks may differentially mediate effects of left and right brain injury on the lateralized brain functions.

Repetitive sensory stimulation in stroke rehabilitation—Perspectives and potential
H.R. Dinse1, J.C. Katterstroth2, T. Kalisch3, M. Tegenthoff4,
1Institute for Neuroinformatics, Neural Plasticity Lab, Germany;
2Dept. of Neurology, BG-Klinikum Bergmannsheil, Ruhr-University Bochum, Bochum, Germany

Background: Rehabilitation employs task specific training and massed practice to drive neuroplasticity mechanisms. However, since many patients suffer from restricted mobility and sensory loss, development of additional and alternative approaches that could supplement, enhance, or even replace conventional training procedures would be advantageous.

Objective: We report effectiveness and feasibility of repetitive sensory stimulation for rehabilitation. The rational is to target plasticity processes within and around those brain areas that became dysfunctional.

Patients and methods/material and methods: We summarize findings from several subacute and chronic stroke patient studies with left or right cerebral artery thromboembolic infarction. We use high-frequency intermittent electrical stimulation of all fingers of the affected hand applied via custom-made stimulation gloves. Treatment time was 2 weeks in subacute, and several months in chronic patients. For the healthy and the affected limb we assessed proprioception, dexterity and grip force.

Results: Repetitive stimulation induced substantial improvement of tactile and sensorimotor performance long lasting when applied over weeks. Furthermore, positive effects of sensory, motor and proprioceptive functions emerged after months of stimulation in long-term chronic patients.

Conclusion: This effectiveness together with the advantage of usage under everyday conditions by laypeople at their homes, makes repetitive stimulation-based principles prime candidates for intervention. A particular advantage of repetitive stimulation is its passive nature, it can be applied in parallel to other occupations, making it easier to implement and more acceptable to the individual.

Posture influence on the pendulum test of spasticity in spinal cord injured patients
E. Azevedo1, K. Alonsoa, R. Mariaa, F. Beinottii, A. Cliqueno.
1Unicamp, Campinas, Brazil; 2Universidade de S Paulo, S Paulo, Brazil

Background: The pendulum test has been used for the assessment of spasticity in patients with different diseases, including spinal cord injury (SCI). However, there is not a standard position for the test.

Objective: To assess whether different patient postures do interfere on spasticity results.

Material and methods: Three individuals with tetraplegia and two with paraplegia went through the pendulum test in three different positions: supine, semi-supine at an angle of 30° and sitting up at an angle of 60°. An electromiometer was attached to the right leg for measurement of knee joint angles. All situations were performed five times on different days and the averages were taken for analysis.

Results: Relaxation index (RI), test duration in seconds, initial flexion angle (Fang) and resting angle (Rest ang) were analyzed at three different positions. Supine: RI (mean/sd) 0.93/0.32; test duration 6.9/1.7; Fang 72.6/22.6; Rest ang 55.7/14.2. Semi-supine: RI 0.97/0.39; test duration 8.9/2.7; Fang 75.7/17.8; Rest ang 63.3/5.3. Sitting up: RI 0.62/0.08; test duration 13.9/4.1; Fang 87.9/13; Rest ang 54.8/12.8. Differences are shown for sitting up position.

Conclusion: Spasticity reduction and an increase in quadriceps femoris relaxation were observed in the sitting up position due to muscles shortening in that position, when compared to the others. Furthermore, in supine and semi-supine positions autonomic dysreflexia symptoms (i.e. arterial hypertension) were observed during the tests.

Quantitative MRI indexes in neuromuscular and muscle diseases
C. Angelini1, M. Fanin2, E. Peterle3. 1IRCSS San Camillo, Venice, Italy; 2University of Padova, Padova, Italy

Objectives: We propose two new types of quantitative measurement to evaluate muscle atrophy by imaging: the quadriceps index and the left vastus lateralis index and compare it in muscle biopsy.

Methods: We have used TI sequences on thigh muscle MRI, at about 15 cm from the head of the femur (second slide of MRI in lower extremities). In these sequences we measured the muscle area of the left quadriceps femoris and of the left vastus lateralis. These measurements were carried out in 11 patients with various types of neuromuscular diseases and myopathies, i.e. 2 lipid storage myopathies (LSM), 1 ALS, 1 FSHD, 1 myofibrillar myopathy, 2 LGMD2A, 1 LGMD1F, 1 myositis ossificans, and 2 aspecific myopathies. We investigated by morphometry and molecular markers of atrophy or autophagy, i.e. MURF, LC3, and muscle biopsies.

Results: By MRI the measurement of the muscle area of the quadriceps femoris in 11 patients, resulted in an average of 3711 mm²± 792, and the muscle area of vastus lateralis in 11 patients had an average of 963 mm²± 303. In the most atrophic sub-group the values ranged from 400 to 900 mm (mean 658.7) and these included cases of LGMD2A, 1F, LSM and ALS.

Conclusion: In ALS and metabolic myopathies a high degree of atrophy was found and similar changes were present in calpainopathy and LGMD1F, due to traspotinopathy. The correlation of imaging indexes with fiber atrophy parameters obtained in muscle biopsy is promising to evaluate rehabilitation in neuromuscular cases.

New approaches to the use of transcranial magnetic stimulation in rehabilitation of patients suffering from cerebral insult
A.V. Musayev1, S.O. Huseynova2, F.K. Balakishiyev2. 1Research Institute of Medical Rehabilitation, Azerbaijan; 2Clinically-Neuropsychological Laboratory, Azerbaijan; *Neurology, Research Institute of Medical Rehabilitation, Baku, Azerbaijan

One of the most perspective aspects of increasing the efficacy of restorative therapy in patients with cerebral insult (CI) is the use of transcranial magnetic stimulation (TMS).

The aim of this research is to assess the TMS method (with the influence on cerebral motor structures).

Material and methods: We recruited 57 patients with a diagnosis of CI. To study therapy efficacy, all the patients underwent neurologic investigation, the assessment of a patient's daily activities (according to the Barthel scale), functional state of central neuromotor system as well as cognitive functions (according to MMSE and FAB scales). All patients received TMS on motor centers of both hemispheres within 10–15 min, 10–12 procedures per course of therapy.

Results: The patients with CI showed regression of paratiss rate (39.4%), spasticity (38.2%), and gait improvement (35.9%). The clinical improvement was confirmed by positive dynamics of the Barthel index which had been increased (p<0.01) and also by the improved functional state of the central neuromotor system (by increased amplitude of evoked motor response and reduced central motor conduction time, p<0.05). The treatment improved the state of main cognitive functions — memory, attention, orientation, etc. (44.8%).

Conclusions: The method developed by us of a patient's therapy with a diagnosis of CI enables the regression of motor deficit, improvement of daily activities, a patient's “quality of life” and correction of cognitive disorders as well. Of course, the functional changes in cerebral cortex, activation of collateral tracts are the underlying basis of its therapy effect.

The use of choline donators in the cognitive rehabilitation after severe brain injury
N.E. Ivanova. Neurology, Polenov, St. Petersburg, Russia

Background: Constant growth of frequency of neurotrauma with consequent cognitive impairment that worsens the prognosis of rehabilitation after traumatic brain injury, a high degree of disability, makes the problem of diagnosis and treatment of cognitive dysfunction socially significant.

Objective: To assess the results of use of the donors of choline during neurorehabilitation of patients with cognitive impairment as the consequences of severe traumatic brain injury.

Patients and methods/material and methods: We identified some particular features of the dynamics of cognitive impairment in the late period of severe traumatic brain injury in three groups of patients: isolated traumatic hematoma, focal contusions of the brain, and a combination of intracranial hematoma with focal contusions. In our study we had enrolled 205 patients with severe consequences of brain injury (the main group 133, the control group 72 observations). We supervised and assessed the dynamics of cognitive impairment after the combined treatment with using the donor of choline (Gliatilin) and acetylcholinesterase inhibitors (Reminyl, Exelon). We used the following scales — MMSE, Barthel, and Rankin, the observation period was 48 months.

Results: The best results were obtained in patients in the combined treatment that included Gliatilin. The combination of Gliatilin with acetylcholinesterase inhibitors in patients with severe mental disorders improves the long-term quality of life.

Conclusion: The analysis of the effects of treatment showed that the inclusion of donor of choline is a promising direction for both prevention and treatment of mental disorders after severe traumatic brain injury.

Task-specific interactive game-based virtual reality rehabilitation system for stroke patients: A usability test and two clinical experiments

J.-H. Shin a, H. Ryu b, S.H. Jang c, S. Kim d. aNational Rehabilitation Center of Korea, Hanyang University, Seoul, Republic of Korea; bDepartment of Industrial Engineering, Hanyang University, Seoul, Republic of Korea; cDepartment of Physical Medicine and Rehabilitation, Hanyang University, Seoul, Republic of Korea; dDepartment of Law, Hanyang University, Seoul, Republic of Korea

Background: Virtual reality is not commonly used in the clinical rehabilitation setting and commercial VR gaming system may provide mixed effects to stroke patients.

Objectives: To develop a task-specific interactive game-based VR system for stroke rehabilitation, RehabMaster™, and to assess usability and clinical efficacy for rehabilitation.

Methods: A participatory design and usability tests were carried out for development of RehabMaster with representative user groups. Also, two clinical trials were carried out. As a first trial for seven chronic stroke patients, we conducted an observational study, in which they received 30 min of RehabMaster interventions for two weeks. Secondly, as a randomized controlled trial, 16 acute and subacute stroke patients were recruited. They were assigned to conventional occupational therapies (OT-only group) or conventional occupational therapy plus 20 min of RehabMaster intervention (RehabMaster + OT group) for 10 sessions. Fugl–Meyer assessment (FMA), modified Barthel Index (MBI), adverse effects and the drop-out rate were recorded.

Results: The requirements of the VR system for stroke rehabilitation were established and reflected on RehabMaster. Reported advantages from usability tests were improved attention, immersive flow experience, and individualized intervention. The first clinical trial showed that FMA and MBI differed between evaluation times (P > .05). The second trial revealed that RehabMaster + OT group improved better than OT-only group (P = .07) in terms of FMA, without effects in MBI. One chronic patient discontinued the trial and no adverse effects were reported.

Conclusion: The RehabMaster is a feasible and safe VR system to enhance upper extremity functions for stroke patients.

The effect of anodal transcranial direct current stimulation to the sensorimotor cortex on somatosensory evoked magnetic fields

K. Sugawara a, H. Onishib, K. Yamashiro a, S. Kojimac, S. Miyaguchib, A. Tsukib, M. Suzukic, H. Kirimoto b, H. Tamakicon, H. Murakamib, S. Kameyamad. aInstitute for Human Movement & Medical Sciences, Niigata University of Health and Welfare, Japan; bDepartment of Neurosurgery, Nishi-Niigata Chuo National Hospital, Niigata City, Japan

Background: Several studies have revealed that tDCS modulated the human motor cortex. However, there are few studies to investigate the change of SEFs using tDCS.

Objective: The aim of the present study is to investigate the effect of anodal tDCS on the sensorimotor cortex under the influence of SEFs.

Material and methods: Seven healthy subjects (24.9 ± 3.8 years) participated in this study. All subjects gave their written informed consent. tDCS was delivered using a direct current stimulator through a pair of saline-soaked surface sponge electrodes (35 cm²). The anode was placed on the left scalp over the area representing the right thenar muscle, and the other electrode was placed above the contralateral orbit. Anodal tDCS was applied for 15 min to the left motor cortex at 1 mA. We recorded SEFs following a 0.5-Hz electrical stimulation of the right median nerve at the wrist using a 306-channel whole-head MEG system both before and after tDCS. The intensity of this stimulation was fixed at 1.2 times that of the motor threshold.

Results: The current strength of N20m was unchanged after tDCS, whereas that of P35m and P60m increased after tDCS (P35-pre: 24.7 ± 12.7 nAm, post: 33.5 ± 11.6 nAm; P60-pre: 30.6 ± 23.3 nAm, post: 36.9 ± 26.5 nAm). The ECD locations of P35m and P60m were unchanged before and after tDCS.

Conclusion: Our study revealed that anodal tDCS of the sensorimotor cortex affects the P35m and P60m components of the SEF.

Use of functional independence measure instrument at a neurological step-down unit

P.D. Gaioll a, T. Falsoni b, P.R.P. Hidalgo c, E.M. Araujo c, N.M. Barros c, R. Lobato b, C. Talermon b, R.A.C. Eid a. aHospital Israelita Albert Einstein, São Paulo, Brazil

Introduction: The Functional Independence Measure (FIM) is an outcome measure of the severity of physical and cognitive disabilities for an inpatient rehabilitation setting. The severity of disability changes during rehabilitation treatment, making changes in the FIM scale an indicator of treatment benefits and its results. The FIM is a seven level scale representing patient’s independence and dependence. So far there is no evidence of the functional profile of patients followed by a physiotherapist at a Neurological Step-Down Unit (NSDU).

Objective: To evaluate the functional profile of patients followed by physiotherapists at the NSDU.

Methods: A cohort study, evaluating the FIM scale of patients admitted to NSDU at the Albert Einstein Jewish Hospital, older than 18 years old, during an eight month period, and that were followed by physiotherapists. FIM scale was applied by trained and certified physiotherapists at day one (when patient was alert and responsive) and at NSDU discharge. The FIM scale rates from 18 to 126 points, evaluating: self care, sphincter control, transfer and mobility, deambulation, communication and social cognition.

Results: During the study period, 137 patients were evaluated, with a median age of 73 years (range of 18–98). There was a significant functional improvement at NSDU discharge when compared to day one (median of 59, range of 18–126 vs. median of 84, range of 18–126, respectively; p < 0.001).

Conclusions: The FIM scale represents applicability during clinical assistance, showing improvement in patients’ physical function at NSDU discharge. This improvement may represent the quality of physiotherapy assistance.

Abstract — WCN 2013

Topic: 10 — Neurorehabilitation
Profile of patients followed by physiotherapy at a neurological step-down unit

Introduction: The Neurological Step-Down Unit (NSDU) is a specific unit for neurological patients, with moderate complexity, that requires intensive care due to high dependence and continuous monitoring. The physiotherapy treatment at the NSDU may vary due to cultural and specific characteristics of each service, region or country, focusing on patients’ respiratory and motor problems. So far there is scarce evidence of patients’ characteristics followed by physiotherapists and demand of this specialty at the NSDU.

Objective: To describe patients’ profile followed by physiotherapy at the NSDU.

Methods: A prospective, observational study, during an 8 month period after the inauguration and physiotherapy service at our NSDU at the Albert Einstein Jewish Hospital, Sao Paulo, Brazil. Demographic data, number of patients’ admissions, number of physiotherapy prescriptions, admission diagnosis, and prevalence of noninvasive ventilation (NIV) use.

Results: During the study period, a total of 297 admissions were registered, of these 137 (47%) had physiotherapy prescription. The median age was 73 years (range of 18–98). Of patients with physiotherapy prescription, 45% (n = 62) had been diagnosed of stroke, followed by 8% (n = 11) of brain tumor resection, 6% (n = 8) of spine arthrodesis, 5% (n = 7) of subarachnoid hemorrhage, and 4% (n = 6) of convulsive crisis. NIV was used in 18% (n = 25) of patients. The median duration of physiotherapy treatment at the NSDU was 2 days (range of 1–34).

Conclusion: Physiotherapy service treats almost half of patients admitted to the NSDU, most of them with stroke diagnoses, low prevalence of NIV and few days of treatment.

Results: The participants decreased their preferred walking speed when walking EC (condition 1) vs. condition 2 (−17%). They also exhibited slightly shorter steps (−3%) and higher cadence (+3%) in EC condition (i.e. 2 vs. 3). LDS was not substantially modified in EC condition (2 vs. 3 +1%, not significant).

Conclusion: In the absence of visual feedback, healthy individuals adopt a more cautious walking pattern (lower speed, shorter steps). However, the local dynamic stability in the frontal plane seems not affected. It is therefore likely that the somatosensory and vestibular feedbacks are sufficient to maintain an optimal gait stability.

Effect of non-robotic equipment on improvement of movements of the upper limb in children with hemiparesis syndrome

N. Sladekova¹, E. Ziatkova¹,², S. Klobucka¹,²; RC Harmony, Bratislava, Slovak Republic; ³Faculty of Nursing and Professional Health Studies, Slovak Medical University in Bratislava, Bratislava, Slovak Republic

Background: Pilot study tested improvement of upper limb movements in children with hemiparesis syndrome.

Objective: The aim of the study was to determine the effect of Armeo® therapy system on movement and the ability to grip of upper limb in patients with hemiparesis syndrome.

Patient and methods: The object of investigation consisted of five patients 10 to 16 years old with impaired upper limbs. They all have taken twenty therapies in the Armeo® system, wherein one therapy lasted 45 min of active exercise and frequency was minimal twice a week. Patients were tested before and after completion of therapy using goniometric investigation and by testing grip of parietic hand (cylindrical, spherical, hook…).

Results: After rehabilitation by Armeo® device the patients achieve greater range of motions in the upper limb which resulted in a higher average output score (M = 615, SD ± 28.723) than the input score (M = 515, SD ± 21.622), t (5) = −9.00, p = 0.001. Significantly better results demonstrate the improvement in hand grip which resulted in higher average output score (M = 34.20 SD ± 18.78) compared with the input score (M = 29.80 ± SD 18.70), Z (5) = −2.023, p = 0.043.

Conclusion: Significant positive results were achieved due to Armeo® therapy system in improving the range of motion in the hemiparetic upper extremity and similar significant results have shown improvement in grip ability of parietic hand.

Mirror therapy for patients with severe arm paresis after stroke — A randomized controlled trial

H. Thieme¹,²,³, M. Bayn¹,², M. Wurg¹,², C. Zange³, M. Pohl², J. Behrens².
¹Erste Europäische Schule für Physiotherapie, Ergotherapie und Logopädie, Klinik Bavaria, Kreischa, Germany; ²Institut für Gesundheits- und Pflegewissenschaft, Martin-Luther-Universität Halle-Wittenberg, Halle, Germany; ³Abteilung Neurologie und Neuroonkologie, Klinik Bavaria, Kreischa, Germany; ⁴Abteilung für Neurorehabilitation, Zürcher Höhenklinik Wald, Wald, Zurich, Switzerland; ⁵Abteilung für Neurologie und Fachübergreifende Rehabilitation, Klinik Bavaria, Kreischa, Germany

Objective: To evaluate the effects of individual or group mirror therapy in patients with severe arm paresis after stroke.

Methods: In this randomized controlled single blinded trial 60 patients with severe arm paresis who underwent an inpatient rehabilitation within three months after stroke were included. Patients were randomized into one of three groups:

1. individual mirror therapy,
2. group mirror therapy and
3. control intervention with restricted view on the affected arm.

We evaluated motor function on impairment (Fugl–Meyer Test) and activity level (Action Research Arm Test), independence in activities
of daily living (Barthel Index), quality of life (Stroke Impact Scale) and visuospatial neglect (Star Cancellation Test).

Results: After five weeks, no significant group differences for motor function were found (P > 0.05). Pre-post differences for the Action Research Arm Test and Fugl–Meyer Test: individual mirror therapy: 3.4 (7.1) and 3.2 (3.8), mirror group therapy: 1.1 (3.1) and 5.1 (10.0) and control therapy: 2.8 (6.7) and 5.2 (8.7). However, a significant effect on visuospatial neglect for the individual mirror therapy compared to control group could be shown (P < 0.01). Furthermore, it was possible to integrate a mirror therapy group intervention for severely affected patients after stroke.

Conclusion: This study showed no effect on sensorimotor function of the arm, activities of daily living and quality of life of mirror therapy compared to a control intervention after stroke. However, a positive effect on visuospatial neglect was indicated.

Standardization of motor free visual perception test (MVPT-3) in Korean adults
S.B. Pyun, S.N. Yang, Y.H. Kim, H.S. Yoon, A. Han, B.J. Ryu, D.Y. Kim, H.I. Moon, T.W. Choi. Korea University, Seoul, Republic of Korea; Jo Eun Hospital, Seoul, Republic of Korea; Sahm Yook Medical Center, Seoul, Republic of Korea; National Rehabilitation Center, Seoul, Republic of Korea

Background: The motor free visual perception test (MVPT) is most widely used in stroke rehabilitation in Korea. But MVPT was not adapted and standardized in Korean, thus test application and interpretation depend on an arbitrary decision. MVPT-3 is the latest version and consisted of 65 standardized in Korean, thus test application and interpretation depend on an arbitrary decision. MVPT-3 is the latest version and consisted of 65 items including visual discrimination, form consistency, visual short term memory, visual closure, spatial orientation and figure ground.

Purpose: This study was performed to establish reference values of MVPT-3 in Korean adults.

Method: The test instructions of the MVPT-3 were translated and adapted to Korean and back-translation was also performed by a proficient bilingual. The original stimuli of MVPT-3 were not changed. Healthy volunteers who aged over 20 years were recruited. People who have a previous history of stroke, neuropsychiatric illness, severe visual impairment, and decrement of K-MMSE scores of more than 1 SD as compared to the same age group.

Results: Three hundred twenty one adults participated in this study and mean age and education years were 50.96 ± 21.03 and 11.64 ± 5.31 years, respectively. Total mean MVPT-3 score is 51.45 ± 8.32 and the score significantly correlated with age and education years. Post-hoc analysis classified age and education years into 5 groups (age: 20–59, 60–79, and over 80 years, education: 0, 1–9, over 9 years).

Conclusion: Visual perception is significantly influenced by age and education. Reference values provided in this study will help to apply and interpret the MVPT-3 in Korean and evaluation of visual perceptual dysfunction in stroke patients.

Diabetic polynecropath prevention method
A. Malkov, V. Ponomarev. Belarusian Medical Academy of Postgraduate Education, Gomel, Belarus

Introduction: In the Republic of Belarus diabetes affects 3900 of every 100,000 people. Diabetic distal sensory polyneuropathy (DDSPN) is one of the most common diabetes complications. 5 years after diabetes manifests 12.5–14.5% of patients are diagnosed with DDSPN (FIELD Study, 2012).

Goal: Develop methods of DDSPN prevention.

Methods: From 2010 to 2012, there were 249 patients examined with type 2 (82%) and type 1 (18%) diabetes without neurologic disorders (male: 179, female: 70, average age 38 ± 13). Vibrational, tactile, temperature, and pain sensitivity of legs were defined and electro-neuromyography (ENMG) was used. There a group of patients (186 people) was picked without manifestations of DDSPN, but with ENMG criteria typical for initial manifestations of this pathology (San Antonio single ENMG program, 1988). They were divided into 2 groups: A. (96 people) — glycemic control, diet and iontophoresis applied to the lower limbs were prescribed; B. (90 patients) — glycemic control and diet were prescribed.

Results: After the treatment ended, 64 people (61%) from group A showed the growth of amplitude and velocity indexes of n. peroneus, n. tibialis, and n. suralis to normal (p < 0.001), which lasted for 6 months. In group B the improvements were for 7 patients (6%). Dipping of above indexes of the examined nerves and clinical manifestations of DDSPN were revealed for 2 (2%) patients in group A, and for 30 (27%) patients in B (p < 0.001).

Conclusion: Delivery of anticholinesterase drugs to lower limbs by iontophoresis is a method of DDSPN prevention on the clinical stage.

Benefits of inpatient multidisciplinary rehabilitation in multiple sclerosis
S. Salhofer-Polanyi, J. Windt, H. Sumper, H. Grill, G. Diemayr, K. Zeheholzer, F. Leutmezer, G. Zulehner, K. Vass, S. Asenbaum-Nan. Department of Neurology, Medical University of Vienna, Vienna, Austria

Background: Rehabilitation is often recommended to MS-patients but data on its efficacy is limited.

Objective: To evaluate the benefit of inpatient multidisciplinary rehabilitation.

Methods: A rater-blinded, randomized, waiting list controlled exploratory study. 19 participants completed the study with ten allocated to the intervention group and nine to the waiting list group. Assessment of outcome parameters was done at baseline and after 3 months. Time walking tests (TWTS) and a 9 hole peg test were used to objectively assess the level of activity, Functional-Assessment-in-MS and MS-Self Efficacy-Scale to assess participation and quality of life and Expanded Disability Status Scale (EDSS) to assess bodily function. Additionally, Rivermead Mobility Index, Berg Balance Scale, Tinetti-Test, MS-Functional Composite and a rater-blinded evaluation of a video-analysis on walking performance were done.

Results: Mean change scores of timed 50 m walk (p = 0.014), walking speed (p = 0.034), 2- min walk (p = 0.204) and 6-min walk (p = 0.034) indicated an improvement favoring inpatient multidisciplinary rehabilitation. We could not demonstrate a benefit for upper limb function and some improvement was seen in other outcome parameters without reaching statistical significance. EDSS remained unchanged.
Conclusion: Inpatient multidisciplinary rehabilitation is effective in MS patients with positive effects on the level of activity as measured by TWTs covering both short and long distance ambulation.

Mirror therapy for improving motor function after stroke
H. Thienea,b, J. Mehrholzf, M. Pohl1, J. Behrensb, C. Dohlea,b. 1Erste Europäische Schule für Physiotherapie, Ergotherapie und Logopädie, Klinik Bavaria, Kreischa, Germany; 2Institut für Gesundheits- und Pflegewissenschaft, Martin-Luther-Universität Halle-Wittenberg, Saale, Halle, Germany; 3Wissenschaftliches Institut, Private Europäische Medizinische Akademie der Klinik Bavaria in Kreischa GmbH, Germany; 4Abteilung Neurologie und Fachübergreifende Rehabilitation, Klinik Bavaria, Kreischa, Germany; 5Abteilung für Neurologische Rehabilitation, Medizin Klinik Berlin-Kladow, Germany; 6Center for Stroke Research Berlin, Charité Universitätsmedizin Berlin, Berlin, Germany

Background: Mirror therapy is used to improve motor function after stroke. During mirror therapy, a mirror is placed in the patient’s midsagittal plane, thus reflecting movements of the non-paretic side as if it were the affected side.

Methods: We conducted a systematic Cochrane review to summarise the effectiveness of mirror therapy for improving upper extremity motor function, activities of daily living and pain, at least as an alternative to all other interventions, mirror therapy may have a significant positive effect.

We included 14 studies with a total of 567 participants. When compared with all other interventions, mirror therapy may have a significant positive effect on pain which is in stable at follow-up assessment after six months. We found a significant positive effect on pain which is in stable at follow-up assessment after six months.

Continuous variables.

We analysed the results as standardised mean differences (SMDs) for continuous variables.

Results: Compared with all other interventions, mirror therapy may have a significant positive effect on pain which is in stable at follow-up assessment after six months.

With some limitations, the results indicate evidence for mirror therapy as an alternative to all other interventions.

Conclusion: Mirror therapy is used to improve motor function after stroke. During mirror therapy, a mirror is placed in the patient’s midsagittal plane, thus reflecting movements of the non-paretic side as if it were the affected side.

Active very early rehabilitation safety and effectiveness following acute stroke
C.M. Kwoka, Physiotherapy Department, Tseung Kwan O Hospital, Hong Kong, Hong Kong SAR

Introduction: Active very early rehabilitation (AVER) emphasizes on early mobilization for target acute stroke patients at ≤24h admission to ASU, whose physiological parameters are within the set limits.

Aims:
1. To evaluate the AVER on its feasibility, and primary & secondary outcomes; and
2. To determine the LOS in ASU with associated factors.

Methodology: A descriptive, quasi-experimental design with pre-and post-tests was employed.

Results: 103 patients were screened and 64.4% (n = 65) were recruited for AVER. Mean time to first mobilization from ASU admission was 17.0 h (SD 4.9). 80% (n = 52) were ischemic stroke. After AVER, the primary daily living and ambulatory independence outcomes were significantly improved, and included Modified Barthel Index (BI-100), Modified Rankin Scale (MRS) and Modified Functional Ambulatory Categories (MFAC) (paired t test, p < 0.001). 70.8% of patients achieved daily living independence (MRS ≤ 2) & 69.2% achieved satisfactory ambulatory independence (MFAC ≥ 5). The secondary safety outcomes like mortality rate and post-stroke complications were low (12.3%, n = 8). They occurred in severe stroke (mean NIHSS 9.75, SD 8.50). The mean length of stay (LOS) was 5.38 days (SD 2.76). The stepwise multivariate regression analysis showed that LOS was associated with NIHSS and MRS post-AVER (p < 0.01). This model correctly predicted 46.1%. Each additional point on the LOS would increase by approximately 193 N1 where N1 is the NIHSS and 795 N2 where N2 is the MRS post-AVER.

Influence of virtual reality environment in robotic-assisted treadmill training on motor functions in children with cerebral palsy
S. Klobucka, E. Ziaikova2, a, Rehabilitation Centre Harmony, Bratislava, Slovak Republic; 2Slovak Medical University, Faculty of Nursing and Health Professional Studies, Bratislava, Slovak Republic

Background: In the past decade there has been a striking increase by approximately 193 N1 where N1 is the NIHSS and 795 N2 where N2 is the MRS post-AVER.

Virtual reality (VR) environments were developed to enhance robotic-assisted treadmill training (RATT).

Objective: To examine the influence of VR environment in robotic-assisted treadmill training on gross motor functions in children with cerebral palsy (CP).

Material and methods: 42 children (25 boys) with bilateral spastic CP, aged 4.3–12.9 years underwent 20 sessions of RATT during a 4–5 week period with a frequency of 3 to 5 times a week using driven gait orthosis Lokomat. Patients were randomly allocated into two groups according to whether they trained in a VR environment (VR-LOKO, n = 26) or not (LOKO, n = 16). Outcome measures were dimension A (lying, rolling), B (sitting), C (crawling, kneeling), D (standing), and E (walking, running, jumping) of the Gross Motor Function Measure (GMFM-88).

Results: After completing 20 sessions, patients of both groups demonstrated highly statistically significant improvement (p < 0.001) in all dimensions of the GMFM. Comparing the average improvement in outcome parameters in both groups (LOKO vs. VR-LOKO), we documented a statistically significant difference (p < 0.05) in the dimension of A, C, and overall improvement in the GMFM in favour of patients in VR-LOKO group.

Conclusion: Results of our study indicate that the environment of VR implemented during RATT affects the amount of the achieved improvement of motor functions in CP patients. VR-based training conditions represent a valuable approach to enhance active participation during RATT in children with CP.

Conclusion: AVER in ASU is feasible, safe & effective. Further research to review the AVER beneficiaries is recommended for future development.

Assessment of cerebral activation patterns while operating a driving simulator with TBI survivors: A functional near-infrared spectroscopy study

Department of Rehabilitation Medicine, The Jikei University School of Medicine, Japan; Department of Legal Medicine, Dokkyo University School of Medicine, Tochigi, Japan; Department of Rehabilitation Medicine, Dokkyo University School of Medicine, Tochigi, Japan; Uekusa Gakuen University, Chiba, Japan

Background and objective: Driving is an important activity of daily living. However, the ability to drive is often affected after traumatic brain injury (TBI). The aim of this study was to investigate the fundamental region of neural activity in healthy subjects, which is believed to be necessary for driving ability and to examine the effect of brain injury on driving safety.

Patients and methods: Experimental studies were performed on 8 healthy right-handed adults and 8 patients with moderate to severe TBI (5; resumed driving, 3; did not resume driving). The participants were asked to drive in the driving simulator. During driving, changes in oxy-Hb levels were measured using functional near-infrared spectroscopy at 34 sites including both hemispheres.

Results: The areas that showed significant activity in healthy subjects spanned from the frontal region to the temporal and parietal regions, and were more prominent in the right cerebral hemisphere than in the left. Patients who resumed driving showed similar patterns as healthy subjects; cortical activations near damaged regions were retained as seen on CT or MRI. However, the patients who could not resume driving showed no cortical activations near the lesions.

Conclusion: Our results provide further evidence that driving a car is a complex cognitive skill, and we believe that it is important to check the site of brain injury and the brain region where the damage has occurred before providing sufficient real car driving practice to patients with brain injury.

Gait rehabilitation in subacute hemiparetic stroke: Robot-assisted gait training versus conventional physical therapy
R. Chanubol, P. Wongphaet, C. Werner, N. Chavanich, L. Panichareon, P. Meier, Ramathibodi Hospital, Mahidol University, Bangkok, Thailand; Neurological Rehabilitation, Charite University Hospital, Berlin, Germany

Background: Despite improved management of patients after stroke, the majority of surviving patients are disabled with impaired walking function. Robot-assisted gait training was introduced as a potential strategy for gait rehabilitation in the severely disabled.

Objective: To compare the effect of robot-assisted gait training and conventional physical therapy on ambulation in subacute hemiparetic stroke patients.

Material and methods: Sixty non-ambulatory stroke subjects were randomly assigned to an experimental or control group. Both groups received a similar type and intensity of rehabilitation, except the gait training session. The experimental group received 30-minute robotic-assisted gait training plus a 30-minute conventional physical therapy while the control group received a 60-minute conventional physical therapy on every working day for four consecutive weeks. Gait function and disability were assessed before, one month after treatment, and 3 months follow-up, using the Functional Ambulation Category, Barthel Index, Berg Balance Scale, Resistance to Passive Movement scale, lower extremity part (REPAS), 10-meter walk test, and 6-minute walk test by a blinded assessor.

Results: The intention to treat analysis revealed significant higher scores of all measures, except the REPAS, in the experimental group compared with the control group at the end of the first and the third month post treatment (p < 0.05).

Conclusion: The robot-assisted gait training plus conventional physical therapy is significantly better than conventional physical therapy alone in subacute stroke patients as regards the ability of ambulation, activity of daily living, balance, gait speed, step length and endurance.

Effect of 8-week rebound therapy exercise on dynamic and static balance of male students affected by Down syndrome

Biomechanics, Islamic Azad University, Tehran Branch, Iran; Neurology, Shahed University, Tehran, Iran

Objective: Balance is a complex motor skill that describes dynamic body posture that prevents the possibility of falling. Down syndrome is a genetic disorder in which chromosome 21 or part of it is tripled. Balance is not perfect in patients with Down syndrome. Rehabilitation may be effective in enhancing balance in these patients. Rebound therapy is a rehabilitation program made possible by the therapeutic use of trampoline.

Methods: 30 students were enrolled in groups. They were matched with mean age of 18.54 years, and mean height of 164/2 cm.15 persons as the test group voluntarily took part in the experiment (i.e. rebound therapy) with mean age of 19/36 years, mean weight of 74/35 kg, and mean height of 165/7 cm. To measure the static balance, BERG standard test was used and TUG test was used for dynamic balance. The balance exercise program was performed by means of a trampoline which lasted 8 weeks, for 3 sessions of 20 minutes each week. For descriptive statistics, mean and standard deviation were used. KS test was employed for the group normalization, and in the section inferential statistics, t-test (dependent and independent) at α = 0.05 was performed and ANOVA test for extra group comparison.

Results: Difference of the variables in posttest measure in the rebound therapy group is found significant, but it isn’t significant in the control group.

Conclusion: It can be concluded that rebound therapy exercise is effective for improvement of static and dynamic balance in the male high school students affected with Down syndrome.

Brain electrical activity in stroke patients under transcranial magnetic stimulation therapy
G.E. Vinajera. Neurophysiology EEG Department, Institute of Neurology and Neurosurgery, La Habana, Cuba

Objective: A double-blind prospective and longitudinal study was carried out to assess electrical brain activity and to evaluate clinical evolution in a sample of 9 subjects with chronic stroke after rehabilitation and application of rTMS (1 Hz).

Methods: The sample in the study was randomly divided into two groups: 5 patients received sham rTMS and 4 patients received real rTMS both with daily sessions for 20 days. Electroencephalograms (EEGs) were recorded before and after rTMS. The neurophysiological measures used were the resting EEG power spectrum, Delta/Alpha ratio (DAR), the spike-frequency and the spike-amplitude. Clinical characterization was assessed using Scandinavian (SS) and Barthel Index (BI) scales.

Results: 1 Hz rTMS caused a tendency to increase \( p = 0.06 \) in the Alpha band power spectra in both brain hemispheres. There was also a decreasing tendency of the Delta band power spectra in both brain hemispheres. DAR diminished 23% more in the 1 Hz rTMS group than in the sham rTMS group, and the spike-frequency also increased in the 1 Hz rTMS group after stimulations. Clinical scales after the rTMS showed a greater tendency to increase punctuations in the SS \( (p = 0.06) \) in the 1 Hz rTMS group.

Conclusions: Stroke patients who received 1 Hz rTMS sessions experienced modifications on resting EEG, suggesting a propensity to the cortical activation in both brain hemispheres and an increment in cortical excitability. The 1 Hz rTMS group had better clinical recovery and brain electrical activity, reflected in the modifications of the SS and DAR.

Feasibility of speed of processing training in middle-aged and older adults with HIV: A pilot study
D.E. Vance\(^a\), P.L. Fazeli\(^b\), \(^a\)School of Nursing, University of Alabama at Birmingham, Birmingham, AL, USA; \(^b\)Center for Nursing Excellence, University of Alabama at Birmingham, Birmingham, AL, USA

Background: Nearly 50% of adults with HIV experience some form of cognitive deficit which can be observed in memory, attention, executive functioning, and speed of processing. In fact, as people age with this disease, this may predispose them for developing even more severe cognitive deficits that impact everyday functioning such as driving. Therefore, it is necessary to develop way to augment such cognitive abilities in lieu of such neurological manifestations.

Objective: The purpose of this study is to examine if a computerized home-based cognitive remediation training program is effective in improving cognitive functioning (i.e., useful field of view, a visual speed of processing measure important for safe automobile driving).

Patients and materials: In this single-group pre-post design experiment, middle-aged (40+) and older participants \((N = 20)\) with HIV received a brief neuropsychological assessment at baseline, given a computerized cognitive remediation training program to be taken home and played for 10 hours, and then reassessed again approximately 6 weeks later.

Results: The attrition rate was 25%. On average, participants spent 8.20 \((SD = 3.43)\) hours engaged with the cognitive training program. From the remaining 15 participants, using an intention to treat approach, participants improved their visual speed of processing \( (t(14) = 2.80, p = .014) \).

Conclusion: These results are encouraging in that they demonstrate that adults with HIV vulnerable of developing cognitive deficits can benefit from cognitive training in the comfort and privacy of their homes. In addition, this particular cognitive ability is very important for driving and everyday functioning.

Neuropsychiatric evaluation of traumatic brain injury
A. Jain\(^a\), R. Mittal\(^b\), A. Sharma\(^c\), \(^a\)Psychiatry, ESIC Model Hospital, India; \(^b\)Neurosurgery, SMS Medical College, Jaipur, India

Introduction: Assessment and treatment of TBI typically focus on physical and cognitive impairments, yet psychological impairments represent significant causes of disability and poor quality of life. Depression and anxiety may be the most common and disabling psychiatric condition in individuals with TBI.

Aims and objective: To investigate the prevalence and determinants of depression and anxiety in patients of TBI and its relationship with injury characteristics. To understand the relationship of depression and anxiety to quality-of-life outcome in TBI.

Material and method: 156 Mild to moderate TBI patients of 18 years or older age were included in this study after applying appropriate inclusion and exclusion criteria. Apart from recording their sociodemographic profile and injury history, all the participants were assessed with PHQ-9,GAD-7, WHOQOL-BREF and GCS to assess depression, anxiety, quality of life and severity of trauma respectively. All the patients were subjected to neurooradiographic to localize sites of injury.

Results: Depression and anxiety was found in 46 vs 29% cases respectively with majority (60%) of depressed cases qualifying for moderate severity as compared to anxiety. First three months after TBI was associated with maximum occurrence of depression and anxiety (68% vs 54%). Strong correlation was found between severity of trauma and severity of depression and anxiety. Left temporal and frontal lobe involvement predominantly caused depression. Depressed and anxious patients had poor quality of life.

Conclusion: TBI patients must be evaluated for comitant moods and anxiety disorders. Timely treatment for these disorders may improve overall outcome and quality of life.

Cortical endogenic neural regeneration of adult rat after traumatic brain injury
X. Yi, G. Jin, X. Zhang, W. Mao, H. Li, J. Qin, J. Shi. Nantong University, Nantong, China

Background: Focal and diffuse neuronal loss happened after traumatic brain injury (TBI). With little in the way of effective repair, recent interest has focused on endogenic neural progenitor cells (NPCs) as a potential method for regeneration.

Objective: To determine whether endogenic neural regeneration happens in the cortex of adult rats after traumatic brain injury.

From the remaining 15 participants, using an intention to treat approach, participants improved their visual speed of processing \( (t(14) = 2.80, p = .014) \).

Conclusion: These results are encouraging in that they demonstrate that adults with HIV vulnerable of developing cognitive deficits can benefit from cognitive training in the comfort and privacy of their homes. In addition, this particular cognitive ability is very important for driving and everyday functioning.

Material and methods: Adult Sprague-Dawley rat models of medium TBI were induced by controlled cortical impact and were divided into sham group and TBI group. Rats were injected with bromodeoxyuridine (BrdU) at 1–7 days post-injury (dpi) to allow identification of differentiated neurons and sacrificed at 1, 3, 7, 14 and 28 dpi for nestin/sosx-2, GFAP/sosx-2, DCX/BrdU and NeuN/BrdU immunofluorescence.

Results: Nestin/sosx-2 NPCs or GFAP/sosx-2 double positive radial glial-like cells emerged in injured cortices and peaked at 3 dpi. The number of GFAP/sosx-2 double positive cells was less than nestin/sosx-2 double positive cells. Nestin/sosx-2 double positive cells from posterior periventricule (pPV) immigrating into injured cortices through the corpus callosum were found. DCX/BrdU double positive neuronal progenitors in peri-injured cortex were found at 3, 7, 14 dpi and peaked at 7 dpi. NeuN/BrdU double positive mature neurons were not found in injured cortices at 1, 3, 7, 14 and 28 dpi.

Conclusion: NPCs from pPV and reactive radial glial-like cells emerged in peri-injured cortices of adult rats after TBI and differentiated into neuronal progenitors, but the latter failed to grow up to mature neurons.

Rho kinase inhibitor fasudil regulates the polarization and function of bv-2 immortalized microglial cell line
1Department of Encephalopathy and National Major Clinical Department of Ministry of Health, Third Hospital, Shanxi University of Traditional Chinese Medicine, Taiyuan, China; 2Institute of Brain Science, Department of Neurology, Medical School, Shanxi Datong University, China; 3Department of Neurosurgery, First Hospital, Datong Coalmine Group, Datong, China; 4Institute of Neurology, Huashan Hospital, Shanghai Medical College and Institutes of Brain Science, Fudan University, Shanghai, China

Background: Increasing data demonstrate that macrophage/microglia have different phenotypic and functional states, and may exert toxic or protective effects in neurological disorders depending on microenvironment. M1 polarization is associated with inflammatory responses, while M2 results in anti-inflammatory effects.

Objective: In this study, we try to explore characteristics of microglia polarization and investigate whether Fasudil can influence the polarization and function of microglia.

Material and methods: A maintained BV-2 immortalized microglial cell line was treated with LPS and/or Fasudil. A BV-2 conditioned medium treated with LPS and/or Fasudil was co-cultured with PC12 cells.

Results: M1 markers iNOS and IL-12 of BV-2 were elevated after LPS stimulation, but significantly declined after Fasudil treatment. M2 marker CD23 was significantly decreased after LPS stimulation (p < 0.001), and elevated after Fasudil treatment (p < 0.05). Simultaneously, LPS stimulated iNOS up-regulation (p < 0.05) and NO production (p < 0.001), but did not influence Arg-1 expression. Fasudil significantly inhibited iNOS expression (p < 0.05) and NO production, enhanced Arg-1 expression (p < 0.05). In LPS-stimulated mouse brain, LPS also induced iNOS expression on CD11b + microglia, while Fasudil inhibited its expression. In contrast, Arg-1 expression on CD11b + microglia was enhanced by Fasudil treatment. Fasudil inhibited NF-κB activity and inflammatory cytokines IL-1b, IL-6 and TNF-α, but increased anti-inflammatory cytokine IL-10, leading to neuroprotective effects in cultured PC12 neurons by a Fasudil-conditioned medium.

Conclusion: These results clearly indicate that Fasudil can convert M1 microglia to an M2 phenotype, inhibiting inflammatory response by controlling a specific polarization in microglia/macrophages. This study was supported by the National Natural Science Foundation of China (81272163).

Impact of two training packages for caregivers on quality of care of neurosurgery patients — A randomized controlled trial
M. Kalyanasundaramab, S. Kuric, M.K. Tewariid, A. Singhh.
bCommunity Medicine, Post Graduate Institute of Medical Education & Research, Chandigarh, India; dCommunity Medicine, Pondicherry Institute of Medical Sciences, Pondicherry, India; cNursing, National Institute of Nursing Education, India; Neurosurgery, Post Graduate Institute of Medical Education & Research, Chandigarh, India

Introduction: Family caregivers of neurosurgery patients function as informal extensions of the health system but they are untrained and unprepared for their new role. It has been felt that their problems related to care provision can be resolved by appropriate training.

Objectives: To compare the impact of two training packages on knowledge and practices of family caregivers of operated neurosurgery patients.

Materials and methods: A randomized controlled trial was done among the operated neurosurgery patients and their caregiver dyads (n = 90). They were randomly allocated to receive training package 1 (TP1 = self instruction manual & one to one training) or training package 2 (TP2 = self instruction manual only). Sequentially numbered sealed envelopes were used for allocation concealment. Primary outcome measure was knowledge gain of the caregivers. A variety of secondary outcome measures was also assessed in three monthly follow ups.

Results: The attrition rate was 15.5%. Intention to treat analysis was followed. Caregivers in the TP1 group had significantly greater in TP1 group. Life satisfaction of the caregivers in the TP1 group improved significantly. We could not find any significant improvement in the degree of patients' disability and in the caregivers' strain between the groups.

Conclusions: Training of caregivers by providing information along with one to one training is an effective strategy for improving the knowledge and skills of caregivers regarding care provision to the operated neurosurgery patients.

Electro-echocardiographic correlation in chronic dialyzed patients and short rehabilitations in ischemic stroke
S.M. Deme, D.C. Janu, L. Petrica, S. Dragan, N.C. Hreniuc, D.S. Ionc, aNeurology, Vasile Goldis Western University of Arad, Arad, Romania; bNeurology, Timisoara, Romania; cNephrology, Timisoara, Romania; dVictor Babes University of Medicine and Pharmacy, Timisoara, Romania

Background: The AURORA study analyses the occurrence of stroke and cardiac events in patients on haemodialysis treated with Rosuvastatin.
Objective: Our aim was to evaluate the efficacy of the different echocardiographic (ECG) indexes in detecting left ventricular hypertrophy (LVH, concentric or eccentric) among patients with chronic renal failure under dialysis and carotid ischemic stroke as a prognostic factor.

Subjects and method: We assessed 59 dialyzed-patients (median age of 55+/-2 years, 30 men) between 2010 and 2012, and followed up for 1 month after the ischemic stroke.

The neurological evaluation was performed using the NIHSS scale and brain MRI. For diagnosis of the ECG-LVH, the following indexes were considered: Sokolov > 35 mm, Gubner > 22 mm, Romhilt > 5 points, Cornell > 28 mm in men and > 20 mm in women and Lewis > 17 mm.

Results: ECHO-LVH was detectable in 70% of all the patients, 29% with concentric hypertrophy (CH) and 22% with eccentric hypertrophy (EH). Considering LV geometry, the Romhilt index also demonstrated superiority in the detection of both CH (SE > 26%) and EH (SE > 36%). All patients presented major hemispheric ischemic stroke syndrome, defined an NIHSS >/= 12 in the territory of the middle cerebral artery (MCA) or internal carotid artery (ICA) and a GCS score < 14. The MRI showed hypersignal T2, lesions primarily in the large MCA territory, in all cases.

Conclusions: 30 patients who were dialyzed, and had ECHO-LVH, and Sokolov > 35 mm died in the first 3 weeks after stroke. The dialysis patients with cardiac hypertrophy and ischemic stroke have a greater mortality, due to cardiac disease. Early rehabilitation have poor outcomes in patients.

Aortic plaque thickness and diabetes as a risk predictor for ischemic stroke rehabilitation

Background: An increased aortic plaque thickness in diabetic patients with ischemic stroke is demonstrated, but data regarding the value as a prognostic risk factor for the cognitive stroke outcome is limited.

Objective: To identify aortic plaque thickness as a risk predictor in patients with diabetes and acute ischemic stroke.

Patients and method: We assessed 95 patients, mean age = 69 ± 12 years, (51 male) with first-ever acute stroke confirmed by brain MRI and an initial post-stroke MMSE score > 15 (mean interval between stroke and examination, 6.5 ± 3 days). All present type 2 diabetes mellitus (T2DM), and insulin therapy was initiated during hospitalization. Carotid plaques were classified as simple or complex on the basis of thickness >/= 4 mm, ulceration, or mobility. The NIHSS scale was performed in days 4–7.

Results: The mean concentration (HbA1c)) was 0.9% lower for the patients with intensive treatment. The number of patients with the aortic plaque thickness mean of 3.4 mm (2.3 to 3.6 mm range) was significantly higher (p > 0.047), and the median NIHSS score in patients with thickness >/= 4 mm was 14 (range 3 to 38), and scores differed depending on the arteriographic findings (P < 0.001). The MMSE score at 7 days was 18.6, and 25.6 at 3 months with major difficulties in attention, short-term memory impairment and aphasia.

Conclusions: Carotid plaque thickness is a simple and noninvasive marker of subclinical atherosclerosis and it is often associated with acute ischemic stroke in patients with type 2 diabetes. Hyperglycemia and MMSE score could not predict deterioration or improvement in cognitive outcome.

Neuroprotective activity of combination of progesterone and curcumin on sub-acute phase changes induced by partial global cerebral ischemia in mice
A. Chakrabarti, A. Prakash, D. Hota, U.N. Saikia, Pharmacology, Post Graduate Institute of Medical Education & Research, Chandigarh, India; 2Histopathology, Post Graduate Institute of Medical Education & Research, Chandigarh, India

Background: There is need to search for neuroprotective agents in stroke to contain morbidity and mortality.

Objective: Progesterone, a neurosteroid and curcumin, a phytophenol were evaluated in combination as neuroprotective agents in a bilateral carotid artery occlusion (BCAO) model in mice.

Material and methods: 48 albino Swiss mice were divided into 4 groups: sham operated, DMSO (0.2 ml)-, Progesterone (15 mg/kg)- and progesterone (5 mg/kg) + curcumin (100 mg/kg)-treated BCAO groups. BCAO was produced for 10 min with aneurysmal clips. The animals were subjected to behavioral, brain biochemical and histopathological studies on day 15 while drug or vehicle treatment was given for 14 days following BCAO. Drugs were administered intraperitoneally. The protocol was approved by the Institutional Animal Ethics Committee.

Results: Compared to the sham group, the BCAO (DMSO treated group) resulted in significant impairment of exploratory behavior (hole-board test) and motor co-ordination (rota rod test) while the seizure susceptibility to kainic acid and anxiety level (elevated plus maze test) were significantly increased; BCAO caused a significant increase in histopathological scores and brain levels of malondialdehyde and TNF-alfa; and a significant decrease in the levels for superoxide dimutase, catalase and glutathione peroxidase. Progesterone-alone caused significant reversal of the values for all the parameters as observed for the DMSO treated group following BCAO. The combination of progesterone and curcumin showed a significant synergistic improvement for all the parameters as compared to those observed with DMSO and progesterone-alone treated groups following BCAO.

Conclusion: The combination of progesterone and curcumin possesses a translational value as potential synergistic neuroprotective agents in stroke.

Complications of intrathecal baclofen pump: Prevention and cure
T. Rizk, Y. Awaad, Pediatric Neurology, National Neuroscience Institute, KFMC, Saudi Arabia; 2Pediatric Neurology, Al-Takahassi Hospital, Riyadh, Saudi Arabia

Increasingly, spasticity is managed with surgically implanted Intrathecal Baclofen pumps. Intrathecal Baclofen pump revision surgery unrelated to programmable pumps during end-of-life is not uncommon, requiring special attention during pre-, intra-, and post-operative management. We aimed to identify and describe complications of
Intrathecal Baclofen pump as well as to report avoidance and management of complications.

Methods and materials: Through 2002–2006, at the department of neurosurgery, Henry Ford and Oakwood Health Systems, Intrathecal Baclofen pumps were implanted in 44 patients; 24 children versus 20 adults; 30 «primary-implant-patients»; 14 «revision-only-patients». We evaluated reasons for revision surgeries and diagnostic work-up requirements.

Results: Eight out of 30 «primary-implant-patients» required 14 revisions and 7 of 14 «revision-only-patients» needed 13 procedures. Seven patients with slowly increasing baclofen-resistant spasticity had either:

i) Unsuspected ump–catheter connector defects [N = 4] with a subcutaneously dislocated intrathecal catheter (N = 1)

ii) An X-ray-documented pump–catheter connector defect [N = 1]

iii) An X-ray-demonstrated fractured catheter with intrathecal fragment [N = 2] requiring laminectomy (N = 1). Injection studies revealed intrathecal peri-catheter arachnoiditis, managed without laminectomy (N = 1), and connector-related dye leakage [N = 3]. Implant infections occurred in 4 cases [3 were pre-operated]. Scintigraphy revealed occult CSF leakage [N = 1]. Intrinsic pump failure [N = 1].

Conclusions: Intrathecal Baclofen pumps, although very gratifying, have a high, technique-related complication incidence during implant life. Meticulous technique, high clinical suspicion, appropriate work-up, and timely surgical management can reduce surgical complications of Intrathecal Baclofen pump implantation.

The efficacy of neuroaid in stroke recovery: A meta-analysis
M.K.D. García, L. Penaserada, C.C. Diesta-Oropilla, R. Espiritu-Picar, P. Noble. Section of Neurology, Department of Neurosciences, Makati Medical Center, Makati, Philippines

Background: Stroke is the third leading cause of death worldwide and is a major cause of morbidity. To date, there is no effective treatment in reducing chronic disability secondary to stroke. NeuroAid is a new treatment option under investigation in stroke rehabilitation research. The Fugl Meyer Assessment (FMA) Scale is the gold standard in measuring sensorimotor function in hemiplegic post-stroke patients against which all other scales are assessed.

Objectives: To determine the efficacy of NeuroAid on motor recovery using the FMA scale in patients with ischemic stroke by meta-analysis.

Results: The meta-analysis included 2 double-blind placebo-controlled studies on NeuroAid. A random effects model and a 95% confidence interval was used which showed no statistical significance with a p value of 0.331 at 4 weeks post-treatment and a p value of 0.088 at 8 weeks post-treatment.

Conclusion: This meta-analysis did not significantly demonstrate the efficacy of NeuroAid in the motor recovery of patients with ischemic stroke when compared to placebo.

Immunological mechanisms of pathogenesis of chronic brain ischemia
Y.N. Madjidova, D.D. Usmanova, aChair of Neurology Department, Tashkent Pediatric Medical Institute, Uzbekistan; bChair of Neurology Department, Tashkent Institute of Postgraduate Medical Education, Tashkent, Uzbekistan

Background: Immunological mechanisms have significant value in the pathogenesis of chronic brain ischemia (CBI).

Purpose: The purpose of investigation was to study immunological status and efficiency of cortexin in the treatment of the patients with CBI.

Material and methods: We examined 187 patients with CBI. The patients were divided into 2 groups: I group included 98 patients who were treated with cortexin, group II consisted of 89 patients receiving therapy without cortexin. The levels of IL1, TNFα and antibodies to myelin basic protein (MBP) in blood serum were determined by immunoenzymatic analysis. Cortexin was injected in a dose of 10 mg during 10 days.

Results: The level IL1 in patients of group I before treatment was 18.4 ± 0.8 pg/ml, after 14.0 ± 0.5 pg/ml (P < 0.05). In patients of group II the level of IL1 before treatment was 17.9 ± 0.6 pg/ml, after 16.8 ± 0.5 pg/ml. The level of TNFα in patients of group I before treatment was 13.2 ± 0.7 pg/ml, after decreased in 1.5 times. In group II before treatment the level of TNFα was 12.8 ± 0.7 pg/ml, after 11.9 ± 0.6 pg/ml. At the first day of study patients observed high levels of antibodies to MBP (0.202 ng ± 0.011 un.opt.dens.). The levels of antibodies to MBP at the 10th day of treatment showed that in patients of group I this parameter was 0.152 ng ± 0.02 un.opt.dens. In group II the levels of antibodies to MBP were decreased by 18.6%.

Conclusion: Cortexin resulted in a decrease of the levels of proinflammatory cytokines that specify its ability to reduce activity of immune inflammation.

Management of post-hemorrhagic hydrocephalus in preterm infants with germinal matrix hemorrhage
A.S. Zidan, H.A. Elkosha, H.A. Hady, M.E.S. Gmaa, Neurosurgery, Mansoura University, Mansoura, Egypt; Pediatric, Mansoura University, Mansoura, Egypt; Neurology, Mansoura University, Mansoura, Egypt

Study design: A prospective study over the period from Jan 2008, to June 2011, by the Department of Neurosurgery, in Mansoura University Hospitals. All preterm babies admitted to neonatal care unit who developed symptoms suggestive of neurological insult were investigated to detect the cause of this insult.

Objectives: Neonatal intraventricular hemorrhage in preterm infants resulting from germinal matrix hemorrhage with subsequent post-hemorrhagic ventricular dilatation and hydrocephalus (PHH) should be managed adequately to minimize neurological morbidity and mortality.

Patients and methods: All preterm infants who are admitted to neonatal unit in Mansoura Children Hospital were eligible to our study. Once we suspect a germinal matrix hemorrhage (GMH), cranial...
ultrasound, and then CT scan brain were done for +ve cases to establish the diagnosis and exclude grades 1 and 4 according to paper, a grading system, only patients with grades 2 and 3 are involved in our study.

**Results:** 33 patients with GMH were involved in our study 21 case (grade 2) and 12 case (grade 3). Ventriculoperitoneal shunts were inserted only for 17 cases who developed post-hemorrhagic hydrocephalus as proved by clinical and radiological follow up.

**Conclusion:** Management of PHH in preterm infants is a debatable issue that needs a careful selection of the treatment modality. Ventriculoperitoneal shunts are needed in a significant proportion of preterm infants with grade II, and grade III GMH who survived and developed PHH.

**Diagnostic and clinical peculiarities of PANDAS**  
K. Tuhtabaeva, G. Sadikova. Neurology, Child Neurology & Medicine Genetics, Tashkent Pediatric Medical Institute, Tashkent, Uzbekistan

Last years was advanced supposition on connection different choreiform hyperkinetic disorders, tics, myoclonias and neurosis like fived states in children with B-hemolitic streptococcus group A (BHSGA).

**Aim of study:** To research peculiarities of course for PANDAS.

**Materials and methods of study:** Examined 17 children at the age from 7 to 15 years with complaints on hyperactivity, chorea form and tic like hyperkinetic disorder, including generalized tic emotional lability, absent-mindedness, disorder of attention, problem with sleeping, and obsessions.

**Results of study:** Acute beginning and wave shaped course with the following full or partial remission were in all 17 patients, and, it has chrome logical connection with acute chronic tonsillitis, and an increase of temperature. In the smears from the fauces children revealed BSHGA, moderately positive were acute phase indices (CPB, cryoglobulins and raise of antistreptolysin-o titers). Symptoms of dysgenia for connective tissue (hypermobile syndrome, dysplastic cardiopathy) were present in 9 children. In 5 people from 11 being examined at MRT-angiography pathologic convolution of carotid and vertebral arteries was revealed. In 9 from 17 patients at record of sleep diagnosis of dysplastic or metabolic cardiopathy was made. By the date of EchoCg Prolapse of mitral valve of the first level was revealed. Confirming criteria for rheumatism were not revealed.

**Conclusion:** Today neurologists together with cardiologists have all bases to review ordinary imaginations on the treatment of neurosis like, choreiform, hyperkinetic disorders in children. From this contingent it is necessary to divide the patients with PANDAS, and, to use new tactics in therapy.

**Bilirubin enhances neuronal excitability by increasing glutamatergic transmission in the rat lateral superior olive**  
C. Li, S. Yin. Department of Otorhinolaryngology, Affiliated Sixth People's Hospital of Shanghai Jiaotong University, Shanghai, China

Hyperbilirubinemia is one of the most common clinical phenomena observed in human newborns. To achieve effective therapeutic treatment, numerous studies have been done to determine the molecular mechanisms of bilirubin-induced neuronal excitotoxicity. However, there is no conclusive evidence for the involvement of glutamatergic synaptic transmission in bilirubin-induced neuronal hyperexcitation and excitotoxicity. In the present study, using gramicidin-perforated patch-clamp techniques, spontaneous excitatory postsynaptic synaptic currents (sEPSCs) were recorded from lateral superior olive (LSO) neurons isolated from postnatal 11–14-day-old (P11–14) rats. The application of 3 μM bilirubin increased the frequency, but not the amplitude, of sEPSCs. The action of bilirubin was tetrodotoxin (TTX)-insensitive, as bilirubin also increased the frequency, but not the amplitude, of mEPSCs. The amplitudes of GABA-activated (I_{GABA}) and glutamate-activated (I_{GLU}) currents were not affected by bilirubin. Under current-clamp conditions, no spontaneous action potentials were observed in control solution. However, the application of 3 μM bilirubin for 4–6 min evoked a considerable rate of action-potential firing. The evoked firing was partially occluded by d,l-2-amino-5-phosphonovaleric acid (APV), an NMDA receptor antagonist, but completely inhibited by a combination of APV and 2,3-dihydroxy-6-nitro-7-sulfamoyl-benzo[f]quinoxaline-2,3-dione (NBQX), an AMPA receptor antagonist. These results indicate that bilirubin facilitates presynaptic glutamate release, enhances glutamatergic synaptic transmission by activating postsynaptic AMPA and NMDA receptors, and

Clinical and neurophysiological features of 79 children with developmental and benign movement disorders
N. Kuzmina, Z. Raffikova, Y. Khakimova, L. Yuldashev.
"Child Neurology Division, Tashkent Medical Consulting Diagnostic Centre, Uzbekistan; Urban Children Clinic No 2, Uzbekistan; Tashkent Medical Children Consulting Diagnostic Centre, Tashkent, Uzbekistan

Background: Developmental and benign movement disorders (DBMD) are characterized by the absence of associated neurological manifestations and by their favorable outcome.

Objective: To analyze clinical and neurophysiological characteristics of the DBMD cases evaluated in our center.

Patients and methods: We recruited patients from our center during the past two years, including children with normal neurologic and psychomotor development. Children with abnormal interictal or ictal EEG, abnormal MRI findings were excluded. Neurological examination, detailed history taking, EEG, and video monitoring were performed.

Results: 79 patients (38 male) were diagnosed with DBMD. The ages at the time of admission ranged between 1 month and 14 years. 52 cases (66%) started within the first year of age versus only 34% of the cases with onset after 12 months. The diagnosis showed a wide spectrum of DBMD including stereotypies 15/79 (19%); benign myoclonus of early infancy 9/79 (11.4%); benign jitteriness of newborns 9/79 (11.4%); transient dystonia of infancy 8/79 (10%); gratification behavior in early childhood 7/79 (8.9%); sleep-related rhythmic movement disorders 6/79 (7.6%); benign paroxysmal torticollis 6/79 (7.6%); benign neonatal sleep myoclonus 5/79 (6.3%); mirror movements 5/79 (6.3%), shuddering attacks 4/79 (5.1%); spasms nutans 2/79 (2.5%); paroxysmal tonic upgaze 2/79 (2.5%); and Sandifer's syndrome 1/79 (1.3%).

Conclusion: Recognition and management of DBMD depend from careful neurological examination, detailed history taking, and home video recordings. We revealed predominance of stereotypies, benign myoclonus in structure of DBMD. Proper identification of DBMD is crucial, as it avoids unnecessary concern, unnecessary and costly investigations, and ineffective and potentially toxic treatments.

Neurological and neuroradiological manifestations of acute dengue fever infection — a single centre study from tropical country
"Department of Neurology, Krishna Institute of Medical Sciences, Secunderabad, India; "Department of Neuroradiology, Krishna Institute of Medical Sciences, Secunderabad, India

Introduction: Dengue virus is generally considered as nonneurotropic, apart from case reports there is paucity of data available on neurological manifestation of acute dengue viral infection.

Methods: A prospective single centre study done at KIMS Hyderabad, during Nov 2007 to Jun2011. Acute dengue virus infection defined as positive serology for IgM antibodies or PCR positive for dengue. CT/MRI brain, EEG and other necessary lab investigations were done. Patients admitted with acute dengue virus infection studied for neurological and radiological manifestations of acute dengue infection and followed for next 6 months. Detailed statistical analysis done with SPSS ver 17 software.

Results: Out of 281 patients with acute dengue fever/DHF who were admitted in our hospital during the study period, 31 (11.08%) had neurological manifestations. Age was 14 to 68 years with mean age of 36.6 years with M:F ratio 2:1. Mean GCS on admission was 11.8. Diffuse slowing to be the commonest finding and there was no correlation of EEG findings on hospital stay or outcome [p = 0.459]. On MRI Pontine T2 hyperintensity and blooming in the thalamus were significantly associated with hospital stay [p < 0.005]. GCS at admission has significant correlation with hospital stay, neurodeficits or condition at discharge & outcome measures [p < 0.005].

Case observation of polyneuropathy as a predicative factor of possible neoplastic process
"Angioneurology and Neurorehabilitation, State Institution 'Institute of Urgent and Recovery Surgery n.a. V.K. Gusak, National Academy of Medical Sciences of Ukraine'; Ukraine; "Department of the Medical Providing, Chief Board of the Ministry of Internal Affairs of Ukraine in Donetsk, Donetsk, Ukraine

Background: According to the recent medical studies a paraneoplastic polyneuropathy that becomes clinically evident before neoplasm diagnosing or metastasis verification is observed in almost 50% of cancer suffering patients.

Objective: To detect the probable interdependence between polyneuropathy development process and subsistence of earlier undiagnosed neoplasm development.

Material and methods: 38 patients with confirmed neoplasm diagnosis (blood disease, lung cancer, ovarian carcinoma, urinary bladder cancer, breast cancer, stomach cancer) were observed in Angioneurology Department of Institute of Urgent and Recovery Surgery n.a. V.K. Gusak presented the first study group. The second group numbered 24 patients with primary diagnosed polyneuropathy. All 62 patients went through the careful neurologic observation. NSS (Neuropathy Symptom Score) and Dyck PJ. (1988) scale determined the polyneuropathy severity grade. Supplementary tests consisted of general clinical examinations and oncomarker analysis (beta-2-microglobulin, Ca 15-3, Ca-125, Ca 19-9, CEA, HCG, Ca 15-3, PSA). EMG with using 4-channel electromyography "Reporter" (Biomedica, Italy) was the principal method.

Results: 49% of patients with active neoplasm got such polyneuropathy EMG-markers as NCV (Nerve Conduction Velocity) lowering to 22–30 m/s as well as reducing amplitude of M-answer by 2–2.5 times. In 8 patients (37%) of the second group a detailed clinical observation and oncomarker analysis showed subclinical neoplastic disease.

Conclusion: An active neoplastic process is very often accompanied by polyneuropathy. The lowering of nerve conductance velocity by EMG and general polyneuritic clinical scene of a patient needs to be examined by somatic detailed test that sometimes allows finding out a neoplastic progress much earlier.

doi:10.1016/j.jns.2013.07.2029
Discussion: Neurological manifestations of dengue present in wide range as encephalitis at one end and GBS or myositis at other end. Dengue associated encephalopathy should be considered as differential diagnosis in patients having fever, thrombocytopenia and recent onset neurological deterioration or in patients having acute encephalitis/encephalopathy of unknown cause. MRI is a useful aid in diagnosis and GCS on admission is an important prognostic factor.

Neuropsychological deficits in ADHD: Development of a classification system
R. Gupta, Allahabad University, Allahabad, India

Background: Recent experimental literature on ADHD has identified unique underlying cognitive dysfunction, specific to ADHD. Therefore, there is a need to incorporate information on cognitive mechanisms underlying ADHD and incule such information in the diagnostic system, which would provide a more sensitive as well as specific tool in differential diagnosis of ADHD.

Objective: The present study evaluated the diagnostic capabilities of certain measures based on cognitive-motivational tests that were chosen with respect to the specific cognitive deficits in Attention Deficit Hyperactivity Disorder (ADHD).

Methods: A total of 240 children (120 with ADHD and 120 healthy controls) in the age range of 6–9 years and 32 children with Oppositional Defiant Disorder (ODD) (aged 9 years) participated in the study. Stop-signal, attentional-disengagement, attentional-net-work, and choice-delay test were administered to all the participants. A total of nineteen parameters were derived from the four tests. Receiver operating characteristic (ROC) analysis and multinomial logistic regression (MLR) was performed to examine the diagnostic efficiency of each parameter.

Results: MLR was performed for combining parameters across tests. Data fusion produced improved overall diagnostic accuracy and a combination of stop-signal reaction time, post-error-slowing, mean delay, switch costs, and %LDR produced overall classification accuracy of 97.8% and with internal validation, the overall accuracy was 92.2%.

Conclusions: Combining performance from different tests enabled an accurate classification of ADHD children from healthy controls and those with ODD. The study has theoretical and clinical implications for the theories of executive control mechanisms that underlie the pathology of ADHD.

Brain wave symmetry in depressive patient's electroencephalography
M. Abdollahi, P. Ahmadi, “Young Researchers and Elite Club, Tabriz Branch, Iran; “Department of Medicine, Islamic Azad University, Tabriz Branch, Tabriz, Iran

Background: One of the most frequent diagnosis of mental disorder is depression. Depression is a common disease among people that need help for psychological problems. Advances in neuroimaging and in quantitative electroencephalography (QEEG) have made it possible to examine features of brain activity that are associated with response. Some of studies suggest that depressed persons in compare of healthy subjects have different brain wave activity. The aim of this study was to find out the probability of hemispheric asymmetry in depressive patients through EEG.

Material and methods: This is a descriptive–comparative study in which 15 depressive persons from among psychiatric clinic clients were selected and studied. The artifact free EEG epoch was analyzed by fast Fourier transformation (FFT) and relative power values of particular frequency bands (delta, theta, alpha and beta) were observed on the brain regions. The results were analyzed by MANOVA analysis.

Results and conclusion: The results of investigation indicated, that depressive patients have hemispheric asymmetry in alpha activity of frontal, temporal and parietal regions. This means that depressive persons have greater alpha activity in right rather than left hemisphere. In addition there is a decrease in theta activity in central and occipital area compared with healthy subjects. These results suggest that the disorder changes the brain wave activity.

Comparison of brain wave patterns in aggressive and non aggressive subjects
M. Abdollahi³, P. Ahmadi³, P. Mazuji³, S. Poorhassan³, M. Habeka³, Philip. University of Ghana, Accra, Ghana

Background and objectives: Human aggression is an important social and clinical problem. There are many studies in determining the criteria for diagnosis and assessment of aggression. The aim of this study was to study aggressive subject's brain wave activity compared with healthy subjects by qEEG.

Materials and methods: The research method was contrastive-descriptive over which some 30 people of aggressive persons compared and contrasted with some 30 nonaggressive persons were demographically similar to aggressive group. The artifact free EEG epoch was analyzed by fast Fourier transformation (FFT) and power values of particular frequency bands (delta, theta, alpha and beta) were observed on the brain regions.

Results and conclusion: Results of variance analysis showed that aggressive subjects' theta activity in frontal, central, parietal and temporal areas is lower than normal subjects. In addition there is an increase in beta activity in frontal, central, parietal and temporal areas compared with nonaggressive subjects. These results suggest that the disorder changes the brain wave activity.

Tongue somatosensory evoked potentials in microvascular decompression treated trigeminal neuralgia
M. Krbot Skorić³, I. Adamec³, G. Grahovac³, D. Chudy³, S. Hainšek³, M. Habe³, aUniversity Hospital Center Zagreb, Croatia; bClinical Hospital Dubrava, Zagreb, Croatia

Background: Somatosensory evoked potentials of the tongue (tSSEP) provide useful information about trigeminal afferent pathway. The aim of this study was to evaluate tSSEP in trigeminal neuralgia treatment with microvascular decompression.

Methods: Two patients with trigeminal neuralgia refractory to conservative treatment underwent microvascular decompression of the trigeminal nerve. tSSEP was performed a month prior to surgery and in the month after the surgery in both patients. Pain frequency and tSSEP were analyzed before and after surgery.

Results: In both patients a complete resolution of pain occurred. In patient 1, tSSEP latencies became shorter then before surgery and wave N1 disappeared. The intensity of stimulation necessary to reach the threshold was 4 mA before the surgery and 1 mA after the surgery. A complete recovery of tSSEP after the operation was achieved in patient 2.

Conclusions: The results of present study demonstrate the value of tSSEP in the evaluation of trigeminal conduction recovery after microvascular decompression.

Reduce the risk in vulnerability in HIV
E. Philip. University of Ghana, Accra, Ghana

Background: Before the people can reduce the risk and vulnerability to HIV, individuals and communities must understand the urgency to the epidemic. They must be given basic facts about HIV/aids, taught set of protective skills and offered access to appropriate services and products.

Methods: A cross sectional community based survey has been conducted between January 2011 and April 2011 by interview of 419 heads of the households regarding the knowledge of HIV transmission means in Accra, Ghana.

Results: Out of the interviewed 419 household heads, 287 (68.5%) were females. 36%, 28% and 34.3% were in the age group of 40+, 31–40 and 15–30 respectively. The findings revealed that only 21 (5%) of study participants mentioned four ways of HIV transmission (unprotected sex, mother to child, sharp materials and blood transusion). On the other hand, 63 (15%) mentioned any three of the above route of transmission, whereas the majority, 209 (50%) and 86 (20.5%) mentioned two and one means of HIV respectively. On contrary about 40 (10%) of interviewed heads of household mentioned hardly any of the transmission means. Males were about 2.4 times more likely to mention unprotected sex as one means of transmission than females.

Conclusion: In general, knowledge of residents of Medina in the capital town of Ghana about HIV transmission and prevention means was low. Appropriate HIV/Aids education means ought to be tailored to residents.

Ineffectiveness of topiramate and levetiracetam in infantile spasms non-responsive to steroids
A.A. Mahmoud. Pediatric Neurology, KFMC, Riyadh, Saudi Arabia

Objectives: To compare the effectiveness of 2 novel antiepileptic drugs Topiramate and Levetiracetam as a second line treatment for infantile spasms when oral steroids fail.

Methods: Forty infants within 2 years of life with clinically- and EEG-proven infantile spasms that did not respond to prednisone (2 mg/kg/day in 2 divided doses) were recruited and randomized into 2 groups. They were randomly assigned to either Topiramate (group 1: 1 mg/kg/day for 3 days then increased by 1 mg/kg/day every 3rd day up to 6 mg/kg/day) or Levetiracetam, (group 2: 10 mg/kg/day for 5 days and then increased by 10 mg/kg/day every 5 days up to 60 mg/kg/day).

Results: Of the 20 patients included in the final data analysis, 11 (55%) were administered with Topiramate and 9 (45%), Levetiracetam. Eighteen patients did not respond to the first drug and subsequently to the other drug when crossed-over, if the first drug proved ineffective. Two patients with infantile spasm responded to either one drug respectively without crossover. Their EEGs improved with time. In accordance with Helsinki Declaration and Belmont Report Ethical codes, we stopped recruitment at 20 patients due to the ineffectiveness of both drugs. Thus, only 20 children were included in final data analysis.

Conclusion: The present study demonstrated the ineffectiveness of Topiramate and Levetiracetam suggesting that current treatment modalities are grossly inadequate underscoring the urgent need for more research efforts to overcome current deficiencies. Two patients with cryptogenic infantile spasm responded to treatment suggesting...
the potential for treatment of such patients with these two drugs which merits further multicenter investigation.

Limbic encephalitis in a child with an atypical presentation
A.A. Mahmoud, Pediatric Neurology Department, KFMC, Riyadh, Saudi Arabia

Background: Limbic encephalitis (LE) is a rare disorder that generally has a subacute onset evolving over days to weeks. Patients present with a variable combination of memory loss, seizures, and psychiatric disturbance, and it is not rare for patients to be initially misdiagnosed.

Patient: We report a previously healthy twelve-year-old boy who developed his first episode of seizures at eight years of age. He had a total of eight prolonged focal seizure episodes, and each episode was followed by a month of behavioral changes and short term memory loss. There was no family history of seizures or other neurological disorders, and he had an otherwise unremarkable neonatal and past medical history.

Results: Magnetic resonance imaging during each episode of seizures showed alternating unilateral brain hemispheric involvement consistent with LE that was followed by resolution for a total of six times. Despite a negative laboratory evaluation for a large panel of paraneoplastic antibodies, the clinical scenario and exclusion of other possible disorders made recurrent LE the most likely diagnosis.

Conclusion: Limbic encephalitis is a rare disorder diagnosed primarily on clinical criteria and often associated with the presence of a paraneoplastic antibody. However, the lack of a positive paraneoplastic antibody in a patient with a triad of seizure, behavioral changes and short memory loss does not exclude the diagnosis. The unique presentation in a seronegative patient like ours may indicate a previously unrecognized antibody. To the best of our knowledge, such a case has never been reported.

Homeostatic plasticity and human visual system
T. Bocci, N. Francini, M. Caleo, S. Tognazzi, L. Maffei, S. Rossi, A. Priori, F. Sartucci. 1Department of Neuroscience, Unit of Neurology, Pisa University Medical School, Pisa, Italy; 2Department of Neuroscience, Neurology and Clinical Neurophysiology Section, Azienda Ospedaliera Universitaria Senese, Siena, Italy; 3Department of Neuroscience, University of Pisa, Italy; 4CNR Neuroscience Institute, Pisa University Medical School, Pisa, Italy; 5Department of Neuroscience, University of Milan, Fondazione IRCCS Ospedale Maggiore Policlinico, Milan, Italy

Background and objective: The ability of cortical networks to regulate neuronal activity within a useful dynamic range, called homeostatic plasticity, has received growing attention. The threshold and direction of excitability changes primed by low- and high-frequency rTMS in the primary motor cortex (M1) can be reverted by a preceding session of tDCS. Whether there is a similar mechanism in human visual pathways is a matter of debate.

Materials and methods: In 15 healthy subjects we evaluated changes in visual evoked potential (VEP) amplitude at two different contrasts (K90% and K20%) by applying anodal or cathodal tDCS (20’, 1.5 mA) to occipital cortex, followed by low- or high-frequency rTMS (0.5 for 20’ and 5 Hz for 60”, respectively).

Results: Anodal tDCS improved the amplitude of VEPs and this effect was reverted by applying high-frequency rTMS (two-way ANOVA, p < 0.001). Concurrently, cathodal tDCS led to a decrease in VEP amplitude, which is reverted in its turn by a subsequent application of 0.5 Hz rTMS (two-way ANOVA p < 0.01). There are no significant changes in RMT values over time (p > 0.5), confirming the spatial selectivity of our protocol.

Conclusion: Our data show that preconditioning excitability with tDCS over the V1 can modulate the direction of plasticity induced by subsequent application of 1 or 5 Hz rTMS. This pattern was observed for both N1 and P1 components; since they appear to be generated in striate and extrastriate cortex, respectively, these findings indicate that homeostatic mechanisms could operate in both primary and higher-order visual areas.

Tongue’s motor evoked potentials in the differential diagnosis between amyotrophic and primary lateral sclerosis: A preliminary report
T. Bocci, L. Briscese, E. Girotti, S. Tognazzi, M. Naraci, F. Sartucci. 1Department of Neuroscience, Unit of Neurology, Pisa University Medical School, Pisa, Italy; 2Department of Neuroscience, Neurology and Clinical Neurophysiology Section, Azienda Ospedaliera Universitaria Senese, Siena, Italy; 3Department of Neuroscience, University of Pisa, Italy; 4CNR Neuroscience Institute, Pisa University Medical School, Pisa, Italy

Introduction: Primary lateral sclerosis (PLS) is a neurodegenerative disorder due to a selective loss of precentral pyramidal neurons. Our purpose was to evaluate preferential impairment of pyramidal tract to bulbar muscles in patients with PLS and identify a reliable electrophysiological method to help clinicians in the differential diagnosis from amyotrophic lateral sclerosis (ALS).

Materials and methods: We recorded motor evoked potentials (MEPs) from tongues and anterior tibialis muscles in six patients with PLS and compared the results, in terms of central motor conduction time (CMCT), amplitude and duration of contralateral silent period (cSP), with those obtained both from age-matched healthy volunteers and patients affected by ALS.

Results: For lower limbs, CMCT resulted significantly increased in PLS and ALS compared with healthy subjects (p < 0.01); we did not disclose differences between ALS and PLS groups (p = 0.417). For tongue’s recordings, CMCT, absolute amplitude of MEPs and cSP were significantly altered in PLS patients towards both ALS patients (p < 0.05) and healthy volunteers (p < 0.01).

Discussion: We showed that tongue’s MEPs are selectively impaired in PLS compared with other motoneuron diseases. Our results strengthen the hypothesis of a proximal axonal degeneration as a pathological marker of PLS, probably reflecting a greater loss of corticomotoneuronal connections rather than in ALS patients. That could be confirmed by the shortening of cSP in cranial nerves, since for bulbar muscles the spinal contribution for the generation of cSP is ruled out.

Tongue’s MEPs could represent an interesting electrodiagnostic test, potentially useful for the early diagnosis of PLS.

Head ultrasound findings in healthy preterm infants: Their correlation with gestational age and mode of delivery
Y. Yueniwati, D.R. Erawati. Radiology, University of Brawijaya, Malang, Indonesia

Background: Brain injury is a major complication of preterm birth. Some perinatal risk factors and demography could increase the morbidity rate in preterm infant. Head ultrasound becomes important diagnostic tool in neonates. Healthy preterm infants could have brain abnormality visualizing on ultrasound examination.

Objective: To analyze the correlation between head ultrasound findings in healthy preterm infants with gestational age and mode of delivery.

Patients and methods: Observational-analytic study using cross sections took place in Saiful Anwar Hospital Malang — Indonesia between July and September 2012. Healthy preterm infants underwent head ultrasound examination within the first four days of life. Fisher Exact test was used to analyze the correlation between head ultrasound findings with gestational age and mode of delivery.

Results: About 89.5% of 38 samples was ≥32 weeks gestational age; and 52.6% of samples had secio caesaria as mode of delivery. There were three abnormal findings in head ultrasound: increasing periventricular echogeneity (5.3%), increasing deep parenchym echogeneity (5.3%) and obscuration of white-grey matter differentiation (5.3%). There is no significant correlation between ultrasound findings with gestational age and mode of delivery.

Conclusion: There were abnormal head ultrasound findings in some healthy preterm infants although there is no significant correlation between ultrasound findings with gestational age and mode of delivery. Head ultrasound in preterm infant could become screening tool for early detection of brain injury.

The effect of epilepsy comorbidity in children with attention deficit hyperactivity disorder
G.-Y. Simb, W.S. Kimc, bPediatrics, St. Mary's Hospital, Chengju, Republic of Korea; cChungbuk National University, Cheongju, Republic of Korea

Purpose: The rate of attention deficit hyperactivity disorder (ADHD) is higher in children with epilepsy than in the general population. The 31–40% of ADHD is accompanied with epilepsy. There are not many studies in ADHD with epilepsy. So we checked the effect of epilepsy comorbidity in children with ADHD.

Methods: This study retrospectively examined the effect of epilepsy comorbidity in children with ADHD. We studied 34 ADHD children with epilepsy at Chungbuk National University Hospital and 38 ADHD children without epilepsy at Cheonju St. Mary’s Hospital because of ADHD with epilepsy or ADHD from January 2005 to June 2010.

Result: In ADHD with epilepsy, there were 12 cases (35.2%) of partial seizure, 11 cases (32.2%) of generalized seizure, 11 other cases (32.2%). Among the abnormal sites found in EEG there were 15 cases in the frontal lobe, 7 cases in the central lobe, 6 cases in the temporal lobe, and 3 cases in the occipital lobe. In ADHD with epilepsy, the combined type is 76.4% and in ADHD without epilepsy, the inattentive type is 50.5% (P = 0.004). There is more learning disability in ADHD with epilepsy than in ADHD without epilepsy (P = 0.01).

Conclusion: In ADHD with epilepsy, the combined type showed 76.4%. There is more learning disability in ADHD with epilepsy than in ADHD without epilepsy. This study showed the effect of epilepsy comorbidity in children with ADHD.

Primary central nervous system lymphoma or vanishing tumor in a patient presenting a Parinaud's syndrome

G. Piccirilloa, L. Lavorgnaa, A. Tessitorec, S. Bonavita, dM. Cirillod, F. Tortorab, M.R. Monsurroa, G. Tedeschi. aDepartment of Neurological Sciences, II Division of Neurology, Second University of Naples, Naples, Italy; bDepartment of Neuroradiology, Second University of Naples, Naples, Italy

A 24-year-old man presented a one month palsy in the upward gaze. MRI, immediately after the onset, showed a single lesion located in the posterior midbrain with a maximum diameter of 2 cm, and perilesional edema, involving the posterior commissure: hypertense in T2, hypointense in T1 and homogeneously enhanced after gadolinium. Once admitted the patient showed signs of Parinaud’s syndrome. CSF showed 1 lymphocyte/μl. and was negative for infection and demyelinating disease. The patient underwent a pulse of methylprednisolone of 1 g/die for five days with no symptom remission. One month later MRI showed: decreased volume of the lesion with unchanged signal characteristics including homogeneous contrast enhancement. HIV serology, serological tests for autoimmune autoantibodies, PET and CT total resulted negative. A diagnosis of primary central nervous system lymphoma was considered and to attempt an histological diagnosis we halted the steroid treatment for two months. At this point, once again the MRI showed a lesion whose size and signal were comparable to the first MRI. Forty days later, as the patient was scheduled for a stereotactic biopsy, we performed another MRI and we found that the lesion had almost completely disappeared: biopsy was no longer feasible. As the lesion had almost regressed, and no other possible explanation could be envisioned by the clinical and instrumental characteristics, we suggested a diagnosis of vanishing tumor: a case in which there is a strong suspicion of brain tumor from the clinical history and in which a gadolinium enhancing lesion spontaneously disappear or decrease, within 3 months, to less than 70% of the initial volume. Most vanishing tumors in the central nervous system might eventually be diagnosed as PCNSL.

Sleep apnea in patients with diabetic neuropathy
A. Osama a, Y. Ashour a, A. Abou-Hagar a, N. El-Shazly b, W. Al-Deeb b, R. Abd Al-Razek c, S. El-Kholy b, aNeurosurgery, Koshigaya Hospital, Dokkyo University School of Medicine, Saitama, Japan; bHuman Pathology, Gunma University, Graduate School of Medical Sciences, University of Koshigaya, Gunma, Japan

Background: Diabetes mellitus (DM) is a major chronic disease with high morbidity, mortality and economic burden. Sleep apnea is an increasingly recognized medical problem with its important role in metabolic, vascular and behavioral aspects. The association between sleep apnea and DM is likely to be complex.

Objectives: To detect prevalence, types and severity of sleep apnea in diabetic patients, and to detect any relation between sleep apnea and diabetic state, diabetic peripheral and autonomic neuropathy and phrenic nerve affection.

Patients and methods: Forty four diabetic patients were included in the study. Another 44 age and sex matched healthy subjects representing the control group were included. All the subjects were evaluated for diabetic state, peripheral neuropathy, autonomic neuropathy and phrenic nerve affection. Sleep disorders were assessed by overnight polysomnography recording.

Results: Sleep apnea was significantly more frequent in diabetic patients (84.1%) than in non-diabetics (18.2%). Obstructive sleep apnea was the most frequent type (65.9%) followed by mixed (13.7%) and lastly central type (4.5%) in the diabetics. All the grades of sleep apneas (mild, moderate and sever) were significantly more frequent in diabetics (45.4%, 18.2%, 20.5% respectively). There was a significant relation between sleep apnea and age of the patient, male sex, uncontrolled DM, duration of DM, diabetic autonomic neuropathy and phrenic nerve affection. There was no relation detected between sleep apnea and diabetic peripheral neuropathy.

Conclusion: Sleep apneas (especially obstructive type) are more frequent in diabetic patients with autonomic neuropathy and phrenic nerve affection.

LAT software based comparative clinical trial of alcohol addicts in Serbia and Austria
M. Jakovljevic a, A. Riegel b, M. Jovanovice c, N. Djordjevic d, K. Patek e, O.M. Lesch f, H. Walter g, bPharmacology and Toxicology, The Faculty of Medical Sciences, University of Kragujevac, Kragujevac, Serbia; cPsychiatry and Psychotherapy, Medical University of Vienna, Vienna, Austria; dPsychiatry, The Faculty of Medical Sciences, University of Kragujevac, Kragujevac, Serbia

Background: Serbia is lacking marketing approval of few essential antcraving medications to treat alcohol addiction. Comparative research was undertaken to provide deeper insight and grounds for reimbursement decisions.

Objective: Comparison of two European samples of alcoholic addicts processed by LAT software to detect major differences related to clinical evolution and treatment.

Patients and methods: 127 (116 males) Serbian and 136 (78 males) Austrian alcohol addicts were clinically followed from January 2011 to March 2012. The patients were assessed using the Lesch alcoholism typology instrument (LAT).

Results: Age of onset was slightly higher in the Austrian sample (28.5 vs 30.0; p = 0.005). The Serbian sample has significantly higher rate of anxiety disorders than in the Austrian sample (89.8% vs 26.5%, p < 0.001). Suicidal tendencies, independent of alcohol intake or withdrawal syndrome, are significantly higher in the Austrian sample (1.6 vs 13.2% p < 0.001). There was no difference between the two samples in Lesch Type IV (26 vs 28), but there was only a slight increase in the Serbian sample in Type I (15 vs 10). In Austria, significantly more Type II patients (32 vs 52) had been included, while the Serbian sample comprised significantly more Type III patients.

Conclusion: Austrian and Serbian patients are quite similar, and that there is no inhibiting factor that would further delay an introduction and reimbursement of the modern antcraving medications in Serbia. The differences in anxiety disorders might be due to the 1990s war, and should be further investigated.

Slug, twist, and E-cadherin as immunohistochemical biomarkers in meningeal tumors
M. Nagashiy a,b, S. Nobusawa a, H. Yokoo a, A. Hyodo a, Y. Nakazato b, aNeurosurgery, Koshigaya Hospital, Dokkyo University School of Medicine, Saitama, Japan; bHuman Pathology, Gunma University, Graduate School of Medicine, Gunma, Japan

Introduction: The overexpression of twist and slug and subsequent down-regulation of E-cadherin facilitate the acquisition of invasive growth properties in cancer cells. It is unclear which of these molecules are expressed in menenchymal tumors in the central nervous system.

Methods: In the present study, we investigated 10 cases each of hemangiopericytoma, solitary fibrous tumor, meningothelial, fibrous, angiomatous, and atypical meningoimas, and 5 cases of anaplastic meningoima for slug, twist, e-cadherin, and n-cadherin immunoeexpression.

Results: Nuclear slug expression was observed in 9/10 (90%) hemangiopericytomas and 5/10 (50%) solitary fibrous tumors, but not in any meningiomas, except for 1 case. Similarly, nuclear twist expression was...

Cannabis sativa induces sedation in mice
R.A. Magaji1, M.G. Magaji2, F. Asema3, S.Z. Paula4, 4Human Physiology, Ahmadu Bello University, Zaria, Nigeria; 4Pharmacology and Therapeutics, Ahmadu Bello University, Zaria, Nigeria

Cannabis sativa (Marijuana) is a tobacco-like substance. It is a dry shredded green and brown mix of flowers, stems, seeds and leaves of Cannabis sativa plant. It is used for medicinal purposes; as a recreational drug and for obtaining fiber. In this study, the effect of acute administration of Cannabis sativa on sedation was evaluated using elevated plus maze and staircase test in mice. Intraperitoneal administration of the cannabis at doses of 250–1000 mg/kg significantly (P < 0.05) and dose-dependently decreased the mean open and close arms entry; with no significance on the open and close latencies except the close arm latency of the 500 mg/kg animal group when compared to the control group. On the other hand, there was a significant (P < 0.05) and dose-dependent decrease in the number of stairs climbed and number of rearing on the staircase test as compared to the control. These results therefore suggested that acute Cannabis sativa administration induces sedation in mice.

We need a paradigm shift in research on reading and dyslexia: Fundamental problems with FMRI studies of written language processing
S. L. Strauss, Baltimore, MD, USA

Background: Over the past two decades, functional MRI has become a widely accepted tool to study reading. fMRI-based research claims that:

1) specific brain sites exist where visual letters are converted to oral language phonemes;
2) these sites are impaired in dyslexic readers; and
3) intensive remediation on letter–sound correspondences (phonics) can literally “repair” these sites.

Psychological models of reading, however, call these claims into question.

Objective: To demonstrate that
1) fMRI is an inappropriate tool to study reading and dyslexia; and
2) the neuroscientific study of reading and dyslexia needs to incorporate the psycholinguistic nature of meaning construction and its neuroanatomic foundation in cortical–subcortical circuitry.

Cortical–subcortical circuitry must be reconceptualized as a feed-forward, not feed-back system.

Materials and methods: Literature reviews are conducted of the formal linguistics of letter–sound mapping, saccades and fixations during reading, cortical–subcortical circuitry, and the psycholinguistics of reading.

Results: Letter–sound mappings differ significantly from what is assumed in fMRI-based research. Eye movement studies reveal that proficient readers do not fixate on fully one third of the words in a visual text display. Cortical–subcortical tracts constitute the feed-forward component of executive functioning. Meaning-construction relies on psycholinguistic strategies far more efficient and effective than letter–sound conversion. The spatial and temporal resolution capacity of fMRI is adequate for identifying letter–sound brain regions, but not for identifying meaning-construction neuroanatomy.

Conclusion: Reading must be described within a meaning-construction psychological paradigm. It is an executive process beyond the technical resolution capacity of fMRI. Its neuroanatomic basis lies in feed-forward cortical–subcortical tracts.

Cardiovascular autonomic function in healthy offspring with parental history of type 2 diabetes mellitus

Background: It has been shown that patients with type 2 diabetes mellitus (T2DM) exhibit altered autonomic activity of cardiovascular system.

Objective: The current study aimed to compare cardiovascular autonomic function between the healthy offspring with and without parental history of T2DM.

Material and methods: Heart rate variability (HRV) and cardiovascular autonomic reactivity of 80 healthy male subjects, between the age group of 18 and 30 years were assessed. The study group consisted of 40 subjects with parental history of T2DM and control group included 40 subjects without parental history of diabetes. HRV was assessed by fast Fourier transformation of supine 5 min ECG epoch recorded at spontaneous respiratory rates. Cardiovascular autonomic reactivity was assessed by deep breathing, Valsalva maneuver, handgrip and head up tilt.

Results: In HRV, all the time domain measures which are the markers of parasympathetic activity were comparable. In frequency domain measures, low frequency (LF) which is the marker of sympathetic activity and high frequency (HF) which is the marker of parasympathetic activity were comparable. Among autonomic reactivity variables, deep breathing and Valsalva ratio which are the markers of parasympathetic reactivity were comparable. Similarly, rise in diastolic blood pressure during handgrip and change in systolic blood pressure in head up tilt which are the markers of sympathetic reactivity were also comparable.

Conclusion: This study concludes that the parental history of diabetes does not have an impact on cardiovascular autonomic function in offspring between the age group of 18 and 30 years.

A case of autoimmune encephalitis caused by antibodies to GABA-B receptor
S. Dhungana4, K. Nunez-Wallace5, C. Van Hook5, J. Kass5. Neurology, Baylor College of Medicine, Houston, TX, USA

Objective: To describe a case of autoimmune encephalitis caused by antibody to GABA_B receptor.

Background: Autoimmune encephalitis resulting from antibodies to GABA_B receptor is uncommon. These patients usually present with early or prominent seizures. About one third of these cases can have an underlying tumor, usually small cell lung cancer. Immunotherapy and treatment directed at the underlying tumor may cause resolution of the condition.

Method: Case report.

Results: We report a case of a 29-year old male presenting with 2 weeks of history of cognitive and behavior dysfunction and new onset generalized tonic–clonic seizures. There were no focal neurological deficits on examination. EEG showed diffusely slow background. MRI of the brain and was essentially normal except for a subtle questionable leptomeningeal enhancement in bilateral occipitoparietal sulci but with no corresponding FLAIR abnormality. CSF analysis demonstrated a lymphocytic pleocytosis and mildly elevated protein. Viral studies were negative. High titers of antibody against the GABA_B receptor was detected in both the serum and the CSF confirming the diagnosis of GABA_B receptor autoimmune encephalitis. CT chest, abdomen and pelvis and a testicular ultrasound were all normal. He was treated with steroids, intravenous immunoglobulin and rituximab but remains encephalopathic three months after the treatment.

Conclusions: GABA-B receptor autoimmune encephalitis is uncommon. Recognition of this condition as well as the other forms of autoimmune encephalitis is important as immunotherapy and treatment of the underlying tumor can be effective.

Thalamic lesions profile by MRI as predictors for outcome in cases of acute disseminated encephalomyelitis
I. Shoukry4, M. Yousry4, H.A. Ghaffar4, H. Moharam4. Neuropediatrics, Cairo University, Cairo, Egypt

Background: Acute disseminated encephalomyelitis (ADEM) is a febrile episode associated with disturbed consciousness, seizures and with headache and altered mental status, negative CSF evidence of Cryptococcus neoformans, high CSF protein (386.2 mg/dL), and positive evidence of Mycobacterium tuberculosis on GeneXpert® analysis. Case II involved a 28 year old HIV-infected female who presented with headache and reduction in loss of consciousness, had negative CSF evidence of Cryptococcus neoformans, high CSF protein levels (315 mg/dL), and positive evidence of Mycobacterium tuberculosis on GeneXpert® analysis.

Conclusion: Despite the paucity of data on its use, Cepheid GeneXpert® PCR technology can be used relatively cheaply within resource-limited settings in the timely diagnosis of TBM so as to improve the prognosis of HIV-infected patients who present with clinical suspicion of TBM.

Thalamic lesions profile by MRI as predictors for outcome in cases of acute disseminated encephalomyelitis
I. Shoukry4, M. Yousry4, H.A. Ghaffar4, H. Moharam4. Neuropediatrics, Cairo University, Cairo, Egypt

Background: Acute disseminated encephalomyelitis (ADEM) is a febrile episode associated with disturbed consciousness, seizures and
neurological dysfunctions. The aim is to correlate between thalamic MRI findings and outcome and to determine if brain imaging can predict sequelae or not.

**Patients and methods:** Thirty two cases of ADEM were recruited in the acute condition. Patients were hospitalized and given pulse methylprednisolone and IVIG. Cranial or crano-spioinal neurological dysfunction was assessed clinically. Brain MRI, digital EEG and lumbar puncture were done for all cases.

**Results:** Mean age at presentation was 4.6 ± 2.4 years. Twenty were males and 12 females. Patients presented with motor weakness (100%), fever (80%), disturbed consciousness and seizure (73%). MRI brain showed multifocul punction to large flocculent high T2 and FLAIR signal intensity involving subcortical white/grey matter junction (86%), periventricular white matter (80%), brain stem (40%), cerebellum (31%) and bilateral thalami (25%). The callososeptal interface was not involved in any of them. Twenty three patients recovered without neurological deficits while 9 showed sequelae. All patients having bilateral thalamic involvement had sequelae. The thalamic lesions were in 2 cases in the form of hemorrhagic foci and necrosis. These two cases had severe neurological deficits in the form of spasticity with speech regression.

**Conclusion:** Thalamic lesions in ADEM are associated with neurological sequelae in the form of spasticity, squint and hemiplegia. MRI findings that may predict severe neurological deficits are hemorrhagic foci, necrosis or edema in thalamus.

**Background:** Meningiomas are primary and the second most common type of benign tumors of the central nervous system derived from meningotheial cells.

**Objective:** To evaluate the clinical outcome of posterior approach microsurgical resection of spinal meningiomas.

**Patients and methods:** 32 patients underwent microsurgical resection via the posterior approach; visual analogue scale (VAS) and medical research council (MRC) were used for clinical evaluation. All patients underwent clinical evaluation, MRI pre- and post-operation. Follow up duration was about 1 year after surgery.

**Results:** The patients enrolled comprise 26 females and 6 males, with a median age of 48 years old (range 22–74). 26 cases experienced clinical improvement following operations. The extent of tumor resection was Simpson Grade I in 5 patients, Grade II in 20, and Grade III in 7. No recurrence could be detected after one year of follow up. There were two cases of postoperative CSF leakage and two cases of worsened neurological status due to operative morbidity. No immediate postoperative mortality.

**Conclusion:** Gross total resection is associated with no recurrence and favorable clinical outcome when applied, regardless of dural origin control.
significant higher than in other neurodegenerative diseases (2.7%).

Conclusion: ALS, PD or MSA patients with cancer showed clinical characteristics unique to each neurodegenerative disease in Japan, compared to other countries. It is necessary to be aware of cancer in patients with ALS, PD or PSP because one-third of their deaths is caused by cancer.

Subacute sclerosing panencephalitis: A familial occurrence of two cases in Kosova
M. Shehu a, S. Ahmeti b, A. Shala c, R. Krasniqi d. aRegional Hospital, Prizren, Kosova; bInfectious Disease Clinic, University Clinical Center of Kosova, Prishtina, Kosova; cRegional Hospital ‘Prim.Dr.Daut Mustafa’, Prizren, Kosovo

Subacute sclerosing panencephalitis is a progressive neurodegenerative disease of children and adolescents. It arises as a late complication of primary measles infection. SSPE is an active brain infection with a defective measles virus. We report two cases of SSPE that developed in two unvaccinated first cousins that come from a rural part of Kosova. Familial occurrence of SSPE is already reported, but the predisposing genetic mechanisms that may be inherited are yet to be proven. Atypical SSPE presentation is found in one of the cases, while the classic one in the other. SSPE is an important disease to be excluded in the differential diagnosis in children manifesting neurodegenerative diseases, especially in developing countries such as Kosova.

Opioid receptors influence blood–brain barrier permeability, cerebral blood flow and serotonin levels following forced swimming exercise in young rats
H.S. Sharma a, A. Sharma a, R. Patnaik b, D.F. Muresanu c. aSurgical Sciences, Anesthesiology & Intensive Care Medicine, Uppsala University Hospital, Uppsala, Sweden; bNational Institute of Technology, School of Biomedical Engineering, Banaras Hindu University, Varanasi, India; cClinical Neurosciences, Medicine & Pharmacy Cluj-Napoca, Cluj-Napoca, Romania

Effect of forced swimming (FS) exercise on cerebral blood flow, blood brain barrier permeability and regional brain serotonin level was examined in young normotensive rats. Subjection of rats to FS for 30 min resulted in marked increase in the regional blood–brain barrier permeability in 14 brain regions. The regional cerebral blood flow (CBF) exhibited significant decrease in 6 brain regions whereas, no changes in 4 brain regions were observed. In another 4 regions there was a mild increase in the regional CBF. Measurement of regional brain serotonin content exhibited increase in few regions while in many other regions the serotonin level was decreased significantly. Pretreatment with naloxone, an opiate receptor antagonist significantly attenuated the breakdown of the BBB permeability and reduced cerebral blood flow changes. The serotonin level also did not alter significantly. This effect was more pronounced in rats treated with high dose (10 mg/kg, i.p.) of the compound, compared to lower (1 mg or 5 mg/kg, i.p.) dosages. These observations suggest that opioids significantly influence FS induced changes in BBB permeability, CBF and serotonin levels, not reported earlier.

Prognosis of benign paroxysmal positioning vertigo: Long term outcome and its prognostic factors
B.K. Kim. Neurology, Eulji Hospital, Seoul, Republic of Korea

Background: Even though Benign Paroxysmal Positional vertigo (BPPV) is most common cause of episodic vertigo, its prognosis is not well defined. In this study we aimed to identify long-term prognosis of BPPV and prognostic factors associated with its recurrence: sex, age, affected canal type, and etiology of BPPV, previous history of BPPV, and time period for cure.

Methods: A total of 1123 consecutive patients were diagnosed with BPPV through 10 years from January, 2000. Using Kaplan–Meier survival analysis, we investigated the cumulative recurrence rate of BPPV and calculated hazard ratio of the variables associated with recurrences.

Result: After excluding intractable cases or follow-up loss before cure, 106,955 patients (mean age: 56.7 ± 13.4 years old, female: 72.97%) were analyzed in this study. The 30 day, 3 month, 6 month, 1 year, 2 year, 3 year, 5 year, 7 year and 10 year cumulative recurrence rates of total subject were 3.8%, 10.9%, 16.4%, 21.8%, 27.6%, 30.8%, 34.1%, 36.0%, 38.3%, 10.9%, 16.4%, 21.7%, 27.4%, 30.6%, 33.9%, 35.8%, and 41.8% respectively. Recurrence rates of female and time period for cure (TPC) more than 1 day were 46.7% and 54.10% respectively, which were higher than those of male (30.9%) and TPC ≤ 1 day (38.4%) with statistical significance in the survival analysis and those were independently raised hazard of recurrence.

Conclusion: We observed that substantial proportion of patients with BPPV recurred. Gender and time period for cure independently raised the risk of recurrence.

Recurrent tetanus in diagnosed breast cancer patients of the Philippine General Hospital
J.E. Bautista, LL. Shiong Shu, J.L. Pascual, P.M. Pasco. Department of Neurology, University of the Philippines – Philippine General Hospital, Manila, Philippines

This is the first report of recurrent tetanus in two cases of breast cancer. The first case is of a 40-year old female with intraductal carcinoma of the right breast who was admitted for tetanus with breast mass ulcers as presumptive focus. She was given anti-tetanus vaccines and appropriate antibiotics. No wound debridement was done for fear of tumor seeding. She was discharged clinically cured of tetanus. Despite adequate treatment, the patient had recurrence of the tetanus 40 days after discharge. The second case is of a 56-year old female diagnosed with intraductal carcinoma of the left breast who developed tetanus after accidentally injuring the breast mass with a door nail. Similarly, she was given anti-tetanus vaccines and appropriate antibiotics. There was no consent to any intervention on the breast mass. She was discharged cured, but returned after 32 days with recurrent tetanus. The recurrence of tetanus in these patients could be due to incomplete elimination of the infection,

Diagnostic challenge and steroid-dependence in a HIV patient with cryptococcal immune reconstitution inflammatory syndrome
K.P. Ng, a L.M. Ling, b K. Tan. aDepartment of Neurology, National Neuroscience Institute, Singapore; bDepartment of Infectious Disease, Tan Tock Seng Hospital, Singapore, Singapore

Background: Cryptococcal immune reconstitution inflammatory syndrome (IRIS) developing in human immunodeficiency virus (HIV) patients has been well described following immune recovery with highly active antiretroviral therapy (HAART). Prompt diagnosis of cryptococcal IRIS and treatment often lead to better outcomes. Diagnosing IRIS may be challenging. Optimal duration of treatment for cryptococcal IRIS is unknown.

Objective: To describe the challenges in diagnosis and treatment of cryptococcal IRIS in a HIV patient.

Patients and methods: Patient followed up in Departments of Neurology and Infectious Disease from 2007 to 2013.

Results: A 43-year-old male HIV patient with multiple opportunistic infections (pneumocystis carinii pneumonia, cytomegalovirus retinitis, cryptococcal meningitis and disseminated mycobacterium avium complex infection) was treated with HAART from Dec 2007. Initial CD4 count of 21 gradually improved to 82 in May 2009. He subsequently developed recurrent episodes of right hemiparesis, numbness, dystartria, dizziness and seizures from Oct 2008 to Jun 2009. Serial brain MRI scans showed progressive T2-weighted white matter hyperintensities and leptomeningeal enhancement, predominantly in the left parietal region. Cerebrospinal fluid showed lymphocytic pleocytosis and negative for bacterial, viral and fungal etiologies. He was initially empirically treated with antituberculosis medications and prednisolone, but his seizures would recur when-ever steroids were tapered. Brain biopsy in Jul 2009 eventually showed cryptococcal meningitis and cerebritis. He remained well with anticonvulsants and oral steroids, but could not be weaned off steroids (currently 5 mg daily) as his seizures would recur.

Conclusion: Cryptococcal IRIS diagnosis can be challenging. Duration of steroid treatment for cryptococcal IRIS may be prolonged.

Prevalence of chronic degenerative diseases and traumatic nervous system in adolescents and adults
G. Baquero Sastre, M. Dominguez. Neurorehabilitation Physiotherapy, Manuela Beltran University, Bogota, Colombia

Introduction: The demographic, social and lifestyle of the population factors have led to the increase in cases of chronic degenerative and traumatic neurological diseases that have significant impacts on the processes of life for people.

Objective: To establish the prevalence of chronic degenerative and traumatic diseases of the nervous system in adolescents and adults.

Materials and methods: Cross-sectional study in which statistical records were taken care of patients over 15 years old seen in 2012 in the health care practices of Physical Therapy Program at the University Manuela Beltran.

Results: During 2012 they attended a total of 4122 people over 15 years old. 25.76% (n = 1062, standard error = 0.00) of these people were intercepted with neurological problems. 17.98% (n = 191, standard error = 0.02) of people with neurological diseases were due to trauma, and 32.39% (n = 344, standard error = 0.02) had chronic degenerative diseases. 44.5% (n = 85, standard error = 0.03) of people with traumatic disease had brain injury, while among those with chronic degenerative diseases the 60.75% (n = 208, standard error = 0.02) reported disease cases, e.g. Alzheimer. 72.94% of people with traumatic brain injury were male (n = 62, standard error = 0.02), and 77.51% (n = 162, standard error = 0.01) of people with Alzheimer's disease were women.

Conclusions: Chronic degenerative diseases tend to be more prevalent diseases in the nervous system than traumatic diseases, the first disease chronic degenerative as Alzheimer, and in traumatic disease as brain injury.

Diffusion-weighted cranial MR imaging in Wernicke's encephalopathy associated with enterocutaneous fistula
B. Caglia1, A. Tekatas2, S. Tuncel3, Y. Celik4. 1Radiodiagnostic, Trakya University School of Medicine, Edirne, Turkey; 2Neurology, Trakya University School of Medicine, Edirne, Turkey

Wernicke's encephalopathy is a rare neurological disease due to tiamin deficiency and characterized by ophthalmoplegiasis, disturbed consciousness and ataxia. It is known that periventricular white matter, medial thalamic nuclei, massa intermedia, and mammillary bodies are affected in Wernicke's encephalopathy. Chronic alcoholism, anorexia, peritoneal dialysis, hyperemesis gravidarum and total parenteral nutrition are the most common causes of Wernicke's encephalopathy. We presented three patients who had Wernicke's encephalopathy due to total parenteral nutrition and tiamin deficiency.

Association between DBH gene polymorphisms and attention deficit hyperactivity disorder in Korean children
M.H. Lim1, C.M. Lee2, H.J. Kwon3. 1Psychiatry, Environmental Center, Dankook University, Cheonan, Republic of Korea; 2Neurology, Dankook University, Cheonan, Republic of Korea; 3Preventive Medicine, Environmental Health Center, Dankook University, Cheonan, Republic of Korea

Attention deficit hyperactivity disorder (ADHD) is a common disorder of the school-age population. ADHD is familial and genetic studies estimate heritability at 80–90%. The aim of the present study was to investigate the association between the genetic type and alleles for DBH gene in Korean children with ADHD. The sample consisted of 142 ADHD children and 139 control children. We diagnosed ADHD according to DSM-IV. ADHD symptoms were evaluated with Conners’ Parent Rating Scales and Dupaul Parent ADHD Rating Scales. Blood samples were taken from the 281 subjects, DNA was extracted from blood lymphocytes, and PCR was performed for DBH polymorphism. Alleles and genotype frequencies were compared using the Chi-square test. We compared the allele and genotype frequencies of DBH gene polymorphism in the ADHD and control groups. This study showed that there was a significant correlation among the frequencies of the rs1611115 (OR = 0.64, 95% CI = 0.42–0.97, p = 0.034) of alleles of DBH, but the final conclusions are not definite. Follow-up studies with larger patient or pure subgroups are expected. These results suggested that DBH might be related to ADHD symptoms.

Neurological complications after neonatal bacteremia: The clinical characteristics, risk factors and outcomes
S.-M. Chu1, L.-F. Hsu2, M.H. Tsai3. 1Chang Gung Memorial Hospital, Taoyuan, Taiwan, ROC; 2Chang Gung Memorial Hospital, Yunlin, Taiwan, ROC

Background: Neonates with bacteremia are at risk of neurological complications, but the relevant information is understudied.

Objective: To characterize the clinical features, risk factors, and outcomes of neonatal bacteremia-related neurological complications (BNCs).

Methods and materials: A retrospective cohort study of neonates with BNCs in a tertiary-level neonatal intensive care unit was conducted. Systemic chart review was performed to identify clinical characteristics and outcomes. A cohort of related conditions was constructed as the control group, and logistic regression was used to identify independent risk factors for BNC.

Results: Of 1075 episodes of bacteremia, 35 neonates had BNCs. Three-fifth (21/35) of BNCs were due to meningitis, six were presumed meningitis and eight occurred after hypoxia and septic shock. The most common pathogen to cause BNC is Group B streptococcus (GBS) (15/35, 42.9%) and Escherichia coli (6/35, 17.1%). The major BNCs consisted of seizure (27), hydrocephalus (19), encephalomalacia (11), cerebral infarction (7), subdural empyema (6), and post-infectious encephalopathy (3). 8 (22.8%) neonates died, and 7 neonates were discharged at critical condition after the family requested and withdrew all treatment. Among 20 survivors, 10 had neurological sequelae when discharged. In the cohort of neonates with meningitis and septic shock, extremely preterm (gestational age <28 weeks) and meningitis caused by GBS were independent risk factors for development of BNC.

Conclusion: Neonatal bacteremia with meningitis is associated with high risk of neurological complications, especially caused by GBS. Aggressive treatment is worth consideration because bacteremia-related neurological complications potentially result in mortality and morbidities.

Vestibular evoked myogenic potentials (VEMPs) from upper limb muscles
E.S. Papathanasiou¹, C. Iosif², S.S. Papacostas². ¹Clinic B, The Cyprus Institute of Neurology & Genetics, Cyprus; ²Cyprus School of Molecular Medicine, The Cyprus Institute of Neurology & Genetics, Nicosia, Cyprus

Background: Vestibular evoked myogenic potentials (VEMPs) are a relatively new method of recording function from the vestibular nervous system. It relies on the fact that the saccule has retained its sensitivity to sound and can be stimulated by such. Recordings are frequently performed from the sternocleidomastoid muscle (cervical VEMPs or cVEMPs) and more recently from the inferior oblique muscle (ocular VEMPs or oVEMPs). Recording from the limbs is rarer and has so far been done in only a few selected muscles such as the gastrocnemius and triceps. A systematic study of all limb muscles within and between individuals has not so far been done.

Objective: To systematically study the characteristics of VEMPs from upper limb muscles.

Material and methods: Fourteen physiologically normal volunteers were recruited (age range 17–25 years, 4 males and 10 females). Together with the cVEMPs and oVEMPs, attempts to record VEMPs in response to moderate intensity (120 dB pSPL) tone (500 Hz) stimulation were done from the deltoid, biceps brachii, triceps brachii and flexor carpi radialis muscles.

Results: Reproducible responses against a background of tonic contraction were obtained from all muscles, with mean initial peak times of 15 ms (cVEMP), 9.9 ms (oVEMP), 11.5 ms (deltoid), 12.3 ms (biceps), 12.12 ms (triceps) and 16.0 ms (FCR).

Conclusion: It is possible to record VEMPs from various upper limb muscles with different mean latencies. This should prove useful in the future to evaluate lesions in the anterior funiculus of the spinal cord at different levels.

Neural correlates of inspection time task performance: A developmental study
S.S. Papacostas³, E.S. Papathanasiou¹, C. Christoforou³, G. Spanoudis³. ¹Clinic B, The Cyprus Institute of Neurology & Genetics, Cyprus; ³Department of Psychology and Center for Applied Neuroscience, University of Cyprus, Nicosia, Cyprus

Background: Inspection Time Task (ITT) is used as an index of individual differences in perceptual discrimination speed. It is a reliable predictor of the relation between processing speed and psychometric intelligence. Converging findings showed that people with higher IQ identify a briefly presented stimulus more quickly and with greater accuracy than those of a lower IQ.

Objective: To examine the neural correlates of developing intelligence by contrasting the behavioral performance as well as the event-related potentials (ERPs) of two groups of children, one with high IQ scores and one with low. To our knowledge, speed of processing as neural correlate of intelligence has not been studied systematically during school age and adolescence.

Material and methods: This study involved two age-matched samples of 158 children aged 7 through 18 years, selected on the basis of their scores on Wechsler Abbreviated Scales of Intelligence. Children performed the ITT while their electro-cortical activity was registered using a high-density 128-channel electroencephalography acquisition system.

Results: Differences were found in the amplitude course of ERPs between ‘high IQ’ and ‘low IQ’ individuals which are consistent with their differences in inspection time. ‘High IQ’ individuals were faster, less prone to err, and demonstrated significantly larger N1 responses. N1 latency and other ERP components did not differentiate between the two IQ groups.

Conclusion: Given the specificity of ERP group differences to the N1, the results of the present study suggested that allocation of attentional resources is more difficult for individuals with lower IQ scores.

Hyperactivity and impulsivity in children with allergic rhinitis
M.-T. Yang⁴, C.-C. Chen⁵, J.-S. Liang⁵, W.-T. Lee³. ³Pediatrics, Far Eastern Memorial Hospital, New Taipei City, Taiwan, ROC; ⁴Pediatrics, National Taiwan University Hospital, Taipei, Taiwan, ROC

Background: Allergic rhinitis (AR) is the most common chronic allergic disease in school-age children. In addition to physical complications, sleep disturbances, poor school performance, and hyperactivity are all mental complications seen in many children related to their nasal allergies. Increased prevalence and odds ratio of attention-deficit/hyperactivity disorder (ADHD) in AR patients were also noted by analyzing the Taiwan’s National Health Insurance Research Database. Inattention and hyperactivity in AR children have not been investigated by objective and scientific measurements.

Objective: The goal of this study was to see if there was a difference in inattention and hyperactivity between AR children and age-matched control children by questionnaires and software.

Patients and methods: In this study, we applied the AR symptom score (TSSS), the ADHD symptom and severity scale (SNAP-IV) and the computerized continuous performance test (CPT) to study the attention and the impulsivity in AR children and age-matched control children (aged 6 to 15 years old).

Results: Fifty-nine AR children and seventeen control children were enrolled. There were no differences of age and gender between two groups. Hyperactivity subscales of SNAP-IV from both parents and teachers scored significantly higher in AR children (p < 0.01). CPT revealed higher commission error rate, shorter reaction time, and higher d-prime (p < 0.01).

Conclusion: AR children were more hyperactive and impulsive than control children. For AR children, behavior and emotion problems in family and at school need close attention and further investigation.

Electrical vestibular stimulation after vestibular deafferentation and in vestibular schwannoma
S.T. Awea, G.E. Awb, M.J. Todd, G.M. Halmagyi
School, University of Sydney, Australia; fInstitute of Clinical Neuroscience, Royal Prince Alfred Hospital, Sydney, NSW, Australia

Background: Vestibular reflexes evoked by human electrical vestibular stimulation (EVS) are used to investigate vestibular function and its pathways. Vestibular schwannoma causes vestibulo-cochlear nerve compression in the internal auditory meatus interrupting the signal conduction along the vestibular pathway.

Objective: We investigated the electrically-evoked vestibulo-ocular reflex (eVOR) after vestibular deafferentation and in vestibular schwannoma.

Patients and methods: EVORs were recorded as binocular 3D eye rotations evoked by bipolar or unipolar, 100 ms current-step at 0.9–10.0 mA with dual-search coils from 4 vestibular schwannoma patients confirmed by MRI, 12 unilateral vestibular deafferentation (UVD), 5 bilateral vestibular deafferentation (BVD), 2 unilateral labyrinthectomy (UL) patients and 17 normal subjects.

Results: After UVD, bipolar EVS elicited no eVOR. After UVD, bipolar EVS of one functioning ear elicited biphasic excitatory eVOR to cathodal EVS with 9 ms latency and inhibitory eVOR to anodal EVS, opposite in direction, at half the amplitude with 12 ms latency, exhibiting excitatory–inhibitory asymmetries. Both excitatory and inhibitory eVORs were maintained with EVS durations and graded with EVS intensities. The eVOR from vestibular schwannoma was consistent with eVOR from UVD demonstrating the functional loss on the lesion side. We found that unipolar EVS activates both ears due to current spread. Unipolar EVS of the UVD ear produced one-third of the bipolar eVOR, instead of the expected absent response.

Conclusion: We showed that eVOR from one functioning vestibular labyrinth was biphasic with a latency difference between the normal and lesion side. This EVS test may be utilized to investigate unilateral vestibular lesion such as vestibular schwannoma.

Vestibular and saccadic abnormalities in Gaucher's disease
S.T. Awea, L. Chen, M.J. Todd, G.M. Halmagyi

Background: Gaucher’s disease (GD) is a hereditary lysosomal storage disease characterized by abnormal deposition of glucocerebroside due to the enzyme glucocerebrosidase deficiency, resulting in multi-organ pathology. GD type III has a progressive neurological involvement.

Objective: To determine vestibular and saccadic abnormalities in GD type III.

Patients and methods: The vestibular and saccadic responses of two siblings with genetically-identified GD Type III on enzyme replacement therapy were evaluated. Vestibular functions were assessed with the head impulse test (HIT), vestibular evoked myogenic potentials (VEMPs) and electrical vestibular stimulation (EVS). Saccadic functions were investigated with volitional horizontal and vertical saccades to ±20°. Three-dimensional head and eye movements were recorded with dual-search coils and VEMP with surface electrodes.

Results: Individual semicircular canal functions were impaired with angular vestibuloocular reflex (VOR) gains to HIT halved and absent horizontal refixation saccades. Ocular and cervical VEMPs to air-conducted clicks were absent in the older sibling and only cervical VEMP was present in the younger sibling indicating otolithic dysfunction. EVS showed prolonged onset latency and attenuated tonic and phasic responses suggesting impaired neural conduction and vestibular function. Horizontal saccadic velocity was miniscule (<30°/s) and multiple back-to-back saccades with saccade–vergence interaction were utilized to minimize eye position error in the older sibling. Vertical saccades, vergence and smooth pursuit were normal in both siblings.

Conclusion: Our findings suggest that GD affects the vestibular nuclei in addition to paramedian pontine reticular formation. These vestibular and saccadic abnormalities may have implications for activities of daily living that requires visual–vestibular interaction.

Syphilitic polyradiculoneuropathy in an immunocompetent patient
S. Zahlane, N. Louhab, N. Kissani

Background: Although the incidence of neurosyphilis has decreased, it is still prevalent. Its most common clinical presentation includes tabes dorsalis and general paresis. In contrast, polyradiculoneuritis has rarely been reported during syphilis. The authors report a case of acute polyradiculoneuritis caused by Treponema pallidum in an immunocompetent patient.

Objective: This case reports the interest to evoke a syphilitic origin in polyradiculoneuropathy.

Case report: A 45 year old man without medical past history was referred to neurolgy outpatient for acute leg weakness and heaviness, walking difficulties. Clinical examination revealed bilateral leg weakness. Deep tendon reflexes were absent at the knees and the ankles, cutaneous hypoesthesia on the legs. There were no pyramidal signs, no cranial nerves abnormalities and no incontinence. Electroneuromyograms showed sensorimotor demyelination and axonal loss evoking polyradiculoneuritis. Lumbar punctures showed an albumino-cytological dissociation (hyperproteinorachy at 2.2 g/l, normal cell count and glucose level).Serum VDRL and TPHA were positive (VDRL: 1/16, TPHA: 1/1280). The VDRL and TPHA were positive in the CSF (VDRL: 1/6, TPHA1/640). Serodiagnostics tests (HIV, Borrelia, hepatitis C and B) were negative. The patient received 30 million units of intravenous penicillin G daily for 10 days, four times with delay of 3 months. Muscular leg weakness disappeared and his clinical condition improved.

Conclusion: Syphilitic polyradiculoneuropathy has rarely been reported. Infection due to T. pallidum is a curable cause of polyradiculoneuritis which may occur in HIV-negative patients; appropriate tests in both serum and CSF should be performed in patients with polyradiculoneuritis.

Sleep problem of premature infants: Clinical utility of the modified Chinese version of the brief infant sleep questionnaire (CBISQ)
S.-M. Chu, Y.-S. Huang, M.H. Tsai. Chang Gung Memorial Hospital, Taoyuan, Taiwan, ROC

Background: Previous studies have suggested differences in sleep quality between preterm and term born infants, and premature infants are at higher risk for sleep-disordered breathing.

Objective: We aimed to evaluate sleep problems of preterm infants and compare the results with full-term infants based on the modified Chinese version brief infant sleep questionnaire (CBISQ).

Methods and materials: To validate the modified CBISQ, we collected 69 6-months old full term infants and 177 premature infants born at <37 weeks of gestation. All parents completed a modified CBISQ. First we examined the test–retest reliability of the modified CBISQ. Then, we compared the questionnaire-responses with other subjective (sleep diary) and objective (actigraphy) measures of sleep. Finally, we evaluated the validity and potential usage of the questionnaire for diagnostic purpose by comparing results to those obtained through nocturnal polysomnography (PSG).

Results: Test–retest reliability of CBISQ was acceptable. The nocturnal sleep duration, number of night waking, daytime sleep duration, time spent with mouth breathing and loud-noisy breathing had significant correlation with sleep diary, actigraphy and polysomnography. The CBISQ showed that the sleep on infants' side, nocturnal sleep duration, being held to fall asleep, number of night waking, daytime sleep duration, subjective consideration of sleep problem, loud-noisy breathing and time spent with crying during night were significantly different between premature infants and full term infants.

Conclusion: The CBISQ is a reliable and valid tool for the measurement of sleep problems in infants. Premature infants have more sleep problems compared to term born infants.

Coronal oblique orientation offers improved visualization of neuroforamina in cervical spine magnetic resonance imaging
W. Freundd, S. Klessingerb, M. Muellera, M.-E. Halatschc, G. Hoepnera, B.L. Schmitzd. Diagnostic and Interventional Radiology, University Hospitals Ulm, Ulm, Germany; bNeurosurgery, Nova Clinic, Biberach, University Hospitals Ulm, Ulm, Germany; cNeurosurgery, University Hospitals Ulm, Ulm, Germany; dNeuroradiology, University Hospitals Ulm, Ulm, Germany

Background: Angulated projections are standard in conventional radiography of the cervical spine but rarely used in magnetic resonance imaging (MRI). Improved visualization of neuroforaminal pathology is necessary especially preoperatively to discern the degree of neuroforaminal stenosis and the cause (osseous or soft).

Patients and methods: In a retrospective setting, 25 consecutive patients with cervical monoradiculopathy were identified. T2-weighted sagittal, coronal oblique and transversal slices were anonymized, generating 75 “cases” consisting of only one spatial orientation. 2 radiologists and 2 neurosurgeons blinded to the diagnosis individually read the cases. One of each pair was experienced with the coronal oblique slices; the other received a 10-minute training. Criteria were site, cause and grading of the neuroforaminal stenosis and the level of confidence on a 100-point visual analogue scale (VAS). We computed interrater agreement and t-tests, taking p < .05 as statistically significant.

Results: The sensitivity to detect the relevant neuroforaminal stenosis was .45 for transversal, .63 for sagittal and .61 for coronal oblique scans. The combination of three planes increased sensitivity to .77 to detect the relevant lesion. The readers felt significantly more confident in attributing the cause of pathology on coronal oblique planes (76.4 VAS points, p = .006) vs. 68.2 (sagittal) vs. 68.6 (transversal).

Interrater agreement was significantly better for experienced (kappa .48) than inexperienced readers (.32, p = .02).

Conclusion: Coronal oblique planes in cervical spine MRI increase sensitivity and confidence in attributing the cause of neuroforaminal obstruction. They are easy to interpret; however, experience with the sequence increases interrater agreement.

Adult onset of mitochondrial encephalomyopathy lactic acidosis and stroke-like episodes (MELAS) syndrome mimicking herpes encephalitis: A case report and review of literature
S. Collorone, S. Pontecorvo, A. Francia. 'Sapienza' University of Rome, Rome, Italy

Background: Mitochondrial encephalomyopathy lactic acidosis and stroke-like episodes (MELAS) syndrome is a multisystem disorder with a widespread phenotypic variability.

Objective: The objective of this work is to report an unusual presentation of MELAS mimicking herpes encephalitis compared to cases described in literature.

Description: A 47 year-old man presented acute onset of confusion, agitation and productive aphasias. He had a history of spina bifida, allergy to acetylsalicylic acid, sensorineural hypoacusis and migraine-like headache. There was no family history of neurological disease. A cerebral magnetic resonance imaging (MRI) showed large bilateral lesions of temporal lobes, hyperintensity in T2-FLAIR and apparent reduction in diffusion coefficient (ADC). Empirical treatment with antiviral and corticosteroids was begun for presumed herpes simplex encephalitis, without improvement in his clinical conditions and reduction of temporal lesions. After one month he developed balance disorder and dizziness so he was hospitalized in our neurology department. Cerebral MRI showed new large lesions (temporal lobe, parietal lobe and calcarine cortex) with same MRI features of first episode. Magnetic resonance spectroscopy (MRS) showed increase in lactate in lesions and liquor confirmed by the lumbar puncture. MELAS was suspected and diagnosis was confirmed by detection of nucleotide 3243 A → G mutation in mitochondrial DNA.

Discussion: Six MELAS cases mistaken for viral encephalitis are described in medical literature: correct diagnosis was achieved after a second stroke-like episode or after ineffective treatment.

Conclusion: MELAS should be included in differential diagnoses of herpes encephalitides on the basis of detailed history, which provides early diagnostic clues, and cerebral MRI features. Our case brings out the importance of MRS: detecting lactate increase in liquor and lesions, MRS could be a crucial aid for early diagnosis.

Contribution of major amyotrophic lateral sclerosis related genes to the etiology of the disease in Chinese
Z.-Y. Zou, X.-G. Li, M.-S. Liu, L.-Y. Cui. Peking Union Medical College Hospital, Beijing, China

Background: Mutations in SOD1, ANG, TARDBP, FUS, VCP, C9ORF72, and PFN1 genes have been identified in ALS patients.
Objective: The objective of this work is to determine the mutations in major ALS-related genes in a large cohort of Chinese familial (FALS) and sporadic (SALS) patients and the genotype–phenotype associations.
Methods: Screening for mutations of SOD1, ANG, TARDBP, FUS, VCP, C9ORF72, and PFN1 genes was consecutively carried out in 20 index FALS patients, 324 SALS patients, and 245 healthy controls.
Results: Overall, mutations were detected in 35.0% (7/20, 95%CI = 14.1–55.9%) and 4.0% (13/324, 95%CI = 1.9–6.1%) of FALS and SALS patients, respectively. SOD1 (5/20, 25.0%) and FUS (2/20, 10.0%) account for all mutations in FALS patients, whereas FUS (6/324, 1.9%) was the most frequently mutated gene in SALS patients, followed by SOD1 (3/324, 0.9%), TARDBP (3/324, 0.9%), and ANG (1/324, 0.3%). No mutations were detected in VCP, C9orf72, and PFN1 genes. Patients with FUS mutations were younger at onset (P < 0.01) and had shorter lifespan (P < 0.01), compared with those without the mutations.
Conclusion: Mutations in major ALS-related genes were present in approximately 35% and 4% of Chinese FALS and SALS patients, respectively. SOD1 and FUS are the most frequently mutated genes both in FALS and SALS patients in Chinese. It appears to be different from the profiles reported in Caucasian ALS patients, in which C9orf72 and SOD1 are the most common mutated genes. Moreover, FUS mutations are associated with an early onset and poor prognosis. The results suggest that there is an ethnic difference in the genetic background of ALS.

Hashimoto’s encephalopathy associated with an elevated intrathecal IgG4 level
Y. Hosoi1, S. Kono2, T. Teradaa, T. Konishi2, H. Miyajima2, 1First Department of Medicine, Hamamatsu University School of Medicine, Hamamatsu, Japan; 2Laboratory of Human Brain Imaging Research, Molecular Imaging Frontier Research Center, Hamamatsu University School of Medicine, Hamamatsu, Japan

Background: Hashimoto’s encephalopathy is a steroid-responsive neurological syndrome associated with the existence of anti-thyroid antibodies, which is characterized by various neuropsychiatric symptoms. The autoimmune mechanisms are thought to play a pathogenic role in this disorder. Recently, some reports showed an elevated serum IgG4 level in patients with Hashimoto’s thyroiditis.
Objective: The pathogenic role of IgG4 in a patient with Hashimoto’s encephalopathy is investigated.
Patient and method: The patient was a 60-year-old Japanese male who presented with a 6-month history of progressive gait disturbance. He developed memory disturbance and involuntary movements of his face and neck 2 months after presentation. The IgG4 concentrations in the serum and cerebrospinal fluid, MRI scans of brain, and response of corticosteroid therapy were investigated.
Results: A neurological examination revealed cerebellar ataxia and grimacing face with cervical dystonia. The MMSE score and FAB score were within normal range. Laboratory tests revealed a high titer of anti-thyroglobulin antibodies in the serum. The serum IgG4 concentration was elevated (298 mg/dl; normal: 4.8–105). A CSF analysis revealed an elevated level of IgG4 (3.5 mg/dl; normal: not detected). There was no clinical finding suggesting complications of IgG4-related disease. A brain MRI revealed symmetrical periventricular high signal intensity on T2-weighted images and FLAIR images. Corticosteroid therapy improved the neurological symptoms, intrathecal IgG4 level, and abnormal MRI findings.
Conclusion: An elevated IgG4 level in the cerebrospinal fluid, as well as in the serum, may provide helpful clues about the possible autoimmune mechanism involved in Hashimoto’s encephalopathy.

Neurological diseases in pregnancy

Objective and materials: Eleven pregnant women aged 28.72 years old (DS +/− 7.18; mean age: 16–37 years) admitted in our
department for 6 months in 2012 (one at the first trimester, three at the second or the last trimester respectively) were prospectively studied.

Results: Three were at their 1st pregnancy, 4 were post-partum while others from 2nd to 4th pregnancies. Some ATCD reported were: miscarriages in 4, trauma during pregnancy, venous thrombosis of the inferior extremities and appendectomy in one respectively. The etiology reported were: epilepsy (E) in 5 while 6 showed DVT, posterior ischemic stroke, and headache (primary, post-PL orthostatic hypotension from the anesthisis during SC) in two patients respectively, and reversible vasoconstriction syndrome in one. Among the epileptic pts; one had its first seizure (S) before pregnancy, and others; S heralding DVT, epilepsy from right MCD, post-traumatic S during pregnancy, and post-partum S in one consecutive case. Two presented CPS and 3 PM secondary generalized S. MRI was normal in 5; DVT and ischemic stroke in 2 patients respectively; multi lacunar P bilateral stroke and right P schizencephaly in two patients. EEG on E cases displayed anterior bilateral left sided dominance SHW and SW. The therapy useful was the small MW anticoagulants in stroke and DVT, and AEDs (CBZ, LTG) in E cases. All patients delivered in term after the neurological improvement except one, which interrupted its 4th pregnancy.

Conclusion: Epilepsy followed by DVT, stroke and headache were the most frequent neurological diseases that occurred during pregnancy.

Vascular burden in acute stroke: An MRI study
K.E. Leea, Y.Y. Sitohb. aDepartment of Neurology, National Neuroscience Institute, Singapore, Singapore; bDepartment of Neuroradiology, National Neuroscience Institute, Singapore, Singapore

Background: Intracranial atherosclerotic disease (ICAD) is the most common mechanism of ischemic stroke worldwide, particularly among Asians. Magnetic resonance angiography (MRA) is a reliable modality for diagnosis. Utilizing magnetic resonance imaging (MRI) as the primary neuroimaging tool for all patients with suspected acute stroke, we prospectively evaluated the association of acute stroke with background ICAD, chronic microvascular ischemic changes (CMI) and microhemorrhages (MH).

Methods: 468 consecutive patients presenting over a three-month period had MRI with axial diffusion weighted imaging, T2W, gradient sequences and 3D TOF MRA performed; 5 patients were too restless for 3D TOF MRA. Fisher’s exact test was used to analyze the data.

Results: Acute stroke with restricted diffusion was reported in 260 (55.6%) patients. ICAD was present in 339 (73.2%); 321 (68.6%) revealed CMI while 168 (35.9%) showed MH. Underlying ICAD, CMI and MB were significantly present in patients with acute stroke (p < 0.0001, p < 0.0001 and p = 0.0154 respectively). In 139 patients, both MH and CMI were present, demonstrating the strong association between them (p < 0.0001).

Conclusion: ICAD is very common in our Asian population comprising largely Chinese, Indian and Malay ethnicities. MRI in acute stroke demonstrated a strong association with underlying ICAD, CMI and MH.

Evolution of regionally accentuated reversible brain grey matter reduction in ultra marathon runners detected by voxel based morphometry
W. Freunda, S. Faustb, F. Birkleinc, C. Billichc, A.P. Wunderlichd, U.H. Schuertza,e. aDepartment of Diagnostic and Interventional Radiology, University Hospitals Ulm, Ulm, Germany; bDepartment of Neurology, University Medical Centre Mainz, Mainz, Germany; cOutpatient Rehabilitation Centre, University Hospitals Ulm, Ulm, Germany

Background: During the 4487 km ultra marathon TransEurope-Footrace 2009 (TEFR09), runners showed catabolism with considerable reduction of body mass. We hypothesized that the athletes have acquired changes to grey matter (GM) brain morphology due to continuous high volume training and will show additional changes during the race.

Material and methods: Prior to the start of the race 13 runners volunteered to participate in this study of planned brain scans before, twice during, and 8 months after the race. A group of matched controls was recruited for comparison.

Scanning was performed with identical 1.5 T Siemens Avanto scanners, in a mobile MRI unit escorting the runners. A volumetric 3D dataset was imaged using a MPRAE sequence. A level of p < 0.05, family-wise corrected for multiple comparisons was set.

Results: Comparison of TEFR09 participants and controls revealed no significant differences regarding the GM brain volume. During the race however, voxelwise morphometry revealed that GM concentration decreases in regionally distributed brain regions. These included the bilateral posterior temporal and occipitoparietal cortices as well as anterior cingulate and caudate nucleus. After eight months, regional GM differences came back to baseline.

Conclusion: We did not observe baseline differences between TEFR09 athletes and rather sedentary controls. However, during the race GM concentration decreased in brain regions normally associated with higher visuospatial and language tasks. Also the possible reduction of the energy intensive default mode network as a means to conserve energy during catabolism is discussed. These changes are reversible after 8 months and seem to be adaptive.

A leprosy patient presenting with ejaculatory dysfunction
C. Baydar, T.K. Yoldas. Department of Neurology, Dişkapı Yıldırım Beyazıt Education and Training Hospital, Ankara, Turkey

Leprosy is a chronic granulomatous disease of the skin and nerves caused by the bacillus Mycobacterium leprae (M. leprae). M. leprae has a high affinity for Schwann cells. This tissue tropism is the basis of the characteristic nerve damage associated with leprosy, often leading to peripheral neuropathy. The ulnar nerve is most commonly involved. The patients predominantly present with mononeuritis multiplex. Sometimes, but not very frequently, involvement of the pudendal nerve is also observed. In this case report, a patient, with a diagnosis of leprosy and presented with ejaculatory dysfunction is followed up.

Voltage-gated potassium channel antibodies (VGKC-Ab) associated with limbic encephalitis: Borderline positive levels in Asian patients?

J.H. Luo a, N.D.M.D. Wijesoma b, K.E. Lee c, Roman-Filip d. aYong Loo Lin School of Medicine. National University of Singapore, Singapore; bDepartment of Neurology, National Neuroscience Institute, Singapore, Singapore

Background: VGKC-Ab has been described in patients with features of limbic encephalitis (LE). In contrast with paraneoplastic LE which typically heralds a poor prognosis, VGKC-Ab-related LE has potential for reversibility. This has thus far been under-documented in Asian patients.

Objectives: The objective of this study is to describe the clinical, serological and neuroimaging features of eight Chinese patients with encephalitis associated with borderline positive titres (100–400 pM) of VGKC-Ab.

Patients and methods: Eight Chinese patients (four males, four females; aged 23–87 years) were identified in a tertiary centre over a 3-year period. Clinical data was acquired from a retrospective review of medical records.

Results: Memory impairment and psychiatric symptoms were prominent in five older patients. Three experienced disorientation and agitation. Three reported sleep disturbances or hallucinations. Two younger patients had seizures. One suffered quadriparesis. All eight had elevated VGKC-Ab (ranging 113–352 pM). Paraneoplastic antibodies were negative in all six tested. Autoantibody testing revealed thyroperoxidase, thyroglobulin, antinuclear, NMDA or NMO antibodies in five patients. CSF studies of five patients showed leucocytosis with lymphocytic predominance in three. Cranial MRI demonstrated hippocampal abnormalities in four patients. Seven patients received intravenous immunoglobulin, methylprednisolone or plasmapheresis. Six patients demonstrated good clinical response to treatment, with four achieving pre-morbid function and two undergoing active rehabilitation. Two exhibited persistent psychiatric deficits.

Conclusions: Clinical features at presentation and response to treatment differ based on age — older patients present with cognitive and behavioural changes while younger patients present with seizures and have better outcome. Concomitant autoantibodies may be a feature in Asian patients with borderline positive VGKC-Ab.

The pharmacological effect of Artemisia absinthium extract in protecting adult rats against lead neurotoxicity

W. Sansar, H. Gamrani. University Cadi Ayyad, Faculty of Sciences Semlalia, Marrakech, Morocco

Lead (Pb) is a heavy metal with no apparent biological function. It is recognized as a dangerous neurotoxin, since it induces morphological and functional abnormalities in the brain. Several studies reported, in the rat brain, the antioxidant and anti-inflammatory effects of aqueous extracts of Artemisia absinthium. Here, we investigated the potential role of A. absinthium aqueous extract in protecting brain against the effect of chronic lead exposure, especially on the dopaminergic neurons together with the glial system. Using immunohistochemistry of tyrosine hydroxylase (TH), the number of dopaminergic neurons in substantia nigra pars compacta (SNpc) was found to decrease by 50% in lead-treated group, while the glio fibrillary acidic protein (GFAP) immunohistochemistry shows hypertrophic immunoreactive astrocytes in the frontal cortex. The quantification of immunolabelled astrocytes shows an increase by 48% in comparison with controls. Pharmacological treatment with A. absinthium aqueous extract (200 mg/l) during 4 weeks restores most of the changes in the glial and dopaminergic systems which occur in lead intoxicated rats. Our findings suggest that A. absinthium might be beneficial for the treatment of the glial and neuronal alterations observed during chronic lead intoxication in adult rat.

The comparisons of adrenergic and vagal baroreflex sensitivity between patients with diabetic neuropathy and control group

T.-H. Hur a, H.-J. Kim a, D.-H. Lee b, T.-K. Lee b. aDepartment of Neurology, Soonchunhyang University Bucheon Hospital, Gyeonggi-do, Republic of Korea; bSoonchunhyang University College of Medicine, Soonchunhyang University Bucheon Hospital, Gyeonggi-do, Republic of Korea

Background: The baroreflex is responsible for maintaining stable blood pressure despite of positional change. Measurement of baroreflex sensitivity (BRS) using beat-to-beat blood pressure monitoring can calculate the adrenergic and vagal components separately. Several indexes during Valsalva maneuver (VM) have recently been introduced and an index of the adrenergic components of the BRS has been validated. Autonomic neuropathy in diabetic patients is relatively common and bears high mortality and morbidity.

Objective: The purpose of this study is to analyze if the adrenergic and vagal components of BRS could selectively be damaged in diabetic autonomic neuropathy (DAN) and if it would be correlated with Composite Autonomic Symptom Scale (COMPASS).

Patients and methods: We prospectively collected patients with diabetic neuropathy and control group. We performed Korean version of COMPASS, and VM using Finapress® in both groups. During VM, four phases from phase 1 to phase 4 were defined and three variables including pressure recovery time (PRT), adrenergic BRS (BRSa), and vagal BRS (BRSv) were calculated.

Results: The statistical consequences of COMPASS, PRT, BRSa, and BRSv in DAN (n = 37) were 37.1 points (±16.9), 2.90 s (1.880–7.250), 5.50 mm Hg/s (2.20–9.50), and 0.27 min/mm Hg (±0.27). Control group (n = 62) was checked as 32.13 points (±18.4), 2.0 s (1.880–26.25), and 0.42 min/mm Hg (±0.29) respectively.

Conclusions: Our study showed that BRSa, BRSv, and PRT in DM patients were lower and longer than in control group. However, there was no meaningful difference in COMPASS between two groups. We concluded that especially, adrenergic component of baroreflex sensitivity (BRSa, PRT) would be more predictive for the severity in DAN.

Neurosyphilis in a young patient presented as rapid cognitive decline: Case report

A. Ungureanu, D. Radu, L. Prodan, C.C. Roman-Filip. Neurology Department, Academic Emergency Hospital Sibiu, Sibiu, Romania

We present the case of a 38 year old man who was admitted for a rapid cognitive decline and headache. CT and MRI studies revealed a normal pressure hydrocephalus. He was assessed for surgery and a ventriculo-peritoneal shunt was realized. Neurologic examination
revealed mild spastic tetraparesis, right Argyll-Robertson pupil, gait disturbance, severe cognitive decline with amnestic aphasia and asymmetric myoclonic jerks predominantly in the lower limbs. The CSF showed normal pressure, 12 lymphocytes/mm³, 0.55 g/L proteins, and positive TPHA test. Serum TPHA and VDRL were intense positive at small dilutions with negative HIV serology. EEG showed a theta rhythm with intermittent generalized triphasic discharges. Psychiatric and neuropsychological examinations showed a MMSE theta rhythm with intermittent generalized triphasic discharges. Serum TPHA and VDRL were intense positive. CSF showed normal pressure, 12 lymphocytes/mm³, 0.55 g/L proteins, and positive TPHA test. Serum TPHA and VDRL were intense positive at small dilutions with negative HIV serology. EEG showed a theta rhythm with intermittent generalized triphasic discharges.

Background: Chronic inflammatory demyelinating polyradiculoneuropathy (CIDP) is characterized by relapsing or progressive dysfunction of the motor and/or sensory fibers of the peripheral nervous system due to inflammatory demyelination. CIDP is important to recognize as it is potentially treatable.

Objective: The objective of this study is to study the clinical and electrophysiological characteristics of patients with CIDP and compare between CIDP patients with and without diabetes mellitus.

Methods: Prospective study of patients referred for electrodagnostic studies in Benghazi who fulfilled the diagnostic criteria of the European Federation of Neurological Societies/Peripheral Nerve Society for CIDP. The patients were studied between August 2003 and 2009.

Results: A total of 85 patients were studied. Their mean age was 57 years (range 27–80) and 48 were males. Fifty-six patients had DM type-II. The mean duration of diabetes was 7 years (ranged 1–20 years). The main duration of illness was 10 months (ranged between 2 and 60 months). Weakness and paraesthesia of the lower limbs were the most common symptoms. Electrophysiological studies were taken on all patients and demonstrated marked slowing and more frequent unrecordable motor and sensory as well as F-wave responses in patient with CIDP and diabetes (CIDP-D). The frequencies of conduction block and electromyographical (EMG) evidence of denervation and reinnervation were similar between idiopathic CIDP (I-CIDP) and CIDP-D.

Conclusion: CIDP associated with diabetes mellitus (CIDP-D) had more severe disease and was associated with more significant and higher frequency of electrophysiological findings that indicated a demyelinative neuropathy compared with idiopathic CIDP (I-CIDP).

The frequency of functional disorders in new neurology-outpatients: An audit study
J.P. Zucchettil, C. Medleyj, S. Alusil, 2Psychologia e Scienze Cognitive, Università degli Studi di Trento, Rovereto, Italy; 2Foundation Programme, Aintree University Hospital NHS Foundation Trust, UK; 2Department of Neurology, The Walton Centre for Neurology and Neurosurgery, Liverpool, UK

Background: A few studies have investigated the incidence of functional disorders among neurological patients. They demonstrate around 16% of patients present with functional symptoms that neurologists are unable to explain organically.

Objective: Information on the nature and relative frequency of diagnoses made in referrals to outpatient neurology clinics is essential to target specific services tailored for patients’ needs. The aim of this study is to address the frequency of functional symptoms among neurology outpatient referrals to The Walton Centre NHS Trust (Liverpool, UK).

Method: 503 medical notes of newly referred outpatients attending neurology clinics at The Walton Centre in June 2011 were collected and screened. For each patient, the following information was gathered: age; main presenting symptom; whether the diagnosis was organic or functional; was the organic/functional diagnosis changed in 1 year time; was a second opinion requested and eventual diagnosis formulated.

Results: 15% of the referrals examined exhibited functional symptoms (n = 77). Of these, 65% (50) were females and 35% (27) were males. Functional disorders were the second most common diagnostic group, with the most common being headache. The most common functional symptoms were, in order: sensory disturbance, blackouts/funny turns/dizziness, seizures. Functional patients had a younger average age of 42.5 years, compared with 48 for all patients. Results confirm those of previous studies.

Conclusions: The percentage of functional symptoms is quantitatively relevant and cannot pass unnoticed, requiring special attention from both the clinicians and the local health service. Different professional approaches must be integrated in a unique multidimensional treatment.

Susac’s syndrome: Three cases with predominant branch retinal artery occlusion at first presentation
T. Seifert-Heldt, A. Barounig, H. Offenbacher, M.K. Storch, M. Weger, B. Langner-Wegscheider, F. Fazekas. 1Department of Neurology, Medical University of Graz, Graz, Austria; 2Department of Ophthalmology, Medical University of Graz, Graz, Austria; 2Department of Neurology, LKH Knittelfeld, Knittelfeld, Austria

Background: Susac’s syndrome encompasses the triad of encephalopathy, branch retinal artery occlusion and hearing loss. At first presentation, this clinical spectrum is usually incomplete which often delays branch diagnosis and appropriate treatment.

Patients: We report three cases of Susac’s syndrome with predominant branch retinal artery occlusion at first presentation.

Results: In two cases, diagnosis was made early in the disease course and aggressive immunosuppression could eventually prevent persistent visual field deficits. In the third patient, diagnosis and initiation of corticosteroid treatment were delayed and persistent visual field deficits developed. Retinal artery fluorescein angiography showed leakage of arteries at first presentation in all three patients.

Pathognomonic corpus callosum hyperintensities on magnetic resonance imaging were found in two of our patients at presentation and helped in establishing the diagnosis early.

**Conclusion:** Only one of our patients showed the full triad of Susac's syndrome including hearing loss. Retinal artery fluorescein angiography revealed to be crucial for early diagnosis and useful in treatment monitoring.

**Anaplastic ependymoma with ependymoblastic multilayered rosettes**  
S. Nobusawa, A. Suzuki, M. Nagaishi, H. Ikota, H. Yokoo, J. Hirato, Y. Nakazato. "Department of Human Pathology, Gunma University Graduate School of Medicine, Japan; 4Department of Pathology, Gunma University Hospital, Maebashi, Japan"

**Background:** Anaplastic ependymoma, WHO grade III, is a malignant glioma with ependymal differentiation characterized by high mitotic activity often accompanied by microvascular proliferation and necrosis, where, generally, much fewer ependymal rosettes are found than in ependymoma, WHO grade II. Ependymal rosettes, forming a single layer of tumor cells, differ from ependymoblastic multilayered rosettes which are characteristic histological features of ependymoblastoma, a variant of central nervous system primitive neuroectodermal tumor.

**Patient history:** A 22-year-old woman had a headache and nausea, and was admitted with a generalized convulsion one month later. Diagnostic imaging revealed a mass lesion of the left frontal lobe. A partial resection of the mass was then performed and the pathological diagnosis was “malignant ependymoma.” The patient deteriorated gradually with local progression and died 23 months after the surgery, at the age of 24. An autopsy was performed.

**Methods and Results:** Microscopic examination showed the aggregation of true rosettes with multilayering of tumor cells resembling the ependymoblastoma histology. Single-layered ependymal rosettes and perivascular radial arrangements of the tumor cells were also observed. FISH analysis and differential PCR revealed the absence of 19q13.42 amplification, a specific molecular hallmark of ependymoblastoma and embryonal tumor with abundant neuropil and true rosettes, supporting the diagnosis of anaplastic ependymoma.

**Conclusion:** Anaplastic ependymoma can quite rarely show ependymoblastic multilayered rosettes. Although differentiating this type of ependymoma from ependymoblastoma is challenging, it is expected that the incorporation of molecular and cytogenetic analyses would facilitate the diagnosis.

**Analysis of background activity in ventilated preterm infants with hypoxic ischemic encephalopathy**  
T. Melashenko, Pathology of Newborn Department, Saint Petersburg Pediatric Medical University, Saint Petersburg, Russia

**Introduction:** The electroencephalogram (EEG) is used as a diagnostic tool for investigation of dysfunction activity and maturity of preterm baby. [1. Alvarado-Guerrero, et al, 2011]. Study of EEG recording of ventilated preterm infants can indicate changes of cerebral activity and diagnose the degree of hypoxic ischemic encephalopathy (HIE).

**Method and study groups:** EEG recordings were obtained with 13 electrodes by using the international 10–20 system placement and investigation of background activity. All EEG recordings was obtained for 80 preterm baby in age corrected with term newborn. Of those, we enrolled preterm ventilated infants with HIE-50 babies and preterm not ventilated infants without HIE-30 babies.

**Results:** All ventilated infants (50/98 ± 4%) have a dominating EEG frequency which is delta activity and not in ventilated infants (19/63 ± 17%). The background depression (amplitude < 25 mV) was observed only for ventilated babies (24/48 ± 13%).

**Conclusions:** Chronic-stage abnormalities of background EEG were diagnosed in ventilated preterm babies with HIE. These changes include dismaturity patterns — slow waves activity (delta frequencies) and depression delta activity.

Background and purpose: From the studied variables in subarachnoid hemorrhage (SAH) risk, hypertension is probably the most controvertible one. The aim of this study was to determine whether confirmed hypertension, prospectively diagnosed with strict criteria, is an independent risk factor for aneurysmal SAH.

Methods: A case–control study was conducted in 2 Colombian cities between July 2004 and June 2005. There were 163 new cases of SAH (mean age 51 years; 107 were women) with 2 controls per case: 1 hospital and 1 community control. Hypertension was defined according to cardiovascular criteria, based on target organ damage. In addition to hypertension, other variables were studied: present smoking, recent alcohol consumption, alcohol dependency, coffee consumption, cocaine use, and body mass index. A multivariate logistic regression model was used to determine whether hypertension was an independent risk factor.

Results: Among the studied variables, including confirmed hypertension, only present smoking became an independent risk factor for SAH.

Conclusions: Confirmed hypertension is not an independent risk factor for aneurysmal SAH.

Dynamics of neurological symptoms in acute period of leptospirosis
M. Barabanova, N. Sviustov, O.V. Stoyanova, V.K. Oranskaya. Nervous System Diseases and Neurosurgery, Kuban State Medical University, Krasnodar, Russia

Background: Leptospirosis is a zoonosis, that, when developing in human, may affect central nervous system. Krasnodar region is endemic for leptospirosis, the morbidity varies from 7.75 up to 29.6 per 100 thousand.

Objective: To investigate the neurological state’s dynamics in patients with leptospirosis.

Patients and methods: 66 patients (average age 49.5 ± 4.2 years old) with an ikterico-hemorrhagic form of leptospirosis were observed.

Results: By the first disease week end 57 (86.4%) patients developed acute encephalopathic syndrome with confusion of consciousness as a depression predominance 36 (54.5%), or psychomotor agitation 24 (36.4%). Focal neurological symptoms appeared at the second week of the disease and were presented by extrapyramidal 6 (9.1%), cerebellar 14 (21.2%) patients, and pyramidal signs with central palsy of limbs 9 (13.7%) and Seizure syndrome 17 (25.8%). Focal neurological deficiency was associated with cerebral edema in 32 (48.5%) cases, serous meningitis 12 (18.2%), serous meningoencephalitis 1 (1.5%) subarachnoid hemorrhoidopathy 1 (1.5%). 68.6% patients developed distal para-infectional polyneuropathy.

Conclusion: When affecting central nervous system, leptospirosis begins with diffuse neurological symptoms, changed by focal neurological deficiency till the second week of the disease end. Depression of consciousness and generation of diffuse and/or focal neurological symptoms is the objective marker of severe clinical course of iktero-hemorrhagic form of leptospirosis.

Isolated cerebral schistosomiasis presenting as seizure in a 32 year old female: A case report
L. Trabocco, V. De Guzman, M. Rosario, E. Esposo, C. Barredo. Institute of Neurosciences, St Luke’s Medical Center, Quezon City, Philippines; Institute of Neurosciences, St Luke’s Medical Center, Quezon City, Philippines; Department of Surgery, St Luke’s Medical Center, Quezon City, Philippines

Schistosomiasis, or Bilharziasis, is a disease caused by parasitic trematodes. It is considered by the WHO as one of the Neglected Tropical Diseases. In Asia, Schistosoma japonicum is more commonly found. Approximately 2.5 million are directly exposed in our country alone. They usually migrate to the gastrointestinal or the genito-urinary veins of the body, to be shed along with the feces and urine, completing their lifecycle outside the body to their corresponding snail hosts. A cerebral manifestation is a rare presentation of the disease. There should be a high index of suspicion, especially in endemic countries, and differentials can include Malaria, Toxoplasmosis or Tuberculoma.

Pseudobulbar affect (PBA) in multiple sclerosis (MS), Parkinson’s disease (PD), stroke and amyotrophic lateral sclerosis (ALS)

Background: PBA is an affective disinhibition group of signs and symptoms characterized by uncontrollable episodes of laughing or crying. Its prevalence in ALS is 34%, in MS 8%, in PD 16% and in stroke 15%. There is currently no conclusive information about the involvement of the pyramidal or extrapyramidal tract in its pathogenesis.

Objective: to diagnose PBA in ALS, MS, PD and non acute stroke.

Materials and Methods: 10 patients with PD, non acute stroke (more than three months since the diagnosis), MS remission recurrence type and ALS that concurred spontaneously to a specialist follow-up between April and June 2012 were evaluated with the CNS-LS and PLACS PBA scales.

Results: There were 23 men and 17 women. The mean age was 54 (±13.31) years for ALS, 37 (±12.14) for MS, 71 (±16.59) for stroke and 61 (±9.92) for PD. Sixteen patients were diagnosed of PBA with de CNS-LS (31.2% PD, 25% ALS, 25% Stroke and 18.8% MS). 9 were diagnosed with PLACS (33.3% Stroke, 33.3% ALS, 22.2% PD y 11.1% MS). Of them all, 75% had pyramidal tract dysfunction, 22.5% extrapyramidal and 5% none of the above. Between those diagnosed by CNS-LS, 75% had pyramidal signs and 25% extrapyramidal. With PLACS the percentages were 88.9 and 11.1 respectively.

Conclusion: PD was the disease with most PBA diagnoses with CNS-LS. With PLACS were ALS and Stroke. MS had the lowest PBA diagnoses with both scales. PBA patients had the same frequency of pyramidal and extrapyramidal dysfunction as the general population interviewed.

Safety of bevacizumab with or without anticoagulant treatment in neuro-oncological patients: A systematic review
G. Simonetti1, E. Trevisan2, P. Gaviani3, E. Lamperti2, A. Salmaggi4, A. Silvani2. 1Department of Neurooncology, Fondazione IRCCS Istituto Neurologico Carlo Besta, Milan, Italy; 2Department of Neuroscience, University and San Giovanni Battista Hospital, Turin, Italy

Background: Neoangiogenesis has recently become a major target for the development of new antineoplastic drugs. The most serious adverse events linked to angiogenesis inhibitors are venous/arterial thromboembolism and hemorrhage. Thus, there is a need to define with more certainty the impact of these new drugs in terms of adverse effects in neurological patients.

Objective: the aim of the study is to assess the risk of venous-thromboembolism (VTE) and bleeding in neurooncological patients treated with bevacizumab with or without concomitant anticoagulant therapy.

Material and methods: a review of published literature was performed in Medline, from which we identified 476 records. We assessed for eligibility 27 full-text articles including retrospective analyses, retrospective reviews, and open label trials. The investigated drugs included bevacizumab alone, bevacizumab plus chemotherapy with/without concomitant radiation therapy; only two articles dealt with bevacizumab in association with anticoagulant treatment.

Results: a total of 2208 neurooncological patients were identified and included in the analysis. Data confirmed that patients receiving bevacizumab had a major risk of developing VTE that increased when bevacizumab is associated with radio-chemotherapy (4.27% vs. 7.46%). Regarding bleeding, data showed that patients treated with anticoagulant had a significantly increased risk of severe intracranial bleeding compared to patients not receiving anticoagulant therapy (0.6% vs 8.2%).

Conclusion: the use of bevacizumab combined with chemoradiotherapy is associated with a higher risk for VTE compared to patients receiving antiangiogenic therapy alone. The associated use of anticoagulants and bevacizumab far increases the risk of developing intra-extra cranial bleeding higher than grade 3, compared to patients receiving bevacizumab alone.

Alexander von Humboldt and his medical research
L. Harms1, L. Dognitz2. 1Department of Neurology, Charité Universität medizin Charité, Germany; 2Department of Neurology, Jewish Hospital, Berlin, Germany

Background: Medical research in the second half of the 18th c was characterised by a remarkable dynamism in theory construction and a turn towards hard science. For a long time Humboldt’s (AvH) contribution to this was overshadowed by his other achievements.

Objective: Inspired by Galvani’s publication of Animal Electricity in 1791, AvH conducted numerous neurophysiologic experiments between 1792 and 1797. He published his results in “Experiments on stimulated muscular and nervous tissue” in 1797. How significant were his findings?

Material and methods: In nearly 4000 stimulation tests by means of electrical power he experimented on 3000 different animals and also on himself. Having perused his publication and analysed his ideas, methods and results, we demonstrate his procedures and achievements with the help of examples.

Results: AvH often drew precise and far-reaching conclusions of which an essential one was that there was no stable nerve excitability, but that it depended on numerous factors. However, perplexing observations are also discussed, such as the additive nature of his experiments and the absence of a systematic approach. AvH conducted his experiments with utmost skill strictly following the procedure of Observation – Experiment – Formal application of mathematics – Conclusion, which was by no means a common approach in physiology at the time.

Conclusion: AvH’s work must be seen in the context of contemporaneous schools of medical thought. Being influential in a number of areas, his major achievement was that he pioneered the exact scientific research methodology of the 19th century. His work reflects 19th c medicine in an enlightening way.

doi:10.1016/j.jns.2013.07.2102
Sorokin.

Background: The atherosclerosis of arteries of the legs causes development of the chronic ischemia, however more expressed neurologic disorders are observed in case of sudden termination of blood flow into the extremity.

Material and methods: We surveyed the man of 49 years old who had sudden pains, numbness and weakness in the legs. Neurologic survey has revealed 2-sided neuropathy of fibular and tibial nerves with expressed paresis of foot. Ultrasonic methods and electromyography are applied to blood flow estimation in the main arteries and a condition of peripheral nerves of the legs.

Results: Duplex scanning has revealed dense and soft circular atheromatous plaques in the abdominal aorta, signs of 2-sided occlusion of the general and external iliac arteries, stenosis of 50% of the lumen of both general femoral arteries and considerable decrease in the speed of blood flow in the right deep and left superficial femoral arteries. Operative intervention was made — thrombectomy from distal aorta, endartectomy from superficial femoral artery of the left hip, bilateral aortofemoral shunting by a synthetic artificial limb, cross-section sympathectomy of the left side. After the operation the blood flow in the legs and the function of fibular and tibial nerves were practically completely restored. However, electromyography showed the evident nature of axonal affection of fibular and tibial nerves from both sides of the foot area, that reflects depth of damage of nervous structures.

Conclusion: On-time prevention of atherosclerotic affection of the main vessels of extremities is necessary for prevention of ischemic neuropathies and persistent incapacity.

Investigating the role of poly-(ADP-Ribose)-polymerase as a therapeutic target in pediatric high grade glioma
Y. Chornenky*, P. Agnihotri**, P. Bukczkowicz**, P. Rakopoulos*, O. Becher*, C. Hawkins*, 1Arthur Medicine and Pathobiology, University of Toronto, Canada; 2Arthur and Sonia Labatt Brain Tumour Research Centre, Hospital for Sick Children Research Institute, Toronto, ON, Canada; 3Preston Robert Tisch Brain Tumor Center, Duke University Medical Center, Durham, NC, USA

Pediatric supratentorial high-grade astrocytomas (pHGs) and diffuse intrinsic pontine gliomas (DIPGs) are devastating pediatric malignancies for which no effective therapies exist. Poly-(ADP-Ribose)-Polymerase (PARP) protein expression is found in ~60% of DIPGs suggesting PARP may be a potential therapeutic target. PARP1/2 were characterized by Western-blotting in normal human astrocytes (NHA), pHGA cell lines (SJG2, SF-188), DIPG cell lines (DIPGM, DIPG58), and one murine brainstem glioma cell line (mBSC). Cell viability in response to different dosages of Olaparib, Veliparib, or Niraparib was determined using the MTT Assay. Levels of PARP activity, apoptosis, and DNA damage were determined by Western blotting against PAR, cleaved PARP, and phosphorylated γH2AX, respectively. Western-blotting demonstrated that, compared with NHA, PARP1 were highly expressed in SJG2, DIPGM, and DIPG58 cells. PARP2 expression was only detected in SJG2 cells. All PARP inhibitors reduced PARP activity as indicated by reduced PAR levels. Olaparib reduced SJG2, mBSC, DIPG58 and DIPGM cell viability at concentrations of 5 or 10 μM (~0.05), Whereas Niraparib induced cytotoxicity at concentrations of 2 μM and above (~0.05). Olaparib and Niraparib induced DNA damage and apoptosis in SJG2 at doses of 5, 10 μM and 2, 5, 10 μM, respectively. Our data provides in vitro evidence that PARP inhibition may be an effective therapeutic avenue for treatment of pHG and DIPG. Furthermore while all PARP inhibitors suppress PARP activity not all PARP inhibitors reduce cell viability. Thus not all PARP inhibitors can be expected to be equally efficacious in a clinical trial setting.

Central nervous system manifestations of lassa fever in Nigeria and the effect on mortality  
P.O. Okokhere, L.A. Bankole, G.O. Akpede. *Department of Internal Medicine, Irrua Specialist Teaching Hospital, Irrua, Nigeria; bDepartment of Paediatrics, Irrua Specialist Teaching Hospital, Irrua, Nigeria

Introduction: Lassa fever (LF) is endemic in Nigeria and causes severe multisystem disease in some infected individuals. The central nervous system (CNS) may be involved in the later stages of the course of the illness resulting in an increase in mortality. There is a paucity of data on the CNS manifestations of LF in Nigeria and the effect on mortality.  
Objective: To determine the CNS manifestations of LF and the effect on mortality.  
Method: 162 patients (85 males and 77 females) who were RT-PCR confirmed for LF and admitted to our hospital between January 2008 and December 2010 were studied. They were grouped into severe CNS (SCNS), non-severe CNS (NSCNS) and no CNS (NCNS) features, respectively.  
Results: 30.9% (50 patients: 24 males; 26 females) had SCNS features (seizure, coma, meningitis, restlessness, ataxia, deafness, disorientation, confusion, tremors, irritability, irrational behaviour); 11.1% (18 patients: 10 males; 8 females) had NSCNS features (miningism, dizziness, vertigo, drowsiness); 58% (94 patients 51 males; 43 females) had NCNS features. Case fatality rates (CFR) were 74% (37/50) for SCNS, 27.8% (5/18) for NSCNS and 13.8% (13/94) for NCNS groups respectively.

Conclusion: A wide spectrum of CNS features was seen in a significant number of our patients. 73.5% (50/68) of patients with CNS features had SCNS manifestations with consequent high CFR.

doi:10.1016/j.jns.2013.07.2107
were all normal. The first out of 3 blood cultures grew Listeria monocytogenes. The patient was treated with IV gentamycin for 2 weeks and a 6-week course of high dose IV amoxycillin and cotrimoxazole. He made steady progress, being left with mild left hemiparesis, and five-week interval MRI confirmed considerable improvement.

**Conclusion:** Listerial infection should be considered in the differential diagnosis of acute myelitis and/or encephalitis with abscess formation, even in immunocompetent patients.

**Viral meningitis triggers anti-NMDA receptor encephalitis**

C. Treepong, T. Termglinchan, M. Apiwattanakul. Department of Neurology, Prasat Neurological Institute, Bangkok, Thailand

**Background:** Anti-NMDA receptor encephalitis is recognized increasingly in the past few years. Like other autoimmune diseases, environmental factors such as infection can precipitate autoimmune disease.

**Objective:** To review clinical course of the patient who had viral meningitis with subsequently developed anti-NMDA receptor encephalitis.

**Patients and methods:** A case report of twenty-seven year old priest who was admitted at Prasat Neurological Institute during 12th November to 14th December 2012.

**Results:** A 27 year-old priest developed fever and nuchal rigidity for 2 weeks before arrival. Neurological examination showed neck stiffness, but fully consciousness. CSF analysis demonstrated pleocytosis 380 cells (lymphocytic predominate) with slightly elevated protein, but normal glucose. PCR for herpes was positive for Human herpesvirus type 7. During the course of intravenous acyclovir treatment, he was improved. But later on he developed acute psychosis, body stiffening with limb dystonia, dysautonomia and altered mental status respectively. MRI brain revealed abnormal signal at left posterior thalamus and left amygdala. EEG showed moderately severe diffuse encephalopathy. NMDA-receptor antibody was detected in CSF. The intravenous methylprednisolone and plasma exchange were started concurrently. Oral prednisolone and symptomatic treatment were continued. He was discharged after one month and his clinical full recovery after 1 month follow up.

**Conclusion:** Human herpesvirus type 7 caused viral meningitis and trigger anti-NMDA receptor encephalitis.

**A novel KRAS gene mutation of Noonan syndrome with severe peripheral nerve hypertrophy**

Y. Ando, T. Kawakami, M. Morita, Y. Aoki, Y. Matsubara, I. Nakano. 1st Department of Neurology, Jichi Medical University, Shimotsuke Tochigi, Japan; 2nd Department of Neurology, Oyama Municipal Hospital, Oyama Tochigi, Japan; ‘Department of Medical Genetics, Tohoku University School of Medicine, Sendai Miyagi, Japan

We reported a female case of Noonan syndrome (NS) with the significant peripheral nerve hypertrophy. Because her gait disturbance gradually deteriorated and the nerve conduction velocity was obviously reduced, we firstly thought she had Charcot–Marie–Tooth disease. But, she did not have the mutation of PMP22 gene. The NS with peripheral neuropathy was comparatively reported as the merger with neurofibromatosis (NF). Cave au lait spots and skin tumors, which are characteristic in NF cases, were not seen in our case.

The RAS/MAPK syndrome including NS, a Cardio-Facio-Cutaneous (CFC) syndrome, Costello syndrome and so on is proposed as a comprehensive concept of the congenital malformation diseases by the molecular abnormality of RAS/MAPK pathway in recent years. A novel KRAS gene mutation (c.211T>G, p.Y71D) was identified in our case. There was a previous report the KRAS gene mutation (c.211T>C, p.Y71H) in CFC syndrome case with peripheral nerve disorder.

We think that the KRAS mutation “p.Y71D”, “p.Y71H” may be related to peripheral nerve disorder closely. In addition, the peripheral nerve disorder is the phenotype of NS, CFC syndrome, and furthermore RAS/MAPK syndrome.

**Oculographic analysis of nystagmus in orthostatic vertigo**

J.-H. Choi, J.-D. Seo, H.-J. Cho, S.-H. Kim, J.-H. Bae, K.-D. Choi. 1st Department of Neurology, Pusan National University Yangsan Hospital, Yangsan, Republic of Korea; 2nd Department of Neurology, Pusan National University Hospital, Republic of Korea; 3rd Department of Neurology, Dong-A University Hospital, Republic of Korea; 4th Department of Neurology, Dae-Dong Hospital, Busan, Republic of Korea

**Background and objective:** To elucidate objective vestibular dysfunction and the mechanisms of orthostatic vertigo.

**Materials and methods:** Thirty-three consecutive patients with orthostatic dizziness/vertigo and profound orthostatic hypotension (OH) were recruited. Profound OH was defined that systolic BP falls of ≥30 mm Hg occurs within 3 min after standing and is sustained for at least 2 min during head-up tilt test. Eye movements were recorded during two orthostatic challenging test, the Schellong and Squatting–standing test.

**Results:** All patients developed vertigo during orthostatic challenging test. Associated symptoms included blurred vision (45%), fainting (42%), and tinnitus (15%). Ten of 33 (30%) patients developed nystagmus during orthostatic challenging test with a latency of several seconds. Five of them showed mixed downbeat and horizontal nystagmus with or without torsional component, while the remaining four had pure downbeat nystagmus. In one patient, pure horizontal nystagmus and prominent downbeat nystagmus mixed with horizontal and torsional component appeared alternatively at a few second intervals. There were no significant differences in the mean drop of the BP between patients with or without nystagmus, but the patients with nystagmus had less longer duration of orthostatic vertigo than in patients without nystagmus (1.1 ± 1.6 vs 11.0 ± 9.7 mon, p < 0.001).

**Conclusions:** The present study demonstrates that OH can give rise to true vestibular vertigo, which may be due to transient ischemia of the peripheral labyrinth or the central cerebellum based on the objective eye movement recording. The nystagmus in longstanding OH might have disappeared due to central adaptation by repetitive orthostatic vertigo.

Transient global aphasia after cerebral arteriography: A possible reversible contrast medium neurotoxicity mimicking stroke

Y. Handok, S. Biguzzi, C. Bomprezzi, S. Morresi, M.G. Passarin, Ospedale Maurizio, Bufalini Cesena, Italy

Background: Cerebral arteriography (CA) is the gold standard in the diagnosis of many cerebral lesions. However it is an invasive procedure with potential complications. Transient neurologic deficits presumably caused by temporary disruption of the blood–brain barrier (BBB) due to nonionic radiographic contrast medium (CM) have been reported in literature.

Case report: A 69-year-old woman with a previous history of subarachnoid haemorrhage following basilar aneurysm rupture, underwent coiling in May 2010, was admitted in September 2011 in our unit for a routine CA. During CA she developed transient global aphasia with a complete recovery in a few minutes. Three hours after CA she presented aphasia again with total loss of the ability to speech and severe impairment of comprehension. An urgent magnetic resonance imaging (MRI) was performed. MRI diffusion did not reveal acute infarction and MRI angiography did not show any stenosis, spasm or occlusion at the cerebral vessels. The electroencephalogram (EEG) demonstrated a slow nonepileptiform activity in the left derivations. The day after another brain MRI was also negative. Neurologic signs and EEG abnormalities improved completely after 3 days.

Discussion: CM is reported to disrupt the BBB temporarily causing an encephalopathy that is usually self-limiting. This case report is atypical because no neuroradiological abnormalities due to a CM encephalopathy were found.

Conclusion: CM injection could be the possible causative factor of transient neurologic deterioration, despite the fact that the mechanism still remains speculative. EEG examination was more sensitive than MRI in detecting the brain injury in these patients.

Structural integrity of medial temporal lobes of patients with acute mild traumatic brain injury

T.M. Luoto1, K. Holli-Helenius2, A. Brander2, M. Waljas2, G.L. Iverson3, J. Öhman4, 1Department of Neurosciences and Rehabilitation, Tampere University Hospital, Tampere, Finland; 2Medical Imaging Centre and Hospital Pharmacy, Department of Radiology, Tampere University Hospital, Tampere, Finland; 3Department of Physical Medicine and Rehabilitation, Harvard Medical School and Red Sox Foundation and Massachusetts General Hospital Home Base Program, Boston, MA, USA

Background: The duration of post-traumatic amnesia (PTA) is commonly used to estimate the severity of brain injury. Lesions in temporal lobes, especially hippocampal regions, are thought to be connected to memory loss. However, conventional neuroimaging has not revealed neuropathological correlates of PTA in MTBI. Texture analysis (TA) is an image analysis technique that quantifies the minor MRI signal changes among image pixels and thus the variations in intensity patterns within the image.

Objective: The objective was to apply the TA technique to MR images of MTBI patients and control subjects and to assess the microstructural damage in medial temporal lobes of patients with MTBI with definite PTA.

Patients and methods: TA was performed for FLAIR images of 50 MTBI patients and 50 age- and gender-matched controls in the regions of amygdala, hippocampus, and thalamus. It was hypothesized that
(i) there would be statistically significant differences in TA parameters between patients with MTBIs and controls, and
(ii) the duration of PTA would be related to TA parameters in patients with MTBI.

Results: No significant textural differences were observed between patients and controls in the regions of interest. No textural features were observed to correlate with the duration of PTA. Subgroup analyses were conducted on patients with PTA > 1 h (n = 33) and compared the four TA parameters to the controls (n = 33). The findings were similar.

Conclusion: This study did not reveal significant textural changes in medial temporal structures that could be related to the duration of PTA.

Immunological profiles of the CSF from anti-NMDA receptor encephalitis patients

K. Tanaka1, M. Tanaka2, M. Fujita3, M. Matsu4, T. Takegami5; 1Neurology, Kanazawa Medical University, Uchinada-Machi, Japan; 2Neurology, Utano National Hospital, Kyoto, Japan; 3Life Science, Medical Research Institute, Kanazawa Medical University, Uchinada-Machi, Japan

Background: Anti-N-methyl-D-aspartate receptor autoantibodies (NMDAR-Abs) are thought to relate closely to the pathogenesis of NMDAR encephalitis. The antibody-titre parallels with the disease activities and antibody-deprivation treatments are effective. This disease is thought to be immune-mediated; however, studies have not been done extensively from the immunological aspects.

Objective: To study the immunological features of the patients with NMDAR encephalitis.

Design/methods:
1) Chronological changes of lymphocyte populations in the peripheral blood (PB) and CSF were studied with flow cytometry.
2) Cytokine concentrations in the CSF and sera were analysed with the cytokine antibody arrays.
3) The antibody-effects on the cells expressing NMDARs were studied under an incubation microscope.

Results:
1) In the early stage, CD4+CD29+ T/CD4+CD45RO+ T cells were increased in the patients’ CSF but not in the PB that gradually decreased parallel to the recovery.
2) There was no significant difference in each cytokine level between the patients’ CSF and the control CSF.
3) The NMDAR-expressed HEK cells that were incubated with patients’ CSF showed a fragmented staining pattern of NMDAR clusters inside the cells, while the cells incubated with the control CSF showed cell surface staining.

Conclusions: The lymphocyte-population profiles in the patients’ CSF suggested the active antibody production in the central nervous system without inflammatory cytokine production. The patients’ CSF stimulated endocytosis of the NMDARs suggesting protective effects of the antibodies for cells damaged from the extreme glutamate stimulation that resulted for the good outcome of this disease.

Compressed sensing technology could accelerate MRI at 7 T
G. Zhang1, G. Xiao2, Z. Dai3, S. Li4, R. Wu5. 1Shantou University Medical College, Shantou, China; 2Math and Applied Mathematics, Hanshan Normal University, Chaozhou, China

Background: Compressed sensing is an innovative theory of signal acquisition and processing based on the areas of applied mathematics. It works by using the mathematical algorithm to make an appropriate domain transformation for the collected signals and changing them into sparse or compressible signals. Afterwards, gathering the compressed signals directly to reconstruct the original signals at speedily, fine quality by the method of reconstruction algorithm. Due to its excellent temporal resolution advantages and satisfactory temporal resolution, compressed sensing has become a research hotspot in the field of medical imaging.

Objective: Based on the compressed sensing image reconstruction algorithm, we aim to use less data to obtain high quality reconstructed images which is good to accelerate medical imaging speed and reduce the radiation.

Material and methods: We firstly make a sparse representation of the image scanned at 7 T via a multiscale wavelet transform by using MATLAB. After being compressed, the retained energy is 99.29%, and the number of zeros is 93.73%. That is, by wavelet transformation, most coefficients are small though almost all the image pixels have nonzero values. Then we use the histogram method of the original image and synthesized image and make sure that the step of compression is significant. Finally, we reconstruct the image by the way of sequential minimal optimization.

Conclusion: This method will be significant to achieve high quality imaging in MRI at 7 T and it can reduce the cost during processing, storage and transmission.

Blink reflex excitability in patients with fibromyalgia syndrome
M.U. Aluct1, A.D. Turhanoglu1, 2Neurology Department, Dicle University, Diyarbakı, Turkey; 2Department of Physical Medicine and Rehabilitation, Mustafa Kemal University Hospital, Hatay, Turkey

Objective: We aimed to investigate the blink reflex excitability in fibromyalgia syndrome.

Subjects and methods: A total of 23 women with FMS and 14 healthy female controls were studied. Blink reflexes were elicited by electrical stimulation of the supra-orbital nerve. The stimuli were applied at first single stimulus and then paired stimulus by using ISIs by 100–600 ms. Electromyography signals were recorded from the right orbicularis oculi muscle.

Results: There are significant differences between FMS and controls in responses obtained by paired stimulus at 200–400 ms. Responses of R2 obtained by ISI at 100–400 ms were smaller than those obtained by single stimulus in controls. This inhibition disappeared in response to paired stimulus by 500, 600 ISI in controls. Yet, in FMS patients, this expected inhibition only appeared for iR2 and cR2 obtained at 100 ms ISI and then did not appear at the paired stimuli at 200–400 ms ISIs.

Conclusions: Lack of BR R2 response inhibition to paired stimulus by ISIs might be an electrophysiologic evidence that indicates central sensitization in FMS.

Determination of expression pattern of big-H3 gene in the process of regeneration in a model of zebrafish eye cryoinjury
G. Ahmedova, F. Yunusov, G. Rakhimbaeva. Neurology, Tashkent Medical Academy, Tashkent, Uzbekistan

Introduction: Humans have a rather limited capacity to regenerate after injury, while other vertebrates such as the zebrafish are capable of regenerating many anatomical structures. One of them is transforming growth factor beta induced regeneration (initially called BIGH3, BIG-H3), which signals have emerged as one of the components of the inductive process. Our investigation focused on the role of BIGH3 in the process of retinal regeneration in zebrafish after cryoinjury, wherein it was important to establish its pattern of expression.

Materials and methods: ABTL wild type zebrafish strains of both sexes 10–14 months of age were bred in standard fish facility conditions. In total, 45 zebrafish were used for the investigation of the process of regeneration in the retina. 40 of them were subjected to cryoinjury. Postinjury measurements were grouped into the following periods: 1 day postinjury (dpi), 2 dpi, 3 dpi, 5 dpi, 7 dpi, 15 dpi, 21 dpi and 28 dpi. RNA from retina was obtained by using the TRIzol reagent. RNA concentrations and purity were measured using UV-spectrophotometry. Equal amounts of RNA were reverse transcribed into cDNA using StrataScript reverse transcriptase. Quantitative RT-PCR was performed for each sample in duplicate, using β-actin primers as control.

Results: Pronounced upregulation of the expression was observed at 5 dpi. At 7 dpi, BIGH3 expression reached the highest point as

Sleep disturbances and risk of arterial hypertension and stroke in the 25–64 year old female population in Russia: WHO program “Monica–Psychosocial” study
V. Gafarova a,b, D. Panova a,b, E. Gromova a,b, I. Gagulina a,b, A. Gafarova a,b
 aCollaborative Laboratory of Cardiovascular Diseases Epidemiology SB RAMS, Russia; bFSBI Institute of Internal Medicine SB RAMS, Novosibirsk, Russia

Objective: To explore the influence of sleep disturbances (SDs) on relative risk of arterial hypertension (AH) and stroke in the 25–64 year old female population in Russia over 16 years of follow-up.

Material and methods: Under the third screening of the WHO “MONICA–psychosocial” program random representative samples of women aged 25–64 years (n = 870) were surveyed in Novosibirsk. The “Awareness and Attitude Towards the Health” questionnaire was used to estimate quality of sleep. From 1995 to 2010 women were followed for incidence of AH, stroke. Cox regression model was used for relative risk assessment (HR) of stroke, AH.

Results: The prevalence of SD in women aged 25–64 years was 64.9%. AH was developed in 33.4% of women, and stroke in 5.1% of women. HR of AH in women with SD was 4.35-fold higher (95.0% CI: 1.29–14.59; p < 0.05) and it was 2.69-fold higher (95.0% CI: 1.01–7.15; p < 0.05) compared to those with good sleep for the first 5 and 10 years of follow-up, respectively. HR of stroke in women with SD was 1.95-fold higher (95.0% CI: 1.01–3.79; p < 0.05) than in those without SD for over 16-years of study. Rates of AH incidence were significantly higher in middle and first-line managers and physical labor workers with SD (p < 0.05). There were tendencies of growth of stroke rates in married women with SD having college degrees.

Conclusions: The prevalence of SD in women aged 25–64 years is more than 60%. Women with SD had significantly higher relative risk of AH and stroke. Rates of AH development were more likely in managers and physical laborers.

Callosal regulation of contrast gain control machinery in the human visual system
T. Bocci a,b, M. Calcio c, L. Restani d, L. Briscese e, E. Giorlia b, S. Tognazzi d, S. Rossi b, L. Maffei b, F. Sartucci a,b, c, d, aDepartment of Neuroscience, Unit of Neurology, Pisa University Medical School, Pisa, Italy; bDepartment of Neuroscience, Neurology and Clinical Neurophysiology Section, Siena University Medical School, Siena, Italy; cCNR Neuroscience Institute, Pisa University Medical School, Pisa, Italy; dDepartment of Neuroscience, Cisanello Neurology Unit, Pisa University Medical School, Pisa, Italy

Background: Vascular cortical areas in the two hemispheres interact via the corpus callosum, but the precise role of the callosal pathway in visual processing remains controversial. As emerged from animal studies, the callosal pathway appears to transfer preferentially information related to high contrasts and low temporal/spatial frequencies.

Objective: Here, we have investigated the function of transcallosal projections in the human primary visual cortex (V1).

Materials and methods: Visual evoked potentials (VEPs) triggered by grating stimuli of different contrasts were recorded before and after functional inactivation of the occipital cortex of one hemisphere via off-line low-frequency repetitive transcranial magnetic stimulation (rTMS; 0.5 Hz stimulation for 20 min). VEPs were recorded in V1 before (T0), immediately after (T1) and 45' following the completion of rTMS (T2).

Results: Low-frequency rTMS has an inhibitory effect on VEP amplitudes at all contrasts in the treated side (p < 0.05). Remarkably, reduction of VEP amplitudes in the inhibited hemisphere at T1 was accompanied by an increase in VEP amplitudes in the contralateral side only at mid-high contrasts (50–90%: two-way repeated-measures ANOVA, p < 0.01). This disinhibitory effect was observed with both central and hemifield stimulation (p < 0.01). No changes in VEP amplitudes were observed when rTMS was applied to a cortical site more anterior with respect to V1 (p > 0.05).

Conclusions: These data provide the first evidence that a mechanism of transcallosal inhibition dampens neural responses at high contrasts in the human visual cortex.

Rabies virus infection is associated with mitochondrial dysfunction
A.C. Jacksona, T. Alandijanyb, W. Kammounic, S. Roy Chowdhuryb,c,
P. Fernyhougeb, G. von Campec, M. Hoffmannc,
P. Fernyhoughb, aInternal Medicine (Neurology) and Medical Microbiology,
University of Manitoba, Canada; bMedical Microbiology, University of
Russia; cPhthisiology, Irkutsk Regional Tuberculosis Hospital,
Irkutsk, Russia

Studies in an experimental model of rabies have shown major structural
changes in the brain involving neuronal processes that are associated
with severe clinical disease. Cultured adult mouse dorsal root ganglion
(DRG) neurons are permissive to infection with the CVS strain of rabies
virus (RABV). RABV-infected DRG neurons show axonal swellings and
4-hydroxy-2-nonenal protein adduct immunostaining, indicating evidence
of oxidative stress, and also reduced axonal growth versus mock-
infected DRG neurons. We hypothesized that RABV infection induces
mitochondrial dysfunction leading to oxidative stress. We investigated
the effects of RABV infection on mitochondrial parameters. In RABV
infection there were increased activities of electron transport chain
Complexes I and IV versus mock infection, whereas Complexes II–III,
citrate synthase, and malate dehydrogenase activities were unchanged.
Increases in Complex I activity, but not Complex IV activity, correlated
with cellular susceptibility to RABV infection. Mitochondrial respi-
ration studies showed that RABV infection increased maximal
uncoupled respiration and Complex IV respiration, whereas coupled
respiration and the rate of proton leak were unchanged. A high
mitochondrial membrane potential was generated. RABV infection
reduced the intracellular ATP level and altered the cellular redox
state with a high NADH/NAD+ ratio. In RABV-infected neurons, basal
production of reactive oxygen species (ROS) was unaffected, but a higher rate of ROS generation occurred with mitochondrial
substrates and inhibitors. We conclude that RABV infection induces
mitochondrial dysfunction leading to ROS overgeneration and oxidative stress. We postulate that the fundamental abnormality is due to the interaction of the RABV phosphoprotein with Complex I leading to its increased activity.

The value of preoperative fMRI in drawing attention to possible unexpected language area representations in a patient with anaplastic astrocytoma
M. Jehna, C. Enzingerab, G. von Campe, M. Hoffermanna,
L. Bruckmannb, G. Reishoferc, F. Payerf, F. Ebnera
aDivision of
Neuroradiology, Department of Radiology, Medical University of Graz,
Graz, Austria; bDepartment of Neurology, Medical University of Graz,
Graz, Austria; cDepartment of Neurosurgery, Medical University of Graz,
Graz, Austria; dDepartment of Neurosurgery, Medical University of Graz,
Graz, Austria

This is a case study of a right handed patient with a grade III anaplastic
astrocytoma in the superior frontal cortex with intra-axial extensions to
the corpus callosum. Presurgical functional MR imaging (fMRI) was
done to visualize language network distribution. Intraoperative direct
cortical stimulation (DCS) was accordingly done to prevent eloquent
functional regions from resection. fMRI results showed a distributed
language network including the left inferior frontal gyrus (pars
opercularis), the left and right frontal orbital cortices, the left insular
cortex, the left superior and middle temporal gyri, the left precentral
and postcentral gyri, and the supplementary area. Additionally,
statistically stable but unusual activation was found in the left superior
frontal gyrus (SFG). During surgery, DCS demonstrated that the
stimulation of the SFG — involved in language function according to
the fMRI — led to amnic disturbances. These deficits in word finding
were persistently reproducible when stimulating the same area.
 Afterwards, tumor removal was performed under navigation and
fluorescence guidance as well as subcortical electrostimulation, thus
preserving eloquent motor and language areas and tracts. Regarding the
results of the fMRI and DCS in this patient, it can be speculated that the
altered distribution of eloquent language areas could be the result of

1. Group of patients with tuberculosis of central nervous system
without HIV-infection (44 patients).

Results:
1st group:
Clinical forms of tuberculosis of the central nervous system: meningitis — 124 (63.3 ± 3.4%); meningo-encephalitis — 66 (33.7 ± 3.4%);
meningo-encephalo-myelitis — 1 (0.5 ± 0.5%); meningo-encephalo-myelitis — 4 (2.0 ± 1.0%); tuberculoma of the brain — 1 (0.5 ± 0.5%);
HIV-associated diseases (n = 181): candidosis of the gastro-intestinal system — 178 (90.8%), pneumocystic pneumonia — 3 (1.5%).
Social characteristics: drug abused (injecting drug users) — 158 (80.6 ± 2.8%), alcohol abused — 14 (7.1 ± 1.8%)

2nd group:
Clinical forms of tuberculosis of central nervous system: meningitis — 38 (86.4 ± 5.0%); meningo-encephalitis — 2 (4.6 ± 3.0%); meningo-
encephalo-myelitis — 3 (6.8 ± 4.0%); meningo-encephalo-myelitis — 1 (2.3 ±
2.0%); tuberculoma of the brain — 0.
Social characteristics: drug abused (injecting drug users) — 3 (6.8 ±
4.0%), alcohol abused — 7 (16.0 ± 3.0%).

Conclusion: Obtained data show severe epidemiological situation of tuberculosis in patients with HIV-infection in the Irkutsk Region of
Russia. Frequent combination of central nervous system tuberculosis
and HIV-infection was revealed. There was comorbidity with
meningo-encephalitis with generalized tuberculosis infection com-
bined with candidosis, and hepatitis in drug abused patients with
HIV-infection.

Epidemiology of tuberculosis of the central nervous system in patients with HIV-infection in the Irkutsk Region of Russia
Y.N. Bykova, T.P. Filippova, O.N. Novitskaya, aNeurology, Irkutsk State
Medical University, Russia; bPathology, Irkutsk State Medical University,
Russia; cPathology, Irkutsk Regional Tuberculosis Hospital,
Irkutsk, Russia

Background: Increasing prevalence of tuberculosis infection in the
Irkutsk Region of Russia remains one of the most common problems.
Objective: This study presents results of epidemiological investiga-
tion devoted to the comorbidity of tuberculosis and HIV-infection in
the Irkutsk Region.
Patients and methods: 240 patients (184 males and 56 females)
aged from 20 to 56 have been observed.

1. Group of patients with tuberculosis of central nervous system and
HIV-infection (196 patients).

2. Group of patients with tuberculosis of central nervous system
without HIV-infection (44 patients).

Results:
1st group:
Clinical forms of tuberculosis of the central nervous system: meningitis — 124 (63.3 ± 3.4%); meningo-encephalitis — 66 (33.7 ± 3.4%);
meningo-encephalo-myelitis — 1 (0.5 ± 0.5%); meningo-encephalo-myelitis — 4 (2.0 ± 1.0%); tuberculoma of the brain — 1 (0.5 ± 0.5%);
HIV-associated diseases (n = 181): candidosis of the gastro-intestinal system — 178 (90.8%), pneumocystic pneumonia — 3 (1.5%).
Social characteristics: drug abused (injecting drug users) — 158 (80.6 ± 2.8%), alcohol abused — 14 (7.1 ± 1.8%).

2nd group:
Clinical forms of tuberculosis of central nervous system: meningitis — 38 (86.4 ± 5.0%); meningo-encephalitis — 2 (4.6 ± 3.0%); meningo-
encephalo-myelitis — 3 (6.8 ± 4.0%); meningo-encephalo-myelitis — 1 (2.3 ±
2.0%); tuberculoma of the brain — 0.
Social characteristics: drug abused (injecting drug users) — 3 (6.8 ±
4.0%), alcohol abused — 7 (16.0 ± 3.0%).

Conclusion: Obtained data show severe epidemiological situation of tuberculosis in patients with HIV-infection in the Irkutsk Region of
Russia. Frequent combination of central nervous system tuberculosis
and HIV-infection was revealed. There was comorbidity with
meningo-encephalitis with generalized tuberculosis infection com-
bined with candidosis, and hepatitis in drug abused patients with

The role of Omega-3 fatty acids in patients with mild cognitive impairment by means of the PHOTOTEST
J. Romero Imbroda, Neurology Department, Hospital Comarcal de Melilla, Melilla, Spain

Background: Omega-3 fatty acids have been shown to improve cognitive function in patients with cognitive impairment. The PHOTOTEST is a short cognitive test indicated for the detection and monitoring of patients with cognitive impairment. It is applicable to illiterate patients and it produces results that are not influenced by educational level.

Objective: To assess, by means of the PHOTOTEST, the benefit of an Omega-3 food supplement in patients with mild cognitive impairment.

Patients and method: A total of 30 patients diagnosed with mild cognitive impairment were randomly divided into two groups: no Omega-3 group with normal treatment; and Omega-3 group with normal treatment plus the Omega-3 food supplement (2 ACUTIL capsules per day: 500 mg DHA + 80 EPA per day). Assessment of cognitive function was done by means of the PHOTOTEST at visit 0 (day 0), visit 1 (3 months) and visit 2 (6 months).

Results: 26 patients (mean age of 72.5 years) completed the study: 13 in the no Omega-3 group and 13 in the Omega-3 group.

PHOTOTEST results:
- Positive but not significant trend (p = 0.15) in the Omega-3 group at 3 months.
- Significant difference (p = 0.003) between the groups at 6 months in favour of the Omega-3 group.

Conclusion: After 6 months with the Omega-3 supplement, the PHOTOTEST results show a significant cognitive improvement in the group that received the Omega-3 supplement compared to the group not receiving any supplement. Omega-3 tolerance was good.

Characteristics of water channel protein aquaporin expression in Parkinson’s disease
A. Hoshia, A. Tsunoda, M. Tada, Y. Ugawa, M. Nishizawa, H. Takahashia, A. Kakita, *Neurology, Fukushima Medical University, Fukushima, Japan; bPathology, University of Niigata, Niigata, Japan; cNeurology, Brain Research Institute, University of Niigata, Niigata, Japan

We have previously reported marked changes in the expression of aquaporin 1 (AQP1) and AQP4 in relationship to amyloid β peptide (Aβ) deposition in human Alzheimer disease (AD) brains (Hoshi A et al. JNEN, 2012). In the present study, we investigated the AQP expression in autopsied brains affected by Parkinson’s disease (PD). Expression of α-synuclein (α-syn), GFAP, AQP1, and AQP4 in the temporal lobes of 11 patients with PD, 5 patients with AD, and 5 age-matched controls was examined immunohistochemically. In accordance with the DLB consensus criteria, the PD patients were classified to neocortical (n = 4), limbic (5), and brainstem (2) groups. In the neocortical group, AQP4 immunoreactivity appeared more intense and the number of AQP1-positive astrocytes was larger than those observed in the other groups except AD group. On the other hand, in the limbic/brainstem groups both AQP1 and AQP4 expressions were not changed in comparison with those of the controls. In the neocortical group, there were negative correlations between expression levels of AQP1 and α-syn, and also between those of AQP1 and Aβ42. Thus, in PD brains AQP expression seems altered in association with pathological processes involving the deposition of α-syn and Aβ.

Autosomal dominant cerebellar ataxias: A systematic review of clinical features

Background: Precise frequency and distinction of diverse clinical features of spinocerebellar ataxias (SCAs) are lacking.

Objective: To assess distinctive or common clinical signs of autosomal dominant cerebellar ataxias (ADCAs), genetically known as SCAs, through a systematic review.

Methods: A structured search was conducted by two independent reviewers in electronic databases up to September 2012. Publications containing proportions or descriptions of ADCA clinical features and written in several languages were included. Gray literature was also included and retrieved publication reference lists were back-searched. Clinical findings and demographic data from genetically confirmed patients were extracted. Data was analyzed by Chi-square test controlling for alpha-error inflation by Holm’s step-down procedure.

Results: One thousand sixty-two publications containing 12,141 patients (52% male) from 29 SCAs were analyzed. Mean age at onset was 35 ± 11 years. Onset symptoms in 3945 patients revealed gait ataxia as the most frequent sign (68%), whereas overall non-ataxia symptom frequency was 50%. Some ADCAs began frequently with non-ataxia symptoms, like SCA7 (visual impairment), SCA14 (myoclonus), SCA13 (developmental delay), and SCA17 (parkinsonism, psychiatric alterations and cognitive impairment). During the overall disease course, dysarthria (90%) and saccadic eye movement alterations (69%) were the most prevalent non-ataxia findings. Some ADCAs were clinically restricted to cerebellar dysfunction and others had frequently other features, allowing categorization into two groups: pure and mixed.

Conclusions: ADCAs encompass a broad spectrum of clinical features with an elevated frequency of non-ataxia symptoms. Some features distinguished several genetic subtypes from each other. An updated Harding’s classification is proposed.

Clinical and physiologic evaluation of breathing patterns of premature children with neurological complications of HIV infection
D. Izyumova, G. Izyumova, Khorezm Regional Multifield Medical Centre, Uzbekistan; V.K. Noonan, M. Dvorak, J. Borisoff, Republican Scientific Centre of Emergency Medical Aid, Khorezm Branch, Urgench, Uzbekistan

Newborn respiratory distress-syndrome is the main factor determining the severity of very preterm infants. The aim: To investigate and estimate the breathing pattern of premature infants with neurological complications of HIV infection in the Aral Sea region of Uzbekistan.

Materials and methods: The project included 27 infants with a gestational age of 27–35 weeks. All of the children were subjected to clinical examination with assessment of imaging studies, showing indicators during bronchography. Data were processed with program “Statistics-6”.

Results: In 21 (74%) cases a complicated course of newborn respiratory distress-syndrome was observed. Development of broncho-pulmonary dysplasia was observed in 7 children, pneumonia in 13, and ventilation was applied gently to 17 children in the first hours after birth, and seizures of apnea were detected in 11 premature children. During auscultation there is broken crepitus, moreover a weakened irregular breathing. While comparing the signs shown by the bronco-phonogram we identified functional abnormalities in the lungs and obtained a regularity of increasing indexes of acoustic breathing equivalent (integral characteristic of energy costs by the broncho-pulmonary system to excite the acoustic signal).

The study of children with broncho-pulmonary dysplasia revealed the presence of airflow obstruction impaired by restrictive type because of the formation of lung parenchyma fibrosis. While assessing breathing patterns showed statistically significant changes of broncho-phonogram indicators. Retention of changes on a broncho-phonogram on high spectrum indicates the presence of latent bronchial obstruction and requires basic therapy.

Conclusions: The use of modern diagnostic approaches can develop algorithms to optimize the research and basic therapy.

Cardiovascular and metabolic complications of spinal cord injury: Findings from a national population health study
J.J. Crange, V.K. Noonan, M. Dvorak, A. Krassioukov, J. Borisoff, School of Population and Public Health, University of British Columbia, Canada; International Collaboration on Repair Discoveries (ICORD), University of British Columbia, Vancouver, Canada; ‘Rick Hansen Institute, University of British Columbia, Vancouver, Canada; Department of Orthopaedics, University of British Columbia, Vancouver, Canada; Department of Medicine, Division of Physical Medicine and Rehabilitation, University of British Columbia, Vancouver, Canada; British Columbia Institute of Technology, Burnaby, BC, Canada

Objectives: To determine if MTBI is associated with microstructural changes in white matter in a large, homogeneous, sample that was carefully screened for pre-injury medical, psychiatric, or neurological problems.

Patients and methods: Participants were 75 patients with MTBI and 40 controls. Nine exclusion criteria were used to rule out pre-existing medical conditions or other confounding factors. The WHO criteria for MTBI were used. Whole-brain DTI (3T-MRI, mean imaging time post-injury 5.8 days, IQR 4.1–7.3) analysis was done with tract-based spatial statistics (TBSS) and the DTI parameters included: (i) fractional anisotropy (FA), (ii) apparent diffusion coefficient (ADC), (iii) radial diffusivity (RD) and, (iv) axial diffusivity (AD).

Results: All MTBI patients and controls were compared using age and gender as covariates and in age- and gender-matched subgroups (n = 40 versus n = 40). None of the DTI parameters (FA, ADC, RD, or AD) showed significant differences between patients and controls (p > 0.01). A subgroup of MTBI patients with more serious injuries by conventional severity criteria (at least one of the following: LOC > 1 min, PTA > 3 h, traumatic lesion on conventional MRI, GCS = 14, total subgroup n = 28) was compared to age- and gender-matched controls. No significant DTI abnormalities were detected in this subgroup (p > 0.01).

Conclusion: In this large homogeneous, premorbidly healthy sample, MTBI was not associated with DTI abnormalities detectable with TBSS.

Acute mild traumatic brain injury is not associated with white matter change on whole brain diffusion tensor imaging
T.M. Luoto, T. Ilvesmäki, A. Brander, U. Hakulinen, P. Ryymin, H. Eskola, G.L. Iverson, J. Ohman, Department of Neurosciences and Rehabilitation, Tampere University Hospital, Finland; Medical Imaging Centre and Hospital Pharmacy, Department of Radiology, Tampere University Hospital, Finland; Department of Electronics and Communications Engineering, Tampere University of Technology, Tampere, Finland; Department of Physical Medicine and Rehabilitation, Harvard Medical School and Red Sox Foundation and Massachusetts General Hospital Home Base Program, Boston, MA, USA

Background: Mild traumatic brain injury (MTBI) is associated with microstructural changes in white matter assessed with diffusion tensor imaging (DTI). However, methodological limitations, such as small sample sizes and failure to control for pre-injury morbidity, can confound the results.

Objective: The objective of this study was to evaluate the association between Type 2 diabetes and SCI, as well as cardiovascular disease (CVD) and SCI, in a large, representative sample.

Patients and methods: Data were obtained from 60,678 respondents to the Statistics Canada 2010 Cycle of the cross-sectional Canadian Community Health Survey (CCHS). Multivariable logistic regression, incorporating adjustment for confounders and probability weights to account for the CCHS sampling method, was conducted to quantify this association.

Results: After adjustment for both sex and age, SCI was associated with a significant increased odds of Type 2 diabetes (Adjusted odds ratio = 1.66, 95% Confidence Interval [1.16, 2.36]), a significant increased odds of heart disease (Adjusted odds ratio = 2.72, 95% Confidence Interval [1.94, 3.82]), and a significant increased odds of stroke (Adjusted OR = 3.72, 95% Confidence Interval [2.22, 6.23]).

Conclusion: These heightened odds highlight the need for future cohort or case–control studies examining a causal relationship between SCI and these secondary complications, which may ultimately result in treatment and prevention strategies targeted towards individuals with SCI.

Another cause of reversible splenial lesion: Hepatic encephalopathy  
E. Ak*, M.I. Yon*, G. Yalcin Cakmakli*, S. Duran*, N. Oztekin*  
*Neurology, Ankara Numune Education and Research Hospital, Ankara, Turkey; **Radiology, Ankara Numune Education and Research Hospital, Ankara, Turkey

Background and purpose: Reversible splenial lesion has been reported to be associated with encephalitis due to different pathogens, mostly viruses, methotrexate toxicity, systemic lupus erythematosus, reversible vasocnstriction syndrome and migraine. But it has not been reported yet under imaging findings of hepatic encephalopathy.  
Case: 58 year-old, male patient was admitted to our inpatient clinic with the complaints of confusion, persisting headache, fatigue and difficulty in balance for one week. He was known to have cirrhosis and portal hypertension for 2 years and type 2 diabetes mellitus for 20 years in his medical history. He was not on any medication and had been lost to follow-up for 3–4 months. There was not any precipitating factor for this attack. Neurologic examination revealed confusion, disorientation to time and place, bilateral dysmetria which was more evident on the right side, bilateral flapping tremor and ataxia. On MRI, T2 and flair images showed symmetric hyperintensities at the level of posterior pons, bilateral cerebral peduncles, posterior limbs of internal capsule, splenium of corpus callosum, posterior regions of the centrum semiovale and periventricular white matter. These areas showed mild hyperintensity on diffusion weighted images, which suggested vasogenic edema around the corticospinal tract. Gradient echo images revealed hypointensity in bilateral globus pallidi suggesting heavy metal deposition. The patient got better both clinically and radiologically under appropriate treatment.  
Conclusion: MRI findings may differ according to the type of liver failure in hepatic encephalopathy. It is the first time, reversible splenial lesion is found to be associated with hepatic encephalopathy.

Spinal cord myelitis after zoster infection  
B.N. Bouzidi, E. Turki, I. Bouchhima, M. Damak, M.I. Miledi, I. Feki, C. Mhiri. Department of Neurology, Hospital Habib Bourguiba, Faculty of Medicine, Sfax, Tunisia

Background: Varicella zoster virus (VZV) can have significant neurologic complications. Myelitis is a relatively rare neurological complication of VZV and may develop in the absence of rash.  
Objective: To report main clinical, biological and MRI features of zoster myelitis.  
Patients and methods: Five patients were followed-up (1992–2012) for zoster myelitis. All patients had lumbar puncture and medullar MRI.  
Results: Our observations concern two women and three men of 17 to 78 years of age. Four patients had history of intercostal rash. After 3 weeks (4–45 days), patients presented paraparesis/plegia, sensory loss, and sphincter dysfunction. Cerebrospinal fluid analysis revealed pleocytosis in two cases, an elevated protein level in all patients. Medullar MRI demonstrated T2 hyperintense lesions with occasional swelling and enhancement. The diagnoses in all 5 cases were supported by laboratory evidence, including increasing titer of anti-VZV antibodies in the CSF. All patients received a 3-week course of intravenous (IV) acyclovir (1500 mg/m²/day) and IV methylprednisolone in 2 cases. Most patients fully recover within 2 months but sphicter dysfunction may persist.  
Conclusion: As the pathogen mechanism of herpes zoster myelitis is considered to be direct viral invasion of the spinal cord with subsequent necrosis or post-infectious, early initiation of acyclovir treatment is necessary for the recovery.

Ethical problems in neurology
E. Mikhalovska-Karlova. Philosophy, Research Institute of Medicine, History of Russian Academy of Medical Sciences, Moscow, Russia

Background: Increase in the role of ethical component in the assessment of the effectiveness of the professional work of neurologist.

Objective: Assess the motivation of medical students and practicing neurologists towards studying biomedical ethics.

Material and methods: 25-year experience of teaching biomedical ethics to lower and upper level students in Moscow medical schools, as well as teaching continuous education courses on biomedical ethics to graduate medical students and practicing physicians neurologists.

Methods: Sociological surveys, self-administered questionnaires, standardized and non-standardized interviews. The motivation index (MI) was calculated in the proportion of 1 to 10 per every 10 persons.

Results: Professional interest towards bioethics among the medical students increases, as they approach graduation and become more involved in clinical disciplines: the lowest interest was demonstrated by first-year students (on average — 0.8), the highest — by the 6th-year students (1.7). Of particular interest was material on professional ethics; here the MI among the 6th-year students reached 0.85. Graduate medical students and doctors practicing neurology and epileptology demonstrate a high level of interest in ethical problems (0.8–0.9). At the same time they admitted that there is a significant deficit in knowledge in the field of bioethics.

Conclusion: In order to radically improve the situation with bioethics education in medical schools of Russia, the bioethics classes should be moved to the curricula of upper level students and included in the system of the continuous medical education.

Six-year survival of progressive multifocal leukoencephalopathy associated with follicular lymphoma
I. Vastagh, Á. Palásti, G. Aradi, A. Tóth, G. Várallyay; G. Rudas
J. Demeter, J. Csomor, S.W. Aberle, H. Budkó, D. Bereczki
G.G. Kovács. 1st Department of Neurology, Semmelweis University, Faculty of Medicine, Hungary; 2MRA Research Center, Semmelweis University Faculty of Medicine, Hungary; 31st Department of Internal Medicine, Semmelweis University Faculty of Medicine, Hungary; 41st Department of Pathology and Experimental Cancer Research, Semmelweis University, Faculty of Medicine, Budapest, Hungary; 5Clinical Institute of Virology, Medical University of Vienna, Vienna, Austria; 6Institute of Neurology, Medical University of Vienna, Vienna, Austria

Background: Progressive multifocal leukoencephalopathy (PML) occurs mainly in immunocompromised individuals as well as associated with immunomodulatory therapies including rituximab. The disease course of PML is usually progressive and fatal. The median survival of patients without HIV infection is only three months. Long-term remission is rare, but rather occurs in HIV-positive individuals.

Objective: To present a long-term remission case of PML associated with follicular lymphoma.

Patient and methods: A 57-year-old male was presented with rapidly progressing neurological signs 6 years ago (modified Rankin-scale was 5). PML was diagnosed by detailed neuroradiological and histopathological evaluations of brain biopsy specimen. The presence of JC virus was demonstrated by immunohistochemistry and PCR examination from the diseased brain tissue. An inflammatory response with abundant CD8 T-cells was prominent. The first appearance of PML preceded the diagnosis of follicular lymphoma and rituximab therapy. Clinical and neuroradiological improvement followed splenectomy, high-dose coticosteroids and later immunochemotherapy including rituximab.

Results: After the termination of chemotherapy the patient was rehabilitated and has been in a stable neurological condition (modified Rankin-scale is 3). Clinical improvement correlated with the neuroradiological result.

Conclusion: The inflammatory form of PML extends the spectrum of JC-virus related brain disease and there is a chance of clinical improvement following immune reconstitution.

Evolutionary ideas in ancient and medieval neuroscience
A. Karenberg. Institute for the History of Medicine and Medical Ethics, University of Cologne, Cologne, Germany

Background: Evolutionary ideas have been essential to understanding the nervous system since antiquity. This lecture will examine the close relationship between the emergence of innovative doctrines and social developments in ancient and medieval times.

Objective: Evolutionary concepts of the pre-modern era are identified and linked to their cultural context.

Material and methods: Important primary sources such as the writings of physicians and philosophers as well as secondary materials are reviewed.

Results: Various interrelations between neurological and political doctrines are demonstrated in detail. E.g., the concept that the brain governs the body corresponds to Plato's idea of a philosopher-king who

hypertension, etc.), and plays a therapeutic role in addressing a number of cognitive and psychological disorders (such as depression, low self-esteem etc.). The aim of our investigation was to detect the relationship between engagement in amateur sports and typological and personal differences of university students. 67 students (34 women and 33 men, age 17–23 years, mean age 20.5 years) of National Taras Shevchenko University of Kyiv, Ukraine participated in this study. The control group included students (220 women and 61 men) with no experience playing sports. It was shown that the group of amateur sportsmen had a higher level of arousal and mobility of neural processes, and a low level of neuroticism, lower level of neurotization, anxiety, psychotic tension and depression. It was established that amateurs had pronounced outward euphoric and less pronounced outward dysphoric reactions to external stimuli and more inclined to direct physical aggression. We found that amateur sportsmen have more pronounced general and spatial anticipation and lesser intensity of burnout and its symptoms and phases. They provided prerequisites for the inclination to sports (physical activity) and allow the achievement of success. Our data indicate that sports prevents the development of burnout and reduces the negative impact of emotional stress, gives socially acceptable ways of aggressiveness, and teaches athletes to cope with difficulties.

doi:10.1016/j.jns.2013.07.2135
rules over the state. Plato’s student Aristotle took the opposing view and described the heart as the seat of perception, motion, and sensation, thus relating this organ to the “acropolis” of a contemporary Greek city. Meanwhile Hippocratic authors shaped the doctrine of the four humors, whose harmonious mixture symbolized the democratic interaction of various groups in a Greek community; diseases including epilepsy and apoplexy were believed to occur if and when the excess of one humor provoked a noxious “tyranny” amongst the inner parts of the body. In 2nd century Rome, the physician Galen was able to synthesize various traditions of neurological thinking, acting like the ruling emperor who integrated various territories into the Roman Empire.

**Conclusions:** A thorough analysis demonstrates that pre-modern evolutionary ideas can be viewed as a direct response to cultural and political circumstances. It would be worth examining later epochs on the same lines.

**Low tryptophan uptake in contrast-enhancing lesions predicts long-term survival in patients with a previously treated glioblastoma: A pet study**

*bNeurology and Pediatrics, Wayne State University, USA; dPET Center and Translational Imaging Laboratory, Children’s Hospital of Michigan, USA; cKarmanos Cancer Institute, Wayne State University, Detroit, MI, USA; cRadiology, Wayne State University, Detroit, MI, USA; cNeurology, Wayne State University, Detroit, MI, USA; dNeurosurgery, Wayne State University, Detroit, MI, USA*

**Background:** MRI has limited prognostic value in patients with a previously treated glioblastoma. Positron emission tomography (PET) imaging with alpha[11C]methyl-L-tryptophan (AMT), a radiotracer tracking tryptophan transport and metabolism via the immunosuppressive kynurenine pathway, can effectively differentiate glioma recurrence from radiation injury.

**Objective:** To evaluate the prognostic value of AMT uptake measured on post-treatment PET in patients with glioblastoma treated with surgery followed by chemoradiation.

**Patients and methods:** AMT-PET was performed in 32 patients (mean age: 60 years) with a previously treated glioblastoma. The PET scans were done 6–62 months after initial surgery after MRI demonstrated a contrast-enhancing lesion suspicious for tumor progression. AMT uptake values were measured (on summed activity images 30–55 min after tracer injection) in contrast-enhancing regions and contralateral cortex, and correlated with survival after PET. A receiver operating characteristic analysis was performed to determine the optimal cutoff threshold to predict 1-year survival.

**Results:** At the end of follow-up, 23 patients were deceased and 9 alive (for up to 83 months). A cutoff threshold of 1.65 for lesion/cortex AMT uptake ratios provided 82% sensitivity/specificity for 1-year survival after PET. Age-corrected Cox regression analysis showed a strong association between above-threshold AMT uptake ratios and shorter survival (odds-ratio: 4.3 [1.5–12.5], p = 0.005). Below-threshold AMT uptake ratios (n = 13) were associated with an additional year median survival compared to patients with high ratios (618 days vs. 257 days).

**Conclusion:** Low AMT uptake on PET, measured in contrast-enhancing lesions suspicious for tumor progression, predicts long-term survival in patients with a previously treated glioblastoma.

**Sleep curtailment is associated with altered autonomic tonus in normal-weight individuals**

W. Moreas,a, D. Poyaresb, L. Bittencourtb, S. Tufikb.

*bSleep Medicine, Universidade de São Paulo, Brazil; bPsychobiology, UNIFESP, São Paulo, Brazil*

**Introduction:** Increased sympathetic tonus has been suggested as a mechanism linking short sleep duration to overweight and hypertension. The present study was proposed to assess autonomic tonus in relation to sleep duration in a representative sample of eutrophic individuals from the general adult population.

**Methods:** A representative sample of the city of Sao Paulo was selected (20–80 years), including 1024 individuals, from which 224 females and 193 males were eutrophic (body mass index < 25). They underwent full polysomnography with ECG recording. Heart Rate Variability (HRV) was analyzed for the whole night using a polysomnography ECG lead (D2 modified). Time and Frequency domains variables were calculated for individuals who slept more (controls) and less than 5 h (experimental group) per night, assessed by objective measures. One-way ANOVA was performed considering insomnia syndrome and AHI > 5 as covariates.

**Results:** Sleep curtailment was significantly associated with reduced SDNN (p = 0.02) and SDNNINDEX (p < 0.01) which are related to a reduction in HRV. RMSS was also reduced (p < 0.01) indicating reduction in parasympathetic tonus, and LF/HF ratio increased suggesting high sympathetic tonus.

**Conclusion:** Sleep shortness was associated with reduced HRV and parasympathetic tonus, and increased sympathetic tonus in eutrophic individuals. These findings support the concept that altered autonomic tonus is associated to sleep curtailment independently from the presence of obesity. This alteration could mediate the link between short sleep, obesity and cardiovascular risk. Longitudinal studies are needed to support this hypothesis.

**Modelling of mismatch negativity indicates age related impairment of cortical dynamics in frontal regions**

*cClinical Neuropsychology, Karolinska University Hospital, Stockholm, Sweden; 3Queensland Brain Institute, The University of Queensland, Brisbane, QLD, Australia*

**Background:** Auditory mismatch negativity (MMN) is an electroencephalographic (EEG) response strongly correlated with attention control. MMN is known to attenuate with age.

**Objective:** In this study we investigated the cortical networks underpinning attention control in the ageing brain.

**Methods:** MMN and dynamic causal modelling was used to study connectivity networks of attention control in healthy young and healthy old subjects. An auditory odd-ball paradigm was used to elicit MMN registered with EEG in two groups of healthy subjects with mean age 74 (n = 30) and 26 (n = 26). Networks with different hierarchical complexity with up to five cortical nodes (right and left primary auditory cortex, right and left superior temporal gyrus, and right inferior frontal gyrus) were analysed using dynamic causal modelling.

**Results:** Bayesian model comparison showed that the five node model with full modulation of all network connections was the most
likely of all the twelve inverted models. Model inversion of the five node model showed that older subjects had significantly increased inhibition of pyramidal cells ($p < 0.05$) with reduced modulation of this activity within the right inferior frontal gyrus ($p < 0.02$).

**Conclusion:** Deterioration in frontal-based control mechanisms caused attenuation of MMN with age. Impairment of cortico-striatal dynamics in the right inferior frontal gyrus on stimulus change provided a neurobiological mechanistic explanation for the reduction of MMN and attention control in the ageing brain.

**Polysomnographic sleep parameters in an aging population**  
W. Moraesa, R. Piovazzanb, L. Bittencourtb, D. Poyaresb, S. Tufikb  
“Sleep Medicine, Universidade de São Paulo, Brazil; bPsychobiology, UNIFESP, São Paulo, Brazil”

**Introduction:** Although many studies have shown the evolution of sleep parameters across the lifespan, not many have included a representative sample of the general population. The objective of this study was to describe changes in sleep patterns in the general population of Sao Paulo throughout adulthood.

**Methods:** We selected a representative sample of the city of Sao Paulo, Brazil that included both genders and an age range of 20–80 yrs. This sample included 1024 individuals that were submitted to polysomnography (PSG) and structured interviews. We sub-divided our sample into 5-year age groups.

**Results:** Total sleep time, sleep efficiency, percentage of REM sleep and slow wave sleep showed a significant age-related decrease ($p < 0.05$). WASO, arousal index, sleep latency, REM sleep latency, and the percentage of stages 1 and 2 showed a significant increase ($p < 0.05$). Furthermore, AHI increased and oxygen saturation decreased with age. The reduction in the percentage of REM sleep significantly correlated with age in women, while the reduction in the percentage of slow wave sleep correlated with age in men. The PLM index increased with age in men and women.

**Conclusions:** Sleep structure and duration underwent significant alterations throughout the aging process in the general population. There was an important effect of age on sleep respiratory parameters and PLM index. In addition, men and women showed similar trends but with different effect sizes.

**Unselected brain imaging in suspected meningitis delays lumbar puncture, can prolong hospitalisation and may increase antibiotic costs - a pilot study**  
“aInstitute of Infection and Global Health, Liverpool University, UK; bThe Walton Centre for Neurology and Neurosurgery, UK; cWhiston Hospital Foundation Trust, UK; dAlder Hey Children’s NHS Foundation Trust, Liverpool, UK; eHealth Economics Group, University of Exeter Medical School, Exeter, UK”

**Background:** Antibiotics reduce mortality in bacterial meningitis; a lumbar puncture (LP) will demonstrate that many patients with suspected meningitis do not need them; but delays reduce chances of culture, particularly if >8 h. Guidelines advise a LP without brain imaging unless specific features are present.

**Objective:** We assessed the duration of hospitalisation and inpatient costs incurred with delays in LP in a Northwest of England teaching hospital.

**Methods:** We screened the cerebrospinal fluid (CSF) database to identify patients with suspected meningitis over 3 months (07–09/2010). Data were recorded from clinical case notes; costs were calculated with established datasets and the British national formulary.

**Results:** 142 patients were screened; 35 had a suspected CNS infection; 10 had a CNS infection proven: 3 bacterial meningitis; 4 aseptic meningitis and 3 viral encephalitis. In total, 19.5% of adolescents reported a TBI in their lifetime. Sports injuries were the most likely mechanism for mTBI among all reported causes (55.8%, 95% CI: 46.9, 4.2). When holding constant sex and grade, adolescents with TBI had significantly greater odds for reported elevated psychological distress (OR = 1.51), attempting suicide (OR = 3.39), seeking counselling through a crisis help line (OR = 2.10), and being prescribed medication for anxiety, depression or both (OR = 2.43). Moreover, they had higher odds of being victimized through bullying at school (OR = 1.70), being cyberbullied (OR = 2.05) or being threatened with a weapon at school (OR = 2.90), compared with adolescents who never had a TBI. Adolescents with TBI had also higher odds of victimizing others and engaging in numerous violent and non-violent conduct behaviours.

**Conclusion:** High rates of TBI among adolescents in the general population, its high association with team-sports and adverse psychological effects highlight the need for urgent prioritization of prevention efforts.

Worldwide record of REM sleep time in a patient with pedunculopontine nucleus area (PPNa) stimulation

D. Neutel1, D. Grabli2,c, K. Karachi2,d, M.-L. Welter2bc, E. Claire2bc, B. Eric2, F. Chantal3, I. Arnulf2cc, Pierre and Marie Curie University, France; cInserm U975 and CRICM, Pierre University, France; bNeurology Department, Pitié-Salpêtrière Hospital, Paris, France

Objective: To study in & 2006 children born in 1986 & 2007 the influence of small-scale irradiation on nervous state of growing organism in children.

Patients and methods: Four patients (3 female, 1 male, 46–69 y old) with Parkinson's disease for 9–22 years had PPNa stimulation for gait disorders. Underwent sleep monitoring after 2 months with and without deep brain stimulation (DBS), in a double blind randomized cross over manner. After 9 months under chronic DBS, male patient had 4 additional sleep monitoring with stimulation on again (n = 2), and 1 and 6 nights after stimulation was stopped. Active contacts were located via normalized MRI.

Results: In the male patient, who had the clearest benefit on gait, REM sleep percentage was 49% (REM sleep time: 210 min; normal values: 17–23%) of total sleep time with stimulation, and 0% without. REM sleep was still increased 9 months later with continuous PPNa stimulation (41% of REM sleep on stimulation). It decreased to 30% after one night and to 9% after 6 nights without stimulation. In the 3 other patients REM sleep was 4–22% without stimulation and 0–21 % with stimulation. The active contacts had similar localization in the 4 patients.

Conclusion: This dramatic, supranormal (twice higher than the higher bound in normal adults), durable and reproducible increase of REM sleep time with PPNa stimulation, followed by a progressive return to low values when stimulation is stopped, suggests that the PPNa stimulates ‘REM sleep on’ systems (possibly in the subcoeruleus nucleus).

Neurologous lesions in children of KYIV, born on the year of catastrophe in chernobyl

O. Yuryk. Laboratory of Orthopedy and Pain Problems, State Institution ‘Institute of Traumatology and Orthopedics of the Academy of Medical Sciences of Ukraine’, Kyiv, Ukraine

Object: To study influence of small-scale irradiation on nervous state of growing organism in children.

102 children born in 1986–1997 years have been examined in dynamics.

At age of 6–7 years in 62% of children autonomous disorders on subclinal level have been observed: 33% with sympaticotonic type and 33% with parasympaticotonic type. Children were irritated and tired quickly, concentration of attention was bad. With sympaticotonic direction of vegetative reactions index Kerdo increased essentially (up to 42.3 ± 3%). Considerable disbalance of cardiovascular tests was noted. In subgroup of these children 23% had congenital orthopedic pathology of spine and lower extremities were marked. With vagoinsular direction of vegetative reaction in children of this age group congenital defects of locomotor and support were less often (14% of cases).

On other hand chronic disorders of bronchopulmonary system and gastroenteric tract (made up 38% of cases) prevailed. With secondary examination of children at the age of 16–17 years it was noted that vegetative disfunction (mainly with sympaticotonic type) was observed only in 27% of examined children but they had more often disorders connected with locomotor an support, namely: chondrosis of vertebrosacral spine, dysplasia of vertebrae and large joint of limbs, flatness of anterior part of feet, congenitaldeformities, syndrome of congenital dysplasia of connective tissue on subclinical level. When patients are at the age of 26–27 years dysfunction of autonomous nervous system has reached only 12%. Sympaticotonic and vagoinssular were almost equally divided among them. Small-scale irradiation affect mainly autonomous nervous system on subclinal level.

Lewy neurite-like structures are rarely associated with Lewy body pathology at the brainstem of multiple system atrophy (MSA)

M. Mimuro, S. Tatsumi, Y. Iwasaki, M. Yoshida. Aichi Medical University, Nagakute, Japan

Background: Two major differences of synuclein pathology between multiple system atrophy (MSA) and Lewy body disease (LBD) are the location of abnormal α-synuclein aggregation, mainly glial or neuronal, and existence of the peripheral organs involvement. We found a case of MSA with numerous Lewy neurite-like swollen structures (MSA neurites). However, it is unclear whether these swollen neurite of MSA are related with Lewy body pathology or not and provide some insights of the relationship between MSA and Lewy body pathology.

Objectives and methods: To clarify the characteristics of the swollen neurites of MSA, we examined 160 autopsy confirmed cases of MSA at our institute. Patient characteristics: age of death 67.3 ± 8.3 years; disease duration to death 7.4 ± 4.1 years. Clinical phenotype was MSA-C (predominant cerebellar involvement) in 84, MSA-P (predominant parkinsonism) in 71. Tissue blocks were taken from the brainstem, and HE staining and immunohistochemical staining for phosphorylated alpha-synuclein were used. We examined for the presence of MSA neurites and Lewy bodies in the brainstem.

Results: Ten cases (6.3%) showed Lewy bodies: 4 cases in the IIId nucleus, 7 cases in the locus coeruleus. Twenty two cases (14%) showed MSA neurites; 20 cases in the IIId nucleus, no cases in substantia nigra. Only one case with MSA neurites had Lewy body pathology.

Conclusion: Lewy neurite-like swollen neurites might be one of the characteristic findings of MSA rarely combined with Lewy body-related pathology.

The increasing number of vehicles in Kenya roads and growth of industries could see a rise in underweight babies. Pregnant women exposed to higher levels of air pollution from industrial/car fumes are likely to have underweight babies.

Methods: We studied data from 3 million births at 14 Research Centers in rapidly industrializing cities by focusing on air pollutants which are produced from combustion of fuels in vehicles and industrial machines, burning firewood and dust particles.

Results: The more pollutants, the higher the risk/chance of infant being underweight, with average weight down by 3 g. A direct consequence is the rise in the rate of infant mortality and childhood diseases as well as later health risks in neurocognitive diseases in life, meaning child mortality rate would go up from 55 in every 1000 live births. Although air pollutants alone could not be associated with mean birth weight, we consider health care systems, premature births, social economic status of demographics and months in which low births rates were observed.

Conclusions: Findings were worse for expectant women staying in polluted environments and who smoked. According to WHO, a child is underweight when it tips the scales at less than 2.5 kg. Air particles could lead to LBW due to their impact on body functions. Most cars pollutants consist of dangerous gases like CO2, lead, sulphur, nitrogenous gases, dust and inhaling them may reduce oxygen uptake. Lead particles in petrol would inhibit certain enzymes and cause damage to the kidneys, brains and nervous systems.

Is education related to cognitive ageing? Results of the interdisciplinary long-term study of adulthood and ageing (ILSE)

W.-D. Moeller1, P. Kropp2, B. Mueller2, aHG-Creutzfeldt-Institute, University of Kiel, Kiel, Germany; bInstitute of Medical Psychology and Medical Sociology, University of Rostock, Rostock, Germany

Objectives: The relationship between educational attainment and cognitive status in the elderly is well known. But studies regarding whether education positively affects the cognitive changes show highly inconsistent results. The aim of our study is to examine the effects of education on trajectories of cognitive abilities at age 63 to age 74.

Methods: Data taken from the Interdisciplinary Long-Term Study of Adulthood and Ageing (ILSE) concerned 321 individuals without dementia (mini-mental-status-test ≥ 25, Folstein 1990) who were born between 1930 and 1932. Cognitive functioning was assessed on 12 subtests in the domains ‘memory’, ‘crystalline intelligence’, ‘fluid intelligence’, and ‘speed of processing’. Education was dichotomized to reflect high or low attainment. General linear models for analysis of repeated measures were used.

Results: In our sample we found cognitive declines in 9 subtests, stability in 2 subtests and improvements in one subtest. Levels of education were unrelated to trajectories of 10 cognitive subtests. In two subtests high educational attainment attenuates the decline. Adjusted for baseline performance analysis shows a benefit of education in 10 of 12 subtests.

Conclusions: The findings support the active cognitive reserve hypothesis. High levels of education promote more efficient cognitive processing, which results in smaller declines, more stability and improvements.

Optical coherence tomography in patients with optic disc oedema

A. Pilat1, F.A. Proudlock2, M. Lawden2, P. Kumar2, I. Gottlob2, aOphthalmology Group, University of Leicester, UK; bLeicester Royal Infirmary, Leicester, UK

Background: On examination optic disc oedema (ODE) can have similar fundus appearance with optic nerve head drusen (ONHD). Previously, optical coherence tomography (OCT) has been used to image the optic disc and peripapillary retinal nerve fiber layer (RNFL) for differential diagnosis between these conditions.

Conclusions: The findings support the active cognitive reserve hypothesis. High levels of education promote more efficient cognitive processing, which results in smaller declines, more stability and improvements.

Changes in presynaptic inhibition during movement restriction of unilateral lower limb in a hemiparetic patient and healthy individuals

M. Morishita1, H. Yamaguchi2, K. Egawa3, A. Hirohata3, M. Kobayashi4, 1Kibi International University, Takahashi, Japan; 2Watanabe Hospital, Shiseikai Medical Corporation, Niimi, Japan; 3Graduate School, Waseda University, Tokorozawa, Japan

Background: We previously reported that movement restriction of the non-paretic lower limb improved gait patterns in hemiparetic patients. Objective: We assessed presynaptic inhibition (PI) to determine if movement restriction of the non-paretic lower limb is regulated by upper motor neuron mechanisms in hemiparetic patients compared with healthy individuals.

Patients and methods: This study included one hemiparetic patient and 16 young healthy individuals. Participants walked with a knee brace on the non-paretic/non-dominant side. The subjects walked normally for about 10 min and then with the brace for another 10 min (gait training period). PI was measured before and after every 5 min in both conditions. PI was assessed in the soleus muscle on the paretic/non-dominant side, and conditioning stimulation of the common peroneal nerve was used prior to soleus H-reflex measurement.

Results: The single limb support time for the paretic/dominant side was longer after gait training in both the hemiparetic and healthy individuals. Two-way ANOVA revealed a significant interaction for time and restriction effects in healthy individuals. After gait training, PI was greater than during normal walking conditions in healthy individuals. In the hemiparetic patient, only slight PI was observed before gait training; but PI appeared to the same degree as in healthy individuals after gait training.

Conclusion: Our results suggest that gait training with a knee brace may be effective not only for improvement of gait patterns, but also for regulation of upper motor neuron systems caused by increasing weight bearing ratio in paretic lower limbs.

doi:10.1016/j.jns.2013.07.2152
Results: Thirty-eight team-members (38/53, 71.7%) completed the questionnaire. Twenty-four responders (63.2%) described the mode of collaboration as multidisciplinary or integrative. Majority of doctors (66.7%) and radiographers (62.5%) expressed a strong belief in benefits of interprofessional collaboration but only 28.6% nurses agreed. Compared with nurses and radiographers, doctors showed a stronger belief that the collaboration would enable a better clinical outcome after endovascular intervention (p = 0.013). While most doctors enjoyed a high degree of autonomy and more opportunities for personal growth and research through the collaboration, most nurses and radiographers had less autonomy and described the collaboration as physician oriented (all p < 0.05).

Conclusions: An interdisciplinary model for neuro-interventional service is feasible.

9.4T MRS characterization of human umbilical cord mesenchymal stem cells that underwent death metabolism
Y. Xiao a, H. Dai a, R. Wu a, b Department of Medical Imaging, The Second Affiliated Hospital of Shantou University Medical College, Shantou, China; cDepartment of Medical Imaging, Huizhou Municipal Central Hospital, Huizhou, China

Objective: To explore the metabolite profile of mesenchymal stem cells (MSCs) that underwent death using 9.4T high resolution NMR Spectroscopy.

Methods: Human umbilical cord mesenchymal stem cells were cultured and collected. MSCs were treated for 0, 6, 12 and 24 h in a stimulated condition which include hypoxia, serum deprivation and changes of microenvironment. Cell death and the mortality rate was detected by light microscopy, Hoechst staining and flow cytometry analyses. Cell metabolite extraction was prepared by methanol–chloroform (M/C) method and analyzed on a 9.4T NMR device. 1H-NMR Spectroscopy was obtained and the metabolite concentration of each time point was calculated.

Results: Necrosis is the major form of cell death in the built model. In the early stage of cell death (6 and 12 h), the fatty acid metabolite concentration increased with statistical significance (p < 0.05), while in the last stage of cell death, the fatty acid peak decreased (p < 0.05).

Conclusions: There are some specific characteristics on MRS of MSCs that underwent death, and the fatty acid peak may serve as a biomarker for cell death.

Long-term cognitive deficits after treated Lyme neuroborreliosis — Neuropsychological profile and demographical characteristics
R. Eikeland a, G.C. Lohaugen a,b,c Neurology, Sarlandet Hospital, Arendal, Norway; c Paediatrics, Sarlandet Hospital, Arendal, Norway; Laboratory Medicine Children’s and Women’s Health Medical Faculty, NTNU, Trondheim, Norway

Background: Lyme neuroborreliosis (LNB) is mostly successfully treated with antibiotics, but 10–50% of the patients report persisting complaints years after treatment. We have previously reported cognitive deficits in LNB patients 30 months after treatment compared to controls.

Objective: To compare the neuropsychological test-profile characterizing persons who did not recover to the profile of persons who did recover after LNB treatment.

Patients and methods: 50 persons were treated for LNB with ceftriaxone/doxycycline. After 30 months the following neuropsychological tests were performed: Trail Making test (TMT), Stroop, California verbal learning test (CVLT) and digit symbol. Clinical recovery was defined as a score of 0 or 1 on a clinical composite score combining subjective complaints and neurological deficits (range 0–52, 0 best), non-recovery > 1. The neuropsychological test-results and demographic data of the recovery (n = 19) were compared to the non-recovery (n = 31) group.

Results: The non-recovery group scored lower on TMT2 (p = 0.022), TMT5 (p = 0.003), Stroop1 (p = 0.001), Stroop2 (p = 0.032), Stroop3 (p = 0.012), Stroop 4 (p = 0.011), and digit symbol raw score (p = 0.009), but CVLT revealed no differences between the two groups. Patients in the non-recovery group were older, (p = 0.001), had more somatic comorbidity (p = 0.09) and a lower educational level (p = 0.003). None of the patients who recovered had pre-treatment symptoms >6 weeks.

Conclusion: Persons who did not recover after treatment for LNB score were worse on the neuropsychological tests TMT2, Stroop1–4 and digit symbol raw score, but not on CVLT. This might reflect a
neuropsychological profile indicating deficits related to attention/executive functions/processing speed and less verbal memory and learning problems.

The relation between benign paroxysmal positional vertigo and motion sickness
D.S. Shin, H.S. Han. Neurology, Saint Carollo, Suncheon-Si, Republic of Korea

Objective: To investigate the clinical signification of BPPV about posterior semicircular canal in patients with motion sickness (MS) and without MS.

Background: The hypothesis of MS is a condition in which a disagreement exists between vision and balance, visually perceived movement and the vestibular system’s sense of movement. We speculated that MS could be in relation of the degrees of nystagmus.

Methods: This is a prospective study of 72 patients from 2011 to 2012. When the Dix–Hallpike maneuver was indicative for BPPV using vestibular nystagmography, a repositioning maneuver was performed. Degrees of nystagmus divided into 3 groups (mild: 1–10, moderate: 11–30, severe: >31° of nystagmus). Motion sickness were identified by history. Patients were followed for 3 months for the resolution and recurrence of symptoms.

Results: MS was noted in 42% of patients with BPPV. It showed a tendency of increasing prevalence with an increasing degree of nystagmus (rho = 0.424, p < .0001). But there is no relation between reduction and presence of MS (rho = 0.129, p > 0.05).

Conclusions: These results suggest that MS had considerable factor to predict the severity of BPPV in posterior semicircular canal.

What factors influence the relationship between feedback on neuropsychological performance and subsequent driving self-regulation?
D. Vance©, M.L. Ackerman©, K.K. Ball©. aSchool of Nursing, University of Alabama at Birmingham, Birmingham, AL, USA; bPsychology, University of Alabama at Birmingham, Birmingham, AL, USA

Background: A recent study indicates that providing feedback about neuropsychological abilities is important to safe automobile driving (based on Useful Field of View test performance, a visual speed of processing measure) and may lead to changes in driving self-regulation. However, 42% of participants who received negative feedback did not report any subsequent increase in driving self-regulation.

Objective: This study extended those findings to investigate potential moderators of the relationship between feedback regarding neuropsychological abilities and driving self-regulation.

Patients and methods: Between 2006 and 2008, 129 insured older (75+) drivers were administered an initial neuropsychological battery and then a telephone follow-up interview after 2 to 4 months after receiving feedback.

Results: Significant interactions included feedback by age, feedback by number of eye conditions, and a trend towards significance for feedback by baseline driving exposure. Follow-up regression results showed that older participants (80–94; n = 39) who received negative feedback significantly increased subsequent avoidance of challenging driving conditions relative to baseline (p = .045). Participants with no reported eye conditions (n = 36) who received negative neuropsychological feedback significantly increased subsequent driving avoidance relative to baseline (p = .007), and participants with low (below median) baseline driving exposure (n = 66) tended to increase subsequent driving avoidance relative to baseline (p < .009).

Conclusion: Older adults with minimal driving exposure, those with no reported eye conditions, and those over 80 years old are more likely to modify their driving habits after receiving negative feedback regarding neuropsychological skills related to driving safety.

A comparison of co-morbidities between the postural orthostatic tachycardia syndrome and generalized dysautonomias
K.R. Chémali, K. McNeely. Neurology, Sentara/Eastern Virginia Medical School, Norfolk, VA, USA

Background: Postural Orthostatic Tachycardia Syndrome (POTS) includes a spectrum of disorders which are also present in generalized dysautonomias. A pathophysiological link of POTS to the Autonomic Nervous System (ANS) is therefore suspected. Comparing co-morbidities of both conditions could shed further light onto that link.

Objective: Compare the prevalence of common disorders in POTS with that of disorders associated with diseases of the ANS.

Patients and methods: We reviewed 74 patients with POTS and retrieved all their associated diagnoses, retaining the 11 most common. We repeated the same process with 109 patients diagnosed with autonomic neuropathy (AN) who did not meet the criteria for POTS.

Results: Ten out of the 11 most common conditions associated with POTS were also associated with AN but to different degrees. Migraine was the most common co-morbidity in POTS (55%). Other common co-morbidities included Chronic Fatigue Syndrome (CFS), Fibromyalgia and Irritable Bowel Syndrome (IBS). In AN, the most common co-morbidities were hypertension (56%), hypercholesterolemia (46%), migraine (40%) and diabetes (30%).

Conclusions:

1. Common co-morbidities between POTS and AN could reflect a common pathophysiology and a predominant role of the ANS in POTS.
2. Hemodynamic and metabolic disorders are more prevalent in AN than in POTS, whereas conditions like Fibromyalgia, CFS and IBS are more common in POTS, which suggests that POTS is a syndromic rather than a disease-based dysautonomia.
3. The high prevalence of disorders such as Fibromyalgia and CFS in both POTS and AN, may point to a role of the ANS in these conditions.

The alpha attenuation test: Assessment of alpha blockade efficiency in narcolepsy
¹Clinics for Endocrinology, Clinical Centre of Serbia, Belgrade University, School of Medicine, Belgrade, Serbia; ²Clinical for Neurology, Military Medical Academy, Belgrade University, School of Medicine, Belgrade, Serbia; ³Institute of Aviation Medicine, Belgrade University, School of Medicine, Belgrade, Serbia; ⁴Institute of Mental Health, Belgrade University, School of Medicine, Belgrade, Serbia; ⁵Institute of Medical Statistics and Informatics, Belgrade University, School of Medicine, Belgrade, Serbia

Background: The alpha attenuation test (AAT) is based on the fact that power spectrum in alpha frequency band of the EEG (8–12 Hz) increases with eyes open, but tends to decrease with eyes closed.

Objective: To assess value of AAT for predicting coming sleep in individuals with narcolepsy and idiopathic hypersomnia.

Patients and methods: Seventy one participants (28 with narcolepsy, 24 with idiopathic hypersomnia, and the rest of the 19 has healthy controls matched to gender and age) underwent AAT which considered modified EEG recording with alternately six times eyes open and eyes closed procedures within the time interval of 12 minutes. Parts of EEG signals were extracted at the same points within the whole sample, and digital filtering with frequency between five and 32 Hz was applied to channels 02-A1 and 01-A2. The parametric statistical analysis of logarithmic transformed alpha attenuation coefficients (AACs) and alpha powers was performed.

Results: Our results show that patients with narcolepsy have significant lower absolute AACs and greater absolute powers during eyes open condition in comparison to patients with idiopathic hypersomnia and healthy controls. The mechanism of alpha blockade appears to be less effective in patients with narcolepsy, and thus responsible for both lower AACs and greater absolute powers with eyes open.

Conclusion: AAT may be a useful screening method for assessment of transitory momentary sleepiness. This test can reveal preclinical sign existence of a condition that can lead a subject to fall asleep.

The era of HIV/AIDS and its neurological complications in the world
B.A. Bukusi¹,², R.N. Mbugua¹,²,³, eClinical Research, Infectious Diseases Control (Kenya Medical Research Institute), Kenya; ²Obstetrics and Gynaecology Clinical Research, Centre for Diseases Control (Kenya Medical Research Institute), Kenya; ³Research, Kenya Network of Women Living with HIV/AIDS, Kenya; ⁴Clinical Research/Psychiatry, Kenya Neurological Society, Kenya; ⁵Research, Kenya Medical Research Institute, Nairobi, Kenya

Background: The central nervous system (CNS) is often affected by HIV infection. Over 40% of AIDS cases present with neurological symptoms and CNS lesion are detected by anatomical and pathological studies in 80 to 90% of AIDS cases. There may be infections and tumours secondary to the immunodeficiency and pathologies occur directly due to the neurotropism of the virus.

Methods: Neurological problems associated with HIV infection include encephalopathies, myelopathies, neuropathies and myopathies. HIV induced encephalopathy may develop at any stages of HIV infection and affects all risk groups equally.

The frequencies reported differ between studies due to differences in sampling methods, geographical factors, diagnostic criteria and investigative methods used. The involvement of HIV infected macrophages and microglial cells has been demonstrated. Indirect mechanisms such as release of lymphokines (tumour necrosis factor-TNF alpha- and interleukin-1) and neurotoxicity of the HIV envelope protein, gp 120, have been suggested.

Results: This disorder is known as cognitive and motor syndrome. It presents clinically as a form of sub-cortical dementia with cognitive problems, motor deficits and behavioural disorders depending on the type and stage of infection. The diagnosis can be made after all other infections and tumours common in HIV patients have been ruled out by appropriate investigations like cerebrospinal fluid analysis, cerebral scan and magnetic resonance imaging.
Conclusions: Neuropsychological studies could be of value in diagnosis and in assessing the response to anti-retroviral treatment. The use of new nucleoside analogue drugs in combination with existing drugs may provide new approaches to managing these patients.

Optimum gradient artifact removal from EEG-data using facet
J. Glaser*, V. Schöpf*, R. Beisteiner*, H. Bauer*, F. Fischmeister*, K. Fischmeister*
*Faculty of Psychology, University of Vienna, Austria; †Department of Radiology, Division of Neuro- and Musculoskeletal Radiology, Austria; ‡Department of Neurology, Study Group Clinical fMRI, Austria; †Department of Neurology, Medical University of Vienna, Vienna, Austria; High Field MR Center of Excellence, Medical University of Vienna, Vienna, Austria

Introduction: Throughout recent years simultaneous recordings of EEG and fMRI has turned into a viable tool for clinical applications. However, elimination of scanner-induced artifacts is still challenging. Here we present an optimum multi-step algorithm which combines various correction steps for the removal of gradient artifacts.

Methods: FACET is a modular toolbox for fast and flexible correction and evaluation of imaging artifacts. Within this toolbox an optimum algorithm (OptGAR) was constructed by combining various pre-processing steps – like slice onset detection and sub-sample alignment – with an adaptive template generation approach to optimally describe the gradient artifact. Residual artifacts are removed using PCA and ANC. This algorithm was evaluated clinically and by automatic comparison to existing algorithms (Allen 2000 and Niazy 2005) via stepwise evaluation.

Results: Across all measures OptGAR outperformed the other algorithms. The median imaging artifact shows a decrease from 69.9 μV for Allen to 64.9 μV for Niazy and 54.7 μV for OptGAR, the RMS ratio an increase from 84.2 (Allen) up to 109.3. Finally, the median residual activity in the theta band (4–8 Hz) shows a decrease from 20.6% (Allen) to 14.3%. For the beta band (12–24 Hz) a decrease from 35.8% (Allen) via 23.2% to only 8.6% (OptGAR) was achieved.

Conclusions: FACET was used to generate a new artifact removal algorithm. This algorithm not only outperforms existing tools but shows a unique performance in reducing the content of slice frequency and its harmonics. OptGAR together with FACET provides a valuable tool for the removal of imaging artifacts from concurrently recorded EEG.

Analysis of spina bifida prevalence in Brazil in the period from 2001 to 2010
V.F.P. Costa, R.D.D. Sousa, J.D.O. Soares, F.O. Gomes, J.E.D.S. Cavalcante, Faculdade de Medicina, Universidade Federal de Goiás, Goiânia, Brazil

Background: Spina bifida is a significant cause of perinatal mortality and a cause of disability in surviving children. At the same time, there is a scarcity of research about its prevalence in Brazil.

Objective: Analyse the presence of spina bifida among liveborn infants in Brazil between the years 2001 and 2010.

Method: The data about liveborn infants and the cases of spina bifida has been retrieved from the system of information about liveborn infants of the Ministry of Health, the Department of the National Health Service. The data collection resulted in a descriptive and comparative analysis of the prevalence of spina bifida among 1000 liveborns in different regions of Brazil.

Results: An increase of 17.28% in the presence of spina bifida was observed in Brazil in 2001–2010. The year of 2004 presented a peak in spina bifida prevalence (0209 cases/1000 liveborns). This was followed by a decrease and another increase of 0190 in 2010. Regional differences apply in the prevalence of the disease, with the highest rates in the southern region (0216) in 2001–2010 and the lowest rates in the Centre-western region (0115) in the same period.

Conclusion: There was a growing tendency of the prevalence of spina bifida in Brazil indicating that the incentive of folic acid intake in pregnant women is desirable as a preventive measure. Prenatal care leading to early diagnosis and reduction in complications is also recommended.

A review of scientific literature on optimal glioblastoma treatment in elderly patients
G. Simonetti, P. Gaviani, E. Lamperti, A. Silvani. Department of Neurooncology, Fondazione IRCCS Istituto Neurologico Carlo Besta, Milan, Italy

Introduction: Glioblastoma (GBM) is the most common primary brain tumor in adults and the incidence steadily increases with age. The diagnostic rate doubles in the age group between 65–84 years and survival is significantly reduced than younger group. Moreover there isn’t an established standard of care: the role of surgery and radio-chemotherapy remain controversial. We assess the scientific literature to define the optimal treatment for older patients.

Material and methods: The recent phase III randomized controlled trials, and five prospective–retrospective uncontrolled phase II trials were identified. A total of 1187 GBM elderly patients, median age 72.4, were enrolled in order to receive: standard radiotherapy (RT) vs hypofractionated RT vs 6 cycles of chemotherapy with temozolomide (TMZ) or standard postsurgical involved-filed RT vs 100 mg/m² TMZ on days 1–7, 1 week on–1week off or supportive care alone vs supportive-care alone in combination with RT. The primary end point was overall survival. Phase II studies compared chemotherapy with TMZ in two cases, radio-chemotherapy by Stupp in two cases, and last compared radio-chemotherapy vs RT alone.

Results and conclusion: Our review did not show a statistically significant superiority of a particular treatment, but demonstrates that all therapeutic decision, both chemo and/or radiotherapy, could improve overall survival of elderly patients with good performance status, rather than palliative care (6.7 months-vs-3.8 months). In particular hypofractionated radiotherapy plus temozolomide chemotherapy may be the best way to treat patients with Karnofsky-Performance-Status (KPS) ≥ 70%. In patients with a poor KPS, RT could be a reasonable choice. A meta-analysis on collected data will be performed.

**Cryptococcus neoformans neoformans** central nervous system infection in a patient with idiopathic CD4 lymphocytopenia mimicking progressive multifocal leukoencephalopathy (PML)

T.S. Silva 1, F.M. Branco Germiniani 2, M. Muro 3, A.C. Crippa 1, E.J. Piovesan 4, H.A.G. Teive 5, S.M. de Almeida 1, 2.*Neurology, Hospital de Clínicas, Universidade Federal do Paraná, Curitiba, Brazil; 2Laboratory, Hospital de Clínicas, Universidade Federal do Paraná, Curitiba, Brazil

**Background:** Cryptococcal brain infection is a life-threatening disease, mostly associated with various causes of immunosuppression.

**Objective:** To report a case of an HIV negative patient who presented with idiopathic CD4 lymphocytopenia and neurocryptococcosis mimicking PML.

**Patient and method:** We report the case of an immunodeficient patient with brain Cryptococcus neoformans neoformans mimicking PML.

**Results:** A 46-year-old male patient was admitted due to chronic headache, with visual impairment and right-sided tremor. Cryptococcus neoformans var neoformans was identified in CSF and he underwent standard treatment. Repeated ELISA serologic HIV testing was negative. Five months after discharge he presented with an intracranial hypertension syndrome. A brain CAT scan disclosed bilateral white matter hypointense lesions with mass effect. Another treatment course for cryptococcosis was performed. Laboratory testing revealed a CD4 + count of 131 cells/mm³. Three months later, both his visual and neurological deficits progressed, as well as the brain lesions on CAT scan. After another two months, he presented with right-sided motor seizures, right hemiparesis and intracranial hypertension. Serologic Cryptococcus testing in the CSF was positive. Extensive investigation for immunodeficiency causes or organ dysfunction was negative. Brain MRI showed bilateral white matter lesions suggestive of PML. A brain biopsy disclosed infection by Cryptococcus neoformans neoformans. After another course of Amphotericin B, his motor deficit and brain MRI lesions resolved completely.

**Conclusion:** This patient with idiopathic immunosuppression showed clinical and MRI findings consistent with PML but pathology revealed an infection with mass effect by Cryptococcus neoformans neoformans, with improvement following etiological treatment.

**Study on neuronal metabolic characterization in peritumoral area of C6 rat glioma using 1 h MRS at 7 T**

M. Yi 1, G. Yan 1, Y. Xuan 2, Z. Dai 2, S. Li 2, R. Wu 2. 1Department of Medical Imaging, 2nd Affiliated Hospital of Shantou University Medical College, China; 2Shantou University Medical College, Shantou, China

**Background:** Glioma has a tendency to infiltrate the surrounding brain tissue for several centimeters from the core of tumor. The insensitive detection of the invasive scope outside the visible tumor border limits the use of structural magnetic resonance (MR) sequences.

**Objective:** This study aimed to establish a repeatable rat glioma model and investigate the validity of spectroscopy, a functional MR method, in the assessment of the peritumoral area of glioma.

**Methods:** The C6 glioma cells were stereotaxically implanted into the right basal ganglia region of twenty SD rats. The SD rats sequentially underwent MR spectroscopy (MRS) at 7 T MR scanner 7 days after operation. Eurlonal metabolites were measured within the tumor center, peripheral solid parts, adjacent normal-appearing tissue, and contralateral white-matter. All spectra were then quantified by LCModel.

**Results:** This C6 rat glioma model had a high degree of repeatability. A significant gradual increased concentration of NAA, Cr, Glu + Gln, macromolecule, and a decreased of Lac, Ala from the tumor center to the contralateral white matter were observed. Moreover, the highest level of Cho and Lip were also found in the tumor peripheral solid parts and tumor center, respectively. There were no significant differences in Ins and Tau peak among the four areas.

**Conclusion:** Our study provides a repeatable animal model for investigating biochemical specificity of glioma. The acquired MRS data supply additional information about the location of glioma potential border.

**Facial palsy as an initial symptom of Lyme neuroborreliosis in an Austrian endemic area**

W. Kindler 1, H. Wolf 1, K. Thier 2, S. Oberndorfer 1. 1LK St. Pölten, St. Pölten, Austria

**Background:** In areas endemic for Borrelia burgdorferi, facial palsy is a possible manifestation of neuroborreliosis. According to this all adult patients admitted with facial palsy to our hospital, are investigated for Lyme neuroborreliosis including CSF analysis.

**Methods:** In this retrospective analysis from 2007 until 2012, we identified 278 consecutive patients who were admitted with facial palsy. All 278 patients underwent clinical neurological examination. 249 of those patients underwent CSF analysis. Demographic and clinical data were analysed according to a protocol.

**Results:** In 14 out of 278 patients (5%), a definite diagnosis of Lyme neuroborreliosis according to the DGN criteria was established. Four patients were classified as possible Lyme neuroborreliosis. Median age of all patients (n = 18) with facial palsy and Lyme neuroborreliosis was 49 (m = 14/f = 4). CSF analysis revealed pleocytosis (median cell count 240/μ), elevated protein (median = 128 mg/dl), and glucose (median 56 mg/dl).

**Conclusion:** In a typical area with endemic Borrelia, the frequency of Lyme neuroborreliosis in patients admitted due to facial palsy is only 5%. The stringent diagnostic workup including also CSF analysis in almost all patients with facial palsy makes this dataset of Lyme neuroborreliosis meaningful. Although as a consequence of this study, general CSF testing in patients with facial palsy can be omitted.

**Incidence of potential drug-drug interactions and its associated factors in neurology wards of two teaching hospitals in Shiraz, Iran**

A. Safar 1, S. Namazi 2, S. Pourhataami 2, A. Borhani Haghighi 2. 1Kazeroon Azad University, Kazeroon, Iran; 2Shiraz University of Medical Sciences, Shiraz, Iran

**Objectives:** Drug–drug interactions (DDIs) are one of the most important problems related to optimized drug therapy. This study...
estimates the rate and factors associated with potential drug interactions in prescriptions in neurology wards of two teaching hospitals in Shiraz, Iran.

**Methods:** Data was retrieved from neurology wards of two teaching hospitals handwritten prescription, every day during a period of 6 months in 2012. DDIs were identified using Lexi-Comp 2012 version 1.9.1. Clinical and demographic characteristics of patients were recorded from their files. After assessment of the detected DDIs for clinical relevance, interventions took place through physicians or nurses for type D and X drug interactions. Patient's age and gender, number of medications and orders, length of hospitalization and type of neurological disorder were examined as associated factors to potential DDIs (pDDIs). Outcome of interventions and any probable adverse drug events were documented. Statistical analysis was performed by SPSS 15.

**Results:** This study included 589 patients. 4942 drug orders and 3874 medications were prescribed and 4539 DDIs were detected, the overall frequency of DDIs was 35.5%. Among neurological agents phenytion was the most prescribed and account for 76 (12.70%) of patients. Factors having the greatest influence on pDDIs incidences included increased number of medications and seizure. 74.24% of interventions were accepted by physicians and nurses.

**Conclusions:** Clinically relevant DDIs are common among patients in neurology ward. Pharmacists along with other health care professionals can play an essential role in management of medication therapy in hospitalized patients.

**Dystonia in the Lights from the North Exhibition of German renaissance drawings and prints from the Musée Du Louvre**

**Objective:** To describe two medieval depictions of dystonia in the Baron Edmond de Rothschild’s Collection from the Musée du Louvre.

**Background:** Medicine and pictorial art often intermingle. Although traditional portraits of some medical conditions are somewhat common, the representation of movement disorders in medieval prints is somewhat unexpected.

**Method:** By careful analysis of two prints of the Lights from the North Exhibition (German Renaissance Drawings and Prints in Baron Edmond de Rothschild’s Collection from the Musée du Louvre), the authors propose that characters were depicted with different forms of dystonia and make some considerations with the historical context.

**Results:** In the Lights from the North Exhibition (German Renaissance Drawings and Prints in Baron Edmond de Rothschild’s Collection from the Musée du Louvre) presented at the MASP (Museu de Arte de São Paulo), two prints by Jean de Cologne, depicted characters with what could be described as different forms of dystonia. In “Christ Arrested”, one of the peasants in the foreground appears to have a left lower limb dystonia, while in “Ecce Homo or Christ presented to the people”, one character engaged in conversation seems to have a more complex, generalized form of dystonia. We discuss briefly the historical context and compare it with the traditional historical association with Saint Vitus’ Dance.

**Conclusions:** We briefly described two depictions of dystonia in medieval prints of the German Renaissance series of drawings and prints in Baron Edmond de Rothschild’s Collection from the Musée du Louvre and made some comments about the historical setting.

**Darwinian and Jacksonian evolution**

G.K. York. *Neurology, University of California, Davis, Fiddletown, CA, USA*

**Background:** The appearance of evolutionary ideas in the nineteenth century had a pivotal impact on clinical neurology. Darwinism evoked a strong reaction but ultimately became the most important idea in nineteenth century biology. Jacksonian evolutionary neurophysiology, while not Darwinian, produced a consistent bedside science.

**Objective:** To examine Darwinian and Jacksonian evolutionary thought.

**Methods:** Historical research.

**Results:** Jean-Baptiste Lamarck promoted the inheritance of acquired characteristics in a comprehensive evolutionary theory. Exploiting the explosion of literacy in 1840s Britain, the volume *Vestiges of the Natural History of Creation* made the transmutation of species a popular concept. Biology exploded when Alfred Russel Wallace and Charles Darwin independently proposed the evolution of species by natural selection.

Seeing the idea of progressive development as the key to existence, the Herbert Spencer applied evolutionary theory to the phylogeny of the nervous system. John Hughlings Jackson adapted Spencerian evolution to the physiology and pathology of the nervous system, thereby constructing a system of bedside cerebral localization. William Gowers synthesized Jacksonian evolutionary neurophysiology in a usable form in his *Manual of Diseases of the Nervous System*. Konstantin von Monakov and Henry Head brought Jacksonian evolutionary analysis to twentieth century neurology.

**Conclusion:** The application of evolutionary theory to neurology has been called “the most successful application of the theory of evolution in medicine.” The medical use of evolutionary theory allowed Hughlings Jackson to escape the religious approbation that enveloped Darwin. This shows that the world will accept medical ideas when the same ideas evoke controversy when applied generally.

**Rubella encephalitis and status epilepticus in a young adult male**

F. Zangar, M. Mansour, I. Bedoui, A. Riahi, J. Zaoueli, R. Mrissa. *Neurology, Militaire Hospital, Tunis, Tunisia*

**Introduction:** Rubella is a childhood disease that was historically widespread. Rubella virus (RV) neurological complications are rare. Viral encephalitis refers to an acute inflammatory process of the brain parenchyma due to direct viral infection.

**Objective:** We report here a case of encephalitis complicated by status epilepticus in a young man from whom it was possible to isolate RV from the cerebrospinal fluid (CSF).

**Case report:** A 24-year-old man was admitted for generalized tonic-clonic seizure that lasted for more than 15 min. The management of status epilepticus required endotracheal intubation and mechanical ventilation in an intensive care unit. Status epilepticus resolved after 1 mg intravenous clonazepam followed by phenobarbital (dose 10 mg/kg). Physical examination revealed erythematous maculopapular rash on the face, the trunk and extremities. The body temperature was 38.2°C. The neurological examination found that the Glasgow coma score was 10/15, meningeal syndrome and a right hypogloss nerve damage. Cerebral magnetic resonance imaging was normal. Electroencephalogram was normal. CSF analysis showed 260
blood cells/mm$^3$ (90% lymphocytes), glucose 4.3 mmol/L (serum glucose level: 8.0, 9 mmol/L), protein 1.77 g/L (normal < 0.4 g/L). Serum and CSF anti-RV immunoglobulin M antibodies were positive. Acyclovir (10 mg/kg × 3/day) was given intravenously for two weeks associated with Phenobarbital 3 mg/kg/day. He remained asymptomatic after 3 years.

**Conclusion:** RV infection causes a benign disease, and neurological complications remain rare. Among the latter, encephalitis and status epilepticus are extremely uncommon complications of rubella.

**Encephalitis complications of sinusitis about 10 cases**

P.C. Mbonda Chimis, A.F. Cisse, L. Nouts, Y. Fogang, D. Toff, K. Tour, M. Ndiaye, A.G. Diop, M.M. Ndiaye. *Neurology, Fann Teaching Hospital, Dakar, Senegal; Neurology, Ignace Deen Hospital, Conakry, Guinea*

**Background:** Sinusitis can cause multiple encephalopathic complications, which although they are exceptional, can be life-threatening and functional.

**Observations:** We report 10 cases of adolescents aged 13 to 19 years with sinusitis and not followed-up, which showed multiple cerebral abscesses in 4 cases, brain empyema in 3 cases, 2 cases of encephalitis and 1 case of cerebral thrombophlebitis.

The germ highlighted in four cases was *Haemophilus influenzae*. For other cases, cultures were negative (probably caused by antibiotic earlier).

All patients were HIV negative, and patients who had suppurative collections received treatment with neurosurgery, favorable for 5 of them while 2 patients died. Patients with encephalitis and cerebral thrombophlebitis received antibiotics for 45 days with favorable outcome.

**Discussion:** The intracranial suppurations of otorhinolaryngology origin are due in 87% of cases of sinusitis, they are certainly due to the late arrival of patients in our hospitals because they often come at the stage of complications, our patients had an average of 14 days after the onset of symptoms, which is consistent with the literature where some come after 1 month.

**Conclusion:** Sinusitis is a disease requiring treatment early, thus avoiding serious complications which are frequent in our country because of the late arrival of patients in hospitals.

**Selective language aphasia for Turkish language from herpes simplex encephalitis (HSE). (Report of one case)**

S. Nazarbaghi. *Urmia University of Medical Sciences, Urmia, Iran*

Herpes simplex encephalitis (HSE) is the most common cause of sporadic fatal encephalitis. Early recognition and diagnosis is very important for treatment with Acyclovir because it is the single most effective treatment. Two antigenic types of HSV are distinguished by serologic testing. Type 1 strains (HSV-1) are responsible for almost all cases of HSV encephalitis.

**Patient:** Patient was a 54 year old, rural Turkish man, who lived at small village near Urmia City in west Azarbayjan, Iran. He is right-handed and his principal language is Turkish. Although he learned Farsi (Persian language) several years ago, he never spoke routinely using Farsi. He arrived at the emergency ward with fever, neck stiffness, disorientation, headache, seizures, and hemiparesis of the right side and Wernicke aphasia. Early brain CT was normal. On LP, there was pleocytosis of 245 WBCs with 75% lymphocytes, sugar 48 mg/dL and protein 140 mg%. CSF HSV-PCR was positive. Later brain MRI shows bitemporal hypersignal lesions consistent of HSE. Treatment with acyclovir 750 mg q8 h i.v. begun immediately on the first hour of admission plus phenytoin. After the second day of treatment, consciousness was better and seizures were controlled. On the 3rd day, he developed total aphasia for Turkish but began speaking using Farsi language. Patient’s son reported that his father never has talked Farsi before.

**Conclusion:** This case shows relative rareness of this selective language aphasia in HSE. Now, the patient speaks both Turkish and Farsi (bilingual) with some dysphasia dominant for the Turkish language.

**Development of clickclinica: A novel smartphone application to generate real-time global neurological disease surveillance data**

B.D. Michael, D. Geleta, T.R. Payne. *The Walton Centre for Neurology, NHS Foundation Trust, UK; Department of Computer Science, University of Liverpool, Liverpool, UK*

**Background:** In the case of severe but rare neurological infections such as herpes simplex virus (HSV) encephalitis, few centres have sufficient cases for the studies, that are desperately needed, to be conducted. Nevertheless, globally the combined burden of these rare neurological infections is very significant. The first step in undertaking such studies is to better understand the epidemiology.

There are barriers to obtaining these data; for example, current surveillance mechanisms make it difficult for the busy doctor to know which diseases to notify, to whom and how, and are also time consuming. Consequently, many cases go un-notified.

**Objectives:** To use novel technology to increase the identification of major neurological infections.

**Methods:** We developed a free clinical guidelines smartphone application, collecting data as the doctor reads.

**Results:** Within the first few months there were >3000 users and >2000 disease notifications, from all across the globe, including resource poor countries.

Some important information was gathered, including: new cases of TB meningitis and rabies; also important clinical information, such as where patients with HSV encephalitis are, and are not, receiving acyclovir within the recommended timeframe.

This is a potential resource for public health institutions and for recruitment into studies; automatically putting doctors notifying a case in contact with the local research nurse.

**Conclusions:** Parallel studies are needed to assess the utility of such applications. Nevertheless, current surveillance mechanisms miss many cases. Applications, such as this, are a novel approach with the potential to generate real-time disease surveillance data to augment current methods.

Hippocampal changes and associations with psychological symptoms in subjects suffering from anorexia nervosa
N.T. Burkert, K. Koschutnig, F. Ebner, W. Freidl, Institute of Social Medicine and Epidemiology, Medical University Graz, Graz, Austria; Institute of Psychology, Karl Franzens University, Graz, Austria; Clinic of Neuroradiology, Medical University Graz, Graz, Austria
Background: Anorexia nervosa (AN) is one of the most and severe diseases with the highest mortality rate of all mental disorders. Individuals with AN show certain personality traits, which precede the onset of the disease, e.g. anxiety, obsessive behaviour, negative emotionality, inflexibility, and perfectionism. Studies found a reduction of total hippocampus—amygdala formation volume, a reduced volume in the parahippocampal gyrus bilaterally, and a hypoperfusion in the amygdala—hippocampus complex.

Objective: Since this region plays a crucial role regarding stress and emotions, the aim of this study was to analyze the volume, thickness, and connectivity of hippocampal subfields, and its relation to specific symptoms.

Patients and methods: Twenty women who were currently suffering from AN, and 20 healthy age-matched control women (CW) were tested. The mean age of the subjects was 21.8 years of age (range 14 to 33), and the mean duration of the illness in AN was 5.7 years. Demographic, personal and behavioural data as well as data regarding cortical volume, thickness, and anatomical connectivity was collected from a 3 T magnetic resonance scanner (MRI). Comparisons between groups were performed using paired t-tests.

Results: Since analyses are currently conducted only preliminary results can be reported in this abstract. The results showed a significant reduction of the hippocampal fissure as well as the fimbria in AN. Correlations with psychological aspects (eating disorder symptoms, personality, and coping) were calculated.

Conclusions: The results can help to better understand biologic mechanisms which might lead to psychological symptoms. Therefore, psychotherapeutic treatments can be improved.

Interobserver agreement and validity of bedside “positive signs” for functional weakness, sensory and gait disorders in conversion disorder
C. Daum, F. Gheorgita, M. Spatola, V. Stojanova, F. Medlin, F. Vingerhoets, A. Berney, G.E. Maccaferri, M. Hubschmid, S. Aybek, Neurology, Clinical Neurosciences Department, Lausanne University Hospital (CHUV), Switzerland; Psychiatric Liaison Service, Lausanne University Hospital (CHUV), Lausanne, Switzerland
Background: Experts in the field of Conversion Disorder (CD) have suggested for the upcoming DSM-V edition to put more weight on clinical findings. To date, neurologists rely on the presence of bedside “positive signs” suggestive of functional disorder to establish such diagnosis. Most of these signs have a strong historical background but no robust data exist concerning their reliability and validity.

Objective: To look at the interrater reliability and validity of common “positive signs” of functional weakness, sensory and gait disorders.

Patients and methods: Standardized video-recorded neurological examination was performed in 20 consecutive CD patients (DSM-IV) and 20 organic controls. Thirty-seven clinical signs (1-general, 15-motor, 5-sensory, 14-gait signs) were systematically rated by two independent blinded neurologists on the video-recordings. Signs showing a significant difference between CD and organic patients (Fisher’s p < 0.05) and a good to excellent interrater reliability (Cohen’s kappa > 0.60) were identified.

Results: Signs which discriminated CD from organic controls (p < 0.05) were:
- Motor: sterno-clido-mastoid test (kappa:0.83), drift without pronation (0.78), co-contraction (0.77), give-way weakness (0.67), concavity of the palm (0.65) and irregular drift in Mingazzini (0.60);
- Sensory: splitting of vibration (0.66) and splitting the midline (0.63);
- Gait: falls towards support (0.83), excessive hesitation (0.66) and General: suffering behaviour (0.62).

Conclusion: Our study identified 11 “positive signs” (out of 37) with a good to excellent interrater reliability that were significantly more frequent in CD patients than organic controls. The use of these signs should be recommended when diagnosing functional weakness, sensory and gait disorders in CD while further studies will aim at validating their specificity and sensitivity in larger samples.

Brain activity in response to different taste stimuli in subjects suffering from anorexia nervosa in comparison to healthy controls

Background: In the Western countries, anorexia nervosa (AN) is one of the most and severe diseases. Patients with AN have an alteration in cortical regions which are responsible for the regulation of feeding behaviour when taste stimuli are administered.

Objective: Therefore, the aim of this study was to analyze the brain activity in response to three different tastes in patients with AN.

Patients and methods: Twenty women who were currently suffering from AN, and 20 healthy age-matched control women (CW) were tested. Demographic, personal and behavioural data as well as imaging data from a 3 Tesla magnetic resonance scanner (MRI) was collected, while four different stimuli were presented to the participants (sucrose, citric acid, umami, and artificial saliva). Functional MRI (fMRI) data was analyzed for regions of interest (insula, orbital frontal cortex, amygdala and anterior cingulated cortex) using the General Linear Model. Additionally data was correlated with pleasantness ratings of the stimuli.

Results: Since analyses are currently conducted only preliminary results can be reported in this abstract. The mean age of the subjects was 21.8 years of age (range 14 to 33), and the mean duration of the illness in AN was 5.7 years. Pleasantness ratings did not differ between the two.

Conclusions: Since fMRI imaging analyses can provide new insights into the neurobiology of ED, the results can help to better understand biologic mechanisms which lead to normal and pathologic feeding behaviour. Therefore, new and more specific treatments can be developed.

Recurrent Wernicke's encephalopathy in a 16 year-old girl with atypical clinical and radiological features
S. Lamdhadea, A. Almulla, R. Alroughanib, Amiri Hospital, Kuwait City, Kuwait; Dasman Diabetes Institute, Kuwait City, Kuwait

Background: Wernicke's encephalopathy (WE) is a clinical diagnosis with serious neurological consequences. Classic triad of ocular signs, altered sensorium and ataxia is only found in one-third of patients. Its occurrence is underestimated in non-alcoholics and is uncommon in children. We aim to draw attention to a rare case, which had additional clinical and radiological features.

Case: A 16 year-old girl, who underwent intestinal corrective surgeries at 2 months of age for congenital ilio-jejunal atresia, presented with 3-week history of vomiting secondary to intestinal obstruction. She developed diplopia after hospitalization. Neurological evaluation revealed restriction of bilateral lateral rectus with horizontal nystagmus, bilateral limb dysmetria and depressed deep tendon reflexes. Brain MRI was normal. She had prompt improvement to thiamine. Four months later, she presented with two-week history of headache, bilateral severe deafness and tinnitus. Clinically, she had severe sensorineural hearing loss, bilateral lateral rectus palsy and gait ataxia. CT head showed bilateral caudate nucleus hypo-densities. MRI brain revealed symmetry of T2 and FLAIR hyper-intense signals of caudate nuclei and gadolinium enhancement of mammillary bodies and vermis. She had significant improvement after IV Thiamine. Headache completely resolved while the ocular movements, hearing and tinnitus improved partially in 72 h.

Conclusions: Recurrent WE in children is uncommon. Headache, tinnitus and deafness are rare additional clinical features. Although MRI study at second presentation showed typical features of WE, the presence of bilateral caudate nuclei hypo-densities on CT scan is uncommon. Prompt treatment with thiamine is warranted in suspected cases to prevent permanent neurological sequelae.

The tongue twister: Hypoglossal nerve neurilemmoma/neurinoma/Schwannoma: A rare cause of cranial XII palsy
J.E.C. Quilisadip, D.B. Elisa Lolita, Department of Internal Medicine, Davao Regional Hospital, Tagum City, Philippines

Background: To present a case report study of CN XII Schwannoma in a 59 year old female.

Objective: Schwannoma is a benign neoplasm of the peripheral sensorimotor nervous system comprising 8–10% of all intracranial tumors. Forty-two cases of CN XII Schwannoma have been described by Ocuna et al (1994) and Piccirilli et al (2007) found 105 cases in the
English literature. Lee et al. (2007) reported only one case in Taiwan and marks the 70th reported case in Medline. In our institution, this is the only case documented.

**Patient/method:** A 59 year-old female was admitted due to tongue numbness and right-sided tongue deviation for ten months. Physical findings revealed all intact except for right sided tongue deviation. The pain cranial CT scan revealed 4 × 3.2 × 3.5 cm left cerebellopontine angle mass extending into the ipsilateral internal auditory canal with a consideration of acoustic or facial nerve Schwannoma; contrast cranial CT scan revealed primary consideration of Schwannoma, meningioma, and cavernous angioma with non-communicating hydrocephalus. Cranial MRI MRA (Magnetic Resonance Angiography) revealed a non-visualization of the left vertebral artery considering hypoplasia or compression by the ipsilateral cerebellopontine angle mass. Interventricular obstructive (non-communicating) hydrocephalus with MR evidence of increase interventricular pressure was noted.

**Result:** She underwent suboccipital craniectomy and tumor excision at the left cerebellopontine area; discharged-improved after 20th hospital day. Histopathological findings showed Antoni A and Antoni B bodies typical of Schwannoma. Eight months post-operative, the patient is functioning well.

**Conclusion:** Because of their scarcity, early diagnosis is intricate. Histopathological result is the best way to confirm the diagnosis.

Can valerian improve menopausal sleep quality?

S. Taavoni¹, N. Nazem Ekbataninb, H. Haghanib, aMidwifery Continuing Education Office, Research Institute for Islamic & Complementary Medicine (RICM) TUMS, Faculty of Medicine, Iran; bNursing and Midwifery Faculty, Tehran University of Medical Sciences, Tehran, Iran

Menopausal women may have sleep problems, which can lead to low quality of life and can use non-pharmacologic methods for its treatment.

Aim: To evaluate effects of valerian on sleep quality in 50–60 years menopause women.

Material and methods: This is a randomized triple-blind controlled trial. 100 healthy 50–60 years menopause women with insomnia, had been selected from 250 volunteers, whom had been visited in public clinics of west of Tehran. Tools had two main parts of personal characteristics and Pittsburg Sleep Quality Index (PSQI). Samples were randomly divided to two groups. Each group received twice a day for four weeks 530 mg of valerian extract or 50 mg starch as placebo. Data analyzed by (T-test). All ethical points were considered by Ethics Committee of Tehran University of Medical Sciences (TUMS).

Results: Equality of personal characteristics and sleep quality before intervention were checked and there were no differences in two groups. Valerian led to significant decrease in average of PSQI in compared to placebo (valerian group before intervention: 9.8 ± 3.6, after one month intervention: 6.02 ± 2.6) (placebo group before intervention: 11.14 ± 4.3, after one month intervention: 9.4 ± 3.9) (p = 0.000). Also 30% in valerian group and 4% in placebo group had five scores decreased. There was a significant difference between sleep square in two groups (p = 0.000).

Conclusion: Findings from this study add to scientific evidence that the support of valerian in the clinical management of insomnia in menopause.

Acknowledgments: Supported by TUMS and registered in IRCT, year 2010–2011.

The essence of informed consent

M.P. McQuillen, B. Khatri, M. Dukic. Department of Neurological Sciences, Stanford College of Medicine, Stanford, CA, USA

According to Beauchamp and Childress, the term “informed consent” did not appear until a decade after the Nuremberg trials, almost 70 years ago. There are three critical elements to the concept, as explicated by Bernat: adequate information, presented in terminology the patient can understand; competence on the part of the patient, to understand and accept or refuse what is proposed; and free choice, without coercion. But what is the essence of this concept for a neurologist, in this day and age of information explosion; limited time to spend with individual patients; and increasing pressure to “get the job done”, most efficiently and in the shortest time possible? A controlled clinical trial of therapeutic plasma exchange in 200 consecutive patients with chronic progressive multiple sclerosis afforded the opportunity to explore the meaning of this concept
in practice. In addition, the author's clinical experience in several different cultures (e.g., Denmark; the Republic of Ireland; and India) has validated the conclusions reached in the controlled clinical trial. Differences between the contexts of research and the care of patients with neurologic disease; the impact of practice guidelines, electronic health records, and other modern "improvements" in the practice of medicine in general, and of neurology in particular, will be discussed. The author's conclusion is that the essence of informed consent is a matter of trust — and the creation and affirmation of trust takes time. The implications of such conclusions for a neurologist in today's climate — academic and clinical — will be expounded upon.

Post-ictal EEG findings in a patient diagnosed with alternating hemiplegia of childhood (AHC)
T. Spina Silva, S.A. Antoniuk, I. Bruk, A.C. Crippa. Neurology, Clinical Hospital of Paraná Federal University, Curitiba, Brazil

Background: AHC is a rare disease which hemiplegic physiopathology remains unclear and EEG reports scarce.
Objective: To report and discuss a case of AHC and its EEG findings.
Patients and methods: This patient was evaluated at the Clinical Hospital of Paraná Federal University, Brazil.
Results: An 8-month-old boy was admitted due to a left hemiconvulsion–hemiplegia episode. His first seizure occurred at 3 months of age, a prolonged tonic–clonic fever related episode. He was previously healthy and had unremarkable psychomotor development. Phenobarbital was prescribed but seizures recurred with the same semiologic pattern. After five episodes, convulsions became fever-free and shortly after they evolved into diminished tonic–clonic jerks plus ocular deviation to the same side. Post-ictal was then characterized by ipsilateral hypotonic hemiplegia lasting 1 to 3 h outdoing post-ictal somnolence. Seizures increased in frequency and were often prolonged. Laboratory and MRI results were normal. Electroencephalography showed slow activity on the right brain hemisphere and no epileptiform activity during left hemiplegia. On few hours he spontaneously recovered from hemiplegia and at discharge his neurologic exam was normal. He was diagnosed with AHC and topiramate was prescribed. One month after he had no hemiconvulsion–hemiplegic events.
Conclusion: Although neither basal neurologic abnormalities nor quadriplegic episodes were present yet; hemiconvulsion–hemiplegic syndrome was excluded and he was diagnosed with AHC due to multiple alternating episodes that spontaneously recovered few hours after onset. We present, therefore, an atypical case of AHC which post-ictal EEG and clinical abnormalities are in accordance, suggesting a cortical origin to AHC hemiplegia.

Neonatal onset of a Canavan disease in a Libyan non-Jewish Ashkenazi patient
L. Lakhdar1, S. Nagi2, N. Miladi1, 1Neurology, National Institute Mongi Ben Hamida of Neurology of Tunis, Tunis, Tunisia; 2Neuroradiology, National Institute Mongi Ben Hamida of Neurology of Tunis, Tunis, Tunisia

Canavan disease is a genetic neurodegenerative disease caused by mutations in the ASPA gene. Important clinical features are macrocephaly, hypotonia, head lag and developmental delay. Patients show elevated urinary concentrations of NAA. We reported here a case of an eight month and a half year old girl, born to related Libyan non-Jewish parents, from complicated pregnancy (eclampsia) and without perinatal risks, brought to our department for the etiologic diagnosis of severe developmental delay. The neurological exam shows total absence of psychomotor development with central hypotonic syndrome and slight spasticity of the lower extremities with bilateral Rossolimo sign and important macrocephaly. Epileptic seizures were not yet expressed in the infant. MRI findings show a hyperintense T2 signal interesting bilaterally and symmetrical all subcortical white matter, and periventricular regions with U fibres involvement and a bilateral signal abnormalities in thalamus and pallidium. Proton magnetic resonance spectroscopy of the brain shows an increase in the concentration of N-acetylaspartic acid (NAA). Although it is a panethnic disease, information on affected individuals in populations of non-Ashkenazi Jewish origin is rather limited. Ongoing research aims at a better understanding of Canavan disease and underlying mechanisms as a basis for new therapeutic approaches.

Relationship of oxyhaemoglobin signal with blood pressure or skin blood flow during cycle exercise at different intensities: An NIRS study
A. Tsubaki, S. Kojima, K. Sugawara, S. Miyaguchi, D. Sato, H. Tamaki, H. Onishi. Institute for Human Movement and Medical Sciences, Niigata University of Health and Welfare, Niigata, Japan

Background: Near-infrared spectroscopy (NIRS) is a widely used non-invasive method to measure human brain activation on the basis of the cerebral haemodynamic response and has allowed researchers to visualize cortical activation patterns during locomotor recovery after stroke. However, NIRS has the limitation that systemic changes influence the measured signals.
Objective: This study aimed to determine the relationship between NIRS signals and skin blood flow (SBF) or blood pressure during dynamic movements.
Subjects and methods: Nine healthy volunteers (21.1 ± 0.8 years; 6 women) participated in this study. Each subject received oral and written explanations of the objectives, measurement techniques, and risks and benefits of the investigation. The study was approved by the Ethics Committee of Niigata University of Health and Welfare and was conducted in accordance with the Declaration of Helsinki. The oxyhaemoglobin signal (O2Hb), SBF, and mean artery pressure (MAP) were measured while the subjects performed multi-step incremental exercise on a cycle ergometer at workloads corresponding to 30%, 50%, and 70% VO2 peak for 5 min.
Results: Pearson’s correlation coefficient between O2Hb signal and MAP was 0.947 (P < 0.01) at 50% VO2 peak. The coefficients between O2Hb and SBF at 30%, 50% and 70% VO2 peaks were 0.454 (P < 0.05), 0.877 (P < 0.01), and −0.707 (P < 0.01), respectively.
Conclusion: Systemic cardiovascular state changes positively influence O2Hb signals during moderate-intensity cycle exercise. However, during high-intensity exercise, a negative relationship was observed. To detect cortical activation, clinicians should pay attention to changes in both SBF and MAP.
Traditionally the cerebellum has been related almost exclusively to motor functions, in spite of the growing evidence that relates the cerebellum to cognitive functions. Until now, no clinical tests have been previously designed to explore the cerebellar cognitive functions. We describe a clinical test designed to explore the cognitive functions of patients with exclusive cerebellar lesions comparing them to normal subjects. The maneuver consists in the application of 4 neuropsychological standardized tests to the three study groups, in two different clinical conditions. During the first clinical condition, these tests were applied to the subjects in the sitting position. During the second clinical condition, equivalent standardized tests were applied in the Romberg’s position. The narration test was the most important test in our study, and the three remaining tests (mental control, category evocation and learning) were applied to evaluate at that same moment, the attention and memory of the volunteers in order to rule out the possibility that an abnormal result in the narration test would be the consequence of having the volunteer’s attention focused on the maintenance of the posture. The standard treatment for tuberculous meningitis (TBM) has under-
are reluctant to accept Directly Observed Treatment Short Course (DOTS) intermittent regimen for TBM since its introduction. There are no randomized trials to compare daily regular regimen with Revised National TB Control Programme (RNTCP-DOTS) regimen.

**Aim:** A prospective study to compare the effectiveness in two groups of TBM patients who were assigned to conventional daily and DOTS intermittent regimen.

**Material and methods:** Patients diagnosed of having TBM according to the diagnostic criteria laid by consensus case definition for TBM at the international TBM workshop were included during the period from September, 2010 to March, 2012. Group I patients received DOTS regimen and Group II patients received conventional daily regimen and they were followed until they completed the course of ATT.

**Results:** A total of sixty eight patients were included in the study of which 36 were in the DOTS group and 32 in the conventional group. Baseline characteristics, clinical features and laboratory parameters between the two groups were similar. There was no statistically significant difference in terms of mortality, morbidity, number of patients who lost to follow up and number of patients who developed drug induced hepatitis between the two groups.

**Conclusion:** DOTS and conventional regimen are equally effective in tuberculous meningitis.

**Quantitative assessment of the autonomic nervous system in young patients with vertebra–basilar dyscirculation**

**N. Nekrasova, I. Grygorova. Neurology, Kharkiv National Medical University, Kharkiv, Ukraine**

Heart rate variability (HRV) has proven to be a sensitive clinical test for early detection of autonomic nervous system (ANS) dysfunction in various neurological disorders. The aim of the investigation is to estimate dependency of ANS dysfunction from the changes of circulation in vertebra–basilar system in young patients.

89 patients aged from 18 to 44 years with clinical picture of spondylogenic vertebra–basilar insufficiency (SVBD) have been under investigation. 3 groups were formed: 1 — 39 patients with angiodystonic stage of SVBD, group 2 — 26 patients with angiodystonic—ischemic stage of SVBD, and group 3 — 24 patients with ischemic stage of SVBD. For blood supply assessment ultrasound dopplerography and duplex scanning were performed; to diagnose the cervical part of the vertebral column the X-ray examination and MRI were done. To evaluate the changes in ANS, the HRV was performed (Cardiolab, Khai Medica). The investigation was done in the rest and after De Kleyen Test. The study of the HRV, obtained after De Kleyen Test was characterized by increasing power of spectrum in the area of very lower frequency (especially in group 1), that reflects activating of sympathetic part of the ANS, providing realization of ergotropic activity. Overstrain of trophotropic activity in group 2 was characterized by increasing power of spectrum in the area of high frequency, that reflects activating of compensatory mechanism of ANS, directed to the normalization of autonomic disbalance.

These data may be used as a marker of involving of autonomic levels of regulation during performing provocative functional probes.

**Clinico-pathological correlates in cerebellar ataxia with neuropathy and vestibular areflexia syndrome (CANVAS)**

**D.J. Szmytekcz, L. Roberts, C.A. McLean, H.G. MacDougall, A.M. Chancellor, S. Mossman, D. Lamont, E. Storey, G.M. Halmagyi.†University of Melbourne, Royal Victorian Eye & Ear Hospital, Australia; ‡Neurophysiology, University of Melbourne, St Vincent’s Hospital, Australia; §Pathology, Monash University, Alfred Hospital, Melbourne, VIC, Australia; ¶Psychology, University of Sydney, Sydney, Australia; ¶¶Medicine, Tauranga Hospital, Tauranga, New Zealand; ††Neurology, Capital Coast Health, Wellington, New Zealand; †‡Pathology, Waikato Hospital, Waikato, New Zealand; †††Neuroscience, Monash University, Alfred Hospital, Melbourne, VIC, Australia; †‡‡Neurology, University of Sydney, Royal Prince Alfred Hospital, Sydney, NSW, Australia**

**Background:** CANVAS is a novel vestibulo-cerebellar ataxia with characteristic clinical features, atrophy of the cerebellum and cranial and spinal nerve sensory ganglia. CANVAS is comprised of the clinical triad of cerebellar ataxia, bilateral vestibular hypofunction and a somatic sensory deficit, and is associated with an abnormal visually enhanced vestibulo-ocular reflex (VVOR).

**Objective:** To further elucidate the pathology underlying CANVAS.

**Patients and methods:** Brain and spinal neuropathology in two CANVAS patient, together with brain and otopathy in another patient was correlated with clinical, neurophysiological and MRI data on 51 CANVAS patients.

**Results:** A marked spinal dorsal root and vestibular, trigeminal and facial neuropathy (giglgonionopathy) was seen on post-mortem histopathology. Brain pathology revealed selective cerebellar cortical atrophy with marked Purkinje cell loss. All patients had brain MRI and 46/51 had evidence of cerebellar atrophy involving anterior and dorsal vermis, and the hemispheric crus I.

**Conclusion:** We have been able to advance the clinical understanding and investigation of CANVAS patients by utilizing recently available post-mortem pathological material, and show that the underlying sensory pathology in CANVAS is in the sensory ganglia, including the spinal dorsal root ganglia, as well as those of cranial nerves 5, 7 and 8. Other ataxias which may present with a combination of cerebellar impairment, a bilateral vestibularhypofunction and a somatic sensory deficit include both spinocerebellar ataxia type 3 (SCA3 or Machado–Joseph disease) and Friedreich’s ataxia. The CANVAS patients that we have identified include members of 7 kindreds and identification of the pathological gene is under investigation.

**Hereditary spastic paraplegia in children**

**R. Kou* F. Al Murshed‡, A. Al Futaisi*. †Child Health, Sultan Qaboos University, Muscat, Oman; ‡Clinical Genetics, Sultan Qaboos University, Muscat, Oman**

**Background:** A large number of children present with developmenta ldelay and spasticity of the limbs. The causes may vary from perinatal events to the structural anomalies of the brain. In a significant group of children no underlying cause is identified. Hereditary spastic paraplegia is uncommon in children. This has to be considered particularly if family history of a sibling is present.

**Objectives:** The aim of the study was to find out spectrum of the hereditary spastic paraplegia in children in Oman.
Methods: This is a retrospective study from January 1994 to December 2012 on children with delayed development, gait disorder and motor handicap with signs of symmetrical pyramidal tract involvement. A detailed perinatal and family history including age of onset of symptoms was recorded. The children were labeled as pure or complicated form on the established diagnostic criteria. In families with more than one affected child, all other siblings and parents were also examined.

Results: Eighty five children, from 36 families were diagnosed to have hereditary spastic paraplegia. Parental consanguinity was seen in 91%. Onset of the disease under one year was in 49 (57.6%). Complicated hereditary spastic paraplegia was the most common type in 81%. Speech involvement, mental retardation and epilepsy were the most common associated abnormalities. Non-specific white matter changes and corpus callosum abnormalities were noted in 21 (24.7%) on magnetic resonance imaging.

Conclusions: The study describes clinical features of 85 children with hereditary spastic paraplegia. Autosomal recessive complicated hereditary spastic paraplegia was seen in 81%.

Can deep brain microstimulation be used to study the thalamocortical connection of the tactile sensation?
H.-J. Jiang, K.-H. Chen, F.-S. law, Institute of Biomedical Engineering, National Taiwan University, Taipei, Taiwan, ROC

Background: The medial lemniscus is crucial for somatosensory signal transmission from peripheral to telencephalon. In the past, applying adequate stimuli in peripheral was essential for investigating sensory functions. An electrical microstimulation (ES) method was developed here to investigate the possibility of bypassing the peripheral receptors to study connections within this pathway.

Objective: To establish a method of microstimulation in rat thalamus that induces sensory cortex response to mimic the tactile response induced in peripheral.

Material and methods: Male Wistar rat was adequately anesthetized and craniotomy was performed. Tactile stimulation (TS) was applied to the hindpaw, and the contralateral responses were recorded by two glass microelectrodes in thalamus and cortex respectively. Then, ES was applied to the thalamus electrode. The cortical action potentials (APs) obtained by ES were carefully compared with those obtained by TS.

Results: The ES strength and duration for inducing APs were between 40 to 90 V and 1 to 2 ms in a total of 5 rats. The APs of ES responses were similar to those of TS. The time latencies of ES APs were compatible to the time lag between thalamus and cortex of the TS APs (7.93 ± 1.22 ms vs. 9.21 ± 1.13 ms).

Conclusion: The similar latency and waveforms of these APs suggested that ES in thalamus can elicit similar responses in cortex as tactile stimuli do in peripheral. This may shed light on the study of a connection within the entire tertiary tactile pathway in a more precise and controllable way.

Sleep disorders in neurological diseases: A preliminary study of the adapted Arabic version of the Pittsburgh Sleep Quality Index scale
Y. Sidhom, M. Ben Djebara, I. Kacem, Y. Hizem, A. Gargouri-Berrechid, R. Gouider. Department of Neurology/Research Unit 03/OR/08-09, Research Unit 12SP21, Razi Hospital, Tunis, Tunisia

Introduction: Sleep disorders in patients with neurological diseases are often underdiagnosed, although their prevalence and their impact on life quality are significant. We aimed to translate the Pittsburgh Sleep Quality Index (PSQI) scale in an Arabic version and to assess the reliability of the translated version in patients with neurological disorders.

Methods: Two independent translators converted the French original version into Arabic version simultaneously. The consensual version was converted back into French by two other independent translators. A comparison between the original and the translated-back versions was performed by an independent expert. A study was conducted among 40 patients to assess the understanding practically. Life quality, depression and anxiety were evaluated respectively by SF36, Beck and Hamilton scale.

Results: Mean age of patients was 53 years. Mean PSQI results were 10.52 (range: 1–18). 82% of patients had an impairment of sleep quality. Depression was diagnosed in 73% and anxiety in 42%. Life quality was impaired in 87.5%. Understanding of the scale was unremarkable. Results of different items were homogenous (alpha Cronbach coefficient: 0.78). A positive correlation was found between PSQI results and age, gender, unemployment, smoking, comorbidities and the age of onset. However, no relationship was noted between the type of the disease, period of progress, depression, anxiety and life quality.

Conclusion: The elaborated Arabic version of the PSQI scale presents the same structural hallmarks. It is a simple and reliable tool to...
evaluate the occurrence and the severity of sleep disorders in patients with neurological diseases.

Paraneoplastic motor neuron disease
I. Kacem, C. Gnaichia, Y. Hizem, L. Sellami, M. Ben Djebara, A. Gargouri-Berrechid, R. Gouider. Department of Neurology/Research Unit 03/0R/08-09, Research Unit 12SP21, Razi Hospital, Tunis, Tunisia

Introduction: Paraneoplastic neurologic syndrome involves neurologic symptoms resulting from damage of the nervous system that are not due to the effects of the primary tumor mass, metastatic disease or other cancer related complications. Paraneoplastic motor neuron disease is rare.

Objective: To describe the clinical and biological features in patients with paraneoplastic motor neuron disease.

Methods: We analyzed, through a retrospective study, the files of patients followed over a four-year (2008–2012) and diagnosed as paraneoplastic motor neuron disease. Diagnosis was made according to Euronet group and Escorial criteria. Electrophysiological examination was performed in all patients. The detection of well-characterized onconeural antibodies and the research of the primitive tumor were made.

Results: We included 6 patients. Mean age was 53 years. All of them had definite Amyotrophic Lateral Sclerosis. Onconeural antibodies were identified in all patients. All patients had definite paraneoplastic syndrome. Breast cancer was found in one patient and lung cancer in another patient.

Conclusion: A motor neuron disease may occur rarely as a paraneoplastic syndrome. It can be isolated or associated with other neurological syndromes. The rapid course of the disorder and the alteration of general state in patients suggest a paraneoplastic syndrome. The identification of the disorder is important because it may lead to the early detection and treatment of the tumor.

The prevalence of abnormalities of the main vessels of the head in the open population of the city of Ulyanovsk
S.V. Burtsev¹, L.A. Belova², N.V. Belova³. ¹Neurology, Ulyanovsk State University, Ulyanovsk, Russia; ²Research Center of Neurology, Russian Academy of Medical Sciences, Moscow, Russia

Background: Every year 18 million people die from cerebrovascular diseases (Estrol C., 2011). The priority direction of neurology is to improve the quality of early diagnostics of cerebral vascular diseases (Suslina Z.A., and etc., 2010).

Aim: To study the ultrasonic signs of abnormalities of the main head arteries in the course of chronic cerebrovascular diseases (CCD).

Materials and methods: 236 persons, 40–59 years old, divided into groups, according to clinical manifestations of CCD. 120 subjects didn’t have any circulatory system disorders, a group with CCD included 116 people. We evaluated the thickness of intima-media complex, the presence of atherosclerosis plaques, stenosis and vessel tortuosity.

Results: The thickening of intima-media complex was visualized in 150 (63.5%) people, atherosclerosis of cervical arteries with stenosis was detected in 75 (31.7%) patients, tortuous cervical arteries found in 75 (31.8%) and tortuous vertebral arteries — in 112 (47.6%) people. The thickening of intima-media complex was more common for the CCD group (75%), than for healthy subjects (43.5%), p < 0.05. Tortuosity of brachiocephalic arteries (35%) and vertebral arteries (64%) in CCD patients was seen more often, than in the group without circulation disorders (17.4% and 26.1%, respectively), p < 0.05. Both groups demonstrated approximately the same frequency of atherosclerosis and stenosis.

Conclusions: The most frequent ultrasound findings in the observed patients are thickening of intima-media complex and tortuosity of vertebral arteries, which are signs of hypertensive angiopathy. Although atherosclerosis with stenosis occurs equally often both in patients with clinical evidence of CCD or without it.

Psychometric diagnostic of cognitive functions and motor skills — Findings from a neuropsychological test battery on Niemann–Pick type C-patients
L. Peintainger, H.H. Klüenmann. Psychiatry and Psychotherapy, University of Regensburg, Regensburg, Germany

Niemann-Pick type C (NPC), a rare genetic lysosomal metabolic disorder caused by a mutation in the NPC1 or NPC2 gene, can affect people at all age. The onset, its symptoms and its progression are very inhomogeneous distributed over all patients. Neuropsychological testings examine areas in the brain which are responsible for cognitive functions like vigilance, concentration, learning, memory, language skills, etc. In addition motor skills can be measured by tests to see how the patient moves in various situations and manages different tasks. Concerning this context it is challenging to have a test battery able to measure those functions in patients with different stages of disease. In this study we tried to tie on a former study to attain the aim to optimize a neuropsychological test battery for adult NPC-patients.

All in all we tested 22 NPC-patients from three countries with 11 tests including the TMT A/B, PPVT, CRFT, Grooved Pegboard as well as German-speaking tests containing suitable norms of age.

Results show that in some cases tests had been too challenging for some patients in advanced phases of their disease also some did not distinguish enough in lower performance ranges. Nevertheless a few showed specific results of the sample’s cognitive functions whereas intraindividual comparisons over time would be interesting. In addition one should think the alternative to relate results of NPC-patients with either older people or in opposite with developmental age of children when norms do not exist in context of particular tests.

Peripheral neuropathies in childhood, a case report of Churg–Strauss syndrome in a Czech patient
Z. Albahári, L. Minxsovi, A. Lukeš, A. Al Mawiri, Š. Štefáčková. ¹Department of Pediatric, Faculty Hospital, Charles University, Czech Republic; ²Department of Internal Medicine, Charles University First Medical Faculty, Czech Republic; ³Department of Neurology, Faculty Hospital, Charles University, Hradec Králové, Czech Republic

Peripheral neuropathies in childhood, a case report of Churg–Strauss syndrome in a Czech patient
Churg-Strauss syndrome (CSS) is a rare form of small-vessel vasculitis. We describe a 17-year-old Czech girl, characterized predominantly by peripheral neuropathy, the presence of cardiac and pulmonary involvement, hypereosinophilia, asthma and sinusitis led to the diagnosis of CSS.

Clinical characteristics and cerebrospinal fluid adenosine deaminase activity in patients with meningitis caused by Varicella-Zoster virus
H.G. Oha, E.J. Rheb, a Department of Neurology, Soonchunhyang University College of Medicine, Cheonan, Republic of Korea; bDepartment of Endocrinology and Metabolism, Kangbuk Samsung Hospital, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea

Background: Varicella-zoster virus (VZV) is an unusual cause of meningitis in the immunocompetent patient. Most cases of VZV-associated aseptic meningitis are associated with the skin rash of primary varicella, localized herpes zoster, or disseminated zoster. The diagnostic value of adenosine deaminase (ADA) activity in cerebrospinal fluid (CSF) of tuberculous meningitis has been well documented. VZV meningitis without zoster rash but having high CSF ADA activity tent to be misdiagnosed as tuberculous meningitis.

Methods: We evaluated patients who were admitted due to meningitis from 2010 to 2012 with VZV PCR-positive CSF. According to existence of zoster rash, patients were divided into two groups. We investigated headache intensity, clinical course, concurrent neurological symptoms, CSF profile, the effect of analgesics, and clinical prognosis.

Results: 13 patients (19–55 years of age) had VZV PCR-positive CSF. Only 3 patients (23%) had a concomitant zoster rash. All two groups had acute onset, no other neurological deficit except for neck stiffness, no hypoglycorrachia and good prognosis. However, patients without rash had more severe headache symptoms, longer headache duration, poorer effect of analgesics, and higher CSF cell, protein, and ADA level than those with rash. (CSF WBC 478.9 vs. 77.7, CSF protein 158.7 mg/dL vs. 56.6 mg/dL, CSF ADA 10.6 IU/L vs. 5.3 IU/L).

Conclusion: The patients with VZV meningitis without accompanying zoster rash tend to present more severe headache and higher CSF ADA activity.

Lyme disease presenting with bilateral facial palsy
R. Ikonomov, a T. Stoyanova, a A. Bocheva, a, b Neurology, MHT Sofia Med, Bulgaria; cNeurology, MHT 2, Sofia, Bulgaria

Objective: The bilateral facial palsy is a rare form of facial palsy, which usually may be a serious diagnostic problem.

Patients and method: We have presented the clinical case of a 59-year old woman with consecutive affection of the muscles of both facial sides, as well as the diagnostic options for the patient. We have carried out many clinical and paraclinical tests — clinical examination, laboratory methods, X-ray examination, computer tomography, magnetic resonance tomography, electromyography, immunology. The patient refused a lumbar puncture to be made.

Results: Following the tests that were described above and the continuous monitoring of the patient, we have established that this is a Lyme disease. The respective etiological treatment was carried out, which leads to a significant improvement in the patient’s condition.

Conclusion: The bilateral facial palsy is a condition, which requires a thorough examination of the patient. One of the common reasons for it may be the Lyme disease, which requires timely diagnosis and early etiological treatment.

Methionine PET and DTI tractography contribution in differential diagnosis of LETM and mimicking disorders: 3 clinical cases presentation
L. Prakhova, a A. Gurchin, a A. Ilves, a T. Matveeva, b J. Nazinkina, a J. Savinseva, a N. Totolyani, b T. Trofinova, b Institute of Human Brain Russian Academy of Sciences, Russia; St.Petersburg Pavlov’s State Medical University, Saint Petersburg, Russia

LETM — spinal cord disorder with MRI presentation of lesion extended over 3 vertebral segments. Differential diagnosis includes demyelination, autoimmune, infectious process, and tumors. Routine diagnostic procedures include conventional MRI, blood, and CSF tests.

In brain pathology [11C]-methionine-PET and DTI-tractography are used to differentiate neoplastic, inflammatory or ischemic lesions. It is limited data on PET and DTI diagnostic value in spinal cord disorders. Clinical cases are presented to demonstrate the significance of these neuroimaging techniques in clinical practice.

59 y.o. female developed subacute progressive cervical myelopathy requiring differential diagnosis between neoplastic, ischemic or demyelinating disorder. Normal [11C]-methionine-PET and brain MRI, spinal cord tracts interruption, negative serology for systemic disorders and AQP4 antibodies, positive CSF-OB complied with the diagnosis of LETM associated with OB-IgG.

21 y.o. female with 2 years history of progressive “autoimmune” myelopathy was treated with corticosteroids, IVIG, immunomodulating and immunosuppressive agents. Positive spinal cord [11C]-methionine-PET and distorted spinal cord tracts on DTI matched the intramedullary neoplastic process. Diagnosis of glioblastoma was confirmed by biopsy. 45 y.o. male presented with rapid progression of paraplegia, and bladder dysfunction. Thoracic spinal cord MRI revealed lesion consistent with LETM. Patient was treated with steroids, and azathioprine without effect. Negative [11C]-methionine-PET confirmed no tumor. MRI revealed diffuse T2-hyperintensive and thickened non-enhancing thoracic spinal cord and enlarged tortuous thickened non-enhancing thoracic spinal cord and enlarged tortuous dorsal spinal vein draining from Th8 to 9 dorsal arteriovenous fistula. Longitudinal spinal tracts were intact which was considered of possible prognostic value for planned neurosurgery.

It is advisable to incorporate [11C]-methionine-PET and DTI-tractography to optimize neuroimaging protocols in LETM and mimicking disorders.

The applications of 7T H-MRS in detecting GLU metabolism during the depression mechanism
Y. Ding, R. Wu, G. Yan. 2nd Affiliated Hospital of Shantou University Medical College, Shantou, PR China; Shantou University Medical College, Shantou, PR China

Background: Internal jugular vein (IJV) thrombosis (Lemierre syndrome), associated with supplicative infection of the upper aero-digestive tract was first described a century ago. The complications associated with IJV thrombosis are potentially lethal and it is therefore important to recognize and treat this condition early. Herein we describe a case of infective IJV thrombosis secondary to pulmonary tuberculosis.

Case: A 33 year old male presented with blurred vision and bifrontal headache. He had a 3 month history of pulmonary tuberculosis and right transverse sinus thrombosis which were started to be treated. He had bilateral papillledema, visual acuity was decreased and he had high intracranial pressure. Cranial MRI an MR venography revealed irregularities in the right transverse sinus consistent with chronic sequel thrombosis. Bilateral carotid and vertebral artery Doppler USG and angiography revealed right internal jugular venous thrombosis. Ultrasonography of neck showed lymphadenopathies in both cervical and submandibular lymph nodes. Aggressive antituberculous treatment along with anticoagulation was continued with nearly full recovery of vision.

Conclusion: We want to report this case as we feel, that with the advent of the antibiotic era, this syndrome has become rare; and so “quite forgotten” or overlooked, by many physicians. When recognized early and treated with appropriate aggressive medical and surgical therapy, death from jugular vein thrombosis is uncommon today.

By being aware of jugular vein thrombosis, the physician can be more vigilant for potential complications and diagnose and treat them earlier.

doi:10.1016/j.jns.2013.07.2209
Background: Nervous system in congenital heart diseases (CHD) has always attracted the attention of pediatricians, surgeons and neurologists. According to most researchers with cyanotic CHD type shows more diverse changes CNS than the evils of “white” type.

Objective: To study the cognitive function in children with cyanotic heart disease before and after surgery in recovery.

Material and methods: A total number of 97 children aged between 4 and 14 years with cyanotic congenital heart disease.

To assess the level of intellectual development, D. Wechsler’s children version was used, which consist of tests adapted for preschool (WPPSI) and school children (WISC) for the Uzbek-speaking children.

Results: The study of cognitive function before surgery showed reduced performance on non-verbal intelligence subtests (65.6%), than on verbal subtests (82.4%). Children experienced some difficulty in carrying out the following tests “Labyrinth”, “Coding”, “Folding the figures”, “Finding similarities”, and “Sentences”.

Thus, suffered more memory, attention, spatial analysis, and thought process that manifest with difficulty in performance of test “Cubes of Kohs” (59.4%). It should be noted that the decline of intelligence is prevalent among patients with seizures (44.9%).

Conclusion: Hemodynamic findings in the brains of children with CHD lead to cognitive impairment, as a reduction in attention and memory, spatial analysis and cognitive functions. In the postoperative period after 1 month period was significant cognitive decline as a result of prolonged cardiopulmonary bypass and the impact of drugs for anesthesia.

Primary mitochondrial DNA mutations and probable variants in Leber’s hereditary optic neuropathy

Introduction: Leber’s hereditary optic neuropathy (LHON) is one of the most common mitochondrial disorders, which mainly leads to vision loss in young males.

Objective: To describe the clinical manifestations of Leber’s hereditary optic neuropathy (LHON), and to determine the genetic mutations responsible for these phenotypes.

Materials and methods: We report the cases of three patients suffering from progressive visual loss. In these patients we have performed genetic study searching for three primary mutations in mitochondrial DNA (m11778G.A, m3460G.A and m14484 T.C).

Results: Two men and one woman have been addressed for a visual loss with optic atrophy. The age varied between 29 and 32 years. The neurological examination was normal except visual disturbances. Visual evoked potentials showed a prolongation of P100 wave. Brain MRI was normal in all patients. We found the point mutation (m14484 T.C) in a single patient.

Discussion: One of three patients had a mutation. The other two may have other mitochondrial genes that are mutated and only reported in a minority of families.

Conclusion: mtDNA is highly polymorphic in nature with very high mutation rate, 10–17 fold higher as compared to nuclear genome. Identification of new mtDNA sequence variations is necessary to establish a clean link with human disease.

A case report: 53-year old Filipino with polynuropathy, organomegaly, endocrinopathy, monoclonal gammopathy, and skin changes (poems) or Crow-Fukase syndrome

C.A.V. Inso, J.A.S. Vatanagul. Internal Medicine, Perpetual Succour Hospital, Cebu City, Philippines

Background: POEMS syndrome or Crow-Fukase syndrome is a rare multi-systemic disease caused by overproduction of vascular endothelial growth factor (VEGF), probably mediated by monoclonal proliferation of plasma cells. Most patients with POEMS syndrome commonly present with extremity weakness. The syndrome is also associated with monoclonal plasma proliferative disorder, along with organomegaly, endocrinopathy, and skin changes. The Mayo Clinic Experience identified only 170 patients to have POEMS syndrome.

Clinical presentation: A 53-year-old man who complained of 18 months duration of progressive weakness and numbness of both upper and lower extremities associated with hyperpigmentation of the skin, hypertrichosis, and bipedal edema. Predominant distal muscle weakness and atrophy was noted. Multiple large non-tender, cervical lymph nodes were noted. EMG-NCV showed polyneuropathy, sensory and motor diffuse, axonopathic and demyelinating, with signs of acute denervation and chronic denervation changes. The distal sensory and motor nerves of both upper and lower limbs were severely axonopathic. Hypothyroidism and impaired fasting glucose was noted and Ig2 microglobulin determination was also elevated. MRI of the spine showed patchy areas of sclerosis involving the vertebral bodies of C3–C5, T2–T5 and T11.

After treatment with cyclophosphamide and prednisone improvement of motor function and neuropathic pain was noted. On follow-up he was already ambulatory with assistance and less dependent for his activities of daily living.

Recommendations: To our knowledge, there is only one published case of POEMS syndrome in the Philippines. Early recognition of POEMS syndrome is important to limit its morbidity, even if not all the features are present initially.

Curcumin nanoparticulate based neuroprotective approach for management of cerebral malaria

K. Jain, S. Sood, K. Gowthamarajan. Pharmaceutics, J.S.S College of Pharmacy, Udthagamandalam, India

Background: Curcumin is a polyphenol derived from the dietary spice turmeric and possesses diverse biological and pharmacological activities.

Objective: To investigate the potential of nanostructured lipid carriers (NLCs) loaded curcumin for management of cerebral malaria.

Materials and methods: Curcumin loaded NLCs (C-NLC) were prepared using microemulsion technique. They were characterized for surface morphology, particle size, zeta potential and ex vivo release studies in sheep nasal mucosa. Toxicity assessment was carried out by SK–N–SH cell lines, hemolytic activity and histopathological studies. Antimalarial efficacy was carried out in Plasmodium berghei ANKA murine model of cerebral malaria.

Results: The NLCs showed average particle size of 18–30 nm with zeta potential of $-33.2 \pm 0.75$ mV. Transmission electron microscopy studies confirmed that NLCs were spherical in shape. In vitro hemolytic
activity and cytotoxicity value of C-NLC in SK-N-SH cell lines revealed that NLCs were not toxic by SRB assay. The ex vivo results indicated that release rate was biphasic and faster from drug suspension as compared to NLCs in simulated nasal fluid. The nasal ciliotoxicity studies were carried out using isolated bovine nasal mucosa which was further subjected to histopathological analysis. Results revealed that nanoparticles formulation had no harmful effect on the microscopic structures of nasal mucosa. The developed C-NLC showed significant antimalarial efficacy. **Conclusion:** C-NLCs could be used as a potential treatment for cerebral malaria.

**Neuropsychological presentation of Ganser symptoms in a case of Chinese speaking corticobasal syndrome patient**

K.P. Yong, S.K.S. Ting, Neurology, Singapore General Hospital, Singapore, Singapore

'Ganser syndrome' refers to a condition of cognitive decline that is characterized by 'near miss' answers to questions. It has been described in both psychiatric and organic brain diseases. However, distinct brain behavior correlation has yet to be defined. We describe a case of corticobasal syndrome with neuropsychological profile in keeping with episode of Ganser symptoms, and the characteristic of Chinese 'alexia' and 'agraphia' seen in this clinical entity. This case illustrates the importance of recognizing neuropsychological characteristic of Ganser symptoms, reemphasizes its association with neurodegenerative diseases, and raises question of role of basal ganglia and frontal–subcortical network dysfunction in producing Ganser symptoms.

**Fatigue in neurosarcoidosis**

R. Hebel, Z. Baneca Majkutewicz. Medical University in Gdańsk, Gdańsk, Poland

Sarcoidosis is idiopathic, autoimmune, multisystemic disorder characterised by the presence of noncaseating epithelioid cell granulomas which can affect any organ. About 5–15% of patients with sarcoidosis have nervous system involvement — leptomeningeal and intraparenchymal infiltration of granulomas that lead most frequently to cranial nerve palsies, basal meningitis and endocrine dysfunction. Fatigue is experienced almost universally by autoimmune disease sufferers. Fatigue can be also one of the symptoms of neurosarcoidosis. It is a disabling problem which decreases the ability of patients to perform previous routine activities and disrupts quality of life. The aim the study was to investigate fatigue in sarcoidosis.

50 sarcoidosis patients referred to the Neurology Outpatients' Clinic with symptoms indicating nervous system involvement were studied. All completed the Fatigue Assessment Scale (FAS). The majority (31–62%) reported fatigue (FAS ≥ 21). We evaluated whether fatigue can be connected with prednisolone usage, abnormal neurological signs, NMR, and pulmonary subtype. 10% of sarcoidosis patients with fatigue had abnormal neurological signs — abnormal sensation, positive Romberg's test, decreased hearing and nystagmus; 10% had changes in the brain NMR scans — thickening of the dura mater — 3 or disseminates changes — 2, and 20% were treated with prednisolone. In order to determine whether there were any associations between fatigue and neurological examinations, NMR, prednisolone therapy and pulmonary sarcoidosis subtype statistical tests were used.

Our studies indicate that there is no statistical correlation between fatigue, abnormalities in neurological examination, NMR, prednisone therapy and pulmonary sarcoidosis subtypes. Fatigue is a common symptom in sarcoidosis patient which changes the quality of their life. Our study will be continued.

**An unusual case of neuro-Behçet disease with coma**

M.F. Oztekin, N. Oztcin, T. Kuz Teksut, E. Efendizade, E. Gurgas, F. Ak. Neurology, MOH Ankara Yıldırım Beyazıt Education and Research Hospital, Ankara, Turkey; Neurology, MOH Ankara Numune Education and Research Hospital, Ankara, Turkey

**Background:** neuro-Behçet disease (NBD) is reported between 5 and 15% among patients with Behçet disease in different large series. CNS manifestations are usually classified as primary neural parenchymal lesions or non-parenchymal (secondary) lesions. MRI is the best method in demonstrating the CNS lesions. Mesodiencephalic junction, pontobulbar brain stem, thalamus and basal ganglia are the most affected parenchymal regions. Diffuse involvement of all of these regions with hemispheric extension is a very rare condition. We present a case of NBD with widespread MRI lesions presented with coma.

**Case:** 35 years old male patient was admitted to the emergency clinic with loss of consciousness. In his medical history, he had diagnosed as having Behçet disease 3 years before admission with frequent oral ulcerations following uveitis in the right eye and arthritis. He had been hospitalized previously and diagnosed as having neuro-Behçet disease with left third cranial nerve palsy and mild quadriparesia. He was treated with steroids following with azothiopurine 100 mg/day. On his neurologic examination, he was in stupor and could not follow orders. He had no neck stiffness and with positive oculocerebral reflexes. On motor examination he had brisk tendon reflexes with bilateral Babinski sign. His MRI showed diffuse hyperintensity lesions extending from tegmental part of the pons to the bilateral midbrain, thalam, lenticular nucleus and right temporal lobe. The patient could not make recovery and died in his 30th day.

**Conclusion:** Exacerbation or "acute attack" of neuro-Behçet disease may involve diffuse parenchymal CNS lesion which may lead to coma.

**Radiological profile of patients of tubercular meningitis (Tbm) and its correlation with severity: A prospective study**

S. Prabhakar, A.K. Garg, M. Modi, N. Khandelwal, P. Singh. Neurology, Post Graduate Institute of Medical Education & Research, Chandigarh, India; Radiology, Post Graduate Institute of Medical Education & Research, Chandigarh, India

Other Topic — WCN 2013
Background: Prospective data describing serial MRI changes and radiological predictors of clinical outcome have not been studied extensively.

Objectives: To access baseline MRI characteristics, serial MRI changes and their correlation with clinical profile in patients with TBM.

Method: 76 patients of untreated TBM were enrolled in 18 months. Detailed CSF examination and baseline MRI were done in all. Imaging was repeated after 3 and 9 months.

Results: Glasgow coma scale, TBM stage and high ADA level (>10) at initial presentation and hydrocephalus had significant association with final outcome. Use of VP shunt in patients with hydrocephalus improved the survival. Radiologically hydrocephalus, exudates and infarcts had significant association with the final outcome. Evidence of radiological improvement on final MRI correlated significantly with good clinical outcome. Tuberculomas, miliary mottling and border zone encephalitis had no influence on outcome.

Conclusions: Presence of hydrocephalus, exudates and infarcts in the baseline MRI are predictors of poor outcome, despite optimum antitubercular therapy. Patients with hydrocephalus undergoing VP shunt have favourable outcome. Sizable proportion of patients may show initial worsening, however, evidence of improvement in final MRI is a predictor of good clinical improvement. Thus serial MRI studies of brain can aid in prognostication of illness in TBM.

Myelitis and H1n1 vaccination

T. A. G. L. Ribeiro, Departamento de Clínica Médica-Neurologia, Universidade Federal de Goiás, Goiania, Brazil

Introduction: The influenza H1N1 vaccine has been used all over the world since the 2009s pandemics and got a significant public health value since then. There are several side-effects reported and it’s also known that vaccination is related to autoimmune reactions as transversal myelitis. We report 2 cases of previously healthy young males with transverse myelitis following influenza-H1N1 vaccination. Both cases had normal brain MRI but images of acute myelitis with T2 high signal and contrast enhancement. The patients were submitted to a 3-5-day pulse of methylprednisolone and evolved impressively well.

Discussion: The World Health Organization estimates 10 to 100 cases of post vaccinal acute adverse effects by 100,000 influenza H1N1 vaccinations. The most common severe neurological cause is Guillain–Barre syndrome. Transversal myelitis is a rare disorder. The important fact is that H1N1 vaccines produce an autoimmune mechanism and several cases of transversal myelitis have been presented. This may lead to a new pathway of investigation in autoimmune triggering.

White matter in aphasia: A historical review of the Dejerines’ studies

H. Krestela1, J.-M. Annoni2, C. Jagella3, 4Neurology and Pediatric Neurology, Inselspital, Bern, Switzerland; 4Neurology, Hospital de Fribourg, Fribourg, Switzerland; 5Neurology, Klinik Baden, Baden, Switzerland

Background: Joseph Jules Dejerine (1849–1917) and his wife, Augusta Dejerine-Klumpke (1859–1927), were both involved in aphasia research. He is best remembered for his description of alexia without agraphia. She is also best remembered for her lecture at the aphasiology meeting in Paris in 1908. It remains unknown how their language processing theory was influenced by the combination of neuroanatomy and functional data from aphasia patients.

Objective: The objective was to describe the contributions of Joseph Jules Dejerine and his wife Augusta Dejerine-Klumpke to our understanding of cerebral association fiber tracts and language processing.

Material and methods: Systematic review of primary and secondary literature.

Results: The Dejerines (and not Constantin von Monakow) were the first to describe the superior longitudinal fasciculus/arcuate fasciculus (SLF/AF) as an association fiber tract uniting the Broca’s area, Wernicke’s area, and a visual image center in the angular gyrus of a left hemispheric language zone. They were also the first to attribute language-related functions to the fasciculi occipito-frontalis (FOF) and the inferior longitudinal fasciculus (ILF) after describing aphasia patients with degeneration of the SLF/AF, ILF, uncinate fasciculus (UF), and FOF. These fasciculi belong to a functional network known as the Dejerines’ language zone, which exceeds the borders of the classically defined cortical language centers.

Conclusion: The Dejerines provided the first descriptions of the anatomical pillars of present-day language models (such as the SLF/AF). Their anatomical descriptions of fasciculi in aphasia patients provided a foundation for our modern concept of the dorsal and ventral streams in language processing.

Anxiety as a consequence of hypokinesia and its correction by citicoline

T. Grigoryan, M. Balasanyan, K. Ashrafyan, Yerevan State Medical University after M. Heratsi, Yerevan, Armenia

Citicoline (cytidine-5-diphosphocholine), a natural endogenous nucleoside in the biosynthesis of phosphatidylcholine, has shown beneficial effects in brain damage, caused by ischemic disorders. As restricted movement activity — hypokinesia (HK) is an important risk factor for the development of mentioned disorders; the aim of present investigation was an evaluation of citicoline effects on neurobehavioral consequences after 15-days of movement restriction in rats.

White, inbred male rats have been used. As a model of HK, all experimental animals were kept individually in narrow cages for 15 days. Animal’s behaviour was evaluated in “Elevated plus maze” test (EPM) after preliminary division of rats with high and low locomotor activity by ‘Open field’ stress exposure. Rats with low locomotor activity, which is characterized by general locomotor activity less than 10, were used in the experiments. Citicoline was administered at a dose of 12.5 mg/kg, i/p, twice a day.

The data obtained showed that after 15-days of movement restriction, main parameters characterized control group of rat’s behaviour in EPM-test were decreased: open time (OT) for 44.6%, open entries (OE) for 46.9%, and central time (CT) for 64.5%. According to experimental data citicoline injection prevents and even increases OT more than twice, OE for 20%, CT for 12.2% in comparison with control.

Thus, our results evidence that citicoline could be used as an effective agent of healthy human pharmacology for the prevention of psycho-neurological consequences of movement restriction — important problem of modern life.

Somatosensory evoked potentials and brainstem auditory evoked potentials in assessment of brainstem dysfunction in multiple sclerosis. Comparison with MRI
V. Ignatov a, L. Todorova b, L. Haralanova a, Velon, M. R. Silva.

Background: Brainstem lesions are common in multiple sclerosis (MS) and often lead to manifestation of neurological symptoms. According to some studies both Somatosensory Evoked Potentials (SSEP) and Brainstem Auditory Evoked Potentials (BAEP) give further valuable information about specific brainstem structures, in particular pathways of deep sensation and auditory pathways.

Objective: To examine the relationship between abnormalities in both SSEP and BAEP in MS and to study whether their impairment correlates with MRI brainstem lesions.

Material and methods: 40 controls and 30 patients with clinically definite MS were examined by both SSEP from median nerve stimulation and BAEP. All patients underwent brain MRI and EDSS assessment. Interpeak latencies (IPL), N9–N13 and P14 latencies were analyzed in SSEP. IPL I–III, III–V, I–V and amplitude ratios (AR) I/III, I/V, III/V, and also BAEP score were assessed in BAEP. Correlation analysis (Pearson) and forward logistic regression were used as statistical methods.

Results: Prolonged P14 latency (SSEP) correlated significantly with prolonged IPL N9–N13 (SSEP), prolonged IPLs and impaired ARs in BAEP (p < 0.005). We found statistically important relationship between MRI brainstem lesions and BAEP abnormalities — prolonged IPLs and impaired ARs (p < 0.005). No statistically significant correlation was found between MRI brainstem lesions and SSEP abnormalities. Higher EDSS score correlated with P14 and AR III/V abnormalities. Statistically significant parameters for predicting brainstem lesions availability were: BAEP score, IPL III–V, AR III/V, AR I/III and EDSS.

Conclusion: Performance of both SSEP and BAEP provides valuable information about brainstem function in MS. SSEP helps to confirm brainstem impairment in MS.

Post-infectious syringomyelia as a consequence of neurobrucellosis

Introduction: The neurobrucellosis manifestations occur in about 5% of all brucellosis cases. They tend to be chronic, protean and a high difficulty in diagnosing. The neurological examination revealed bilateral hypoacusis, paraparesis with discrete spasticity, glove and stocking hypoesthesia, diminished reflexes except heightened knees reflexes and bilateral Babinski. The CSF examination disclosed elevated proteins (478 mg/dL), low glucose (24.0 mg/dL) and 160 leukocytes (75% mononuclear), positive Rosa Bengal and Wright (1:320) reactions and positive culture of Brucella in the CSF. The brain and spine MRI were initially normal but displayed 4 months later, supratentorial white substance non-specific hypersignals and diffuse hypersignal form C2 to D9 with medullary enlargement on all extent of the lesion. The electromyography showed signs of polyradiculoneuropathy. The patient was treated with rifampicine, doxicicline and cotrimoxazol with a favorable outcome. Follow-up at 2 years kept showing the same medullary lesions in spite of good recovery, suggesting a post-infection syringomyelia.

Conclusion: The case described distinguishes himself by the unusual gathering of neurological symptoms with imagingological findings that persisted two years later, despite the favorable outcome of the patient.

Time related changes in electrophysiologic findings of two patients with pons infarctions: Auditory startle reflex and transcranial magnetic stimulation parameters
M. Sohtaoglu Sevindik, M. Erdemir Kiziltan, M. Bozluoclay. Neurology, Istanbul University Cerrahpasa Faculty of Medicine, Istanbul, Turkey

Background: Enhancement of auditory startle reflex (ASR) was previously reported in cerebrovascular disease (CVD). In CVD exaggerated ASR may be due to disruption of corticoreticular
inhibitory fibers. Exaggeration of ASR offers an important potential in clinical rehabilitation of stroke patients since it may be useful for augmenting voluntary movements.

**Objective:** In this study we present two patients with pons infarctions whose various ASR and motor evoked potential (MEP) parameters were examined at the time of stroke onset and 3 months later.

**Patients and methods:** Two male patients, aged 40 and 34 with clinically and radiologically established pons infarctions underwent neurophysiological examinations on the acute stage of CVD and 3 months later on follow-up. ASR parameters were recorded bilaterally in orbicularis oculi, sternocleidomastoid, biceps brachii and abductor pollicis brevis muscles and MEP and cortical silent period (CSP) characteristics were noted.

**Results:** We have observed that in our stroke patients, characteristics of ASR, MEP and CSP showed changes over time. Patients with right and left pons infarctions had fairly similar electrophysiological results at disease onset and follow-up. On chronic stage in both patients total ASR probabilities were increased, muscles that had no reflex response in acute period showed marked reflex responses, MEP and CSP became apparent.

**Conclusion:** Our results suggest that enhancement of startle reflex and changes in MEP and CSP might be an indication of bulbar and cortical reorganisation and plasticity after brain injury.

**A novel Csf1r mutation in hereditary diffuse leukoencephalopathy with spheroids**

**Background:** The differential diagnosis of adult-onset leukoencephalopathy is very broad. A brain biopsy is often needed when no definite diagnosis can be made based on a biochemical analysis and imaging. Hereditary diffuse leukoencephalopathy with spheroids (HDLS) is a rare autosomal-dominant leukoencephalopathy with heterogeneous phenotype and variable age of onset caused by a mutation in the colony stimulating factor 1 receptor (CSF1R) gene.

**Objective:** To present the clinical picture and a novel CSF1R mutation in a new case of HDLS.

**Material and methods:** Case report.

**Results:** A 45-year-old woman presented with a pain syndrome over the left hemisphere. Clinical examination showed hypertonia of the left arm and leg with pyramidal signs. Subsequently, a severe cognitive decline and a painful dystonia of the left hand developed and she became bedridden. Brain MRI showed extensive confluent periventricular and subcortical white matter lesions without contrast-enhancement. After an extensive diagnostic work-out a definite diagnosis could not be made and a brain biopsy was performed. Pathological examination showed leukoencephalopathy and giant neuroaxonal swellings (spheroids), compatible with a diagnosis of HDLS. Molecular genetic analysis revealed a novel mutation in the CSF1-R gene (c.2466G>A, p.Met822Ile). As a curative treatment is lacking at this moment, our patient deteriorated progressively and eventually died less than 3 years after the onset of the disease.

**Conclusion:** HDLS is a rare autosomal-dominant inherited neurodegenerative disorder with leukoencephalopathy. Brain biopsy and genetic analysis are needed to confirm the diagnosis. To date only mutations in the CSF1R gene have been linked to this disorder.

doi:10.1016/j.jns.2013.07.2227
Background: International medical exchange programs have multiple benefits to neurology trainees and their home institutions including the provision of humanitarian aid, new learning and teaching opportunities, clinical independence, reputation, and a better-educated global health workforce.

Methods: A survey was electronically distributed to all program directors in the U.S. and Canada by the American Academy of Neurology (Oct. 2012–Feb. 2013) to assess the training opportunities, institutional partnerships, and support available to postgraduate neurology trainees to participate in electives in countries outside of Western Europe, Australia, Canada, and the U.S.

Results: A total of 143/234 (61%) program directors responded. Most (53%) programs allow global health electives; however, just 33% provide financial support and 55% state that less than 10% of trainees actually go abroad. Among programs that do not allow global health electives, 86% cited a lack of funding, 55% stated there were no formal programs or partnerships with international sites, and 31% perceived no interest by residents. Only 12% of programs solicit philanthropic donations. If funding were not an issue, 93% of program directors believed their residents would have time to participate in global health training.

Conclusions: In spite of high perceived interest, only half of U.S. and Canadian neurology training programs currently permit global health electives, and the number of trainees venturing abroad remains a minority of all trainees in all programs.

Toxoplasma encephalitis in an immunocompetent diabetic patient

N. Oztekin1, F. Oztekinb, aNeurology, MOH Ankara Numune Education and Research Hospital, Ankara, Turkey; bNeurology, MOH Ankara Yildirim Beyazit Education and Research Hospital, Ankara, Turkey

Background: Toxoplasmosis may have severe consequences in immunocompromised patients but cerebral toxoplasmosis is very rare in immunocompetent patients. Herein we present a case of toxoplasma encephalitis in an immunocompetent diabetic patient.

Case: A 54 year old female was admitted with abrupt onset visual loss, weakness evolving to quadriaparesis in two weeks, lethargy and high fever. She was diabetic. Neurologic examination revealed a stuporous patient with poor cooperation. Fundi were bilateral optic atrophy. The CSF pressure was high and the cell count was >100/mm. Culture and Gram staining of the CSF was negative. MRI of the brain was obtained on day 2 of hospital stay. MRI showed high signal intensity lesions on T2 weighted and FLAIR images. A second MRI was obtained 10 days later. This MRI showed high signal intensity lesions on FLAIR images. The patient was treated with IV methylprednisolone and IV Gancyclovir. However, the patient deteriorated and died on the 6th hospital day.

Conclusion: Cerebral toxoplasmosis is a rare localized form of toxoplasmosis and the diagnosis is usually difficult. In this case, the patient had diabetes mellitus and was immunocompetent at the time of presentation. The diagnosis of this localization of toxoplasmosis is based on a careful history and physical examination, laboratory investigations, and MRI. The MRI showed high signal intensity lesions on FLAIR images consistent with toxoplasmosis. A toxoplasma encephalitis must be kept in mind in the differential diagnosis diabetic patients with encephalitic signs and symptoms.

New gene mutations identified in recessive Charcot–Marie–Tooth Tunisian families

Background: Charcot–Marie–Tooth (CMT) disease is the most common hereditary neuropathy resulting from mutations in more than 69 genes, such as MPZ, GDAP1 and SH3TC2 genes, with a wide spectrum of phenotypic manifestations.

Objective: To describe the clinical spectrum and molecular characteristics of new mutations in MPZ, GDAP1 and SH3TC2 genes associated with CMT.

Patients and methods: We included CMT Tunisian families with new mutations. Clinical features and electrophysiological findings were studied.

Results: Three families with 7 affected members presenting with motor and sensory polyneuropathy were identified. Phenotype in all affected individuals was characterized by an early-onset (2.6 years). Consanguineous union was found in two families. Three new mutations occurring in the MPZ, GDAP1 and SH3TC2 genes were identified, they were associated with autosomal recessive inheritance. A novel MPZ gene mutation including non sense c.310311-G/p.Asp104GlyfsX18 mutation in a Déjèrine-Sottas Disease was found. Homozygous missense c.117+3A-G mutation in GDAP1 gene in twins leads to axonal neuropathy with pyramidal signs. Homozygosis missense c.1969G-A/p.Glu657lys mutation in SH3TC2 gene was responsible for demyelinating neuropathy with severe scoliosis.

Conclusion: The identification of new mutations associated with different clinical and electrophysiological presentations stresses the broad phenotypic spectrum with MPZ, GDAP1 and SH3TC2 mutations.

Predictors of endothelial dysfunction in obstructive sleep apnea syndrome
P. Šiarnik, Z. Čarnická, K. Krížová, K. Klobučníková, B. Kollár, P. Turčaní, M. Sýkora. 1st Department of Neurology, Faculty of Medicine, Comenius University, Bratislava, Slovak Republic; 2nd Department of Neurology, University of Zagreb, Zagreb, Croatia

Introduction: Obstructive sleep apnea syndrome (OSA) is a highly prevalent disorder, which is associated with increased cardiovascular morbidity. One of the most important mechanisms responsible for development of vascular diseases in patients with OSA could be atherosclerosis. Endothelial dysfunction is an initial process and a key component of atherogenesis. Using peripheral arterial tonometry (PAT) we investigated the relationship between reperfusion hyperaemia index (RHI), which is regarded as being representative of endothelial function, and potential vascular risk factors in population with suspected OSA.

Methods: We enrolled 31 patients (42.1 ± 11.7 years) with suspected OSA, without history of regular medication or history of cardiovascular disease. Besides gaining general clinical characteristics, we performed polysonography, assessment of PAT, assessment of baroreflex sensitivity and blood tests.

Results: Significant inverse correlation was found between RHI and apnea–hypopnea index (AHI) (r = −0.550, p = 0.001), and between RHI and desaturation index (r = −0.533, p = 0.002). Positive correlation was found between RHI and minimal nocturnal saturation of blood with oxygen (r = 0.394, p = 0.028). In stepwise multiple linear regression analysis AHI was the only significant variable to determine RHI (β = −0.522, p = 0.003). We found no significant correlation between RHI and other sleep, clinical or biochemical characteristics. RHI in population with severe OSA (AHI above 30) was significantly lower than RHI in the rest of the population (p = 0.012).

Conclusion: AHI was the only significant independent predictor of impaired endothelial function expressed by RHI determined using PAT. RHI was decreased significantly in population with severe OSA.

Effect of albendazole therapy in patients with seizure and radiological lesion consistent with neurocysticercosis: An open labeled randomized placebo controlled trial
R. Paudel, L. Thapa, B.R. Pokhrel, P.V.S. Rana. Neurology, College of Medical Sciences, Chitwan, Nepal

Background: There are controversies in using albendazole in treatment of solitary cerebral cysticercosis.

Objective: To evaluate the effectiveness in resolution of solitary cerebral neurocysticercosis and seizure free status after one week of albendazole therapy.

Methodology: Randomized placebo controlled trial was done in sixty consecutive patients of solitary cerebral cysterceral lesions attending the Neurology Department at a tertiary hospital in Nepal during the time period November 2009 to December 2010. Treatment group was given oral albendazole and similar looking tablets were given to placebo group along with a short course of steroid and antiepileptics. Follow-up head CT scans were done at end of one, three and six months to look for resolution of lesion. They were followed up for any seizure recurrence during treatment.

Results: Out of a total of 60 patients (treatment n = 28 and control group n = 32), at one month follow-up complete resolution of cyst was observed in 25% (n = 7) of patients in treatment as compared to 15.6% (n = 5) in the placebo which was statistically not significant (p > 0.05). Resolution rate at 3 and 6 months follow-up was also not significant. There was also insignificant difference in seizure recurrence rate on follow-ups.

Conclusion: The present study showed that patients treated with albendazole therapy did not differ statistically in both the outcome measures in terms of complete resolution of the lesion and seizure free status.

Atypical Bickerstaff's brainstem encephalitis: Clinical vigilance ensures favourable prognosis

Background: Bickerstaff's brainstem encephalitis (BBE) is a rare autoimmune inflammatory disorder of the central and peripheral nervous system, often sharing common features with Miller-Fisher's and Guillain–Barré syndrome. It typically presents following an upper respiratory tract infection, with reduced consciousness, ataxia, symmetrical ophthalmoplegia, tetraparesis, and electrophysiological evidence of motor axon degeneration and central involvement.

Objective: To stress the importance of high clinical suspicion in regard to atypical BBE cases.

Patients and methods: A 19-year-old, previously healthy male presented to the Emergency Room with a 12-hour history of drowsiness, unsteadiness, and upper extremity tremor. 10 days before, he was diagnosed and treated for GI tract infection. Physical examination revealed severe truncal ataxia, lower-extremity areflexia, right abductor opcular palsy, horizontal nystagmus, dysarthria and hoarse voice. He then developed psychomotor agitation and verbal aggression. Repeated laboratory (serum and CSF), radiological (MRI) and electrophysiological (EMG-magnetic stimulation) tests were negative. However, anti-GM1 and anti-GQ1b antibodies were strongly positive. The patient was readily treated with a 5-day course of intravenous immunoglobulin, displaying prompt and complete remission of his clinical picture.

Conclusion: BBE is a rare neurological entity, of which the diagnosis relies on high clinical suspicion, exclusion of alternative diagnoses, and supportive laboratory evidence. Atypical symptoms, and/or absence of electrophysiological and radiological findings should not rule out the diagnosis. Hence, a great clinical vigilance is required, as prompt delivery of treatment ensures the favourable prognosis of the disease.

Sudomotor function was impaired in 2 patients, cardiovagal function abnormal in 4, and orthostatic hypotension was noted in 1 patient. Baroreflex adrenergic sensitivity was abnormal in all but 1 patient tested and was severely reduced in 9, and excessive in 3. The autonomic findings did not correlate with headache severity, number of concussions, time from concussion to evaluation, or postural catecholamine measurements.

**Conclusion:** Autonomic testing in patients with persistent symptoms following concussion revealed ANS impairment in all, with features suggesting adrenergic insufficiency in most patients studied and excessive adrenergic ANS activation in a minority of patients. This pattern of impairment did not correlate with clinical features in this cohort of patients.

**Comparative neuronal uptake and cytotoxicity of anti-Hu and anti-Ri antibodies in rat cerebellar and hippocampal slice cultures**

J. E. Greenleeb, S. A. Clawsonb, B. Woodb, K. E. Hill, N. G. Carlsonab, c, d, e, f, g, h, i, j, k, l, m, n, o, p, q, r, s, t, u, v, w, x, y, z, {, |, ~, }.

**Neurology, University of Utah Health Sciences Center, Salt Lake City, UT, USA; Research Service, Veterans Affairs Medical Center, Salt Lake City, UT, USA; Neurology, University of Utah School of Medicine, Salt Lake City, UT, USA; Neurology, University of Utah School of Medicine, Salt Lake City, UT, USA; Neurobiology and Anatomy, University of Utah School of Medicine, Salt Lake City, UT, USA; Center on Aging, University of Utah School of Medicine, Salt Lake City, UT, USA**

**Background:** Anti-Hu and anti-Ri are paraneoplastic autoantibodies recognizing intracellular antigens present in essentially all neurons. At autopsy, brains of patients with anti-Hu antibody show neuronal destruction. In contrast, anti-Ri antibody is less clearly associated with neuronal death, and patients with anti-Ri antibodies may respond to treatment. We have demonstrated that anti-Yo antibodies, associated with paraneoplastic cerebellar degeneration, accumulate intracellularly in cerebellar Purkinje cells in slice cultures of rat cerebellum and that antibody accumulation is followed by cell death. The present study was conducted to determine whether anti-Hu and anti-Ri antibodies are also taken up by neurons and whether uptake of either antibody is cytotoxic.

**Objective:** To evaluate neuronal uptake and cytotoxicity of anti-Hu and anti-Ri antibodies in slice cultures of rat cerebellum and hippocampus.

**Materials and methods:** Rat cerebellar and hippocampal slice cultures were incubated with anti-Hu or anti-Ri antibodies and evaluated over time for antibody uptake and for cell death. Specificity of anti-Hu cytotoxicity was confirmed by adsorbing anti-Hu IgG with recombinant HuD protein.

**Results:** Anti-Hu and anti-Ri antibodies accumulated in cerebellar and hippocampal neurons. Anti-Hu antibodies produced cell death which was significantly reduced by adsorption of anti-Hu IgG with recombinant HuD protein. In contrast, neurons accumulating anti-Ri antibodies showed no evidence of cell death as compared to controls.

**Conclusions:** Anti-Hu and anti-Ri antibodies entered and accumulated in cerebellar and hippocampal neurons. Anti-Hu antibody associated neuronal death involved reactivity with HuD protein. Anti-Ri antibody did not affect neuronal viability and may cause neuronal dysfunction rather than cell death.

**doi:** 10.1016/j.jns.2013.07.2238
strong color and a strong sound do not have the same significant influence when the person is happy (strong emotion). Therefore a positive activation of the limbic system (happiness) may inhibit visual and auditory hyperexcitability. This is important to make a decision.

A fast method for determination of the parameters of pulsed-CEST MRI
G. Xiao1, Z. Dai2, P.Z. Sun3, R. Wu4, aDepartment of Mathematics and Applied Mathematics, Hanshan Normal University, Chaozhou, China; bDepartment of Radiology, 2nd Affiliated Hospital of Shantou University Medical College, Shantou, China; cAthinoula A. Martinos Center for Biomedical Imaging, Department of Radiology, Massachusetts General Hospital and Harvard Medical School, Charlestown, MA, USA

Objective: The object of the research is to demonstrate a fast method for simultaneous determination of labile proton fraction ratio and exchange rate and other parameters of pulsed chemical exchange saturation transfer (pulsed-CEST) MRI.

Methods: Mathematical models have been developed to describe pulsed-CEST contrast. We simulated pulsed-CEST MRI in MatLab (MathWorks, Natick, MA) for Z-spectra and asymmetry spectra using matrix exponential algorithm. The number of repetition of the sequence is 256. Each Gaussian-shaped pulse was divided into 101 steps, and the evolution within each step was modeled assuming a constant amplitude. We also calculated the above spectra by using the fourth/fifth-order RKF(ode45 in MatLab; MathWorks, Natick, MA, USA) with an absolute error tolerance for each integration step of 10^{-6}, and compared with the results obtained by our method. Calculations were performed using MatLab on Pentium® Dual-Core CPU (2.2 GHz) with 2-GB RAM. There was a good agreement between them, and this method was much faster than the RKF method (by a factor of approximately 1000 in this study). We simulated that the error of the labile proton fraction ratio, exchange rate and other parameters less than 5%.

Results: This method will be useful for determination of labile proton fraction ratio and exchange rate and other parameters, and for analyzing the pulsed-CEST contrast mechanism and/or investigating the optimal RF pulse parameters such as the RF pulse duration or pulse flip angle.

Spg4 mutations in Brazilian patients with hereditary spastic paraplegia
M. Franca Jr. a, A. D’Azevedo b, D.B. Dogini b, H.A.G. Teive b, J.A.M. Saute b, L.B. Jardim a, I. Lopes-Cendes a, b, Department of Neurology, University of Campinas (UNICAMP), Campinas, Brazil; bDepartment of Medical Genetics, University of Campinas (UNICAMP), Campinas, Brazil; cDepartment of Internal Medicine, Universidade Federal do Paraná (UFPR), Curitiba, Brazil; dDepartment of Internal Medicine, Universidade Federal do Rio Grande do Sul (UFRS), Porto Alegre, Brazil

Background: Hereditary spastic paraplegia (HSP) is a heterogeneous group of neurodegenerative disorders characterized by progressive lower limb weakness and spasticity. There are 31 causative genes identified to date, but mutations in the SPG4 gene are the major cause of autosomal dominant (AD) HSP in Europe/the USA accounting for 40–50% of all patients. Little is known about the frequency of SPG4-related HSP in Brazil.

Objective: To determine the frequency of SPG4-HSP among Brazilian patients with AD-HSP and to describe the mutational spectrum in this population.

Patients and methods: We recruited 34 unrelated families with AD-HSP from three university hospitals; patients underwent a complete clinical evaluation as well as detailed family history. Genomic DNA was extracted from lymphocytes and used in PCR reactions with primers designed to cover the 17 exons of the SPG4 gene. Mutation screening was performed by automatic sequencing and multiplex ligand probe amplification (MLPA).

Results: We found eight previously described mutations in SPG4: c839delAG (frameshift), c.1267G>T (missense), c.1378C>T (missense), c.1413+5G>A (splicing-site mutation), c.1495C>T (missense), c.1651G>C

(missense), c.1741C→T (nonsense) and c.1849T→G (nonstop). Three novel mutations were identified, each one in a single family: c.1626C→T (splice-site mutation), c.1255G→T (nonsense) and c.1667delCA (frameshift). MLPA revealed no large deletion/duplication in these patients.

**Conclusion:** SPG4 mutations were found in 32% of the Brazilian families with AD-HSP. In this cohort, we found no large deletion/duplication in SPG4.

Hypokalemic paralysis caused by de novo mutation of the Scn4a gene
M. Heinsoo, Neurology, North-Estonia Medical Centre, Tallinn, Estonia

The aim of the case presentation is to point out the importance of de novo mutations as a cause of sporadic periodic paralysis. 32 year old, previously healthy male was admitted with sudden proximal tetraparesis. He had also weak trunk muscles, but his breathing was normal. Deep tendon reflexes and sensation appeared normal. Cervical MRT, EMG and lumbar puncture were performed a couple of hours after admission with normal results. Blood test showed K+ 2.3 mmol/l. All other tests, including thyroid markers were normal. The patient received K+ replacement. After 9 h he was totally improved. Despite negative family history and late onset hypokalemic periodic paralysis was considered and his tests were sent for genetic analysis to GENDIA lab in Antwerp, Belgium.

Result of genetic test: a likely pathogenic heterozygous SCN4A: c.3404G→A variant was identified in exon 18 of the SCN4A gene by sequencing.

To prove the de novo origin of the variant analysis of the parents is planned.

**Conclusion:** The phenotype of sporadic periodic paralysis with de novo mutations could be very different. The reason for later onset and fewer attacks remains unclear. To provide a better understanding in this group of patients a larger study is needed.

Cognitive impairment and depression in geriatric patients
T. Rudkouskaya, M. Khitrun, P. Buiko, K. Tsurko, V. Chyzhyk, V. Velugina. Chair of Neurological and Neurosurgery Diseases, Belarusian State Medical University, Minsk, Belarus

**Background:** The elderly often suffer from cognitive impairment (50%) and depressive symptoms (120.3%). These two pathologies have a bilateral connection and may influence each other.

**Objective:** To study the correlation between cognitive status and depression level of patients with encephalopathy of different genesis.

**Material and methods:** 29 patients with encephalopathy of different genesis were proposed to undergo a battery of tests which consisted of 2 blocks: cognitive — the Montreal Cognitive Assessment (MoCA), the Short Cognitive Performance Test (SKT) and emotional — Hamilton Rating Scale for Depression (HDRS). Inclusion criteria became MoCA score of ≤25.

**Results:** According to the level of depression all patients were divided into 3 groups: without depression — 12 persons (410.4%), mild — 10 (34.5%), moderate and high — 7 (24.1%). Patients without depression had average score of SKT 6.8, with mild depression — 4.3, with moderate and high depression — 7.3. In the group without depression was found a moderate negative statistically significant relationship between the scores of depressive symptoms and cognitive impairment (p = 0.66 ± 0.2; p < 0.05). In the group with moderate and high depression was found a moderate positive statistically insignificant relationship (in this group it is necessary to increase the sample).

**Conclusion:**
1. Patients with encephalopathy of different genesis often suffer from depression (58.6%), which requires obligatory medical, psychological and social correction.
2. With increase of cognitive impairment depressive symptoms decrease in patients without depression. With increase of cognitive impairment depressive symptoms increase in patients with moderate and high depression.

Connectivity changes after peripheral end-to-side coaptation following brachial plexus avulsion: a dynamic causal modeling (DCM) study
F. Fischmeisterab,c, A. Aminia, A. Geisslerab,c, R. Schmidhammerd, R. Beisteinerab,c, aDepartment of Neurology, Study Group Clinical fMRI, Medical University of Vienna, Austria; bDepartment of Neurology, Medical University of Vienna, Austria; cHigh Field MR Center of Excellence, Medical University of Vienna, Austria; dLudwig Boltzmann Institute for Experimental and Clinical Traumatology, Vienna, Austria

**Introduction:** Following end-to-side coaptation of the phrenic to the musculocutaneous nerve using autologous nerve grafts the phrenic nerve has to perform a double function: independent control of breathing and elbow flexion. This results in activation of the diaphragm area with breathing but also with diseased arm flexion (Beisteiner et al. 2011). However, it is unclear whether this activation is driven by the SMA or other changes in connectivity.

**Methods:** One patient participated in this study, one year post surgery. fMRI was acquired while elbow flexion of the diseased arm or forced abdominal inspiration was performed. To assess effective connectivity changes with DCM, several classes of models with forward and/or backward or without connection between M1 and diaphragm were generated.

**Results:** Model comparison indicated the necessity of a forward connection between M1s of the arm and the diaphragm. Introducing a backward connection slightly increased the performance of this model. Within this model the instruction to perform arm flexion showed a strong enhancing effect on the forward connection of SMA to M1 arm (increasing M1 arm and M1 diaphragm activity) and a weak, but still significant positive effect on the SMA to M1 diaphragm connection (increasing M1 diaphragm activity).

**Conclusion:** Our results demonstrate the importance of a forward connection between the M1s of the arm and the diaphragm. We conclude that this specific cortical neuroplasticity as outlined by our final DCM model provides the neurophysiological basis for rehabilitation after peripheral end-to-side repair.

This study was supported by the Austrian Science Fund (P23611).

Beyond Kluver–Bucy syndrome: Colorful clinical picture of bilateral anterior cerebral artery infarction
F. Ak, G. Yalcin Cakmakli, M. Karakoc, A. Taskiran Sag, N. Oztekin, Neurology, Ankara Numune Education and Research Hospital, Ankara, Turkey

Introduction: Kluver–Bucy syndrome, which is mostly caused by bilateral anterior temporal lobe lesions, is characterized by typical triad of hypersexuality, hyperorality and hyperphagia. Bilateral anterior cerebral artery (ACA) territory infarction is very rare and it has been reported even more rarely to cause Kluver–Bucy syndrome.

Case: 51 year-old male patient was hospitalized with the complaint of difficulty in speech and left sided hemiparesis. Hemiparesis improved quickly. The neurological examination revealed apathy, loss of spontaneity and impoverishment of speech, loss of normal intonation, he was giving one-word answers to all questions. Diffusion weighted MRI images showed bilateral acute ischemic lesions in ACA territories, more prominent on the right side. Cerebral and cervical BT angiography showed aplasia of A1 segment of left ACA. In the follow-up, we have observed that the patient had hypersexuality, playing with his penis and talking inappropriately about women around; hyperoralism, taking all objects to his mouth; hyperphagia, trying to eat his wife’s and other patients’ meals after his own; disinhibition and utilization behavior. Detailed neuropsychological tests revealed prominent impairment in verbal and categoric fluency, motor sequencing (Luria’s three step test), inhibitory control (go/no-go test), resistance to interference (Stroop test) and mild impairment in recent memory (enhanced cued recall). Visual attention and task switching (trail making A and B), abstract thinking and conceptualization were intact. The patient was then followed up under low dose olanzapine treatment and was getting better quickly.

Conclusion: Bilateral ACA infarction may lead to a colorful clinical picture including Kluver–Bucy syndrome triad.

Immunopathological significance of ovarian teratoma in patients with anti-N-methyl-d-aspartate receptor encephalitis
E. Tabata, Department of Neurology, Saga University, Saga, Japan

Background: Although the clinical importance of ovarian teratoma in anti-N-methyl-d-aspartate receptor (NMDAR) encephalitis has been considered, investigations of ovarian teratoma in anti-NMDAR encephalitis remain limited.

Objective: To clarify differences in NMDAR distribution and lymphocyte infiltration in ovarian teratoma between patients with and without anti-NMDAR encephalitis.

Methods: Participants initially comprised 26 patients with ovarian teratoma. NMDAR distribution and lymphocyte infiltration in ovarian teratoma were examined using immunopathological techniques. Clinical, laboratory, and radiological data were compared between patients showing features of encephalitis. Anti-NMDAR antibodies in serum and cerebrospinal fluid were also measured in encephalitis patients.

Results: Neuronal tissues were obtained from ovarian teratomas in 22 patients (after excluding 4 patients who did not satisfy the inclusion criteria), and presence of NMDA receptor subunits was revealed in all patients. The encephalitis group (n = 3) showed frequent lymphocyte infiltration, unlike the non-encephalitis group. In particular, dense B-lymphocyte infiltration near neural tissues was observed in the severe encephalitis group.

Conclusions: Differences in lymphocyte infiltration of ovarian teratomas between anti-NMDAR encephalitis and non-encephalitis patients suggest the immunological importance of ovarian teratoma as the site of antigen-presentation in anti-NMDAR encephalitis.

Computer-based diagnosis of neurological and psychiatric illness in historical persons
P. Garrard a, T. Peters b, aStroke and Dementia Research Centre, St George’s, University of London, London, UK; bInstitute of Archaeology and Antiquity, University of Birmingham, Birmingham, UK

Retrospective diagnosis of illness in historical figures is a popular pastime, but the paucity of detailed information about clinical features and disease progression often make its results less than fully reliable. Modern computer-based diagnostic programmes have been used to supplement historical documents and accounts, offering more objective approaches to the retrospective investigations of the medical conditions of historical persons. In the case of King George III, modern technology has been used to strengthen the findings of previous reports rejecting the popular diagnosis of variegate porphyria in the King, his grandson Augustus d’Esté, and his antecedents King James VI and King James I. Alternative diagnoses based on these programmes are suggested. The Operational Criteria in Studies of Psychotic Illness (OPCRIT) programme and the Young mania scale have been applied to the features described for George III and suggest a diagnosis of bipolar disorder. The programme SimulConsult was applied to Augustus d’Esté and suggests a diagnosis of neumomyelitis optica rather than acute porphyria as the leading diagnosis, with multiple sclerosis, as proposed by others, as a secondary possibility. James VI’s and James I’s complex medical history, clinical features and behavioural traits were also subjected to SimulConsult analysis; acute porphyria was rejected and the unexpected diagnosis of attenuated (mild) Lesch–Nyhan disease offered. We will review these approaches with regard to the methodology and validity. Textual analysis of the written and verbal outputs of historical figures indicates possible future developments in the diagnosis of medical disorders in historical figures.

Prevalence of asymptomatic and symptomatic spondylotic cervical spinal cord compression
J. Bednarik a,b, M. Kerkovsky a, Z. Kadanka, Z. Kadanka Jr. a, M. Nemec a, I. Koválova a, B. Jakubcová a, “Department of Neurology, University Hospital Brno, Czech Republic; bCentral European Institute of Technology, Masaryk University, Brno, Czech Republic; cDepartment of Radiology, University Hospital Brno, Brno, Czech Republic

Background: Cervical spondylotic myelopathy (CSM) is the most frequent cause of the lower paraparesis in subjects above the age of 50. Magnetic resonance imaging (MRI) is able to detect asymptomatic
spondylotic cervical cord compression (ASCCC). The prevalence of both CSM and ASCCC increases with age, but the reason is not known. **Objective:** To estimate the prevalence of both ASCCC and CSM in a general population above the age of forty.

**Patients and methods:** Fifty-nine randomly chosen healthy volunteers, recruited irrespective of the presence of signs of CSM, 37 women and 23 men, aged 65 (median), 42–82 (range) years participated in the study. All underwent MRI examination on a 1.5 T device using standard images and diffusion tensor imaging (DTI) at the level of maximum compression and at C2/3 as a reference. Subjects with MRI signs of cervical cord compression were examined clinically.

**Results:** MRI signs of cervical cord compression were found in 31 individuals (52.5%). Focal impingement was present in 6 cases (10.2%), and wide compression in 25 subjects (42.4%). The cross-sectional area at the level of compression <50 mm² was present in 2 cases and T2 hyperintensity in 2 subjects. DTI parameters showed no significant difference between subgroups with and without signs of compression. Clinical signs of symptomatic CSM were found in 2 cases (3.4%).

**Conclusion:** Prevalence of ASCCC in our group is higher than previously reported. The predictive significance of different types of compression remains to be established in future prospective evaluations of larger groups of subjects.

**Effects of hyperventilation on axonal excitability parameters in diabetic polyneuropathy**

**D. Verdelean**, G. Akça, F. Kızılay, M.K. Balci, H. Uysal, D. Macerollo, E. T. Varga, O. Györ, Sz of Neurology, Baba Antalya, Turkey; D. Macerollo, E. T. Varga, O. Györ, Sz of Neurology, Baba Antalya, Turkey; E. T. Varga, O. Györ, Sz of Neurology, Baba Antalya, Turkey; Internal Medicine and Endocrinology Department, Akdeniz University, Faculty of Medicine, Antalya, Turkey

**Abstract**

Axonal excitability is a physiological concept connected with the characteristics of myelin and membrane of the peripheral nerve. Evaluation of axonal excitability provides important information about the peripheral nerve. It has not been one of the routine electrophysiological evaluations but suitable for use in experimental studies and helps in understanding pathological conditions and gives important information about pathophysiology. The mechanisms of diabetic polyneuropathy have not been understood clearly. We used the short TROND protocol to measure the axonal excitability parameters in 11 healthy subjects and 7 patients with diabetes mellitus (DM) with polyneuropathy. The short TROND protocol was performed before and at the 20th minute of deep hyperventilation of healthy subjects and diabetic patients. Venous blood pH, pO2, and pCO2 values were recorded before hyperventilation and at the 20th minute of hyperventilation. The “hyperventilation score” was evaluated before and after the hyperventilation by asking the patient the degree of the numbness in the extremities and face or by seeing the carpopedal spasm. Although, significant changes in pH values occurred, the “hyperventilation scale score” of the DM group was lower than the score of the control group. When the values of DM and control group after hyperventilation were compared, Ted (10–20 ms), Ted (40–60 ms), Ted (90–100 ms), Ted (peak) and superexcitability at 5 ms were statistically significant. There was a significant change in the hyperpolarization section of threshold electrotonus during hyperventilation in patients with DM.

**DM patients have different responses to hyperventilation, and pH changes have different effects on diabetic polynuropathy when compared with healthy subjects.**

**Cross-border mobility of junior neurologists to and within the European Union: A major challenge for the health care system**

**A. Macerollo**, E.T. Varga, O. Györ, X. Kobeleva, W. Struhl, J. Sellner, D. Macerollo, E.T. Varga, O. Györ, Sobell Department of Motor Neuroscience and Movement Disorders, National Hospital of Neurology and Neurosurgery, Institute of Neurology, University College London, London, UK; Department of Neuroscience and Sense Organs, Aldo Moro University, Bari, Italy; Department of Neurology, University of Szeged, Hungary Institute of Genomic Medicine and Rare Disorders, Semmelweis University, Budapest, Hungary; 2nd Clinic of Neurology, Mures County Emergency Hospital, Targu-Mures, Romania; Department of Neurology, Medizinische Hochschule Hannover, Hannover, Germany; Department of Neurology, General Hospital of the City of Linz, Linz, Austria; Department of Neurology, Christian-Doppler-Klinik, Paracelsus Medical University, Salzburg, Austria; Department of Neurology, Klinikum rechts der Isar, Technische Universität München, München, Germany

**Abstract**

**Background:** There is a dynamic flow of medical doctors within and to Europe, particularly since the entry of more countries to the European Union (EU) in 2004 and 2007.

**Objective:** To assess interest and motives for cross-border mobility among residents and junior neurologists from member states of the EU and neighboring countries.

Methods: Questionnaire-based paper survey among 118 participants of a neurology course for young neurologists in 2011.

Results: Ninety-seven (82%) returned the survey. Most of them had at one point considered relocating within or to the EU for postgraduate education (87%) or employment (71%). Common motives were superior prospects for clinical training (85%), better resources at work and academic environment (both 80%), and higher income (70%). 52% of the surveyed would intend to return to their home country some time, yet 43% would not mind moving to another EU country. The attractiveness of the EU for migration is ranked over the United States, Australia/New Zealand or Switzerland (only 5% would instead prefer these options). The most common reasons which discourage cross-border relocation are the loss of family connection (53%) and uncertainty (40%), whereas language issues were less relevant (20%).

Conclusion: The interest of the upcoming generation of neurologists to relocate within and to the EU is strong. The driving forces are additional training and career opportunities as well as inadequate remuneration in certain regions. Therefore it is critical to take action to harmonize training and working conditions in Europe in order to ensure neurology service and patient care.

Atypical case of influenza vaccinated acute encephalopathy diagnosed by pathological approach. A case report and review of the literature

C. Atsumi1, N. Sasaki2, K. Kawaguchi3, T. Hirayama3, H. Takasuna3, Y. Tanaka4, M. Doi4, M. Takagi5, Y. Hasegawa5. 1Department of Neurology, St. Marianna University School of Medicine, Kawasaki, Japan; 2Department of Neurosurgery, St. Marianna University School of Medicine, Kawasaki, Japan; 3Department of Pathology, St. Marianna University School of Medicine, Kawasaki, Japan

Background: Influenza is one of the viral infections that cause epidemic or pandemic disease every year, and it is generally known as the most common and often causes serious complications. Preventive medicine for influenza achieved remarkable results by the spread of worldwide influenza vaccine. On the other hand, it may cause unusual neurological disorders such as acute encephalopathy by influenza vaccination. Influenza vaccinated acute encephalopathy (IAE) is rare and its pathology is unclear.

Objective: We describe a 24-year-old male who presented with headache and difficulty of speech but no focal neurological deficits the day after influenza vaccination. 10 days later, generalized convulsive seizure presented and urgent hospitalization in neurology. Neurological examination presented amnestic aphasia. Furthermore, blood examination, viral cultures and CSF were negative. Brain MRI, DWI and FLAIR showed localized subcortical white matter hyperintensity area in the left inferior temporal gyrus. After hospitalization, convulsion attack became frequent and aggravatated. Brain biopsy showed central chromatolysis around the Nissl bodies without inflammatory or demyelination changes. We started steroid pulse therapy after brain biopsy, and his neurological disorders and convulsive seizure improved immediately. Radiological examination improved and subcortical white matter lesion completely disappeared three months later with favorable outcome.

Conclusion: We concluded in this case that neuronopathy occurred due to toxic influence. Permeability obstacle of cell membrane and excitatory amino acid was excessively released triggered by the influenza vaccine. This case showed a different pathology from ADEM. IVAE is very important as influenza vaccination may have neurological sequels.

Cytomegalovirus infection presenting with multiple low cranial nerve palsies

C.K. Ha, H.-K. Park. Department of Neurology, Inha University Hospital, Incheon, Republic of Korea

Background: Cytomegalovirus (CMV) is a viral genus of the viral family known as herpes viruses. Although they may be found throughout the body, CMV infection is typically unnoticed in healthy people, but can be life-threatening for the immunocompromised patients. Diagnosis is usually done histologically by finding the inclusion bodies in infected tissue. We experienced one unusual case of CMV infection involving multiple cranial nerves.

Case: A 55-year old man had severe left eyeball pain, three months before admission. He then presented with throat pain, dysarthria and severe dysphagia with dehydration. On admission, neurological examination showed left seventh, ninth, tenth and twelfth nerve

doi:10.1016/j.jns.2013.07.2255
palsies with severe pain in occipital area. He had uncontrolled diabetes mellitus and chronic otitis media. The CSF test revealed increase in white cell counts compatible with viral meningoencephalitis. HIV antigen test and brain MRI were negative. The initial diagnosis was herpes occipitotemporalis. After treatment of steroid and acyclovir, the low cranial nerve palsy improved partially, but dysphagia and peripheral type facial palsy were persistent. One month later, he complained of abdominal pain, and colonoscopy with pathology found CMV colitis. He took gancyclovir and then the cranial nerve palsy disappeared, in addition to abdominal pain.

Conclusions: While spinal nerve root involvement by CMV may occur in around 1% of HIV patients, involvement of multiple cranial nerves is distinctly rare in healthy persons. The CMV infection must be considered in patients with low cranial nerve palsy.

Differential diagnosis of vertigo using computer vertigometry data

L.P. Maryenko, S.A. Likhachev. Neurology, Republican Research Center of Neurology and Neurosurgery, Minsk, Belarus

Background: Vestibular dysfunction is divided into: vertigo, dizziness, visual, psychogenic, and proprioceptive.

Objective: New method developed for detection of objective signs of vestibular dysfunction (vertigometry) in persons with vertigo paroxysms in history. Method is based on videostimulation of patient with panoramic image in horizontal plane, which is modeling rotatory vertigo.

Methods: We examined a group of 35 patients, 29 of them women and 6 men with complaints of dizziness in the anamnesis. An average age in the group was 51.2 ± 2.1 yr. Research group included diagnoses such us: 8 patients with position dependent peripheral vestibular syndrome, 12 patients with vestibular paroxysms in vertebral artery syndrome, and 5 patients with vegetative instability. At the moment of study patients did not complain of dizziness and no spontaneous nystagmus was registered. Vertigo attack was provoked under electronystagmographic control, not complain of dizziness and no spontaneous nystagmus was registered.

Results: It has been found that in patients with position dependent peripheral vestibular syndrome sensation of vertigo corresponded to stimulation presentation with velocity of 132.9 ± 16.6°/s and provocan nystagmus had velocity of slow phase 112.9 ± 16.6°/s. In patients with vestibular paroxysms in vertebral artery syndrome sensation of vertigo corresponded to stimulation presentation with velocity of 66.4 ± 16.6°/s and provocan nystagmus had velocity of slow phase 48.5 ± 16.6°/s.

Conclusion: The new method (vertigometry) allows finding objective signs of vestibular dysfunction in people with vertigo paroxysms in the anamnesis.

Development of the Oxford Participation & Activities Questionnaire: Semi structured interviews with potential users

Background: There is growing interest in the management of long term conditions and maximising the cost effectiveness of treatment, in part by keeping people active and participating in the community. The Oxford Participation and Activities Questionnaire (Ox-PAQ) initiative aims to develop and validate a patient reported outcome measure (PROM) for the assessment of participation and activity in patients experiencing a range of health conditions.

Objective: To gain the views of a variety of professionals on current PROMs and discuss the challenges and possible future developments that this area might face. Such views would be used to inform the on-going development of the Ox-PAQ.

Material and methods: Fifteen participants from across Europe with a range of expertise including regulation, commissioning, health economics, reimbursement, clinical practice, academic research, government and clinical trials, took part in semi-structured interviews.

Results: A range of views were expressed in relation to the appropriate length of PROMs, presentation of PROM data, use of PROM data and utility measurement. There was general agreement that existing measures have a number of limitations, including difficulty in interpretation, poor sensitivity to change and limited coverage across domains of health.

Conclusion: There is significant diversity in the professionals’ views of PROMs. This is largely, but not exclusively, explained by the background of the individual whose views are being expressed. Developing an instrument such as the Ox-PAQ may benefit from such input, whilst at the same time recognising that a ‘one size fits all’ approach is unlikely to be successful.

Conclusion: The SPV profile of horizontal positional nystagmus can be useful in diagnosing calanithis, cupulolithis and diverse central and peripheral vestibulopathies.

Gangliogliomas of the conus medullaris: A case report
E. Manojlovic Gacic1, D. Iveticb, M. Skender Gazibara3, aInstitute of Pathology, Medical Faculty, University of Belgrade, Serbia; bDepartment of Neurosurgery, Military Medical Academy, Belgrade, Serbia

Background: Gangliogliomas are rare primary tumors of the CNS and are exceptionally found in the conus medullaris.

Objective: To present a case of ganglioglioma in the conus medullaris.

Methods: A 33-year old male presented with a 3-year history of morning low back pain, gait disturbances and increasing weakness of both legs. There were no bladder and bowel dysfunctions. Neurological examination revealed weak patellar reflexes, decreased ankle and plantar reflexes, numbness in L4-S1 dermatomes and normal strength of the group of hip muscles. The remaining muscle groups were graded 3 in the right lower limb and 4 in the left lower limb on a scale of 5.

Results: T1-weighted MRI disclosed expansive intradural mass at the Th12-L1 vertebral levels, with postcontrast heterogenous signal enhancement. Patient underwent Th12-L2 laminectomy, followed by maximal tumor resection. Microscopical examination revealed two components typical for gangliogliomas. The one was composed of irregularly oriented Synaptophysin, Neurofilament and Chromogranin A positive ganglion cells with large vesicular nucleolated nuclei and abundant eosinophilic cytoplasm. The other one, glial component, consisted of elongated bipolar glial fibrillary acidic protein positive pilocytic astrocytes. Rosenthal fibers, occasional granular bodies, conspicuous calcifications, and hyalinized blood vessels with typical perivascular lymphocytic cuffing were also observed. Proliferative Ki-67 index was low. Six months later, there was no tumor recurrence or change in neurological status.

Conclusion: Clinically and on MRI, conus medullaris gangliogliomas could be mistaken for more frequent ependymomas or astrocytomas. Accurate diagnosis depends on appropriate tumor sampling followed by detailed pathohistological and immunohistochemical analysis.

Role of ionic derangement and inflammatory factors in the development of hepatic encephalopathy following bile duct ligation
S. Dhanda, R. Sandhir. Department of Biochemistry, Panjab University, Chandigarh, India

Background: Encephalopathy and brain edema are serious central nervous system complications of liver failure characterized by various neurological symptoms. A growing body of evidence demonstrates that inflammation causes worsening of hepatic encephalopathy (HE) along with proinflammatory mechanisms that act synergistically with ammonia toxicity causing alterations in neurotransmission, leading to neuropsychiatric problems.

Objective: The study was designed to investigate the role of edema, ion shifts, neurotransmitters and inflammatory cytokines in the progression of HE.

Material and methods: HE was induced by bile duct ligation (BDL) surgery in adult male Wistar rats. Development of animal model of HE was assessed by routine liver function tests along with 99mTc labeled mebrofenin hepatic biliary clearance test. BDL animals were compared with sham controls (SC) in terms of edema, Na, K, Ca levels, inflammatory factors (ELISA), neurotransmitters (HPLC) and neurobehavioral tests.

Results: A large fraction of 99mTc-mebrofenin was cleared from the liver of SC rats within 5 min, whereas 99mTc- mebrofenin was retained in BDL rats. Significant edema was observed in the cerebellum region which accounted for an increase in water content in whole brain. The tissue sodium and calcium concentration changed in a manner similar to that of water content. Preliminary data showed altered inflammatory cytokines, neurotransmitter levels following BDL along with considerable decline in the cognitive and motor capabilities of BDL rats.

Conclusion: Overall, prevention of ionic derangement, inflammation and restoration of neurotransmitter levels can provide new strategies for the prevention of HE.

Ethanol leads to poor impulse control in a T-maze based impulsivity task in rats
M. Saghazadehab, A. Mesdaghiniaa, aDepartment of Pharmacology, Kashan University of Medical Sciences, Kashan, Iran; bInternational Branch, Shiraz University of Medical Sciences, Shiraz, Iran

Background: Impulsivity often is accompanied by violent acts. Aggressive individuals are likely to experience general difficulties with impulse control and emotional regulation, and they show impaired social cognition. Several studies suggest that different neurochemical mechanisms can influence impulsivity, and that impulsive behaviour has no unique neurobiological basis. Alcohol intoxication is often associated with poor decision making, disruptive and irrational behaviour.

Objective: The present study investigated the effects of acute administration of ethanol on tolerance to delay reward in rats. Thus the possibility that alcohol may shift the choice towards the immediate reward was examined.

Material and methods: After acclimatization, different groups of rats were given the choice in a T-maze between two magnitudes of reward: Small (one food pellet) delivered immediately versus large (eight pellets) delivered after programmed delays (15, 30 and 60 s). After training trials different doses of ethanol which was diluted with water were administered IP in a volume of 5 ml/kg before impulsivity tests. In statistical analysis, the percent of animals that chose the arm baited with large reward were signiﬁcant lower. Ethanol administration of ethanol on tolerance to delay reward in rats. Thus the possibility that alcohol may shift the choice towards the immediate reward was examined.

Results: Ethanol at a dose of 1.0 g/kg produced a signiﬁcant decrease in preference for large and delayed reinforcer throughout the session, although there were marked individual differences in the size of the effect.

Conclusion: These results indicate that ethanol increases preference for the immediate reinforcer, which can be constructed as evidence of an enhancement in impulsive behaviour and reduction in self control.

Clinical data packages of drug approval for neurological diseases in Japan
K. Sakushimaab, H. Nakamuraa, A. Hashizumea, bPharmaceuticals and Medical Devices Agency, Tokyo, Japan; cDepartment of Regulatory Science, Hokkaido University Graduate School of Medicine, Sapporo, Japan; dDivision of Neurology, National Center Hospital, National Center of Neurology and Psychiatry, Tokyo, Japan

Background: Many new drugs for neurological diseases have been approved in Japan since the foundation of Pharmaceuticals and Medical Devices Agency (PMDA) in 2004. However, it is difﬁcult to plan and conduct clinical trials of neurological diseases because many rare and intractable diseases are included in this area.

Objective: To describe and analyze the drug review reports of neurological disease after the foundation of PMDA in 2004.

Methods: Drug review reports of neurological diseases from 2004 to 2012 were included. Three neurologists evaluated review reports independently. Target condition, clinical trial design for efﬁcacy, primary outcome, and whether the drug was designated for orphan drug were abstracted.

Results: Forty-four review reports except for three diagnostic use drugs were evaluated. With regard to target condition, 8 drugs were approved for epilepsy, 6 for Parkinson disease, and 5 for spasticity or dystonia. In analysis of pivotal clinical trial design including Japanese for efﬁcacy, randomized controlled trial (RCT) data was conducted in 30 drugs, open-label single-arm trial in 8 drugs. Eight reports out of 15 reports with orphan drug designation had RCT data of Japanese. Five drugs were approved based on the public knowledge-based application.

Conclusion: Many drugs were approved in various indications and clinical data package depended on the target condition. This analysis is useful and helpful in the drug development in neurological diseases.

Alternative splicing of canonical transient receptor potential type3 (TRPC3) ion channel expression in the human brain
Y. Kim,a,b, A.J. Moorhousea,b, P.P. Bertrandc, M. Klugmanna,b, Stevensa, A.M.B. Collieb, B.T. Hills, K. Fennerc, E. Gazdickc, Roche, Basel, Switzerland;iAix-Marseille University, AP-HM, Service de Center, Saitama Medical University, Saitama, Japan; hF. Hoffmann-La
Marsden NHS Foundation Trust, Surrey, UK; gInternational Medical Sciences, Royal Melbourne Institute of Technology, Melbourne, VIC, Australia

Background: TRPC3 channels are nonselective cation channels in the TRPC subfamily. TRPC3 channels are activated by low cytosolic Ca2+ and G protein-coupled receptors (via phospholipase C–diacylglycerol signaling). TRPC3 channels are expressed throughout the central and peripheral nervous systems, and in particular associated with neuronal survival, development, and neurotransmission in the cerebellum. Recently, we have discovered a novel TRPC3 splice variant (designated TRPC3c) in rodents. TRPC3c isoform lacks exon 9, and has a much higher activity and cerebellar expression than the unspliced TRPC3b isoform.

Objective: To compare TRPC3c versus TRPC3b mRNA transcript expression in the human brain.

Methods: Total RNA was extracted from several post-mortem brain regions of 10 control subjects (donated to NSW Brain Bank Network). The cDNA obtained from reverse-transcription was amplified using SYBR-green qPCR reagent with primers specific to TRPC3b or TRPC3c isoforms. Amplicon templates of the isoforms enabled quantitative analysis of transcript levels.

Results: Among the brain regions, TRPC3c isoform represented from ~4% to 30% of the total TRPC3 mRNA level (TRPC3b + TRPC3c). The cerebellum had the highest relative proportion (0.29 ± 0.051, n = 8), significantly greater (p < 0.01, ANOVA, Holm–Sidak multiple pairwise comparison) than the hippocampus (0.067 ± 0.011, n = 7); midbrain (0.036 ± 0.0096, n = 5); and pons (0.075 ± 0.047, n = 6). The relative TRPC3 levels from the motor cortex (0.11 ± 0.03, n = 6; p = 0.116) and medulla (0.13 ± 0.035, n = 2; p = 0.664) were not significantly different from the cerebellum.

Conclusion: These findings show that TRPC3c expression is broadly significant in the human brain. The abundance and high activity of the TRPC3c subunit is compatible with significant roles in neuronal Ca2+ homeostasis, such as Ca2+-induced excitotoxicity during hypoxia.

Flow cytometric analysis of cerebrospinal fluid is low diagnostic without atypical morphology or prior history of hematologic malignancy
G.H.J. Stevens,a A.M.B. Colliea, B.T. Hillb, K. Fennera, E. Gazdicka, L.A. Rybickia, E.H. Hsia, Rose Ella Burkhardt Brain Tumor and Neuro-Oncology Center, Cleveland Clinic, Cleveland, OH, USA; Pathology, Cleveland Clinic, Cleveland, OH, USA; Taussig Cancer Center, Cleveland Clinic, Cleveland, OH, USA; Quality Health Science, Cleveland Clinic, Cleveland, OH, USA

Background: Flow cytometric analysis (FCA) of cerebrospinal fluid (CSF) has utility in detecting central nervous system (CNS) involvement by hematologic malignancies. Yet, the majority of samples are negative by FCA.

Objective: Identify pre-test characteristics of CSF specimens that will allow the rational use of FCA in the diagnosis of hematologic malignancy in CSF.

Design: Retrospective data was collected from the medical record and flow cytometric reports for all CSF samples submitted for FCA between 2007 and 2009. Patients: 423 patients for whom 501 CSF samples were submitted for FCA.

Results: A positive diagnosis of a hematologic malignancy was made in 41 specimens (8.2%). The FCA-positive specimens showed atypical morphology, either blasts or atypical lymphocytes, in 98% of
Increasing awareness of health professionals may change this high in the pregnant women, with an increasing frequency towards populations, the present study revealed that RLS risk is remarkably

**Discussion:**
In accordance with the previous reports from other respectively).

**Conclusions:** These data support a policy in which FCA of CSF is actively discouraged unless atypical lymphocytes or blasts are seen on Wright-stained slides or a history of hematologic malignancy is present.

**Neurology, Gaziantep University, Gaziantep, Turkey;**

**Neurology, Istanbul University Cerrahpasa School of Medicine, Gaziantep, Turkey**

**Background:** Restless Legs Syndrome (RLS) is a common disorder that may severely impair sleep. According to the results of Turkish Adult Profile and Epidemiology of Sleep Study (TAPES), the prevalence for RLS was reported as 5.2% in general population, with a higher risk for women (7.3%).

**Objective:** The aim of the present study was to determine the risk of RLS and to find out its range according to the trimesters and associated demographic and medical conditions in pregnant women in a Turkish population. Local Ethics Committee approved the study and informed consents were obtained from all cases before inclusion.

**Patients and methods:** 241 pregnant women were included and given a face-to-face interview in the present study. The demographic features; past medical history; detailed history for the past gravidities, and the current pregnancy; sleep characteristics during the current pregnancy and the presence of RLS symptoms according to the International RLS Study Group criteria were recorded on a previously structured form.

**Results:** RLS was diagnosed in 94 out of 241 pregnant (39%). The RLS diagnosis was aforementioned in only two out of 94 RLS cases. Long pregnancy period and having an associated chronic disease showed statistical significance in RLS cases (p < 0.001, p < 0.001, respectively).

**Discussion:** In accordance with the previous reports from other populations, the present study revealed that RLS risk is remarkably high in the pregnant women, with an increasing frequency towards delivery. It also disclosed that RLS is widely underdiagnosed. Increasing awareness of health professionals may change this situation.

**3D visualization of human spinal cord microanatomy demonstrated with contrast-enhanced x-ray microtomography**

**Human Anatomy and Embryology I, University Complutense, Madrid, Spain;**

**Theoretical Biology, University of Vienna, Wien, Austria;**

**Neurology Unit, Hospital General Universitari, Valencia, Spain;**

**Breast Prevention Imaging Unit, Hospital Marina Baixa, Villajoyosa, Spain**

Current methods for visualizing CNS microstructure in three dimensions depend mainly on reconstructions from serial sections, which are labor intensive and time consuming, or on methods such as confocal microscopy, which requires cleared samples of very limited size. Using a new combination of contrast staining and x-ray microtomography imaging (microCT), we have demonstrated high-resolution 3D visualization of neural microanatomy in whole slices of human spinal cord several mm thick. Staining the spinal tissues with potassium dichromate alone resulted in strong x-ray contrast between gray matter and white matter compartments, and allowed clear differentiation of Rexed laminae and the dorsal and ventral gray commissures. Similar contrasting and visualization were obtained with a simple inorganic iodine (Lugol) stain, which required only two days for 4–5 mm thick samples. Both methods are simpler and faster than Weigert-type stains. Using standard software, details and paths of axonal bundles entering the gray matter from the white matter could be clearly visualized in 3D. Tomographic imaging yields size-calibrated images, so that accurate in situ measurements of microanatomical features are possible. Because microCT imaging is non-destructive, the potassium dichromate samples can be post-processed for Weigert-type myelin stains allowing validation of the microCT data with light microscopy. These methods establish the potential of ex vivo microCT imaging for quantitative assessment of microstructure on spinal cord for a wide range of normal and pathological studies.

**A long-term evaluation of latency of pediatric brain tumors diagnosis in province of Delta-Egypt**

H.I. Maaty.

**Neurosurgery, Benha University, Cairo, Egypt**

**Background:** Tumors of CNS represent the principal solid neoplasm in children and the second one after leukemia in frequency. Previous studies concluded that delay might exist between symptom onset and diagnosis (latency).

**Objectives:** This study was designed to assess the hospital based features of latency of pediatric brain tumor diagnosis in six main hospitals in the province of Delta-Egypt, as well factors that are important in predicting early clinical diagnosis.

**Methods:** From 2005 to 2011, 456 children with brain tumors were enrolled in this study. Clinical presentation, site, pathology and outcome of tumors were assessed. Pre-diagnostic symptomatic period (PSP) was analyzed as regard clinical presentations to make clear the common reasons of delay in diagnosis.

**Results:** 250 patients were male and 206 were female. Median age at diagnosis is 8.2 years with range from <1 year to 16 years. 60% of tumors were infratentorial. The most common tumors were low grade glioma (27.5%), medulloblastomas (25.7%), high grade glioma (15.3%) and craniopharyngioma (8.7%). The median PSP interval was
60 days. 35% of our patients were properly diagnosed within the first month of symptom onset. Medulloblastomas exhibited significant shorter diagnostic period in comparison to the other pathological subtypes.

**Conclusion:** Most frequent pathology in our experience was low-grade astrocytoma, then medulloblastoma. The appropriate diagnosis of pediatric brain tumors still generally requires months and frequent visits to various physicians. High level of awareness, a detailed medical history, and repeated and serious neurological sign interpretation should lead to earlier diagnosis and higher prospect of total tumor resection.

**CPAP therapy reversed paradoxical weakness in myasthenia gravis with obstructive sleep apnea**

K.-H. Ji, S.W. Noh. Neurology, Inje University College of Medicine, Busan Paik Hospital, Busan, Republic of Korea

**Introduction:** Myasthenia gravis (MG) is a disease in which auto-antibodies against the acetylcholine receptor at the neuromuscular junction result in muscular weakness. Easy fatigability of the muscles and restoration of strength after rests are characteristic. Therefore, most patients with MG usually feel refreshed after nocturnal sleep. However, rare patients with MG complain morning weakness so called paradoxical weakness (PW). We report patient with OSA showing PW. CPAP therapy successfully terminated PW.

**Case:** Sixty-year-old obese woman with MG was admitted to the hospital because of general weakness, which was more severe in the early morning and improved slowly over a few hours of resting in awaking. She complained of weakness, especially in swallowing and eye-opening. She was diagnosed as MG and had a thymectomy five years ago. She took a fixed dose of pyridostigmine and azathioprine and 20–40 mg of prednisolone. In history, she had been loud snoring and witnessed apnea. In addition, she complained of recent body weight gain. In-lab polysomnography revealed severe OSA. Following successful CPAP therapy reversed PW within a week.

**Conclusion:** Sleep-disordered breathing is common in MG. We speculate that PW might be due to chronic exposure of repetitive hypoxia despite ongoing respiratory efforts during nocturnal sleep which resulted in accumulation of muscular fatigability in the morning. Weight gain secondary to chronic steroid therapy might be another one. It can aggravate the severity of underlying OSA or even lead to development of OSA. Early screening of OSA and adequate management such as CPAP therapy might be crucial to treat MG patients.

**A case of primary Sjögren’s syndrome presented with dysautonomia as initial manifestation**

J. Park. Neurology, Presbyterian Medical Center, Jeon-Ju, Republic of Korea

Neurological involvement occurs in 10–42% of the primary Sjögren’s syndrome (pSS). Distal sensory neuropathy is the most common, pandysautonomia without sensory neuropathy is extremely rare in the pSS as initial manifestation. We describe the case of pSS presented with bladder dysfunction, paralytic ileus and postural intolerance. A 27-year-old woman developed paresthesia in the both arms 1 week before admission and progressed paresthesia in the legs and trunk below the chest with myalgia. At admission she couldn’t urinate and defecate. On examinations she was revealed with abdominal distension, decreased deep tendon reflexes and sensation for the temperature in the extremities. Autonomic symptoms and signs included no bowel sound during auscultation, increased perspiration on the whole body, bladder distension and postural intolerance with normal pupil sizes and light reflex. Abdomen CT revealed urinary bladder distension and diffuse dilated colon without obstruction suspected paralytic ileus. She had positive anti-SS-A/Ro Ab, anti SS-B/La Ab, positive anti-nuclear antibody (titer 1:40, homogeneous pattern) and anti dsDNA antibody of 38.05 IU, but with negative rheumatoid factor, anti-Sm Ab and Anti-RNP Ab. Salivary scan revealed decreased activity of both the parotid glands and sublingual glands. Motor and sensory nerve conduction studies of median, ulnar, radial, peroneal and sural nerves are mild delayed terminal latency with normal amplitude and velocity. During months her symptoms recovered without steroid or IVIG. This case suggests that pSS should be listed in the differential diagnosis of acute autonomic failure as well as chronic form.

**Paleocerebellar electrical stimulation prevents streptozotocin retinopathy**

N. Kresyun, T. Muratova. Neurology, University Clinic of Odessa, Odessa, Ukraine

**Background:** Oxidative stress and inflammation are implicated in the pathogenesis of retinopathy in diabetes. Fastigial electrical stimulation (ES) alleviates experimental ischemic brain trauma.

**Objective:** To investigate effectiveness of electrical stimulation of paleocerebellum upon streptozotocin (STZ)-induced retinopathy in rats.

**Methods:** A group rats which received ES of culmen/pyramis lobules and another group received analo-
gous stimulations of the parietal brain cortex. The retina was used to investigate effectiveness of electrical stimula-
tion (ES) alleviates experimental ischemic brain trauma.

**Results:** Antioxidant capacity and the levels of intracellular antioxidant, GSH (reduced form of glutathione) levels were decreased by about 25–30%, and oxidatively modified DNA (8-OHdG) and nitrotyrosine were increased by 35–65% in the retina of diabetic rats. The levels of interleukin-1-beta (IL-1-beta) and vascular endothelial growth factor (VEGF) were elevated by 27% and 85% respectively, and the nuclear transcription factor (NF-kB) was activated by 1.7 fold. ES prevented diabetes-induced decrease in the antioxidant capacity, and increase in 8-OHdG and nitrotyrosine; however, it had only partial beneficial effect on retinal GSH. ES also inhibited diabetes-induced elevation in the levels of IL-1-beta, VEGF and NF-kB. Haematoxylin and eosin stained sections revealed outer reticular layer as well as inner nuclear layer thinning were prevented as well.

**Conclusion:** Paleocerebellar ES causes the beneficial effects of the metabolic and morphological abnormalities induced in the retina of rats treated with STZ.

Neurological disorders in hospitalized HIV infected patients: Experience from a European Central Hospital
H. Nzwalo a, R. Pazos b, J. Botas b, M.J. Aleixo b, M.J. Águas b, aNeurology, Faro Hospital, Faro, Portugal; bDoenças Infecciosas, Hospital Garcia de Orta EPE, Almada, Portugal

Background: Neurological manifestations of HIV infection are frequent and diverse. Combination antiretroviral therapy (ART) has changed HIV-associated manifestations including the majority of neurological disorders. Few studies in Europe have accessed pattern of NDs associated with HIV.

Objective: To characterize the occurrence of neurological disorders (NDs) in a European central hospital.

Methods: Retrospective case series of HIV hospitalized patients with NDs from an infectious disease service between 2004 and 2010.

Results: We identified 140 patients with NDs; the majority were males — 105 (75%); the mean age 42 years (range 19 to 89 years old). The most common manifestations were focal signs (55/39.2%), followed by confusional state (29/20.7%), seizures (23/16.4%), and cognitive deterioration (22/15.7%). Mean and median CD4+ count were 130 cells/mm3 and 105 (75%); the mean age 42 years (range 19 to 89 years old). The most frequent and diverse. Combination antiretroviral therapy (ART) has changed HIV-associated manifestations including the majority of neurological disorders. Few studies in Europe have accessed pattern of NDs associated with HIV.

Discussion: Responses recorded from different active sites showed nearly the same features which are difficult to explain with the known electrophysiological criteria. Further studies involving different sites must be performed to be more confident about the origin of these potentials.

Subacute cerebellar degeneration associated with metabotropic glutamate receptor-1 antibodies: New paraneoplastic accompaniments
R. Lorio a, V. Damato b, D. Plantone b, M. Mirabella b, E. Hulsenoomb, M.G. Vitac, A. Bizzarro c, P. Sillevis Smitt d, aCatholic University, Roma, Italy; bNeurology, Erasmus Medical Center, Rotterdam, The Netherlands

Background: Subacute cerebellar degeneration associated with metabotropic glutamate receptor type 1 (mGluR1) autoantibodies is an uncommon syndrome known to be part of the spectrum of paraneoplastic cerebellar degenerations associated with neuronal autoantibodies.

Objective: To report new paraneoplastic accompaniments of subacute cerebellar degeneration associated with antibodies to mGluR1.

Methods: Case report.

Results: We describe a patient with a history of mycosis fungoides who developed a subacute cerebellar ataxia. The ataxia worsened after the removal of a prostate adenocarcinoma. Autoantibodies specific for mGluR1 were detected both in the patient's serum and cerebrospinal fluid. The patient was treated with intravenous immunoglobulins (2 g/kg every month for six months) and steroids with improvement of the cerebellar ataxia.

Conclusions: To our knowledge, this is the first case of subacute cerebellar degeneration with mGluR1 antibodies associated with mycosis fungoides and prostate adenocarcinoma.

life, reaching 89.0 cm. The patient was born with CP: 35 cm, Apgar: 7.9. Mother informs that the child presents tonic crisis 3–4 times/day, lasting 10 s, with diuresis. A respiratory discomfort is noticed depending on the position of the head. There is a similar family history, who died with 9 months.

**Results:** MRI shows the presence only of hindbrain and midbrain structures with extensive malformations. The cerebellum has a significant shift to the right and severe compression by the presence of fluid beneath the tent of the cerebellum. Only a small portion of the telencephalon, near the tent of the cerebellum and the occipital bone, is visible. The huge volume of the skull is due to the fluid accumulated. There was no closure of the cranial vault, with persistence of the fontanelles. The midbrain aqueduct has its diameter size noticeably reduced, which implies difficulty in CSF flow.

**Conclusion:** This is an unusual case of a congenital giant macrocephaly associated with hydrocephalus and encephalomalacia formation, which reflects its difficult treatment choice.

**Blink reflex excitability abnormalities in multiple sclerosis**

C. Cabib³, E. Martinez-Heras¹, S. Llufriu¹, J. Casanova-Molla¹, Y. Blanco², A. Saiz², J. Valls-Sole¹. ¹EMG Unit, Neurology Department, Hospital Clinic, University of Barcelona, Spain; ²Center for Neuroimmunology, Neurology Service, Hospital Clinic Barcelona and Institut d’Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Barcelona, Spain

**Background:** Brainstem dysfunctions in multiple sclerosis (MS) may be caused by either local brainstem lesions or changes in excitability modulation from supranuclear inputs. We hypothesized that while brainstem lesions lead to abnormalities in latency of BR (AbLat), supranuclear lesions lead to abnormalities in excitability measures (AbExc).

**Objective:** To assess abnormalities in BR excitability in MS patients and their correlation with MRI-supranuclear lesions.

**Patients and methods:** In 20 patients and 10 control subjects, we measured latencies and area of R1, R2 and R2c to single unilateral supraorbital stimulation of either side. We calculated the R2c/R2 ratio as a measure of asymmetric excitability enhancement. Patients were classified as having AbLat or AbExc when the values were above the mean + 2 SD of our control group reference data. Brainstem and hemispheres (hll) MRI-lesion load were measured with computer-assisted software (FSL). T-test and Spearman’s test were used for statistics.

**Results:** AbLat were found in 8 patients (7 of them had pontomedullary lesions).

AbExc were found in 7 out of 7 remaining 12 patients. In these patients, a significantly larger R2c/R2 ratio (p = 0.03 with respect to controls) coincided with a significant enhancement of R1 amplitude (p = .0001 with respect to the contralateral side). They also showed a positive correlation between R2c/R2 ratio and ipsilateral hll (r = 0.357), but only one had a lesion that compromised the trigeminal-facial circuit.

**Conclusion:** Asymmetric BR excitability enhancement correlates with unilateral brain lesions in MS. These tests add information for the functional evaluation of the effects of brain LL on brainstem circuits.

A case of isolated hypoglossal nerve palsy secondary to an internal carotid artery dissection  
L. Grunsell, P. Hughes. Hurstwood Park Neurological Centre, Haywards Heath, UK

An isolated hypoglossal nerve palsy is uncommon, dysfunction of the nerve usually occurs as part of a complex syndrome and therefore this case is unusual. We present a 49 year old gentleman who noted altered sensation of the left side of his tongue when brushing his teeth; he denied all other symptoms apart from a mild headache. Examination only revealed an isolated left hypoglossal lesion with deviation of the tongue to the left on protrusion. Investigation with MRI and CT scans in the stroke unit was normal. The diagnosis was finally revealed with MRA imaging. The scan demonstrated images consistent with compression of the hypoglossal nerve and features of a dissecting left sub-cranial internal carotid artery aneurysm. Further imaging with a CT angiogram confirmed a 12 mm dissecting aneurysm at the high cervical segment of the left ICA. The consensus from the neurovascular MDT was to take a conservative approach, given the thromboembolic risk posed by the aneurysm, aspirin 75 mg daily was initiated. This case, a young man with a combination of isolated hypoglossal nerve palsy and headache, highlights the need to consider all differential diagnoses affecting the hypoglossal nerve along its course from the brain stem nucleus to the carotid artery. The case demonstrated the importance of thorough clinical examination and history taking as well as collaboration with neuroradiology to reveal the diagnosis.

doi:10.1016/j.jns.2013.07.2282

Background: A clinical diagnosis of Dementia with Lewy bodies (DLB) has good specificity but low sensitivity and is particularly challenging in patients with an uncertain diagnosis (possible DLB). DaTSCAN™ ([123I]Ioflupane) is a radiopharmaceutical able to visualize the dopamine transporter receptors in the brain.

Objective: To evaluate the impact of DaTSCAN™ SPECT imaging on dementia diagnostic category and the diagnostic confidence of clinicians in patients with a diagnosis of possible DLB.

Methods: 187 patients with possible DLB were recruited from 21 centers in 6 European countries. Patients were randomized to have a DaTSCAN™ (n = 127) or to have no-imaging (n = 60). The proportion of patients with changes in clinical diagnosis (from possible DLB to probable DLB or non-DLB) and changes in the confidence of diagnosis was compared at 8 and 24 weeks of follow-up.

Results: More patients in the DaTSCAN™ group had a change in diagnostic category after 8 weeks (61% vs 4%; P < .0001) and 24 weeks (71% vs 16%; P < .0001) compared to the control group. Significantly more patients in the imaging group were given more confident diagnoses during follow-up. Clinicians were more likely to change the diagnostic category if the DaTSCAN™ image was abnormal (82%) than if the image was normal (48%).

Conclusions: DaTSCAN™ SPECT imaging significantly contributed to change of diagnostic category and improved diagnostic confidence, proving to be a useful adjunct in the diagnosis of dementia in patients with possible DLB. Changes in diagnostic category were less frequent in the control group despite a six-month prospective follow-up.

Background: Friedreich’s ataxia (FRDA) is the most common autosomal recessive ataxia, characterized by spinal cord and cerebellar damage. However, little is known about progression of such damage over the time.

Objective: To evaluate progressive gray and white matter (GM and WM) atrophy in FRDA.

Material and methods: Thirteen FRDA patients and 13 age-and-sex matched controls underwent a VBM protocol in a 3 T scanner (Philips Achieva) two years apart. To examine differences, we used flexible factorial design assessing time × groups, using uncorrected height threshold of P < 0.001.

Results: Mean age of patients was 27.4 years. In FRDA, there was GM atrophy in right inferior temporal gyrus (peak MNI coordinates x = 54, y = −6, z = −34.5), left superior temporal gyrus (x = −40.5, y = 13.5, z = −37.5), left inferior temporal gyrus (x = −51, y = −24, z = −33), left middle temporal gyrus (x = −64.5, y = −54, z = −1.5), left parietal lobe (x = −58.5, y = −51, z = 43.5), and right frontal middle gyrus (x = 36, y = 42, z = 34.5). We found WM atrophy in FRDA patients in left cerebelum (x = −6, y = −43.5, z = −58.5), left caudate (x = −9, y = 15, z = −3), right postcentral gyrus (x = 61.5, y = −9, z = 16.5), left cingulate gyrus (x = −6, y = −3, z = 33), and left superior frontal gyrus (x = −6, y = 31.5, z = 49.5).

Two new heterozygous mutations of Htra1 gene in a Caucasian patient affected by CARASIL
S. Bianchi\textsuperscript{a}, C. Di Palma\textsuperscript{a}, G.N. Gallus\textsuperscript{b}, I. Taglia\textsuperscript{a}, A. Poggiani\textsuperscript{a}, F. Rossini\textsuperscript{a}, A. Cerase\textsuperscript{b}, A. Rufa\textsuperscript{a}, D. Muresanu\textsuperscript{c}, M.T. Dottia\textsuperscript{d}, A. Federico\textsuperscript{a},
\textsuperscript{a}Department of Medical, Surgical and Neurological Sciences, University of Siena, Siena, Italy; \textsuperscript{b}Neuroradiologia e Neurointerventistica, Azienda Ospedaliera Universitaria Senese, Siena, Italy; \textsuperscript{c}Medical School, Cruja, Romania

Background: Cerebral Autosomal Recessive Arteriopathy with Subcortical Infarcts and Leukoencephalopathy (CARASIL) is a hereditary cause of recurrent lacunar stroke and cognitive decline associated with alopecia and spondylosis deformans, due to mutations in the HTRA1 gene on chromosome 10q. Firstly described in Asian pedigrees, CARASIL has been reported so far in only one Caucasian family.

Objective: To report a Caucasian case of genetically-confirmed CARASIL patient with new compound heterozygous mutation of the HTRA1 gene.

Patient and methods: The proband was a 29-y-o Romanian patient, born from a non-consanguineous marriage, who presented two previous ischemic stroke episodes. Clinical examination and brain MRI, as well as direct sequencing of exons 1–9 of HTRA1 gene, were evaluated.

Result: Neurologically she showed ataxic gait, pyramidal signs with severe leukoencephalopathy at MRI. Common inherited and genetic causes of early-onset leukoencephalopathy were excluded. Direct sequencing of exons 1–9 of HTRA1 in the proband identified two new heterozygous mutations: a G to A transition at position 961 (c.961G → A) in exon 4 (inherited from the father) and a G deletion at nucleotide position 126 (c.126delG) in exon 1 (inherited from the mother). Both parents showed diffuse with matter changes in absence of vascular risk factors.

Conclusion: The clinical features and the absence of parents consanguinity suggest that this diagnosis should be considered in otherwise unrecognized forms of sporadic early-onset leukoaraiosis with stroke-like episodes. Moreover CARASIL could be underestimated in Caucasian population.

A blood brain barrier biorepository for disease-specific human brain microvascular endothelial cells: A new tool for neurologic and psychiatric research

T.R. Roesel, Cervoe. Orig. McLean, VA, USA

Background: Blood brain barrier (BBB) dysfunction has been implicated in many illnesses such as stroke, traumatic brain injury, Parkinson's disease, Alzheimer's disease, schizophrenia, multiple sclerosis, as well as more uncommon conditions such as chronic Lyme disease, chronic fatigue syndrome, Gulf War-related illness, and HIV dementia. Investigations on BBB neurophysiology are limited by nonavailability of disease-specific human brain microvascular endothelial cells (HBMECs) for in vitro culture experiments, despite routine availability of normal, non-disease related HBMECs.

Objective: The objective is two-fold: 1) To confirm the need for a biorepository for disease-specific HBMECs, and 2) to present a schematic for establishing the first BBB bank to make disease-specific endothelial cells from patient donated brains available for clinically relevant translational medical research.

Material and methods: Non-oncological brain tissue banks were identified worldwide. These repositories were queried by website evaluation and/or email questionnaire. The scientific literature was reviewed for HBMEC isolation and cryopreservation techniques for protocol development.

Results: Seventy-seven non-oncological brain banks or their umbrella networks in 16 countries were identified, along with 8 commercial vendors. None offer disease-specific HBMECs, although 11 non-commercial banks provide disease-specific HBMECs with advanced notification, should a disease appropriate donor become available. The administrative requirements, equipment, material, and protocols essential for a functioning disease-specific HBMEC biorepository are reviewed.

Conclusion: Establishment of a biorepository for cryopreserved disease-specific HBMEC is feasible. Such a bank would provide needed cells for BBB-related translational medicine studies in neurology and psychiatry. With greater pathophysiological knowledge, interventions to increase BBB resiliency in specific diseases can be explored.

Sleep and breathing in 100 healthy Caucasians—A polysomnographic study in self-perceived good sleepers

B. Högl¹, D. Gabelia², T. Mitterlinga², M. Biermayra³, E. Brandauer³, S.V. Schönwald³, W. Poewe³, B. Frauscher³. ¹Department of Neurology, Innsbruck Medical University, Innsbruck, Austria; ²Department of Neurology, Hospital de Clinicas de Porto Alegre, Porto Alegre, Brazil

Background: Normative studies for sleep using polysomnography have been performed, but are mainly historic and published prior to the introduction of the currently valid scoring criteria.

Objective: To investigate objective sleep parameters in healthy adults and establish normative polysomnographic values according to AASM.

Methods and participants: One-hundred subjects (f/m 40/60) aged 20–80 years who perceived themselves as healthy sleepers were recruited from the representative Austrian population. In a two-step procedure (telephone and face-to-face interviews) patients with any evidence for sleep disorders were excluded. Full-night polysomnography was performed and scoring of sleep, respiration and arousals was performed according to AASM.

Results: Total PSG sleep time decreased with age, from 6.9 (5.3–7.6) for those in their 20s to 6.3 h (3.6–7.3) (median; range) in the over 60s age group. Sleep efficiency decreased with age from 87% (71.9–94.1) in those in their 20s to 79.7% (44.5–90.9) (median; range) in those >60 yrs. The apnea hypopnea index (AHI) increased with age, with those in their 60s having a significantly greater AHI than subjects below 50 years of age.

Conclusion: This study provides normative PSG data according to AASM criteria. Our data show that there is unrecognized sleep-disordered breathing in the population. Even in subjectively healthy sleepers, and after exclusion of suspected sleep-disordered breathing, BMI > 30 and excessive daytime sleepiness, 3 subjects had moderate to severe sleep apnea. Based on these data screening for sleep apnea in asymptomatic elderly is recommended.

Evaluating variability of fMRI in the sensorimotor cortex—A multicenter study*

1Department of Neurology, Group Clinical fMRI, Vienna, Austria; 2Department of Neurology, Medical University Vienna, Vienna, Austria; 3High Field MR Center of Excellence, Medical University Vienna, Vienna, Austria; 4Department of Psychology and Centre for Neurocognitive Research, University of Salzburg, Salzburg, Austria; 5Department of Neurology, Heimhich-Heine-Universität Düsseldorf, Düsseldorf, Germany; 6Department of Radiology, Medical University of Innsbruck, Innsbruck, Austria; 7Department of Neurology, Christian Doppler Klinik, Paracelsus Medical University Salzburg, Austria; 8Department of Neurosurgery, Medical University Vienna, Vienna, Austria; 9Institute for Diagnostic Radiology, Stiftungsklinikum Mittelrhein, Koblenz, Germany

Background: More and more patients with planned neurosurgical interventions undergo fMRI-scans with localization of the primary sensorimotor cortex being one of the most frequently requested clinical tasks. Reliability of fMRI-localization is an important issue since changing the resection margins in the range of millimeters might dramatically change the functional outcome of surgery. Up to now dependence of fMRI-localization on the investigating site was only assessed in healthy volunteers, but is not known for patients with pathological brains.

Objective: To evaluate between-site-variability of fMRI in the sensorimotor cortex using a somatotopical and a motor task.

Methods: 15 patients with planned neurosurgical intervention due to unilateral brain pathology underwent fMRI-scans at 3 experienced clinical sites. fMRI-scans included a motor (first clenching of hand contralateral to pathology) and a somatosensory task (vibrotactile stimulation of digitus 2/3 contralateral to pathology). fMRI-variability was assessed with:

1. center-of-activation (COA) variability,
2. activation-size-ratio (SR),
3. activation-overlap-ratio (OR) and
4. intraclass-correlation-coefficients (ICC).

Results: Median COA variability was 5.7 mm (IQR 3.2–7.9 mm, maximum 16.5 mm) for the motor task and 5.8 mm (IQR 3.4–8.0 mm, maximum 12.0 mm) for the sensorimotor task. Median SR was 48.7% (IQR 40.8–66.1%; motor) and 30.8% (IQR 14.0–39.3%; somatosensory) respectively. The figures for OR were 33.0% (IQR 26.6–43.2%; motor) and 4.0% (IQR 1.1–10.2%; somatosensory). ICC was 0.23 (motor) and 0.20 (somatosensory).

Conclusion: Correspondence of fMRI-localizations is quite good between centers. In single patient localization differences can amount up to 16.5 mm. This figure needs to be considered in clinical practice and for clinical studies with multicentric designs.

The phenomenology and epistemology of konzo: Readings from the Kahemba Outbreak, Democratic Republic of Congo. Part I: Socioeconomic aspects

1Neurology, University of Kinshasa, Kinshasa, Congo; 2Sciences de Base, University of Kinshasa, Kinshasa, Congo; 3Programme National de Nutrition, Ministère de la Santé, Kinshasa, Congo; 4Neurology, University of Kinshasa, Kinshasa, Congo; 5Neurology, Center for Research on Occupational and Environmental Toxicology, Oregon Health & Science University, Portland, OR, USA

Abstract: Konzo was first described in 1965 in the Democratic Republic of Congo in the Kahemba Outbreak. At the time, the International Committee of the Red Cross declared it a medical emergency of international concern. Konzo is a severe, non-communicable, subacute neurological condition caused by acute cyanide poisoning due to cassava consumption. It is characterized by weakness, ataxia, and loss of consciousness and can progress to death in a few weeks. Konzo has been associated with konzo and 87 non-konzo according to WHO criteria, were recruited in sectional study on demographic and economic profile. The socio-economic profile was evaluated by the Home. All children were tested negative for HIV and HTLV-1.

Objectives: To determine the demographic characteristics of household-affected by konzo; quantify the level of economic distress associated with konzo and elucidate the relationship between economic distress and cyanide poisoning.

Subjects and methods: 210 children aged 8.83 ± 2.57 years, 123 konzo and 87 non-konzo according to WHO criteria, were recruited in sectional study on demographic and economic profiles of patients affected by konzo. The work had included a literature review, a survey by structured interviews, observations and sampling of cassava flour and urine samples for biochemical analyzes in search of markers of cyanide poisoning. The socio-economic profile was evaluated by the Home. All children were tested negative for HIV and HTLV-1.

Results: The frequency of konzo was 79.47% for children aged <15 years and 56.9% for females. Exposure to HCN cassava flour is equivalent konzo children and non-konzo (p = 0.503), the severity of konzo was proportional to the poverty of the family socioeconomic environment overall (p = 0.008). The nutritional status of...

Predictors of Poor self-rated health in a Senegalese male elderly population utilizing the social and health center of Ipres, Senegal
abNeurology, Fann Teaching Hospital, University Cheikh Anta Diop, Senegal; 1bPreventive Medicine and Public Health, Fann Teaching Hospital, University Cheikh Anta Diop, Senegal; 1bAristide Le Dantec Teaching Hospital, University Cheikh Anta Diop, Senegal; 1bNeurology, Fann Teaching Hospital, University Cheikh Anta Diop, Dakar, Senegal

Background: Self-rated health is associated with morbidity and mortality. It is an indicator of quality of life. The objective of this study was to identify predictors of poor self-rated health in a Senegalese male elderly population of patients utilizing the Social and Health Center of IPRES, Dakar-Senegal for health care.

Methodology: During a cross-sectional study conducted in a sample of 546 elderly male 55 years and over utilizing the health center, data on sociodemographic characteristics, lifestyle, social network, past medical history, and self-rated health were collected from 2004 to 2005. Self-rated health was assessed with a single question as proposed by Mossey and Shapiro: "How do you perceive your health?" with responses in five categories: excellent, very good, good, fair and poor. Uni, bi and multivariate logistic regression analyses were performed.

Results: The patients had a mean age of 68 years (±7.4), were married, and educated with high social network. Alcohol consumption and smoking were rare. Hypertension, arthritis, gastrointestinal and genitor-urinary diseases were more frequent. Self-rated health was poor (72%), Family history of dementia, stroke, epilepsy, head injury, illiteracy and weak social network were predictive of poor self-rated health while being married and age 60–74 years were protective.

Conclusion: It is necessary to take into account these results for primary prevention of poor self-rated health in this population.

Neural plasticity: Role of PPARα activation
A.E. Katsoo-ridaki, F. Malliou, M. Marselos, M. Konstandi. Department of Pharmacology, University of Ioannina, School of Medicine, Ioannina, Greece

Peroxisome proliferator-activated receptor (PPARα) is expressed in neurons and astrocytes and its activation provides neuroprotection against noxious biological reactions induced by cerebral ischemia. The present study has focused on the role of PPARα activation in neural plasticity. For this purpose, SV129 wild type mice were treated with either fenofibrate (FEN) or oleuropein, PPARα activators, for 2 and 4 days, respectively. Similar treatment protocol was followed in Pparα-null mice. The data of this study revealed that fenofibrates significantly up-regulated the brain-derived neurotrophic factor (BDNF), the neurotrophic factors NT-4/5 and NT-3, as well as the corticotrophin releasing factor receptor-1 (CRF-R1) and PPARα in the prefrontal cortex (PFC). NT-4/5 and CRF-R1 were increased by FEN and oleuropein in the hippocampus. Oleuropein also markedly up-regulated the brain-derived neurotrophic factor (BDNF), the neurotrophic factors NT-4/5 and NT-3, as well as the corticotrophin releasing factor receptor-1 (CRF-R1) and PPARα in the prefrontal cortex (PFC). NT-4/5 and CRF-R1 were increased by FEN and oleuropein in the hippocampus. Oleuropein also markedly up-regulated the brain-derived neurotrophic factor (BDNF), the neurotrophic factors NT-4/5 and NT-3, as well as the corticotrophin releasing factor receptor-1 (CRF-R1) and PPARα in the prefrontal cortex (PFC). NT-4/5 and CRF-R1 were increased by FEN and oleuropein in the hippocampus. Oleuropein also markedly up-regulated the brain-derived neurotrophic factor (BDNF), the neurotrophic factors NT-4/5 and NT-3, as well as the corticotrophin releasing factor receptor-1 (CRF-R1) and PPARα in the prefrontal cortex (PFC). NT-4/5 and CRF-R1 were increased by FEN and oleuropein in the hippocampus. Oleuropein also markedly up-regulated the brain-derived neurotrophic factor (BDNF), the neurotrophic factors NT-4/5 and NT-3, as well as the corticotrophin releasing factor receptor-1 (CRF-R1) and PPARα in the prefrontal cortex (PFC). NT-4/5 and CRF-R1 were increased by FEN and oleuropein in the hippocampus. Oleuropein also markedly up-regulated the brain-derived neurotrophic factor (BDNF), the neurotrophic factors NT-4/5 and NT-3, as well as the corticotrophin releasing factor receptor-1 (CRF-R1) and PPARα in the prefrontal cortex (PFC). NT-4/5 and CRF-R1 were increased by FEN and oleuropein in the hippocampus. Oleuropein also markedly up-regulated the brain-derived neurotrophic factor (BDNF), the neurotrophic factors NT-4/5 and NT-3, as well as the corticotrophin releasing factor receptor-1 (CRF-R1) and PPARα in the prefrontal cortex (PFC). NT-4/5 and CRF-R1 were increased by FEN and oleuropein in the hippocampus. Oleuropein also markedly up-regulated the brain-derived neurotrophic factor (BDNF), the neurotrophic factors NT-4/5 and NT-3, as well as the corticotrophin releasing factor receptor-1 (CRF-R1) and PPARα in the prefrontal cortex (PFC). NT-4/5 and CRF-R1 were increased by FEN and oleuropein in the hippocampus. Oleuropein also markedly up-regulated the brain-derived neurotrophic factor (BDNF), the neurotrophic factors NT-4/5 and NT-3, as well as the corticotrophin releasing factor receptor-1 (CRF-R1) and PPARα in the prefrontal cortex (PFC). NT-4/5 and CRF-R1 were increased by FEN and oleuropein in the hippocampus.

Objective: To report a case of limbic encephalitis followed by NMO.

Case report: A 50-year-old woman presented with subacute memory loss, confusion and behavioral changes. A brain-MRI showed a T2-weighted hyperintense medial temporal cortex. Two months later an ovarian teratoma was removed. One year later she started to exhibit inflammation in the spine and subsequently in the optic nerve resembling neuromyelitis optica. She was treated with plasma exchange and steroids with benefit. A subsequent anti-neuronal antibody screening proved positive for anti-AQP4 antibodies in the serum and for anti-NMDAR antibodies in the serum and CSF. Human leukocyte typing disclosed class I allele B8 and class II DR3-DQ2 (DRB1*03-DQB1*02).

Conclusion: NMDAR-encephalitis can present with attacks that can mimic a demyelinating disease. However, to our knowledge this is the first case of NMDAR-encephalitis followed by AQP4-Ab positive NMO. The hypothesis that our patient had two distinct syndromes is supported by the typical association of NMDAR-encephalitis with teratoma whereas NMO is generally not a paraneoplastic disease. The possible coexistence of multiple autoantibody-associated neurological syndromes is increasingly recognized. The HLA typization suggests that a genetic predisposition played a significant role in the development of these two uncommon autoimmune disorders.

AQP4-neuromyelitis optica following NMDAR-encephalitis: A case report
M. Zoccara1a, I. Zulianiib, M.V. Saddic, G. Serra2a, M.F. Pelizzia2a, I. Rosellinia1b, L. Peddone2b, A. Ticca3b, B. Giometto2b.
1aUniversity of Padova, Padova; 1bU.O. di Neurologia, Ospedale di Treviso, Treviso, Italy; 2aS. Francesco Hospital, Nuoro, Nuoro, Italy

Background: NMDAR-encephalitis is an autoimmune disorder often associated with teratoma. Neuromyelitis optica (NMO) is an inflammatory demyelinating disorder of the CNS associated with Aquaporin-4 antibodies.

Objective: To report a case of limbic encephalitis followed by NMO.

Case report: A 50-year-old woman presented with subacute memory loss, confusion and behavioral changes. A brain-MRI showed a T2-weighted hyperintense medial temporal cortex. Two months later an ovarian teratoma was removed. One year later she started to exhibit inflammation in the spine and subsequently in the optic nerve resembling neuromyelitis optica. She was treated with plasma exchange and steroids with benefit. A subsequent anti-neuronal antibody screening proved positive for anti-AQP4 antibodies in the serum and for anti-NMDAR antibodies in the serum and CSF. Human leukocyte typing disclosed class I allele B8 and class II DR3-DQ2 (DRB1*03-DQB1*02).

Conclusion: NMDAR-encephalitis can present with attacks that can mimic a demyelinating disease. However, to our knowledge this is the first case of NMDAR-encephalitis followed by AQP4-Ab positive NMO. Low-grade glioma growth kinetics before and after CCNU alone
E. Rocib, B. Cakani, G. Fejzo, P. Djamandib, A. Rojib, M. Petrib, G. Kaloshi. UHC Mother Theresa, Tirana, Albania
Background: Previous studies have reported that low-grade gliomas (LGG) grow continuously and that temozolomide and PCV have an impact in their growth kinetics.

Objective: No data exists on the impact of CCNU alone. The aim of this study was to evaluate the effect of first-line CCNU alone chemotherapy.

Material and methods: The mean tumor diameter (MTD) of LGG was evaluated on serial magnetic resonance images before (n = 28), during, and after (n = 36) treatment with neoadjuvant CCNU.

Results: Before CCNU onset, MTD increased linearly over time (range 2.1 to 4.9 mm/year). During treatment with CCNU alone, 91% of patients experienced a decrease of MTD. After CCNU discontinuation, 28 of 33 patients who responded, an ongoing decrease of MTD was observed. Unresponsive tumors resumed their progressive growth within a year.

Conclusion: Our results confirmed that CCNU alone is an effective treatment for progressive LGG and its pattern of MTD decrease is comparable with previous study using temozolomide and PCV chemotherapy.

Cardio- and cerebrovascular risk is associated with decreased slow wave sleep in patients with chronic kidney disease

A.V. Lindner a, K. Rona b, K. Fornadi c, A.S. Lazar b, M.E. Czir d,b, A. Dun a,b, R. Zoller a, O. Veber a, A. Szentháry a, Z. Kiss a, E. Torony a, M.Z. Molinar e, I. Mucz i,j, M. Novak k,l, Department of Neurology, Semmelweis University, Budapest, Hungary; Institute of Behavioural and Biomedical Research Institute at Harbor, UCLA, Torrance, CA, USA; Department of Behavioural Sciences, Semmelweis University, Budapest, Hungary; Angau Hungary Limited, Semmelweis University, Budapest, Hungary; Dept. of Transplantation and Surgery, Semmelweis University, Budapest, Hungary; Division of Nephrology, University of Toronto, Toronto, ON, Canada; Los Angeles Biomedical Research Institute at Harbor, UCLA, Torrance, CA, USA; Institute of Pathophysiology, Semmelweis University, Budapest, Hungary; Division of Nephrology, McGill University, Montreal, QC, Canada; Dept. of Psychiatry, University of Toronto, Toronto, ON, Canada

Background: Previous studies reported that sleep fragmentation and decreased slow wave sleep related to certain cardiovascular risk factors e.g. cholesterol levels, obesity in general population.

Objective: Our study aims to analyze association between cardio- and cerebrovascular risk and slow wave sleep in patients with chronic kidney disease.

Patients and methods: 100 kidney transplanted and 50 wait-listed hemodialyzed patients underwent polysomnography. The ten-year coronary heart disease risk was estimated for all patients using the Framingham Score. Moreover, the ten-year estimated risk of stroke was calculated according to the modified version of the Framingham Stroke Risk Profile. In multivariate linear regression models logarithmic transformed Framingham scores were used for estimating association between slow wave sleep and cardiocerebrovascular risk.

Results: Mean age was 51 ± 13 yrs, ratio of males was 56% in the population. Slow wave sleep was reverse related to cardiovascular and stroke risk (Spearman’s rho: 0.259, p = 0.003; –0.209, p = 0.011). In multivariate linear regression models the lower ratio of slow wave sleep was independently associated with the logarithmic transformed Framingham cardiovascular (beta = −0.211; 95% Cl: −0.45 to −0.007) and cerebrovascular scores (beta = −0.155; 95% Cl: −0.033–0.0) after adjusting for important co-variables (apnea-hypopnea index, serum albumin and hemoglobin levels, type of renal replacement, Charlson comorbidity index, sleep efficiency).

Conclusion: Decreased slow wave sleep was found to be an independent predictor of higher cardio- and cerebrovascular risk score in patients with chronic kidney disease.

Is transient global amnesia (TGA) hereditary?

M.M. Dupuis a, F. Evrard a, S. De Bruijn b, J. Segers-van Rijin b, F. Dupuis a, P. Jacquere a, G. Picard a, O. Ghysens a, K. Dahan c, C. Verellen d, Clinique St Pierre, Ottignies, Belgium; Neurology, Hagaziekenhuis, Den Haag, The Netherlands; Institut de Pathologie et de Génétique, Gosselies, Belgium

Background: TGA is a well established clinical syndrome, with an overall annual incidence of 3 to 8/100,000. 75% of the cases occur between the ages of 50 and 70 but rarely before 40. Stress, physical exercise and migraine are reported risk factors. MRI diffusion abnormalities in SCA2 are frequently demonstrated. Once affected, a patient has an annual relapse rate of 6–10%.

Objectives: To draw attention to a possible genetic factor in TGA for this individual predisposition.

Patients and methods: Hodge’s diagnostic criteria were applied. Only first degree affected relatives were enrolled in the database. We review the published familial TGA and include 7 families reported recently by one of us. 6 of them were of the same hospital and were compared to a database of 127 consecutive TGA.

Results: The 6 families represent 4.7% of 127 TGA cases (95 CI 1.05–8.45%). We found 9 published familial TGA. Together with our 7 families, this topic gathers 41 cases in 16 families (mean age: 61.8–22 women—12 migraineous). Migraine and stress were frequent risk factors. These familial cases were not distinguishable from sporadic cases.

Conclusion: We suspect that familial TGA is globally underestimated and under-reported. If confirmed, a genetic link, even if rare, could provide helpful information in the understanding of the physiopathology of TGA as did the rare cases of familial Parkinson’s or Alzheimer’s disease. We propose a systematic inquiry of familial cases and their reporting, and DNA sampling of these families to set up a genetic research.

Telemedicine—Is tele-EEG, tele-electrophysiology and telecytology possible—A feasibility study

E. Braemer a, F. Idris a, N. Ahmad a, D. Duran b, B. Bassa c, I. Jafar d, B. Kress e, U. Meyding-Lamade f, Neurology, Krankenhaus Nordwest, Frankfurt/Main, Germany; gPARSB Institute of Health Science, Universiti Brunei Darussalam, Brunei; hBrunean Stroke and Rehabilitation Centre, Jerudong, Brunei; iNeuroradiology, Krankenhaus Nordwest, Frankfurt/Main, Germany

Background: A high end class stroke and teaching network by the help of telemedicine is established between the Department of Neurology, Krankenhaus Nordwest (KHNW), Germany and Bruneian Neuroscience Stroke and Rehabilitation Centre (BNSRC), since 7/2010.

Objective: This pilot study was conducted to validate the feasibility of tele-electrophysiology, tele-cytology and tele-electroencephalography carried out between KHNW and BNSRC.
Methods: 20 randomly selected patients for tele-electrophysiology, somatosensory evoked potential on the median nerve of the arm and tibial nerve of the leg and the nerve conduction were examined. 10 EEGs and 10 samples of CSF were examined and analyzed in both hospitals via a secure internet connection.

Results: Tele-electrophysiological part exhibits that findings made by neurologists from both sides are identical, tele-cytological part shows that both sides made the same results; tele-electroencephalographical part shows feasibility although there was a considerable inter-rater variability.

Conclusion: All studies revealed, evaluation of tele-cytology, tele-EEG and tele-electrophysiology is feasible. Evaluation of tele-electrophysiology and tele-cytological studies showed a high concordance between the evaluations. Concordance of the results of the tele-EEG examination was lower. This is most likely due to a high inter-rater variability, since EEG interpretation is highly influenced by examiner characteristics.

Quality of diagnosis and treatment of acute stroke depends on ability to recognize know and treat differential diagnosis and stroke mimics. As there is a lack of neurological knowledge in many areas of the world, this might be a useful future tool to deliver expert advice from one part of the world to another part of the world.

Evolution in modern and future neurology and neuroscience

D. Steinberg, Fiddletown Institute, Fiddletown, CA, USA

Background: Evolutionary theories are ubiquitous in modern neuro-science. There is ongoing research on scales from the molecular and genetic, to organs, organisms and populations. After an introduction to the diversity of current evolutionary neuroscience, this presentation will focus on a possible future. Utilizing John Hughlings Jackson’s evolutionary neurophysiology and his doctrine of concomitance, a new direction for evolution in cognitive neuroscience will be suggested.

Objective: To examine the diversity of evolutionary notions in neuroscience and a possible future.

Material and methods: Research.

Results: A commonality of the diverse applications of evolutionary ideas to neuroscience is identified, and a potential future for evolutionary neurophysiology is suggested.

Conclusion: Evolutionary theories have been essential in the development of neuroscientific ideas. Though the diversity of systems and scales is extensive, the shared concept of evolution provides a unifying feature. By carefully examining the past and present of evolution in neurology and neuroscience, one possible future application of evolution is identified.

Background: Central nervous system (CNS) infections are severe diseases, caused by a wide variety of pathogens. The rapid diagnosis and management of these infections can reduce mortality and neurological sequelae but diagnostic laboratory tests are not readily available in all settings, especially in resource-limited countries.

Objective: In 2010, hospital-based surveillance was initiated in Tbilisi, Georgia to determine pathogens causing acute meningitis and encephalitis, and to enhance laboratory capacity for the diagnosis of CNS infections.

Patients and methods: Hospital staff collected cerebral spinal fluid (CSF) and acute and convalescent sera from patients meeting a clinical definition for meningitis/encephalitis. Specimens were tested by bacterial culture and RT-PCR for HSV types 1 and 2, mumps virus, enterovirus, varicella zoster virus (VZV), Streptococcus pneumoniae, Haemophilus influenzae type B (Hib), and Neisseria meningitidis.

doi:10.1016/j.jns.2013.07.2303
Results: From October, 2010 through February, 2013, 199 patients were enrolled. One hundred eleven (56%) were children <18 years old. Pre-testing clinical diagnosis was bacterial meningitis in 82 (41%), viral meningitis in 95 (48%), viral encephalitis in 13 (7%), and TB meningitis in 9 (5%). By PCR, 25 CSF samples were positive for S. pneumoniae, six for N. meningitidis and one for Hib. Viral multiplex PCR of CSF identified enterovirus in 37 (19%) cases; other viral pathogens identified included VZV (6), HSV1 (2), and HSV2 (1). S. pneumoniae was isolated by culture in five cases.

Conclusion: This study expands the understanding of the range of pathogens causing CNS infections in Georgia. These findings affirm enteroviruses and bacteria as important CNS pathogens.

Deficits in episodic memory relate to reduced hippocampal volumes in very-low-birth-weight (VLBW) young adults
G. Løhaugena, K.J. Bjulandb, M. Martinussenb, J. Skranesb, a, G. De Fi, G. Gekas. a

Background and aims: The hippocampus is regarded as a core structure for learning and memory functions. Academic problems are commonly reported in VLBW (bw ≤ 1500 g) children and adolescents, and the aims of this hospital-based, long-term follow-up study were to perform a comprehensive memory assessment in VLBW young adults and investigate the relationship between hippocampal volume and episodic memory compared to age-matched term born controls.

Methods: Forty-two non-disabled VLBW and 61 age-matched controls were examined at age 19 with the WAIS-III, Wechsler Memory Scale-III and cerebral MRI. An automated MRI technique (FreeSurfer ver. 5.1) at 1.5 Tesla for morphometric analysis of hippocampal volumes was applied.

Results: The VLBW group was at a disadvantage compared to controls on tests assessing visual immediate/delayed memory and working memory. The VLBW group had similar relative left (mean 0.244 (SE 0.003) mm³, p = 0.242) and smaller right (mean: 0.243 (SE 0.004) mm³, p = 0.027) hippocampal volumes vs. controls (left 0.249 (SE 0.003) mm³; right 0.253 (SE 0.003) mm³). Significant correlations were found between left (r = 0.344, p = 0.030) and right (r = 0.038, p = 0.016) relative hippocampal volumes and visual immediate memory. Working memory function was associated with right hippocampal volume (r = 0.392, p = 0.015).

Conclusion: We found that being born preterm with VLBW has long-term negative consequences regarding memory functions, persisting into young adulthood. The relative hippocampal volumes were reduced in VLBW young adults compared to term born controls. Positive correlations were found between hippocampal volume and immediate visual and working memory function in the VLBW group.

Serial magnetic resonance imaging of acute necrotizing myelitis
E. Papageorgiou, K. Psychogios, D. Tzanetakos, I. Markakis, I. Xydkis, G. Gekas. Neurology, 'St. Panteleimon' General State Hospital, Nikaia, Greece

Background: Acute necrotizing myelitis (ANM) is a rare spinal cord disorder occurring in the setting of infections, systemic autoimmune conditions, paraneoplastic syndromes or neuromyelitis optica; occasionally it may be idiopathic.

Objectives: To describe serial MRI findings in a case of idiopathic ANM involving the entire length of the spinal cord, including the anterior horns.

Patients and methods: A 25-year-old male was admitted to our department for severe back pain, numbness and leg weakness progressing over a few hours. On examination he presented paraplegia, lower limb areflexia, a T4 sensory level and loss of sphincter control. On admission, spinal MRI was unremarkable; however one week later it revealed lower cervical cord swelling and diffuse T2 hyperintensity of the entire thoracic cord extending to the

Epidemiology and etiology of acute flaccid paralysis of infectious origin in Georgia
T. Akhvlediani a, R. Rowlinson b, R. Shakarishvilia c, T. Tsertsvadze c,d, N. Tatishvili e, N. Kvirkvelia f, D. Chkhartishvili g, M. Kapiani d, E. Dueger b, J. Sejvari h, N. Akiashvili i, N. Beradze j, L. Dziguad d, L. Malania h, M. Farrell b, E. Duerger e, J. Sejvari f, Division of High-Consequence Pathogens and Pathology, Centers for Disease Control and Prevention, Atlanta, GA, USA

Background: With the ongoing elimination of poliovirus worldwide, understanding of other causes of acute flaccid paralysis (AFP) is increasingly important. Although studies of AFP have been conducted in developed countries, the epidemiology of non-poliovirus AFP in much of the developing world, specifically Central Asia and the Caucasus, has not been systematically investigated. This hospital-based surveillance study is the first attempt to identify and characterize cases of AFP in Georgia.

Objective: This study aims to characterize clinical, laboratory, and electrodiagnostic features of AFP admitted to four tertiary clinics in Tbilisi, Georgia.

Patients and methods: We enrolled patients >6 weeks of age meeting a clinical case definition for AFP. For each patient, we collected CSF, acute and convalescent serum, nasopharyngeal and stool samples to test for: Campylobacter jejuni, cytomegalovirus, enteroviruses, influenza virus, and tick-borne encephalitis and West Nile viruses. Nerve conduction studies and electromyography were performed in each patient.

Results: Between January, 2012 and December, 2012, we enrolled, nine patients; three were children <15 years of age. Based upon clinical and electrodiagnostic features, we classified six cases as Guillain–Barré syndrome, one case each of Fisher syndrome, transverse myelitis, and post-vaccine poliomylitis. Laboratory testing for the pathogens assessed was all negative.

Conclusion: These preliminary findings suggest that the etiologies of AFP in Georgia vary, and GBS contributes substantially. Future investigations will focus on continuing to define the etiologies of AFP in the Caucasus, determine subtypes of GBS, and identify concurrent or antecedent infectious etiologies of AFP.

Neurophysiological endophenotype in non-demented carriers of apolipoprotein E and apolipoprotein J/clusterin Alzheimer’s risk variants
N.V. Ponomareva a,b, T.V. Andreeva b, M. Protasova b, L.I. Shagam b, D.D. Malina a, A.Y. Goltsvo a, A.A. Mitrofanov b, E.I. Rogayev a,c, Research Center of Neurology RAMS, Russia; aInstitute of General Genetics RAS, Russia; bInstitute of Psychiatry, Moscow, Russia; cUniversity of Massachusetts Medical School, Worcester, MA, USA

Background: GWAS studies have provided evidence that in addition to apolipoprotein E (ApoE), CLU (rs11136000) genotype is associated with risk of Alzheimer’s disease (AD) (Harold et al., 2009; Lambert et al., 2009; Golenkina et al., 2010). The use of multilocus genotype patterns that combine SNPs at different susceptibility genes provide a helpful approach to predict genetic risk for AD. Brain endophenotype derived from EEG may be valuable marker for genetic predisposition to AD.

Objective: This study was aimed at determining the possible effect of ApoE and CLU polymorphisms on spontaneous EEG and EEG reactivity in response to letter fluency task (LFT) and to hyperventilation in non-demented adults.

Material and methods: We examined quantitative EEG during resting, LFT and under hyperventilation in 142 non-demented adults, stratified by ApoE and CLU polymorphism.

Results: A pattern involving ApoE ε4 and CLU CC genotypes was associated with the decreased upper alpha power in spontaneous EEG, more pronounced event-related desynchronization (ERD) during LFT and the presence of high-voltage delta-activity, theta-activity and sharp-waves under hyperventilation. The increased ERD in the carriers of ApoE ε4 and CLU CC genotypes may reflect greater “effort” to perform the task and/or may result from neuronal hyperexcitability.

Conclusion: The data suggest that neurophysiological endophenotype of non-demented individuals at genetic risk for AD, characterized by dysfunction of alpha rhythm-generating structures and hyperexcitability, may be revealed decades before the clinical symptoms of AD.

Fulminant intravascular malignant lymphomatosis manifesting as cerebral vasculitis: A case report
E. Papageorgiou, G. Matikas, V. Koukouni, G. Gekas, Neurology Department General Hospital of Nikaia, Athens, Greece

Background: Intravascular malignant lymphomatosis (IVL) is a rare and aggressive non-Hodgkin type lymphoproliferative disorder with a predilection for the CNS and skin.

Objectives: To describe a fulminant case of IVL with CNS involvement.

Patients and methods: A 46-year-old male was admitted to our department because of gait instability and right leg weakness. Previous hospitalization for a longstanding history of fever of unknown origin had failed to demonstrate any evidence of infectious, inflammatory or systemic disease and the patient had been discharged, remaining afebrile for the following two weeks. Neurological examination in our department revealed right cerebellar and pyramidal signs. Brain MRI demonstrated multiple bilateral T2 hyperintense lesions, suggesting CNS vasculitis. DSA was normal. CSF examination disclosed a slight lymphocytic pleocytosis with elevated protein and positive oligoclonal bands. The patient was put on intravenous methylprednisolone but his condition deteriorated rapidly and a repeated MRI demonstrated a new lesion. Due to respiratory failure he was transferred to intensive care unit. A new bone marrow biopsy showed clusters of abnormal large B-lymphoid cells in bone marrow sinusoids, consistent with IVL. Despite receiving the adequate treatment, the patient died a month later.

Results and conclusions: IVL must be considered in the differential diagnosis of cerebral vasculitis. The diversity of clinical manifestations and the absence of specific hematological and neuroradiologic findings contribute to a potentially lethal diagnostic delay. Although in cases with CNS involvement, brain biopsy remains the gold standard and repeated bone marrow biopsies can be elusive.

Anti-NMDAR encephalitis: Clinical and immunological characterization of a case series
L. Zuliani¹, M. Zoccarato², S. Sartori³, M.F. Pelizzab, I. Rosellinib, V. Argentierno³, P. Marson³, A. Suppiej⁴, B. Giometto².
¹U.O. di Neurologia, Ospedale di Treviso, Treviso, Italy; ²University of Padova, Padova, Italy; ³Division of Pediatrics, University of Padova, Padova, Italy; ⁴Immunotransfusion Section, University of Padova, Padova, Italy

Background: Anti-NMDAR encephalitis is an encephalitic multi-stage disorder that can be associated with ovarian teratoma. It is generally responsive to tumour removal and immunotherapy.

Objective: To report clinical and immunological data of a series of patients with autoimmune encephalitis and NMDAR-Ab.

Patients and methods: Between 2005 and 2012, 295 patients suspected for autoimmune encephalitis were screened for NMDAR-Ab on a cell-based assay. NMDAR-Ab positive patients' clinical data were collected.

Results: Sixteen patients were included in the study (9 females; age range: 9–77 years; mean follow-up: 23 months. CSF inflammation was found in 9 patients; brain MRI abnormalities in 7 cases. After encephalitis onset a tumour was found and removed in three patients (two teratomas and a germ cell testicular tumour). One patient had a teratoma removed 8 years before and in another a breast tumour was diagnosed. Fifteen patients received an immunomodulatory treatment and in 13 patients there was a confirmed improvement. Eight patients had prominent psychiatric sequelae.

Conclusion: This study confirms some known features of anti-NMDAR encephalitis: involvement of both sexes and all ages; low rate of neoplastic cases; and general response to immunotherapy. Psychiatric involvement was a striking clinical feature, at onset, but also with major consequences in terms of outcome. Atypical findings included a diagnosis of teratoma several years before encephalitis and breast tumour. The full spectrum of the syndrome and the role of tumour and other triggering factors need to be explored. Prompt recognition of the syndrome and antibody screening is fundamental to improve the outcome.

L2 hydroxyglutaric aciduria (L2HGA): Phenotypic variability in C241A–G mutation patients
E. Emna², A. Imen³, K. Fatma³, K. Naziba³, F. Faiza³, T. Chahnez³.
²Department of Neuropediatrics, CHU Hedi Chaker, Sfax, Tunisia; ³Biochemical Department, La Rabta, Tunis, Tunisia; ⁴Humain Molecular Genetic Department, FMS, Sfax, Tunisia

Introduction: L2HGA is a rare AR metabolic encephalopathy. We report clinical studies in 8 Tunisian families with 17 affected patients. Inter and intra familial phenotype variability is discussed.

Methods: We performed a retrospective study of L2HGA patients carrying the same homozygous mutation. Clinical, biological and radiological data were analyzed.

Results: The mean age of our patients was 15.82 years. Mean age at onset was 2.8 years. The disease onset was progressive except in two patients. Symptoms at onset were variable (psychomotor delay, gait difficulties...). Clinical examination showed mental retardation, cerebellar syndrome (16), pyramidal syndrome (15), extra pyramidal stiffness and chorea (2). Epilepsy was noted in 7 patients and febrile seizures in 9. MRI revealed demyelinating subcortical leukodystrophy with the basal ganglia and caudate nucleus involvement in all patients.
Discussion and conclusion: L2HGA is characterized by progressive mental and neurological deterioration. Marked intra and inter familial variability has been reported. Our study confirms this variability even in patients carrying the same gene mutation. There is a phenotypic variability from one family to another and even in the same family since some siblings had clinical symptoms (epilepsy, ophthalmoplegia, extra pyramidal stiffness...) not found in others. There is also a variability regarding age and mode of onset. It appears that the type of mutation does not play a complete role in different clinical phenotypes. Environmental factors, oxidative stress and disturbances of other unknown secondary metabolic pathways related to L2HGA may contribute to this variability in phenotype.

Anti-NMDA-receptor antibody encephalitis in a teenage boy
C.E. Sommeling, P. Santens. Neurology, Ghent University Hospital, Ghent, Belgium

Background: Anti-NMDA-receptor antibody encephalitis is a neuroautoimmune disease associated with the presence of antibodies targeting synaptic proteins. It most frequently occurs in young women, most common in the context of an ovarian teratoma. Clinical presentation includes variable combinations of psychiatric symptoms, autonomic dysfunction, alterations of consciousness and movement disorders. Treatment consists of tumor removal and immunosuppressive measures. Prognosis is usually favorable, but recurrence of encephalitis has been reported.

Objective: We describe an unusual presentation of anti-NMDA-receptor antibody encephalitis.

Material and methods: One 16-year old boy was followed during fourteen months.

Results: This teenage boy with Klinefelter, presented with impaired alertness. He was first hospitalized elsewhere after developing paresthesias and a nonfluent aphasia. There, a non-organic problem was suspected. During hospitalization with us, he developed orofacial dyskinesias, choreiform movements and autonomic instability. Radiography of the thorax showed a mature teratoma and gave us, together with the clinical findings, the clue to test for anti-NMDA-receptor antibodies. These were positive in CSF and blood. Treatment was performed by tumor resection, high-dose intravenous corticoids, plasma exchange and cyclophosphamide pulse therapy. After four months the patient was discharged in good condition. Recently, we restarted immunosuppressive therapy because of behavioral problems and hyperphagia in the context of persistent presence of antibodies.

Conclusion: A teenage boy with Klinefelter, who presented with impaired alertness, orofacial dyskinesias, choreiform movements and autonomic instability, was diagnosed to have anti-NMDA-receptor antibody encephalitis on a mature mediastinal teratoma. Teratomas occur more often in patients with Klinefelter. Follow-up until today is favorable.

C9orf72 expansion in atypical parkinsonism

Background: Systemic lupus erythematosus (SLE) has a much higher incidence in Asian and African populations than in Western populations. Up to 50% of patients suffer from neuropsychiatric symptoms of different pathogenesis.

Case presentation: We report a 13-year-old girl with a diagnosed SLE, predominantly rheumatic symptoms. She rapidly developed confusion, focal epileptic seizures with secondary generalization and left sided hemiparesis combined with high fever and tachycardia. Initial showed right hemispheric cortical DWI-positive lesions in the MCA territory. After 2/12 progressive MRI lesions to subcortical regions in both hemispheres with additional microbleeds appeared and neither arterial occlusion, typical vasculitic changes, nor meningeal enhancement was observed.

CSF was without significant pathology. Aggressive treatment with high dose corticosteroids and iv immunoglobuline G was started, followed by one cycle of iv cyclophosphamide and plasma exchange. The patient deteriorated with a septic syndrome, respiratory failure, increase of liver enzymes, severe thrombopenia and anemia, colitis and secondary infectious complications.

After stabilization of vital functions, again thrombopenia developed together with EEG abnormalities, since 2011 rituximab was given with no side effect. The patient recovered tremendously without any persistent motor dysfunction, was able to resume schooling and has no neuropsychological deficits except occasional headache and fatigue. CD20 lymphocytes are mentioned. The patient has been free of new somatic and neuropsychiatric SLE manifestation since two years.

Conclusion: Rituximab was well tolerated and long term effective in this case of juvenile SLE with life threatening cerebral lupus vasculopathy. Further studies have to establish the therapeutic significance of rituximab in severe neuropsychiatric lupus.

Systemic juvenile lupus erythematosus long lasting remission of severe neurological symptoms after treatment with rituximab
A. Mastri1, C. Moth1, E. Craemer1, I. Jafaar1, B. Kress1, U. Meyding-Lamade2.
1Bruneian Stroke and Rehabilitation Centre, Jerudong, Brunei; 2Neurology, Krankenhaus Nordwest, Frankfurt/Main, Germany

Background: Recently, an intronic expansion in C9orf72 was reported as a major cause of familial and sporadic FTD and ALS. These cases exhibit TDP-43 pathology. Screening in other neurodegenerative diseases has been performed and expansions detected in patients with FTD-ALS and parkinsonism, clinical-PSP and clinical olivopontocerebellar-atrophy.

Objective: To screen for the C9orf72 hexanucleotide repeat expansion in pathologically-confirmed atypical parkinsonism cases including MSA, PSP and CBD; and in clinical cases with a phenotype consistent with CBS.

Methods: To provide a qualitative assessment of the presence of an expanded (GGGCC)n in C9orf72, we performed a repeat-primed-PCR reaction. PCR products were analyzed on an ABI3730 and visualized using GeneMapper-software.

Results: Screening for the expansion was performed in 96 MSA, 177 PSP and 18 CBD samples and no expansion was detected. Screening in 102 CBS cases detected a massive expansion in 3 cases. The initial
presentation was an akinetic–rigid syndrome followed by cognitive decline. One case developed bulbar palsy in the late stage. Two cases had a family history of a similar disorder. Interestingly we also detected an expansion of 27 repeats in another case presenting with atypical parkinsonism. The significance of this short expansion remains unknown.

**Conclusions:** We conclude that the C9orf72 expansion can be detected in clinical cases presenting with parkinsonian syndromes that may have overlapping features with the FTDA–ALS spectra. We failed to detect an expansion in pathologically proven cases with MSA, PSP or CBD, and this confirms that C9orf72 is not related to alpha-synuclein or tau pathology.

**A rare case of bilateral and symmetric high intensity T2 signal of corticospinal tracts at brain MRI: Neurolyme**

bDepartment of Neurology and Stroke Center, Versailles Saint-Quentin en Yvelines University, Versailles Hospital, Versailles, France;

bDepartment of Radiology, Parly 2 Clinic, Le Chesnay, France;

bDepartment of Neurology, Fondazione IRCCS Istituto Neurologico ‘Carlo Besta’, Italy; 4Università Vita-Salute San Raffaele, Milan, Italy

Neurolyme is defined as the neurological involvement secondary to systemic infection by the spirochete Borrelia. Acute meningoradiculitis is the most common presentation of neurolyme whereas meningoencephalitis is less frequent. We report a case of borrelosis meningoencephalitis with corticospinal tract involvement. A 60-year-old man developed a progressive gait disturbance for 6 months and weight loss of 15 kg for 1 year. The neurological examination disclosed an ataxosposmodic walk with a positive Romberg sign, a reflex tetrapyramidal syndrome with a paraparesis. Cerebral MRI showed bilateral corticospinal tract FLAIR hypointensities (internal capsules, mesencephalon, pons and cerebellar peduncles) without contrast enhancement. Medullar MRI was normal. Lyme serology was positive. The lumbar puncture revealed a lymphocytic pleocytosis (11 elements, protein 1.48 g/l, normal glycorachia and intrathecal anti borrelia antibody synthesis. The electroneuromyogram showed a sensormotor axonal polyneuropathy. Paraneoplastic, immunologic, metabolic and others infectious causes were excluded. Later, he mentioned a tick bite 1 year ago, without erythema, in an endemic zone. He was treated with IV ceftriaxone 2 g/day for 4 weeks with clinical improvement. Cerebral MRI at 3 months was clearly improved but remains abnormal. Bilateral and symmetric hyperintensity signal on T2-weighted images of corticospinal tracts has been reported mainly in amyotrophic lateral sclerosis and more rarely in metabolic diseases such as Krabbe disease, X-linked adrenoleukodystrophy or infectious diseases such as HTLV1. To our knowledge this MRI pattern has not been previously reported in neurolyme.

**The impact of recurrence: Brain tumor patients’ quality of life**

C.Y. Finocchiaroa,b, A. Petruzzia, E. Lamperti4, L. Rainoldia, G. Simonetti2, A. Silvani2. 1Clinical Neurooncology Unit, Fondazione IRCCS Istituto Neurologico ‘Carlo Besta’, Italy; 4Università Vita-Salute San Raffaele, Milan, Italy

**Background:** Few studies have investigated the differences of psychological outcomes between patients with brain tumor recurrence and those without recurrence.

**Objective:** The objective of this study was to determine whether the quality of life of patients with brain tumor recurrence differs from quality of life of those without recurrence.

**Patients and methods:** The study enrolled 52 patients with brain tumor recurrence and 63 without it. Mini mental state examination score ≥25 was patients’ inclusion criteria for the study. We used the following tools to assess psychological effects of patients’ specific condition: functional assessment of cancer therapy-brain (FACT-Br), psychological distress inventory (PDI) and hospital anxiety and depression scale (HADS).

**Results:** Our study found that patients with brain tumor recurrence showed a more compromised social/familiar [t(88.15) = 2.53, p < .05] and emotional well-being [t(106) = 2.15, p < .05] as compared with patients without recurrence. In addition, patients with brain tumor recurrence experienced more stress than those without it. Also levels of anxiety and depression were higher in patients affected by brain tumor recurrence. Moreover patients with brain tumor recurrence reported a worse functional status.

**Conclusion:** Our results highlight that while the patients without recurrence of brain tumor showed a significant psycho-physical wellbeing, the patients with recurrent brain tumor lived an impairment of their overall quality of life, both in physical and psychological wellbeing. The results underline the necessity to support patients with recurrent brain tumor, in order to help them to improve their level of self-acceptance and their adjustment to tumor-related problems.

Mild cognitive disorders with background psycho-vegetative syndrome. Some of the metabolic aspects
L. Knyazeva, V. Shmyrev, L. Sokolova, a,b. aFederal State Budgetary Institution ‘Teaching-Research Medical Center’ President of Russian Federation Administration, Moscow, Russia; bFederal State Budgetary Institution ‘Clinical Hospital #1’ President of Russian Federation Administration, Moscow, Russia

Background: Often the mild cognitive disorders develop in background of psycho-vegetative syndrome (PVS) not infrequently in frames of anxiety or anxiety depressive disorders. Cognitive disorders coexist with anxiety and depressive conditions, and later they can aggravate resulting in professional and social disadaptation. These studies of cerebral metabolism in mild cognitive disorders with background PVS will allow to make patient’s complaints objective, and to improve the treatment and prevention of cognitive disorders.

Objective: To investigate cerebral metabolism in patients with PVS to improve the treatment and prevention of cognitive disorders.

Material and methods: To study cerebral metabolism, 29 patients with age under 55 with mild cognitive disorders and 20 healthy volunteers without signs of cognitive disorders as a control were examined. Cerebral metabolism was estimated with the help of neuroenergy mapping (NEM) — the detection of level of constant potentials (LCP), slowly varying potential of millivolt range reflecting membrane potentials of neurons, glia and hematocerephalic barrier.

Results: Normal results of LCP were obtained in 17.2%. Increased metabolism was observed in 58.6%. Decreased metabolism was seen in 24%. Background metabolism in patients with PVS significantly differed from the reference values. In control group of healthy volunteers the background metabolism didn’t differ from the reference values.

Conclusions: Assuming all the data on increased metabolic processes in 58.6% of the examined subjects that indicate to the activation of backup pathways, it is reasonable to recommend sedation in combination with antioxidants and non-stimulating neurometabolic drugs to the patients with mild cognitive disorders with background PVS.

Bickerstaff brainstem encephalitis — A case report

Background: Bickerstaff brainstem encephalitis (BBE) is a rare, postinfectious, immuno-mediated disorder clinically presenting with acute ophthalmoplegia, gait ataxia and occasionally decreased level of consciousness. Clinical signs result from the inflammatory lesion in the region adjacent to the IVth ventricle and the mesencephalic reticular formation.

Objective: We present a characteristic case of BBE.

Patients, methods and results: A week after a nonspecific enteritis the 58 year-old male patient noticed paraesthesia on his face and arms. A day later, vertigo developed and his gait got unstable. On the next day he became drowsy, and we found mild abducent palsy, gaze-evoked horizontal nystagmus, severe dysarthria, tetraataxia, and Babinski sign on his right side, serious gait ataxia and forced crying. In his T2 weighted MR images the region around the IVth ventricle and the left middle cerebral peduncle showed increased signal with blurred edge, spectroscopy was characteristic for inflammation. CSF analysis proved elevated protein level with normal cell count. Anti-ganglioside (GQ1b) antibody tests were negative. Five-day high dose methylprednisolon therapy was followed by slow improvement. A week later the patient was able to walk without help. His ophthalmoplegia and dysarthria ceased but forced crying persisted. Repeated CSF proved to be normal; his MRI abnormalities did not change. Two months later the patient was symptom free.

Conclusion: Majority of post infectious central nervous system disorders are acute disseminated encephalomyelitides. If brainstem signs are dominated, BBE has to be taken into account. The differential diagnosis is based on cranial MRI.

Isolation and culture of hair follicle stem cells (HFSCs) and their use for regeneration of the sciatic nerve in rat
L.B. Hejazian, M.B. Hejazian, F. Moradi, B. Esmaeilzadeh, F. Moghani Ghoroghi, M. Bakhtiani, A. Aslani, K. Mansouri, M. Nobakht. Anatomy, School of Medicine, Babol University of Medical Science, Babol, Iran; Physical Education and Sports Sciences, Dept. of
Background: Hair follicle stem cells (HFSCs) can differentiate into neurons, astrocytes, Schwanns and oligodendrocytes. The aim of this study was to evaluate the effects of transplantation of HFSCs on functional recovery after injury to the sciatic nerve in the rat.

Objective: The evaluation of the effects of transplantation of hair follicle stem cells on regeneration of the sciatic nerve in rat.

Materials and methods: The middle of the sciatic nerve of Wistar rat was cut (N = 40). Three groups were studied afterward. First, control group in which the nerve cut remained intact. Second, the epineurium at the cuts was sutured together. Third, the end cut was sutured and 500,000 hair follicular stem cells (HFSCs) injected in the site of nerve cut. For this purpose the bulge region of rat was isolated and the cells were cultured. After eight weeks, electrophysiological and histological assessments were performed.

Results: The results of amplitude (12/26 mV), latency (1/6 ms) of electrophysiology study showed better results in the third group (P < 0.05). The results of histology showed that the number of axons was significantly higher in the HFSC group (806/67 n) than the other experimental groups (P < 0.05). Also, the myelin sheath was thicker in third group than others (1/46 μm).

Conclusion: We showed that the transplantation of HFSCs had potential capability of regeneration of sciatic nerve injury in Wistar rat.

Posterior reversible encephalopathy syndrome associated with tacrolimus and renal failure after liver transplantation
E.D. Ciftci, S. Kibaroglu, U.S. Benli. Neurology, Baskent University, Faculty of Medicine, Ankara, Turkey

Posterior reversible encephalopathy syndrome (PRES) is a small vessel microangiopathy of the cerebral vasculature that occurs in 0.5–5% of solid organ transplant recipients, most commonly associated with tacrolimus. Clinical manifestations include hypertension and neurologic symptoms like headache, visual disturbances, focal deficits, mental status changes, and seizures. We report an adult liver transplant recipient who developed PRES associated with tacrolimus and acute renal failure. A 53-year-old woman with familial Mediterranean fever underwent liver transplantation due to cryptogenic cirrhosis. Two months after liver transplantation, she presented with nausea, vomiting, dizziness and poor oral intake and was hospitalized due to renal dysfunction, hyponatremia and pancytopenia. At the fifth day of admission, she had an acute mental deterioration with a tonic–clonic seizure, but neurologic examination and brain CT scan was unremarkable, and tacrolimus level was normal. Her hospitalization was further complicated with vancomycin resistant enterococci septicemia and renal failure requiring hemodialysis. In the meanwhile tacrolimus levels remained normal, except for three days. At one month of hospitalization, five days after the first hemodialysis, her mental status suddenly worsened and a second generalized seizure occurred. Bilateral parietooccipital hypodensities and brain edema seen on control brain CT were suggestive of PRES. Brain MRI showed T2 and FLAIR hyperintensities in the parietooccipital, frontal regions, basal ganglia and brain stem which were also compatible with PRES. She did not show any clinical improvement, despite cessation of Tacrolimus and intensive renal replacement therapy. In this case, although PRES was primarily associated with tacrolimus neurotoxicity, renal failure could not be ruled out in the etiology. PRES is a rare but potentially serious complication of solid organ transplants.

The “dormant potential” of the non-dominant hemisphere: Interemispheric asymmetry of cortical plasticity
A. Scalise, V. Russo, A. Fontana, I. Pittaro-Cadore, S. Simeoni, G.L. Gigli. Neurology, University of Udine Medical School, Udine, Italy
Background: Transcranial magnetic stimulation (TMS) studies have documented handedness related functional asymmetries in corticomotor excitability.

Objective: To use TMS in comparing changes in cortical excitability of dominant (DH) and non dominant hemisphere (NDH) in both right-handed and left-handed subjects in function of a bimanual non-fatiguing motor task.

Material and methods: Thirty enrolled subjects were classified as right or left handed according to their description of the hand used for writing and completed the Edinburgh Handedness Inventory. For each subject, cortical excitability was separately assessed in each hemisphere. By means of TMS, MEP amplitude, motor threshold, and silent period were assessed. Then subjects performed regular repetitive bilateral opening-closing movements of the index finger onto the thumb. MEPs of the first dorsal interosseus were recorded before exercise, immediately after exercise periods of 30, 60, 90 s and after 15 min of rest. We evaluated if post-exercise facilitation and delayed facilitation were present. Hemispheric differences of MEP amplitudes registered after rest were related to handedness score.

Results: Mean threshold was lower for DH compared to NDH. MEP amplitude was increased in exercise condition, independently of the hemisphere stimulated. In rest condition, only NDH presented increased MEP amplitude, showing delayed-facilitation. Handedness scores and MEP asymmetry in rest condition were positively correlated.

Conclusions: DH and NDH answer differently to motor requests and scores and MEP asymmetry in rest condition were positively correlated.

A comparative-study on selective attention and executive function between patients with/without bipolar disorder based on Stroop test

A. Kazemi, I. Sadri. Psychology, Islamic Azad University Tehran Medical Branch, Tehran, Iran

Background: Investigations indicate that patients with bipolar disorder are often accompanied by changes in cognitive processes and abilities. These include reduced attentions and executive capabilities.

Objective: The objective of present study is a comparison on selective attention and executive function between patients with/without bipolar disorder based on Stroop test.

Materials and methods: In this study, comparative and analytical methods are used. The statistical sample was 34 males with bipolar disorder selected by available sampling method in psychiatry hospital and 34 men without disorder selected by random sampling method in Tehran city. The measuring tool is Stroop test. The results were analyzed using T-test method.

Results: The obtained results showed a significant difference between two groups in selective attention, executive function and their dependent variables including the experiment time, reaction time, and numbers of errors, unanswered questions and correct answers in response to consistent and inconsistent stimuli (P < 0.05).

Conclusion: It was found that patients with bipolar disorder in selective attention, executive function and their dependent variables in response to consistent and inconsistent stimuli have inappropriate conditions compared to the normal individuals.

Listeria rhomboencephalitis in an immunocompetent young adult complicated by cerebral venous thrombosis

E. Farhat, M. Zouari, A. Ben Mahmoud, F. Tentati. Neurology, National Institute Mongi Ben Hamida of Neurology of Tunis, Tunis, Tunisia

Background: Listeria monocytogenes rhomboencephalitis (LMR) is a rare complication with high level of mortality and sequelae.

Objective: We present a case of seronegative LMR in a healthy person. Diagnosis was based on clinical, imaging findings and improvement after specific antibiotic therapy.

Case report: A 19-year-old woman was admitted with diplopia, inability of mastication and swallowing, preceded by fever, headache and nausea. The neurological examination showed isolated asymmetrical palsies of almost all cranial nerves. Brain magnetic resonance image (MRI) found exclusive brainstem lesions. Cerebrospinal fluid (CSF) examination revealed lymphocytic pleocytosis, hyperproteinorrhachia without hypoglycorrhachia. Blood cultures and Gram staining of the CSF were negative. Treatment with acyclovir was introduced with worsening and hypoventilation requiring mechanical ventilation. LMR was suspected and empirical therapy with ampicillin and gentamycin was started. On follow-up MRI, an extensive CVT was noted and treated by heparin. Her neurological condition improved gradually. Gastrostomy was carried out.

Discussion: In contrast to other listerial CNS infections, the majority of LMR cases occur in previously healthy adults. Isolated brainstem localization is rare but very suggestive of the diagnosis. Pons and medulla's cranial nerves are the most commonly affected, our patient has an involvement of almost all cranial nerves. Sepsis and meningeal signs are often absent. Gram stains of CSF resulted positive in only 14%, and CSF cultures are positive in 45% of cases. Two mechanisms are discussed: hematogenous spread or migration along axons of LMR.

Conclusion: To our knowledge, this is the first case of CVT due to LMR in immunocompetent adult.

Acute myelopathies following epidural and spinal anesthesia

A. Honig, A. Lossos, M. Gumori, Z. Meiner. aNeurology, Hadassah Medical Center, Jerusalem, Israel; bRadiology, Hadassah Medical Center, Jerusalem, Israel; cRehabilitation, Hadassah Medical Center, Jerusalem, Israel

Background: Spinal and epidural anesthesias (E-SA) are widely used and are generally regarded as safe with a very low frequency of permanent neurological sequelae.

Objective: To asses cases of Myelopathy following E-SA.

Methods: In order to describe the different clinical and imaging features of E-SA induced myelopathy, we have retrospectively reviewed cases of patients hospitalized and diagnosed in our institute during 2004–2012.

Results: Ten patients developed progressive spinal motor, sensory and autonomic dysfunction within 3–24 h following E-SA. The different entailed mechanisms had different clinical phenomena. Three 25–30 years-old women manifested with acute myeloradiculitis related to peripartum epidural spinal anesthesia causing toxic damage to the spinal cord. Six 32–71 year-old patients had a direct traumatic damage to the spinal cord. Their manifestations ranged from a Conus Medullaris injury that resulted in Brown-Sequard like spinal cord injury and detrusor instability (5 patients) to direct cervical spinal cord injury...
causing Tetraparesis (1 patient). Empirical steroid treatment was beneficial in the disappearance of the local edematous effect and hence in rapid clinical improvement. MRI in these nine patients revealed corresponding T2-hyperintense spinal cord lesions. In one 74-year-old patient, the spinal anesthesia contributed to local hypoperfusion and spinal ischemia. 

Discussion: Although rare, myelopathy caused by E-SA occurs usually in a perisurgical clinical setup or following a procedure of regional pain control. Main clinical characteristics include a acute spinal deficit and corresponding specific imaging findings. Spinal MRI in this clinical study appeared highly specific and diagnostic of inadvertent spinal cord injury and toxic or ischemic effect.

Is cortical excitability affected by sleep fragmentation?
A. Scalise, I. Pittaro-Cadore, A. Serafini, L. Fratticci, G.L. Gigli. Neurology, University of Udine Medical School, Udine, Italy

Background: Sleep deprivation (SD) influences cortical excitability. Alterations in movement-related cortical plasticity are present in Restless legs Syndrome (RLS), characterized by sleep fragmentation (SF).

Objective: We evaluated the effect of SF on cortical excitability using transcranial magnetic stimulation.

Material and methods: After a night of spontaneous sleep (basal condition—BC) and after a night of fragmented sleep (fragmented condition—FC), MEP amplitude, motor threshold (MT), silent period (SP) and intracortical inhibition were assessed in healthy subjects. In both conditions, MEPs of the first dorsal interosseus were recorded before exercise, immediately after the exercise periods of 30, 60, 90 s and after 15 min of rest. We evaluated if post-exercise facilitation and delayed facilitation were present. Before each session, Stanford Sleepiness Scale (SSS) was completed.

Results: MT and SSS were increased in SF. No significant differences for MEP amplitude or SP or intracortical inhibition were found. In both conditions MEP amplitude was larger than baseline after 30 and 60 s of exercise (post-exercise facilitation) and also after rest (delayed facilitation). Comparing the two conditions at each time point we found no significant differences in MEP amplitude.

Conclusions: We suggest that SD and SF represent different phenomena that can depend on various networks acting on motor cortex. SF seems to impair the restorative cognitive benefits of sleep via alterations in hippocampal synaptic plasticity, involving mechanisms different from altered SD. We speculate that the contradiction between our SF data and our previous results in RLS may not be associated to SF, but related specifically to RLS pathophysiology.

Psychological burden of brain tumor patients and their caregivers

Background: Brain tumors not only impact patients’ quality of life, but also reduce seriously the caregivers’ quality of life.

Objective: We aim to describe brain tumor patients and their caregivers’ quality of life during the illness and assess the existing relation between clinical and psychological features of patients and their caregivers.

Patients and methods: The study involved 72 patient/caregiver couples. Mini Mental State Examination score ≥25 was patients’ inclusion criteria for the study. To evaluate various psychological features, we used the following tools: Hospital Anxiety and Depression Scale (HADS), Functional Assessment of Cancer Therapy-Brain (FACT-Br) for patients and HADS, Caregiver Reaction Assessment Scale (CRA), 36-Item Short-Form Health Survey (SF-36) for caregivers.

Results: Quality of life was more compromised in caregivers than in patients. The impairment of caregivers’ quality of life appeared mainly in a significant reduction in their mental health. Most caregivers experienced more anxiety [t(142) = 6.11, p < .001] and depressive symptoms [t(142) = 2.87, p < .01], as compared with patients. Clinical and psychological features of patients did not correlate with psychological patterns of their own caregivers.

Conclusion: Although an anxiety and depression condition is somewhat expected both in brain tumor patients and in their caregivers, high levels of anxiety and depression in caregivers must become an important end-point in clinical trials in that such levels
compromise their quality of life and worsen their ability to provide care. It is important for physicians paying attention not only to the patient’s pathology, but also to potential caregiver’s physical and psychological disorders.

Neuro-Behcet’s disease: Report of 51 patients
A. Bourazzâ, E.J. Abdelhafid, J. Oumerzouk, Y. Hsaini. aNeurology of Military Hospital Mohamed V, Morocco; bMohammed V Souissi, Rabat, Morocco

Background: Behcet’s disease (BD) is a chronic, relapsing, systemic disorder of unknown etiology. Neurologic involvement in BD is one of the most devastating manifestations of the disease.

Objective: This study was conducted to describe the clinical and prognostic aspects of neurologic involvement in BD among patients attending a department of neurology in a military hospital in Rabat (Morocco).

Material and methods: Fifty one patients had evidence of and fulfilled the diagnostic criteria of neurobehcet’s disease (NBD). These patients underwent laboratory and imaging investigations, including lumbar puncture and computed tomography scanning or MRI.

Results: The study included 33 men and 18 women aged from 17 to 54 years. The analyses of the result found the typical parenchymal NBD in 69% characterized by lesion of brainstem and atypical parenchymal NBD in 31% dominated by venous occlusion. All patients received high dose steroids, and 59% were treated with a combination of steroids and cytotoxic agents. The follow-up was good in the atypical parenchymal NBD.

Conclusions: Our study shows that the atypical parenchymal NBD had good prognosis than parenchymal NBD, and aggressive intervention with corticosteroids and cytotoxic agents may be early in order to diminish and stabilize the negative effect of neurologic involvement.

Dual effect of H89, a potent protein kinase a inhibitor, on H2O2-induced apoptosis and Nrf2 stabilization
H. Digaleh, F. Khodagholi. Neuroscience Research Center, Shahid Beheshti University of Medical Sciences, Tehran, Iran

Background: We investigated the effect of H89 as a selective and potent inhibitor of protein kinase A (PKA) on PC12 neuronal cells. It has been reported that high levels of neural PKA produce more synapses; however its possible involvement in apoptotic cell death has been shown. Nuclear factor erythroid-2 related factor 2 (Nrf2) as a cytoprotective factor, enhances the antioxidant capacity in the cells and protects them against cell death.

Objective: Effect of H89, a PKA inhibitor, on H2O2-induced apoptosis and Nrf2 stabilization.

Material and methods: Morphological analysis of apoptosis was determined by AO/EB and Hoechst staining. PC12 cells were differentiated and treated with different concentrations of H89 (5, 7 and 10 μM) and H2O2. Nrf2 level increased and caspase3 level was significantly modulated, in contrast to H2O2-exposed group. However, high concentrations of H89 (15 and 20 μM) upregulated caspase3, by about 2 and 4 folds, and inhibited Nrf2 stabilization. Consistently, H89 treatment in 15 and 20 μM concentrations, solely, upregulated pro-apoptotic factor, caspase3, and Nrf2 level decreased, in contrast to control cells. Hoechst and AO/EB staining confirmed the data obtained from western blot analysis.

Conclusion: H89, a PKA inhibitor, has dual effects in apoptosis and survival depending on its concentration.

Correlation between errors committed by patients with bipolar disorder in Bender-Gestalt test and their pessimism and guilty conscience
A. Kazemi, P. Anjedani Moghadam Araghi. aIslamic Azad University Tehran Medical Branch, Tehran, Iran; bPsychology, Islamic Azad University Tehran Medical Branch, Tehran, Iran

Background: Bender-Gestalt test is one of the most widely used neuropsychological tests, and also an important tool for evaluation of motor and visual coordination. Bender test expanded this concept on how the performance of a person may be affected by the perceptual and motor maturation as well as organic or functional impairments. Investigations using this test have also been used in patients with bipolar disorder.

Objective: The objective of this research is to study of the correlation between errors committed by patients with bipolar disorder in Bender-Gestalt test and their pessimism and guilty conscience in PANSS test.

Materials and methods: In this study the correlation method was used. The statistical sample included 35 males with bipolar disorder selected by available sampling method in a psychiatry hospital in Tehran city. The measuring tools were positive and negative symptom scale (PANSS) and Bender-Gestalt test. The results were analyzed using Spearman’s correlation test.

Results: According to the obtained results a meaningful correlation among pessimistic and guilty conscience scores, and the twelve committed errors in Bender-Gestalt test in patients with bipolar disorder was not observed.

Conclusion: The results of this study showed that the pattern of errors committed by bipolar patients in Bender-Gestalt test did not show any significant relationship. Based on this finding, diagnostic evaluation, therapeutic interventions and rehabilitation for these patients should be improved.

Alginato oligosaccaride upregulates Ampk and induces mitochondrial biogenesis in H2O2-exposed Pc12 cells
F. Khodagholi, S. Khorangian Tusi, F. Foolad. Neuroscience Research Center, Shahid Beheshti University of Medical Sciences, Tehran, Iran

Background: Many studies show mitochondrial dysfunction in aging and some diseases such as Alzheimer’s disease (AD). Mitochondrial biogenesis is a special defensive mechanism that many factors involved in it include:
1) AMPK and CREB as stimulator of PGC-1α;
2) NRF1 that is stimulated by PGC-1α; and
3) Tfam expression and initiation of mitochondrial DNA replication.

Objective: Effect of alginato oligosaccaride on mitochondrial biogenesis.

Materials and methods: PC12 cells were pretreated by AOS for 12 h, then exposed to compound C (10 μM), AMPK inhibitor, for 12 h. Then, cells treated by H2O2 (150 μM) for different times. In addition, we compared the effects of enzymatically depolymerized unsaturated AOS with heat-degraded saturated AOS. The level of mentioned factors was determined by Western blotting and the mitochondrial number was measured by Mito Tracker Red fluorescent staining.

Result: After H2O2 treatment, AMPK, PGC-1α, NRF1, Tfam and Cytochrome c increased and reached the highest level at 8 h after exposure, and then continually started to decrease. Also, phospho-CREB/CREB ratio increased but the highest level was at 12 h. Pretreatment with AOS caused a significant increase in the level of AMPK, PGC-1α, NRF1, Tfam, Cytochrome c and phosphor-CREB/CREB ratio in H2O2-induced cells and stayed higher than H2O2-treated cell till 24 h. In the group with compound C, we found a weaker effect of AOS on the induction of mitochondrial biogenesis. The results showed that heat-degraded saturated AOS has more effect on this pathway compared to enzymatically depolymerized unsaturated AOS.

Conclusions: Mitochondrial biogenesis is involved in AOS-mediated protection.

Duane syndrome: A case report
H. Akgun1, M. Yucelb, S. Alayc, O. Ozd, F.C. Gundogana, Z. Odabasib, S. Demirkaya1. 1Department of Neurology, Etimesgut Military Hospital, Ankara, Turkey; 2Department of Neurology, Kasimpasa Military Hospital, Istanbul, Turkey; 3Department of Neurology, Gulhane Military Medical Academy, Ankara, Turkey

Background: Duane syndrome is a rare facial nerve anomaly characterized by restriction of adduction of the eye. The exact pathogenesis of this syndrome is not well understood. The outcomes of the surgery depend on the type of the syndrome and the age at which the surgery is performed.

Material and methods: The subject is a 20-year-old woman who was diagnosed with right Duane syndrome at the age of 3 years. She was referred to our clinic for the evaluation of a new episode of right ocular deviation at the age of 5 years. Her medical history was unremarkable. She was taking no medications at the time of examination. At 20 years of age, she had right Duane syndrome and complete right superior oblique palsy. In addition, she had left Duane syndrome. She had a left and right left inferior oblique palsy. She had a left and right superior rectus palsy.

Results: The patient did not improve with the conservative treatment. She underwent an orbital decompression surgery for the right eye and a superior rectus recession surgery for the left eye. The patient had a complete recovery of her right eye at the 1-month follow-up.

Conclusions: Duane syndrome is a rare facial nerve anomaly characterized by restriction of adduction of the eye. The exact pathogenesis of this syndrome is not well understood. The outcomes of the surgery depend on the type of the syndrome and the age at which the surgery is performed.

Background: Duane's syndrome is characterized with a defect in the nucleus of the sixth cranial nerve and/or a developmental defect of the sixth cranial nerve axon. It was first described in 1879 by Heuck in a patient with a serious eye movement restriction and globe retraction. Alexander Duane reported a series of 54 cases in 1905 and the syndrome was named after him. Heterochromia can be seen in Duane’s syndrome.

Objective: In this report we would like to present a rare case of Duane syndrome with heterochromia.

Patients and methods: A 38-year-old male patient presented to our outpatient clinic with complaints of double vision which he had since childhood. He stated that his complaints increased especially when looking to the left. The color of his eyes had been different since birth. His right eye was green, and his left eye brown. On the neurological exam left sided sixth cranial nerve palsy was present. Other neurological findings were normal.

Results: On his brain MRI and brainstem thin slice MRI, the intracystern part of the sixth cranial nerve was visualized on the right but not on the left side.

Conclusion: Because of its rare nature and the absent left sixth cranial nerve on the brain MRI we found this case worth reporting.

Avicenna's description of Willis circle
A. Zaraganiab, C. Karimic, S.A. Ahmadi, A. Borhani-Haghighid

Background and objective: Willis circle is an interconnection between anterior and posterior, and right and left cerebral circulations. It supplies brain and neighboring structures. Although this circle was noticed briefly and incompletely by ancient doctors, it is described completely by Thomas Willis in the book of Cerebri Anatome in 1664. In this study, the description of Avicenna, who was one of the most important scientists of the medieval period, about Willis circle is investigated. It can be important to shed light on a part of history of neurology.

Method: Arabic and Persian versions of Canon on Medicine, Avicenna's medical encyclopedia were studied and his point of view about Willis circle was compared with current and also ancient terms.

Results: Avicenna (980–1037) was one of the great scholars in medieval time. He wrote about this circle in the third volume of the Canon, in the section about head diseases. According to Avicenna's description, Willis circle was well known. Persian scholars can dissect in the ancient and medieval era. With regard to this, they had good information about human bodies and progress the previous Greco–Roman knowledge.

Conclusion: There is a gap between the knowledge of the medieval Persians and current era. It was acquired in the Renaissance, when western scholars refused the medieval knowledge, created the new paradigm of medicine and became the leadership of science. It seems that many of the eastern medieval findings were forgotten in this transmission. Therefore many well known subjects in the medieval era were rediscovered by western scientists after 16th century AD.

Rhinocerebral mucormycosis: Clinical features and prognosis, two case reports and review of the literature
A. Riahi, I. Bedoui, N. Touati, O. Ben Ouaday, M. Mansour, J. Zaouali, R. Mrissa. Department of Neurology, Military Hospital, Tunis, Tunisia

Background: Rhinocerebral mucormycosis is a rare opportunistic fungal infection of the upper airways. Cerebral involvement is exceptional and life threatening.

Objective: We report two cases of rhinocerebral mucormycosis and we discuss their clinical features and prognosis.

Case report: Patient A, a 60 year old diabetic woman presented with fever, acute multiple right cranial nerve palsy (Garsin’s syndrome), Few days later, a stroke with left side paralysis occurred. Cerebral-MRI showed right middle cerebral artery stroke with occlusion of the right carotid and a thickening of cavum mucosa. CSF analysis showed lymphocyte-type meningitis. Viral, bacterial and fungal serologies and cultures were negative. Cavum biopsy confirmed the diagnosis of mucormycosis.

Patient B, a 69 year old man with history of mucosa-associated lymphoid tissue pulmonary lymphoma, has presented a left frontotemporal and retro-orbital headache with exophthalmia for one year. Cerebral-MRI showed liquid filling ethmoidal cells with a thickening of the left maxillary sinus mucosa. Facial CT-scan showed a left retro-orbital tissular process with bone lysis. Biopsy confirmed the diagnosis of orbital mucormycosis.

Discussion: Rhinocerebral mucormycosis is a life threatening infection and outcome is highly dependent on early diagnosis and treatment. Diagnosis is based on the biopsy. Both patients were treated by Amphotericin B, Fluconazole IV for 4 weeks. The outcome was good with clinical, biological and radiological improvement for patient B, while patient A had died of a massive pulmonary embolism.

Conclusion: Our observations highlight the various clinical features of rhinocerebral mucormycosis. Some features like cranial nerve palsies and strokes should be considered of severe prognosis.

An unusual case of subacute sclerosing panencephalitis (SSPE) with cognitive decline and simultanagnosia
Z. Ozdemir, A. Soysal, G. Gul, N. Behrem Gayir, B. Ciftci Kavaklioglu. Bakirkoy Prof. Dr. Mazhar Osman Mental Health and Neurological Diseases Training and Research Hospital, Istanbul, Turkey

Objective: To introduce a case of subacute sclerosing panencephalitis (SSPE) presenting with cognitive decline, hemiparesis, simultanagnosia, and diagnostic MRI findings.

Case report: A 21-year-old male patient was admitted to our hospital with hemiparesis, hesitant speech and progressive cognitive decline in the absence of myoclonus. His sister defined that the patient had an epileptic seizure one month ago and then developed disorientation. Neurological examination revealed prolongation of reaction time, disorientation of time and person, slight hemiparesis on the right side, hyperactive deep tendon reflexes and simultanagnosia. T2-weighted and FLAIR MR images showed extensive gray matter changes involving both temporal an parieto-occipital regions that are more prominent on the left side. EEG revealed recurrent periodic sharp and slow paroxysms. Extensive serum and BOS analysis for metabolic and infectious diseases revealed negative results. A diagnosis of SSPE was confirmed by elevated serum and BOS measles IgG titers.

**Conclusion:** SSPE is a slowly progressive degenerative disease of the central nervous system caused by a latent defective measles virus infection. Hallmarks of this entity include progressive cognitive decline, myoclonia, a generalized periodic pattern on EEG, and deep white matter abnormalities on MRI. In our case, although patient and relatives did not define any myoclonic jerks, we suggested a diagnosis of SSPE according to especially cognitive decline and MRI results. EEG and CSF examinations confirmed this disease.

**Carcinomatous meningitis from cervix uteri carcinoma**  
B. Zilami\(^1\), E. Basha\(^2\), B. Cekrezia\(^3\), E. Hutic\(^4\), E. Roci\(^5\).  
\(^1\)Neurology, American Hospital, Tirana, Albania; \(^2\)Neurology, Central Military Hospital, Tirana, Albania; \(^3\)Oncology, American Hospital, Tirana, Albania  
A right handed female patient, 52 years old, was presented at emergency with a headache with nausea, vomiting and seizures; the symptoms started two weeks ago with nausea and vomiting. At another diagnostic center CT was performed on the head that was normal; after she was released from hospital she had an episode generalized seizure. The patient was diagnosed seven years ago with cancer of uterine cervix T1b. She had surgery, and then she was treated with chemotherapy. Six months before PET scan was performed where bone metastasis, mediastinal and peritoneal metastasis were seen, she has eight cycles of chemotherapy. After chemotherapy PET scan was performed, and full metabolic regression of the lesion was found. The neurological symptoms started two weeks after the last cycle of chemotherapy. The patient is somnolent and has dyssarhythmia and monotonous speech, left monoparesis, bilateral Babinski, and meningeal signs. MRI of the head and the spine with gadolinium revealed multiple vertebral metastases; lumbar puncture was performed on multiple areas of contrast enhancements of meningeal tissue in the brain and at the thoracic region. CSF histopathology examination revealed squamous cell poorly differentiated carcinoma. After oncologic consultation, it was recommended that the patient should have intrathecal methotrexate treatment but that was refused by her family members. Carcinomatous meningitis from uterine cervix-related malignancies is a rare complication; its incidence has increased probably survival time from the primary disease is extended. This rare complication occurs in the advanced stage of cervical cancer. MRI of the head is a useful tool for the diagnosis but the lumbar punctures for neoplastic cells are the gold standard, and the prognosis remains poor.

**Concomitant radio-chemotherapy with CCNU after radical removal of newly diagnosed glioblastoma: Preliminary results of a single center retrospective study**  
**Background:** When given concurrently with radiotherapy, Temozolomide has led to improved survival in GBM patients raising the possibility of its radiation potentiation.  
**Objective:** This study was conducted to determine the relative contribution of concomitant CCNU in patients with newly-diagnosed GBM.  
**Patients and methods:** We identified all patients operated on for a supratentorial GBM and further treated with radiotherapy and CCNU-based chemotherapy either in a concomitant and adjuvant (group 1) or adjuvant only (group 2) setting. The primary endpoints of this study were progression-free survival (PFS), overall survival (OS) and the secondary endpoint was the toxicity.  
**Results:** Forty-two patients (group 1, n = 20; group 2, n = 22) were included in this study. The two arms were well balanced according to their baseline characteristics (including age, KPS). The median follow-up was 15.7 months (95% CI, 12 to inf months). A borderline statistical difference (p = 0.07) was observed according to the PFS between two groups (12 vs 8 months). The median survival OS was 19 months (95% CI 14.1 and 24.7 months) with RT plus CCNU and 11.6 months (95% CI 11.2 and 17.2 months) with adjuvant group, p = 0.09 by the log-rank test. Hematological toxicity was absent during concomitant chemoradiation and mild (9%) in adjuvant therapy.  
**Conclusions:** Concurrent and adjuvant CCNU is associated with improved survival compared to adjuvant CCNU alone. These results highlight the contribution of CCNU in the radiation effect when given concomitantly.

A case of spontaneous intracranial hypotension with cerebellar symptoms

S. Korkmaz, K. Hamamcioglu, M. Aksu, M. Ozturk. Neurology Department, Acibadem University Medical Faculty, Turkey; Neurology Unit, Acibadem Kayseri Hospital, Turkey; Neurology Department, Erciyes University Medical Faculty, Kayseri, Turkey; Radiology Department, Erciyes University Medical Faculty, Kayseri, Turkey

Spontaneous intracranial hypotension (SIH) is a rare clinical syndrome caused by spontaneous cerebrospinal fluid (CSF) leak, mainly characterized by postural headache and low CSF pressure. Besides postural headache, common accompanying clinical features include neck pain, nausea, vomiting, dizziness, vertigo, ataxia, blurred vision, and diplopia. More severe neurological manifestations such as parkinsonism and bulbar weakness occur infrequently.

Diagnosis of SIH should be considered in patients presenting with postural headache, which cannot be attributed to another cause. Neuroimaging, particularly MRI, is very useful in establishing the diagnosis and in identifying the site of leak. Herein, we describe a case with postural headache, normal CSF pressure, and typical MRI findings of SIH. However, our case had quite atypical symptoms such as dysarthria, dysphagia, and ataxia for SIH. A 64-year-old man, previously healthy, presented with postural headache, nausea, vomiting, dysarthria and ataxia. Onset of symptoms was 2 years ago. His medical and family histories were unremarkable. There were no trauma and surgery history especially on the spinal. On neurological examination, there were dysarthria, ataxia, bilateral extensor plantar response, and bilateral dysmetria. Laboratory findings were normal. Opening pressure of CSF and the other biochemical tests were normal. Coronal and sagittal T1-weighted gadolinium-enhanced MRI revealed pachymeningeal enhancement, sagging of the brain, effacement of the perimesencephalic cistern.

In conclusion, the clinical spectrum of SIH can be wide as to include cerebellar and bulbar symptoms. The presence of clinical suspects for SIH and MRI findings is very important for diagnosis.

doi:10.1016/j.jns.2013.07.2347

Primary dural MALT lymphoma mimicking a meningioma: A case report

I. Taifas, A.C. Zeghoudi, Y.S. Cordoliani, C. Hubert, V. Sudacevschi, P. Pencalet, D. Concescu, F. Pico. Department of Neurology and Stroke Center, Versailles Hospital, University of Versailles Saint-Quentin en Yvelines, Versailles, France; Department of Radiology, Private Hospital of Parly 2, Le Chesnay, France; Department of Radiology, Versailles Hospital, Versailles, France; Department of Neurosurgery, European Hospital of Paris La Roseraie, Aubervilliers, France

Background: Primary dural lymphoma is a rare subtype of primary central nervous system lymphoma. Mucosa-associated lymphoid tissue (MALT) lymphomas are the most common subtype of non-Hodgkin's lymphomas primarily involving the dura. They usually appear as single or multiple extra axial lesions with homogeneous contrast-enhancement mimicking a meningioma.

Abstract — WCN 2013
No: 2438

Primary dural MALT lymphoma mimicking a meningioma: A case report

Background: Amyotrophic lateral sclerosis (ALS) is a fatal neurodegenerative disease of unknown etiology. Various ALS-like disorders mimic the clinical feature of ALS, but prognosis is thought to be better. Objectives: We report 3 cases of ALS-like disorders and we discuss the clinical, electrophysiological features, etiologies and the outcome of this disorder.

Case reports: Three patients (2 men, 1 woman, mean age: 51 years) has presented with limb weakness and wasting associated with brisk muscle stretch reflexes and fasciculation, without any sensory involvement. EMG showed a motor neuron disease in 3 cases. Etiologic investigation had found respectively a sigmoid adenocarcinoma, a Gougerot-Sjögren syndrome (GSS) and a monoclonal gammopathy. All patients underwent etiologic treatment and had been followed for 2 years. Two patients have been stabilized without reversibility of the symptoms. The disease course has just slowed down in the third patient (with monoclonal gammopathy), which may imply that underlying etiology was not correctly treated. Discussion: ALS-like must be searched in case of an anterior horn disease by an exhaustive assessment. Treatment of the causing pathology has been reported to improve the disease course and even reverse the symptoms, especially in infectious and toxic causes. In our patients, handicap didn't improve; instead we noted a stabilization or slow evolution of the symptoms, which extend the life span. Conclusion: The importance of recognizing ALS-like syndromes lies in the potential reversibility of the disease, or at least, a delayed mortality.

doi:10.1016/j.jns.2013.07.2348
Case report: A 54-year-old woman presented with a two-month history of ataxia and left hearing loss. MRI showed an extra-axial tumor arising from the left cerebellar tentorium, measuring 5 cm x 3.7 cm x 2.3 cm, infiltrating the left internal auditory canal and the left foramen lacerum, T2 hyperintense, and T1 isointense, with homogeneous contrast enhancement. This pattern was highly suggestive of a meningioma. The biopsy showed a lymphoid infiltrate, without evidence of B-lymphocyte clonality. The patient improved after incomplete surgical resection and corticoid therapy. She was admitted one year later, for a one-month history of unusual headache, with nausea and vomiting. Brain MRI showed an enhancing tumor of the left tentorium with mass effect. A stereotactic biopsy established the diagnosis of a mucosa-associated lymphoid tissue, a subtype of low-grade marginal zone non-Hodgkin lymphoma (CD 20+, CD3, CD79A).

Discussion: This case demonstrated the potential pitfall of imaging findings of dural MALT lymphoma, a rare condition which can lead to a misdiagnosis of meningioma.

Depression in LRRK2-associated Parkinson disease
L. Robbanaa, R. Rafrafi, S. Ben Sassi, Z. El Hechemi, F. Hentafi, Psychiatry F Department, Razi Hospital, Tunisia; *Neurology Department, National Institute Mongi Ben Hmidia of Neurology, Tunis, Tunisia

Background: The prevalence of the leucine-rich repeat kinase 2 gene (LRRK2) at the PARK8 locus on chromosome 12p11.2 in Parkinson’s disease (PD) varies according to the geographical and ethnic origins. In North Africa it represents about 35.7% of sporadic forms. Depression is one of the most common non-motor symptoms of Parkinson’s disease (PD). However the prevalence and the pattern of depression are lacking for LRRK2 (leucine-rich kinase 2)-associated PD patients.

Purpose: The purpose of this study was first to describe depression in LRRK2-associated PD patients, secondly to look for the impact of depression on activities of daily living and finally to compare prevalence of depression between LRRK2-associated PD patients and sporadic PD patients.

Methods: 40 patients diagnosed with PD-related LRRK2 G2019S mutation and 60 patients with sporadic PD were included in the study. All patients undergoing antidepressant, hypotension, corticoid or anti-tuberculosis treatment were excluded. Depression was screened by the Geriatric Depression Scale-long form. The impact on activities of daily living was assessed by Schwab and England Scale (indexed in UPDRS).

Results and discussion: Ninety six patients fulfilled inclusion criteria (thirty patients with PD-related LRRK2 G2019S mutation and sixty-six with PD sporadic form). 23 patients with mutation and 57 with sporadic PD had depression. Our results suggest that depression in PD is associated with increased disease severity and limitations in the activities of daily living but not with the l-dopa dose.

Conclusion: The association between depression and PD-related LRRK2 G2019S mutation needs further clarification.

Hirayama disease and IgA deficiency: An unusual coincidence or a complex syndrome
M. Petrowa, O. Grigorova, G. Georgieva, L. Penev, L. Traykov, Department of Neurology, Medical University Sofia, Bulgaria; *Department of Radiology, City Clinic Sofia, Sofia, Bulgaria

Background: Hirayama disease (HD) is a rare lower motor neuron disease. Although various possibilities have been proposed for the etiology of HD, the exiting theories are insufficient.

Objective: Here we present the first case of HD in Bulgaria and discuss the pathophysiological, immunological and imaging characteristics of the disease.

Patients and methods: The patient had a complete and thorough medical, neurological, neuropathological (EMG, SSEP, MEP), radiological (3 T MRI), and immunological evaluation.

Results: A 21-year-old man presented with a 2-year history of gradual loss of muscle mass and weakness in his left hand extending to the forearm. Neurological examination revealed moderate atrophy and slight weakness of the intrinsic left hand and forearm flexors, as well as slight weakness of some intrinsic right hand muscles. EMG showed chronic neurogenic changes in both hands. Conventional cervical MRI and cervical MRI in the fully flexed position demonstrated typical features for HD. Additionally, immunological tests revealed selective IgA deficiency.
Conclusion: The most widely accepted hypothesis for the underlying pathogenic mechanism of HD is cervical myelopathy based on the spinal flexion mechanism. However, it does not explain the natural history of the disease. Several recent studies report different immunological changes in patients with HD. Together with typical MRI findings, our patient also has a selective IgA deficiency. This data suggests that additional immunological mechanism may play a role in the pathogenesis and progression of HD, but this finding warrants further study.

Macular tuberculosis and optic neuritis: Rare association with tuberculosis meningo-encephalitis
J. Mounach, A. Laktaoui, K. Reda, A. Rouimi, Mohamed V Teaching Military Hospital, Rabat, Morocco; Moulay Ismail Military Hospital, Meknes, Morocco

Introduction: Tuberculosis is an endemic disease responsible for death and morbidity in developing countries.

Case report: A 50-year-old man with no medical history was admitted to the emergency department for meningism associated with fever and confusion. The ophthalmic exam showed a decline in left visual acuity, a reduction of light perception, VIth nerve left oculomotor paralysis, and confusion. The ophthalmic exam showed a decline in left visual acuity, a reduction of light perception, VIth nerve left oculomotor paralysis, and confusion.

Discussion: This case report shows the importance of systematic ocular fundus in the presence of systemic tuberculosis and outlines the assessment of color retinography to unmask vitreous lesions. It shows the importance of radiological imaging in the semiological study of orbital and cerebral lesions.

Intracranial dural arteriovenous fistula: A rare cause of myelopathy
Centro Hospitalar de Trás-os-Montes e Alto Douro, Vila Real, Portugal; Centro Hospitalar do Porto, Hospital de Santo António, Porto, Portugal

Introduction: Intracranial dural arteriovenous fistula (DAVF) is a rare acquired abnormality whose clinical manifestations are dependent on the pattern of their venous drainage.

Case report: A 50-year-old male presented with a progressive gait disturbance which started 4 months before. He also developed urinary incontinence and constipation. Cervical MRI revealed an extensive spontaneous hyperintensity involving medulla oblongata and cervical medullar transition until C3 suggesting a tumoral or inflammatory/infectious lesion. The serological and CSF syphilis reactions were positive. He was started with penicillin. In 3 weeks the lesion progressed rapidly to flaccid tetraplegia with a respiratory dysfunction. No other symptoms were found including headache or cervical pain, tinnitus, fever or previous trauma. The cervical MRI showed the same lesion extending now until C5 with epidural venous plexus dilatation and “flow voids” suggesting an arteriovenous shunt. The angiography confirmed a DAVF at the level of jugular foramen fed by the jugular and hypoglossal branches of ascendant pharyngeal artery and a petrous branch of middle meningeal artery; venous drainage was to a suboccipital vein and this one drains to a perimedullar vein being that this phenomenon was responsible for the clinical presentation. The fistula was occluded and in the control angiography no abnormality was found. At a neurological exam he presents a flaccid tetraparesis grade 3 (MRC) and regained partial autonomous ventilation.

Conclusion: Rare reports of intracranial DAVFs with perimedullary venous drainage were found in the literature. These usually present with myelopathy, rarely hemorrhage. Endovascular therapy is the gold standard. An attempted recognition of this entity is crucial for a better neurological outcome.

Isolated psychosis with an organic etiology: A diagnostic challenge

Introduction: In a patient presenting with neuropsychiatric symptoms, especially in the absence of a previous psychiatric history, it is obligatory to exclude an organic etiology.

Clinical cases:
1. A 68 yo female, with history of myocardial infarction, spontaneous abortion (1st trimester), persistently positive IgM anticardiolipin antibody titers presented with a 3 month neuropsychiatric syndrome (euphoria, disinhibition, hyper-religiosity, delusions of grandeur, executive dysfunction, visual hallucinations) and later seizures. She had no psychiatric history. Brain MRI showed old subcortical and basal ganglia ischemic lesions. She met the criteria for primary antiphospholipid syndrome. She improved with hypo-coagulation, anti-epileptics and neuroleptics.
2. A 47 yo female presented with Behçet’s disease (BD) which was diagnosed at 32 yo (recurrent ulcers, uveitis, erythema nodosum). By then she had psychiatric symptoms, and was stabilized with neuroleptics. At 45 yo she had active BD and started with disinhibition, hyper-religiosity, delusions of grandeur and obsessive cleaning. Brain MRI excluded acute lesions, electroencephalogram and CSF were normal. Psychiatric symptoms improved under quetiapine and sodium valproate.
3. A 51 yo female, with unremarkable personal history, was admitted in hospital to donate a kidney to her husband. Two days after surgery she started behavioral (agitated, disinhibition, obsessive cleaning) and sleep changes, followed by persecutory delusion. CSF showed pleocytosis (45 leucocytes/ul—44 lymphocytes, 1 polymorphonuclear), proteins 0.26 g/dL and glucose 0.66 g/dL. PCR analysis was positive for enterovirus. She recovered with supportive treatment and was discharged asymptomatic.

Discussion: We presented rare causes of organic psychosis. Psychiatric symptoms, even if isolated, can be the form of presentation of neurological disorders. It highlights the importance of an early recognition in order to ensure proper treatment.

Prophylaxis of pediatric headache with Topiramate
S. Al Faqih. National Hospital, Swaida, Syria

Background: Headache (HA) is a very common neurological problem in the pediatric population. Topiramate (TPM) is currently approved in children 2 years of age and older as an adjunctive treatment of partial and primary generalized seizures. Historically, anticonvulsants have proven effective for adult HA and, in fact, given this, and the availability of safety data on TPM in the pediatric population, it is an agent that holds promise for HA prophylaxis in children. There is at least one small case report indicating efficacy in pediatric migraine but there are no studies to date including patients with CDH and mixed type HA. Objective: To determine if Topiramate is an effective agent in the treatment of headache, including migraine, chronic daily headache (CDH) and mixed type headache, in the pediatric population. Methods: A retrospective chart review was conducted of patients seen in the pediatric HA clinic at Children's Hospital and treated with TPM. Results: 30 patients were treated with TPM. Responses to TPM were as follows: Ha free (11); significant (>75%) reduction in headache (9); moderate (50–75%) reduction in ha (5); four patients stopped TPM secondary to side effects; and three patients failed to respond. Overall, 67% of the patients treated with TPM achieved HA freedom or significant improvement. In those patients with CDH, 73.6% achieved HA freedom or significant improvement and 36.8% became HA free. Conclusions: TPM is a well tolerated and efficacious medication for the treatment of pediatric HA and is effective in much smaller doses than generally needed when treating seizures.

Neurophysiological study in infantile neuroaxonal dystrophy: Retrospective review of seventeen North-African patients
I. Kraoua1, M. Romani2, H. Benhouma1, H. Klaa2, A. Hassen-Rouissi2, E.-M. Valente3, N. Goidier-Khouja1, I. Ben Youssef-Turki1, 1Department of Child and Adolescent Neurology, National Institute Mongi Ben Hmida of Neurology, Tunis, Tunisia; 2IRCCS Casa Sollievo della Sofferenza, Mendel Laboratory, San Giovanni Rotondo, Roma, Italy

Background: Infantile neuroaxonal dystrophy (INAD) is a rare autosomal recessive neurodegenerative disorder due to PLA2G6 mutations. Objective: To characterize both the EEG patterns and EMG findings in INAD. To compare EEGs and EMGs according to the age in patients who had serial exams. Patients and methods: Over 7 years (2005–2012), 17 patients were diagnosed INAD according to Nardocci criteria and carrying PLA2G6 mutations. EEGs were performed in 14 patients and reanalyzed according to background activity, fast rhythms, and epileptiform activity. EMGs were obtained in all but one patient. Results: EEG was normal in seven patients and abnormal in seven with fast rhythms in six all aged more than 2 years old with additional few slow waves and spikes in three of them, while one child had generalized spike waves predominantly in the centro-temporal regions. Two patients with fast rhythms on EEG had earlier investigations that reported normal findings. EMG showed axonal motor neuropathy in eleven patients, sensory and motor neuropathy in two patients and horn cell involvement in one. The two remaining patients had normal EMG which was performed before 2 years of age. Four patients with abnormal EMGs had earlier exams that were normal. Conclusion: Although not specific, neurophysiological findings, namely the presence of fast rhythms on the EEG and signs of chronic denervation are highly suggestive of INAD in the appropriate clinical and imaging context. EEG pattern and EMG findings depend on the stage of the disease course and normal exams in the early stage do not exclude the diagnosis.

Relationship between paraneoplastic cerebellar degeneration and overexpression of C-erbB-2 gene in breast cancer
Hospital das Clínicas, Universidade Federal de Goiás, Goiânia, Brazil; Faculdade de Medicina, Universidade Federal de Goiás, Goiânia, Brazil

Background: Case report of a 38-year-old woman with cerebellar ataxia.

Objective: Case report.

Patients and methods: The cerebellar ataxia manifested itself through dysarthria, nystagmus, finger-to-nose test – nose indicating severe impairment mostly left – coarse tremor of the upper limbs, with bradykinesia, with dysdiadochokinesia and Babinski sign and Hoffman negative, also presenting a history of nodulectomy in the left breast. Presented with a new nodule of 3.1 × 2.1 cm, diagnosed as infiltrating ductal carcinoma grade 2, estrogen receptor positive, progesterone receptor negative, C-erbB-2 positive 3+, ki67 of 27% and CK5 negative, the patient was referred to neoadjuvant chemotherapy and posterior quadrantectomy of the left breast. Imaging and laboratory tests showed no indication of metasteses in the central nervous system or in any other system. The final neurological diagnosis was paraneoplastic cerebellar degeneration (PCD), a rare syndrome that occurs in less than 1% of breast cancers.

Results: The case associated to a literature review demonstrated a possible connection between PCD and C-erbB-2 strongly positive.

Conclusion: Although most of the series with PCD and antibody positive show that this disturbance rarely respond to treatment, early recognition of this rare complication of breast cancer is imperative, since there may be neurological improvement with appropriate therapy, for example, removal tumor, plasmapheresis, IVIG, cyclophosphamide, rituximab or glucocorticoids.

Frequency and clinical presentation of dizziness in neurological emergency department
S. Naseem, A. Mike.
Department of Neurology, University of Pecs, Pecs, Hungary

Background: Sensation of dizziness occurs frequently, and may be caused by various different disorders rendering the differential diagnosis challenging in the neurological emergency department (NED).

Objective: We investigated the frequency and clinical presentation of different dizziness syndromes at our NED to improve diagnosis assignment during patient evaluation.

Patients and methods: We retrospectively analyzed medical records of patients who attended the NED with a chief complaint of dizziness/vertigo over a 5 month period (n = 100). We collected demographic data, information about clinical presentation (disease course, triggers, associating symptoms), previous history and co-morbidities, findings of the neurological examination and diagnostic tests.

Results: Dizziness was more prevalent among elderly (mean: 59.21 ± 19.54) and far more frequent among females (7:3). The most common cause of dizziness was benign paroxysmal positional vertigo (BPPV), and the 5 most common occurring syndromes (BPPV [21%], vertebrobasilar stroke [20%], internal medicine disorders [17%], psychiatric disorders...
Ionizing radiation plays major role in the treatment of brain tumours, but side-effects may restrict the efficiency of therapy. In the present study, our goals were to detect the functional and morphological changes that result in the administration of l-alpha glycerylphosphorylcholine (GPC), a deacylated derivative of phosphatidylcholine, in a rodent model of hippocampus irradiation.

Anesthetized SPRD rats were subjected to 40-Gy irradiation of one hemisphere of the brain, with or without GPC treatment (50 mg/kg per os). After the irradiation the rats received GPC or the vehicle at the same time every second day at 5 days per week. The effects of partial rat brain irradiation on the spatial orientation and learning ability of rats were assessed in the Morris water maze (MWM) test, which was performed once before and two times after the irradiation. At the same time morphological changes were detected by MRI to define the time-point for histological examinations. Irradiation of 40-Gy resulted in moderate neurological deficit both at the level of cognitive function and morphology after 4 weeks of irradiation. The MWM test was found to be a highly sensitive tool for the detection of neurofunctional impairment. We found that the place navigational function of the rats was impaired by the irradiation and the treatment with GPC could prevent this damage. Marked protective effect of the GPC was detected as concerns of the histopathological findings.

Targeted brain irradiation induced notable changes in the central nervous system. GPC supplementation provides significant protection against irradiation-caused functional and morphological disturbances.

[15%], vestibular migraine [10%]) from the 12 established diagnoses covered 83% of all cases. Migraneous vertigo and psychiatric disorders were underdiagnosed, and BPPV was overdiagnosed (false positivity). One-third of patients presented reoccurring dizziness episodes, and 32.3% of them had psychiatric disorders. Chronic dizziness (>3 months) occurred most commonly (47.4%) in patients with a psychiatric disease. Isolated vertigo occurred in 50% of vertebrabasilar stroke cases. Seventy percent of patients with vertebrabasilar stroke had two or more vascular risk factors.

Conclusion: Careful history taking and bedside evaluation provided in most of the cases the base for diagnosis, and laboratory and imaging techniques only had additional confirming and supporting roles.

Changes of esophageal peristalsis in patients with non-erosive reflux disease and functional heartburn following non-invasive brain stimulation
S. Vigneri a, A. Inviati b, S. Bonventre b, G. Cosentino b, G. Giglia a, S. Maccora b, S. Indovino b, F. Brighina b, B. Fierro b. Neurology, Policlinico Paolo Giaccone, Palermo, Italy; Emergency Surgery, Policlinico Paolo Giaccone, Palermo, Italy

Results: The study showed statistically higher values of all followed parameters iCI, CHD, AH comparing them to controls (p < 0.01 – 0.0001). Also statistically significant changes between AH: CHD, AH: iCI and CHD:iCI (p < 0.05 – 0.02) were documented. Close correlations between LP-PLA2 and IMT stiffness were documented in all followed groups.

Conclusions: Our results documented significant changes in IMT, aortic stiffness and LP-PLA2 in all followed groups (iCI, CAD, AH) compared to controls. A close correlation was found between these parameters and LP-PLA2. The measurements of IMT, stiffness and LP-PLA2 are very useful parameters for assessing cerebrovascular and cardiovascular risk. They represent significant prognostic power to ascertain subjects with an increased risk for onset and outcome of cerebrovascular and cardiovascular events.

Background: New specific vascular inflammatory marker LP-PLA2 may predict future cerebrovascular and cardiovascular events in patients with iCI, MI, coronary artery disease (CAD) and arterial hypertension (AH). In the past years there were discussions regarding its relationship with intima-media thickness (IMT), arterial stiffness and plaque morphology.

Objective: The aim of this study was to assess the changes in IMT, stiffness, LP-PLA2 and their mutual relationships in a prospective, multidisciplinary, multicentric study.

Materials and methods: Materials consist of 436 subjects divided in four subgroups
1. iCI (n = 171), mean age 69 +/- 11 years, men 52%,
2. CAD (n = 87) mean age70 +/- 9 years, men32%,
3. AH (n = 124) mean age 60 +/- 10 years, men 46%, healthy controls (n = 56), mean age 47 +/- 13 years, men 55%. In all subjects, neurological and cardiological examination, ICI confirmed by CT/MRI, SPECT, battery of biochemical/haemotological investigations,

1. IMT using ultrasonography by radio-frequency data analysis.

Results: The study showed statistically higher values of all followed parameters iCI, CHD, AH comparing them to controls (p < 0.01 – 0.0001). Also statistically significant changes between AH:CHD, AH: iCI and CHD:iCI (p < 0.05 – 0.02) were documented. Close correlations between LP-PLA2 and IMT stiffness were documented in all followed groups.

Conclusions: Our results documented significant changes in IMT, aortic stiffness and LP-PLA2 in all followed groups (iCI, CAD, AH) compared to controls. A close correlation was found between these parameters and LP-PLA2. The measurements of IMT, stiffness and LP-PLA2 are very useful parameters for assessing cerebrovascular and cardiovascular risk. Materials and methods: Nineteen subjects (18–65 years) with GERD symptoms, PPI trial and an endoscopy ruling out esophagitis were enrolled. Esophageal manometry was performed before and during transcranial direct current stimulation (tDCS, 1.5 mA) of the right precentral cortex. Half of the patients were randomly assigned to anodal and the other half to sham stimulation. Distal wave amplitude and pathological wave percentage (peristaltic waves < 30 mm Hg, simultaneous or not propagated waves, or absent peristalsis) were measured after the patients swallowed ten subsequent water bolii. Lastly, a 24 hour pH-bilimetry was performed to subdivide NERD by FH. The values obtained before and during anodal or sham tDCS were compared by repeated-measures ANOVA with Time (before–during) as within-subject factor, and Stimulation (anodal-sham) and Sub-group (NERD-FH) as between-subjects factor.

Results: We observed a significant increase of distal wave mean amplitude (p = 0.02) and a decrease of pathological wave percentage (p < 0.01) either in NERD and FH subjects exclusively with anodal tDCS. No significant differences were documented in distal wave mean amplitude following anodal tDCS in NERD compared with FH patients, while post-hoc analysis confirmed that pathological wave percentage significantly improved after stimulation only in NERDs (p < 0.001).

Conclusion: Anodal tDCS can differently improve esophageal manometric features in GERD sub-categories.

Cerebral malaria with corpus callosum splenium lesion

A. Eker1, H.K. Suer2, O. Tosun1. 1Department of Neurology, Near East University Faculty of Medicine, Nicosia, Cyprus; 2Department of Clinical Microbiology and Infectious Diseases, Near East University Faculty of Medicine, Nicosia, Cyprus

Cerebral malaria is the most severe neurological complication of infection with Plasmodium falciparum malaria. Mortality is high and some surviving patients with sustained brain injury manifest as long-term neuro-cognitive impairments. Cerebral malaria is seen in 2% of malaria cases. In endemic areas it affects mainly children. Occurrence in adults is far less. Here we report a 27-year-old man with cerebral malaria who has a rare but suggestive radiologic finding for malaria. He has been admitted to our emergency department with fever, diarrhea, muscle pain, headache and progressive drowsiness. He visited Sierra Leone, Africa 5 days ago. His physical examination revealed icterus, hepatosplenomegaly and dark urine. At his neurological examination, he was lethargic and had a score of 6 on the Glasgow Coma Scale. He has meningeal irritation signs with neck stiffness. Cranial MRI performed urgently and showed focal restricted diffusion in corpus callosum splenium in diffusion weighted imaging. Epileptic attacks have been observed and his EEG revealed generalised severe background slowing. Blood smears showed Plasmodium falciparum. Urgent antimarial treatments have been administered and the patient regained consciousness. Anti-epileptic medication was progressively reduced and the treatment was finally stopped after normal EEG was obtained. Awareness of clinical and radiological features of malaria and cerebral malaria is really important for early recognition and treatment. Taking the visiting history of an endemic area is helpful for diagnosis.

Ictal characteristics of common vestibular disorders

M.S. Welgampola1, C. Lechner2, H. MacDougall2, C. Todd2, M. Halmagyi2, 1Neurology, University of Sydney, Royal Prince Alfred Hospital, Australia; 2School of Psychology, University of Sydney, Sydney, NSW, Australia

Background: Peripheral and central vertigo are associated with nystagmus, the spatiotemporal characteristics of which may point to its origin. Objective: To capture the ictal attributes of episodic vertigo.

Methods: Thirty patients presenting to a neuro-otology clinic with episodic vertigo were taught to record spontaneous, gaze-evoked and positional nystagmus; three demonstrated ictal fluctuation in hearing threshold (15–60 dB). Their horizontal slow phase velocities (SPV) ranged between 10 and 52°/s and the SPV profile was constant over a 60 s recording interval. Two undertook consecutive recordings over 10–15 min intervals

doi:10.1016/j.jns.2013.07.2367
and demonstrated irritative, paretic and recovery nystagmus. Sixteen subjects fulfilled the criteria for clinically definite (6) or probable (10) vestibular migraine. Their ictal nystagmus was characterized by spontaneous horizontal (6) vertical upbeat (4) or downbeat (4) nystagmus with a constant SPV profile (SPV range: 5–25°/s) and 2–3 fold enhancement during positional testing. Four subjects had short-lived paroxysmal positional nystagmus consistent with posterior canal BPV. The slow phase velocities, plotted as a function of time, could be fitted into a 5th–8th order polynomial curve which peaked at 3–10 s (range: 15–95°/s) and had declined to 0 by 60 s.

Conclusion: Home-video nystagmography is feasible, enables a detailed study of the ictal profiles of central and peripheral vestibulopathies and facilitates differentiation between common causes of episodic vertigo.

Neurosarcoidosis: A Tunisian case series

Background: Neurosarcoidosis (NS) more commonly occurs in the setting of systemic disease. Neurologic manifestations are found in 5 to 20% of cases and symptoms may be mild or even severe. Clinical presentations and imaging findings in nervous system are highly variable.

Objective: The aim of this study was to determine the different clinical and radiological presentations of neurosarcoidosis and describe the evolution under corticosteroids.

Materials and methods: A retrospective study was conducted from 2005 to 2013, in the adult department of neurology at the National Institute of Neurology Mongi Ben Hamida in Tunis, including seven patients hospitalized for suspected neurosarcoidosis.

Results: The mean age of our patients was 36.85 ± 11.61 years with a female predominance (sex ratio 1.33). Multiple cranial nerve involvement was the most common clinical sign (6/7). Five patients had a headache with an increased intracranial pressure in three patients. Only one patient developed seizures. Endocrine disorders were noted in 3 patients. Lymphocytic meningitis was noted in 5 patients. MRI showed several radiological aspects: hydrocephalus, pachymeningitis, sellar and suprasellar infiltrates and hyperintense cranial nerves. The mainstay of medical treatment in neurosarcoidosis is corticosteroids, and all patients received this therapy alone. Six patients improved or stabilized, whereas only one deteriorated.

Conclusion: Sarcoidosis should be suspected in patients with unexplained neurological symptoms even in the absence of any systemic manifestations. Biopsy of neural tissue is often not practical and the diagnosis must be inferred through other tests, often coupled with biopsy of extra neural organs.

Time related patterns of blood pressure response in patients with orthostatic hypotension during prolonged tilt testing
Y. Balash*, T. Gurevich*, H. Machmuda*, D. Klepikov*, A. Ezra*, N. Giladi*, C. Peretz*. "Tel Aviv Sourasky Medical Center, Israel; bTel Aviv University, Tel Aviv, Israel

Introduction: Orthostatic hypotension (OH) is a common, frequently under diagnosed, disabling and treatable condition with prevalence up to 30%. OH is usually diagnosed with the tilt test (TT). The optimal duration of TT needed to detect OH, or whether standing longer than 3 min contributes to diagnosis, remained unclear. We aimed to assess various time-related patterns of blood pressure (BP) responses in patients with OH.

Methods: The protocols of prolonged (40 min), vertical position drug-free TT were studied in 745 consecutive individuals during 2010–2011 years.

Results: 296 subjects (40%) among the 745 referred for TT had OH. This group included 36 of the 83 patients (30%) younger 20 years (young group, YG), and 116 of the 260 subjects (46%) who were elder 65 years (elderly group, EG). The female: male ratio was 66:33 for the OH-YG group and 55:45 for the OH-EG group. Around 25% of the OH-EG patents developed a decrease only in systolic BP (SBP), around 25% only in diastolic BP (DBP), and 50% in both. In OH-EG, SBP dropped within 5–35 min, while DBP dropped within 10 min.

Conclusions: Individuals referred for TT had a 40% probability for OH. The prevalence of systolic and diastolic OH was similar, but their temporal patterns were different. Extending TT beyond 35 min is important to detect delayed systolic OH.

Peripheral paraneoplastic neuropathy, an uncommon clinical onset of sigmoid cancer
N. Touati, I. Bedoui, A. Riahi, R. Lansari, M. Mansour, J. Zouali, R. Mriisa. Department of Neurology, Military Hospital, Tunis, Tunisia

Introduction: Peripheral paraneoplastic neuropathy (PPN) is rare. Multiple myeloma and tumors of the lung, breast, kidney and ovary are most commonly implicated. Colorectal cancer rarely presents with neurological paraneoplastic disorder.

Objective: We report an unusual rectum adenocarcinoma presentation revealed by a sensory neuropathy. Our message is that an occult malignity should always be researched when we have subacute sensory neuropathy.

Case report: A previously healthy 56-year-old woman was admitted because of progressive ascending weakness and ataxia gait, beginning 6 weeks ago. Neurological examination revealed a flaccid and areflexic quadriaparesis associated with glove and stocking distribution of sensory loss. No sensory conduction velocity was detected in neurophysiological studies. Complete microbiological and virological investigations on blood, urine and CSF specimens, anti-nuclear antibody and tumor markers were negative. Lip biopsy also was normal. Only Anti-Hu antibodies were positive on blood and CSF. A whole body computed tomography scan was completely unremarkable. At the time of the diagnostic workup an episode of rectal bleeding occurred. Colonoscopy demonstrated an exophytic process of the rectum at 15 cm from the anal verge. No improvement was obtained after surgery and intravenous immunoglobulin. Our patient died from dysautonomic disorder related to her neuropathy.

Discussion and conclusion: Only 0.05% of cancer patients suffer from paraneoplastic neurological syndrome, of which less than 10% had rectal cancer. We conclude that, an occult malignity should always be researched when we have subacute sensory neuropathy.

Vestibular manifestations in a migrainous population
C.G. Videla, A. Bisonni, E. Doctorovich, E. Cristiano. Neurology, Hospital Italiano de Neurología, Buenos Aires, Argentina

Introduction and objectives: Vestibular symptoms are common manifestations observed in patients with migraine. This coincidence is greater than the statistic possibility of presenting two high prevalence diseases in general population. The aim of this study is to describe the neuro-otological findings in patients assisted by a headache unit during a year.

Material and methods: 460 patients evaluated in the period from January 1, 2012 and January 1, 2013 met criteria for migraine according to the International Headache Society. All patients underwent an auto filling questionnaire, in order to evaluate the presence of vestibular symptoms. Those patients who reported vestibular symptoms were referred to neuro-otological section for a specialized examination.

Results: 400 patients had a diagnosis of migraine without aura and 60 migraine with aura. 108 patients (92:16; MSA:MCA) reported the presence of positive vestibular symptoms, the diagnoses were: migraine–vertigo (43), benign paroxysmal positional vertigo (30), Basilar-type migraine (12), acute vestibular hypofunction (10), central positional vertigo (6), Ménière syndrome (5) and acoustic neurinoma (2).

Conclusions: We confirmed a high prevalence of vestibular disorders in our migraine population (23.5%). Vestibular disorders occur more frequently in patients with migraine without aura. 55% of patients with vestibular pathology showed a clear association with migraine etiopathogenesis; in 34% the relationship between the two disorders was likely/probably and 10% of the cases were attributable to merely statistical chance.

Paediatric narcolepsy – A seven-year experience
S. Aurangzeb, Z. Ziaiwalla. Clinical Neurophysiology, John Radcliffe Hospital, Oxford University Hospitals Trust, Oxford, UK

Prevalence of narcolepsy varies from 0.05 to 0.02% in adults and although narcolepsy is considered to be a disease of adulthood, most cases have their onset in childhood. Diagnosis is frequently delayed or misdiagnosed because of unfamiliarity with paediatric narcolepsy and variable presentations.

Objective: To describe the clinical and polysomnographic features of children with narcolepsy.

Patients and methods: 38 children diagnosed with narcolepsy at John Radcliffe Hospital, Oxford, between January 2005 and October 2012, are included in this study.

Results: The mean age of onset was 9.61 ± 3.51 years. 12 children had a predisposing insult and two of them reported swine flu vaccination prior to symptom onset. Full tetrads of narcolepsy symptoms were seen in only 18.4% while 52.6% children presented with three out of four cardinal symptoms. Excessive daytime sleepiness was the most common symptom (100%), followed by cataplexy (86.84%), hypnopompic hallucinations (60.5%) and sleep paralysis (28.9%). Change in the facial expression was noticed by 15.62% parents while the characteristic “cataplectic facies” were seen in 36.8% children in the clinic. Disturbed night sleep was reported in 89.5% children, excessive dreaming in 71.1% and parasomnias in 68.4% children. The mean sleep onset latency on multiple sleep latency test (MSLT) was 2.95 ± 2.98 min and mean sleep-onset rapid eye movement (SOREM) was 3.

Conclusion: Narcolepsy must be considered in the differential diagnosis of hypersomnia, even in the absence of classic signs and clinicians must be vigilant towards ancillary features. MSLT, following a strict protocol, is diagnostic in most children.

IFCN guidelines for cervical vestibular evoked myogenic potentials
E.S. Papathanasiouab, T. Murofushib, F. Akinb, J.G. Colebatchd,e. aClinical Sciences, Cyprus Institute of Neurology & Genetics, Nicosia, Cyprus; bDepartment of Otolaryngology, Teikyo University School of Medicine, Kawasaki, Japan; cAudiology, VA Medical Center, Mountain Home, TN, USA; dUNSW Clinic School, Sydney, NSW, Australia; ePrince of Wales Medical Research Institute, Sydney, NSW, Australia

Background: Cervical vestibular evoked myogenic potentials (cVEMP) are electromyograms evoked by high-level acoustic stimuli recorded from the tonically contracted sternocleidomastoid (SCM) muscle, and have been accepted as a measure of saccular and inferior vestibular nerve function. As more laboratories are publishing cVEMP data, there is a wider range of recording methods and interpretation, which may be confusing and limit comparisons across laboratories.

Objective: To recommend minimum requirements or guidelines in the recording and interpretation of cVEMPs in the clinic and for diagnostic purposes.

Material and methods: We have avoided proposing a single methodology, as clinical use of cVEMPs is evolving and questions exist about its underlying physiology and its measurement. The development of guidelines by a panel of international experts may provide direction for accurate recording and interpretation.

Results: cVEMPs can be evoked using air-conducted (AC) sound or bone conducted (BC) vibration. The technical demands of galvanic stimulation have limited its application. For AC stimulation, the most effective frequencies are between 400 and 800 Hz below safe peak intensity levels (e.g., 140 dB pSPL). The high pass filter should be between 5 and 30 Hz, the low pass filter between 1000 and 3000 Hz, and the amplifier gain between 2500 and 5000. The number of sweeps averaged should be between 100 and 250 per run. Raw amplitude correction by the level of background SCM activity narrows the range of normal values. There are few publications in children with consistent results.

Conclusion: The present recommendations outline basic terminology and standard methods. Because research is ongoing, new methodologies may be included in future guidelines.

Successful treatment of carotid–cavernous fistula through a percutaneous orbital approach
A. Garcia de la Fuentec, R.A. Rangel-Guerrab. cHospital and University Federation of Adult and Geriatric Psychiatry Christus Muguerza, Mexico; bNeurology, Hospital Universitario Jose Eleuterio Gonzalez, Nuevo Leon, Mexico
Material and methods: 72 y/o white female during the last 2 months developed gradually scleral congestion, ocular pain, proptosis, chemosis and decreased visual acuity of the left eye without pupillary involvement, and without extraocular nerve paresis. The rest of the neurological and neuro-ophthalmologic examinations were within normal limits. Carotid cavernous fistula on the left side was suspected. Digital subtraction carotid angiography was performed which revealed a carotid cavernous fistula (type “C” of the Barrow classification). The fistula was fed by the meningoypophysyal trunk (Fig. 1). Endovascular approach was tried though the meningoypophysyal trunk was unsuccessful.

Then, venous approach was intended to be done through the inferior petrosal sinus, but the cavernous sinus was thrombosed. It was decided to perform a percutaneous transorbital approach with catheterization of the cavernous drainage vein and a glue injection occluded the fistula without injection occluded the fistula without complications.

Conclusion: Percutaneous orbital approach is a useful tool in the management of carotid cavernous fistula, when neither arterial nor venous access was possible.

The “weekend effect” — Observations from a neurology inpatient service
S. Shafigat1, F. Fiazuddin2, I. Haq3, M. Islam4; 1Neurology, Aga Khan University, Karachi, Pakistan; 2Community Health Sciences, Aga Khan University, Karachi, Pakistan

Background: Patients admitted to hospitals on weekends are at increased risk of adverse outcomes, including mortality. Whether this specifically holds true for neurological patients is unclear.

Objective: We undertook this study to investigate whether the so-called “weekend effect” extended to a neurology service providing care in a developing country.

Patients and methods: Mortalities occurring over a ten-year period (January 2000 through December 2009) on an inpatient neurology service at a tertiary-level hospital in Karachi, Pakistan, were reviewed. Deaths were categorized by primary diagnosis, day and month of admission, and day and month of death. Mortality rates were compared using the chi-square test.

Results: Of 9966 admissions during the study period, 601 (6.03%) patients died before discharge. Mortality rate for patients admitted on weekends (165 deaths from 2382 admissions, or 6.93%) was significantly higher than for patients admitted on weekdays (436 deaths from 7584 admissions, or 5.75%; \( p = 0.035 \) for weekend versus weekday comparison, reflecting an excess of 1–18 deaths per 100 admissions for patients admitted on weekends). When analyzed by the three leading primary diagnoses, this weekend effect was present in patients with stroke, although not in those with epilepsy or CNS infection.

Conclusions: Neurological inpatients admitted on weekends are at greater risk of dying in the hospital than those admitted during the rest of the week. These observations raise important questions about the appropriateness of work schedules, staffing patterns and, ultimately, the quality of care delivered in hospitals on weekends.

Ethical quality of clinical trials in Lebanon: Result of a national survey
F. Abou-Mrad. Neurology, Saint Charles Hospital, Faculty of Medicine, Lebanese University, Baabda, Lebanon

Medicine shall exceed mere knowledge therefore every specialty shall remain a bridge to real medicine. Neurology cannot be applied without considering the context and its impact on the practice.

Objectives: This study is considered the first to analyze the situation in Lebanon concerning the ethical frame of therapeutic trials in order to compare the two largest groups of industrials and developing countries. The national survey was held in 144 hospitals working in the Lebanese environment characterized by a plurality of communities.

Method: Three methodological tools were used: a questionnaire (IRB, pharmaceutical companies, patients), direct and semi-direct interviews. The analysis about the ethical quality of IRB works legitimacy was developed according to Berdeu chart.

Results and discussion: There is heterogeneity in the practices of essential definitions regarding biomedical research and its limitations. IRB regulations are rather permissive to researchers and industrial promoters. The future of research and the protection of concerned participants are at stake. The scientific expertise within IRBs, and the criteria applied in determining ethical opinions are major concerns. The absence of a pharmacovigilance system or of a competent authority in health safety increases the seriousness of the current situation.

Conclusion: The field is now open to industrial promoters, and the right goal of clinical trials is under questioning. The country has to decide to which extent it will accept and support clinical and scientific investigations implying citizens’ participation. This mission is essential and necessary to avoid transforming research into oppression and manipulation of the human being.

Valsalva maneuver shows prolonged sympathetic outflow in patients with a history of mild traumatic brain injury
M.J. Hilz1,2,3, J. Koehn2, F. Ammon2, J. Marcus2, S. Flanagan5, P. De Fina1, R. Baltadzhieva1,2, S. Schwab1, S. Moeller2; 1Dept. of Neurology, University of Erlangen-Nuremberg, Erlangen, Germany; 2Dept. of Neurology, New York University Langone Medical Center, New York, NY, USA; 3Dept. of Medicine, New York University Langone Medical Center, New York, NY, USA; 4Dept. of Psychiatry, New York University Langone Medical Center, New York, NY, USA; 5Dept. of Rehabilitation Medicine, New York University Langone Medical Center, New York, NY, USA; 6IBRF, International Brain Research Foundation, Flanders, NJ, USA

Background: Increased mortality rates persist years after mild traumatic brain injury (mTBI) and might result from central autonomic dysregulation (Hilz et al. J Neurotrauma 2011;28:1727–38).

Objective: To determine whether Valsalva maneuver (VM) refines autonomic pathophysiology in post-mTBI-patients.

Methods: In 25 patients (GCS 13–15; 34.0 ± 13.2 years, tested 4–98 months after mTBI and 29 controls (31.3 ± 12.2 years), we monitored respiratory frequency (RESP), RR-intervals (RRI) and systolic blood pressure (BP) at baseline and during three VMs (15 s, 40 mm Hg strain). At baseline, we assessed total autonomic modulation as RRI-coefficient of variation (CV), RRI-standard-deviation (SD), RRI-total-powers, sympathetic modulation as RRI-low-frequency-powers (LF),
parasympathetic modulation as RRI-RMSSDv and RRI-high-frequency-powers (HF), and baroreflex sensitivity (BRS).

We calculated Valsalva-ratios (VR) and – as indices of sympathetic withdrawal – intervals from the highest BP-value during phase-IV-overshoot to the time when BP had decreased by 60% (60%-BP-recovery-time) and 90% (90%-BP-recovery-time) of the differences between phase-IV-BP-maxima and baseline-BP. We compared patient- and control-parameters before and during VMs (ANOVA, post-hoc analysis; significance: p < 0.05).

Results: At baseline, RRI-CVs, RRI-SDs, RRI-total-powers, RRI-LF-powers, RRI-RMSSDs, RRI-HF-powers and BRS were lower in patients than controls. During VMs, RRLs, BPs, and VRs were similar in both groups, while 60%- and 90%-BP-recovery-times were significantly longer in patients than controls.

Conclusions: Baseline autonomic modulation was reduced in mTBI-patients. During VM-challenge, only prolonged 60%- and 90%-BP-recovery-times unveiled altered autonomic adjustment in mTBI-patients with prolonged sympathetic hyperactivity. Sympathetic hyperactivity upon challenge may contribute to increased cardiovascular risk years after mTBI.

Acknowledgement: The study was partially funded by the IBRF, Flanders, NJ, USA.

Genetic modifications present in choroid plexus neoplasias and associated disturbances of psychoneural development
E. Castro-Sierra1, F. Chico-Ponce de León2, P. Dhellemmes3, F. Arenas-Huerto2, P. Eguía-Aguilar4, M. Perezpeña-Diazconti5, A. Sánchez-Boiso5, S. Martínez-Rodríguez1.1Laboratory of Psychoacoustics, Hospital Infantil de México Federico Gomez, Mexico City, Mexico; 2Department of Neurosurgery, Hospital Infantil de México Federico Gomez, Mexico City, Mexico; 3Department of Molecular Immunology, Research Institute for Microbial Disease, WPI Immunology Frontier Research Center (IFReC), Osaka, Osaka, Japan; 4Department of Neurology, National Toneyama Hospital, Osaka, Japan

Choroid plexus papillomas or carcinomas are rare forms of brain neoplasias. Some years ago, Steichen-Gersdorf et al. found a choroid plexus papilloma associated to a case of hypomelanosis of Ito and a 17p: Xq translocation in this female patient (Hum Genet 1993; 90:611–613). Recently, a 10-month-old girl with a Brachmann–Cornelia de Lange syndrome (BCLS) and a choroid plexus papilloma of the third ventricle of the brain was operated upon and studied at Hospital Infantil de México Federico Gómez (HIMFG) in Mexico City. Karyotypes (GTG bands) of the proband and her parents undertaken at HIMFG were normal. Array CGH analyses of blood DNA of these 3 persons carried out at BlueGnome's Laboratory in Cambridge, U.K., set in evidence amplification of genes SPNS2, GGT6, SMTNL2, PELP1, MYBBP1A and ALOX15 in chromosome 17p of the proband. Since MYBBP1A is a proto-oncogene and ALOX15 participates in development of cancer and metastases of tumors, further FISH analyses of these 2 genes were implemented at HIMFG. Amplification of both genes was also found in the tumor of the case under study but not in an unrelated papilloma of the choroid plexus. The possible genetic counseling, diagnostic and prognostic importance of the findings, especially regarding genetic modifications of chromosome 17p in choroid plexus tumors and associated clinical disturbances of psychoneural development of the type of hypomelanosis of Ito or BCLS, is discussed.

BAFF controls neural cell survival through BAFF receptor
S. Tada1, T. Yasui2, T. Okunou3, Y. Nakatsujia, H. Mochizuki2, S. Sakoda1, H. Kikutani1.1Department of Neurology, Osaka University Graduate School of Medicine, Japan; 2Department of Molecular Immunology, Research Institute for Microbial Disease, WPI Immunology Frontier Research Center (IFReC), Osaka, Osaka, Japan; 3Department of Neurology, National Toneyama Hospital, Osaka, Japan

Background: B cell activating factor (BAFF) is a fundamental survival factor for B lymphocytes and its effect on B cells has been extensively investigated. However, its effect on the central nervous system (CNS) has not been clarified.

Objective: To explore the novel mechanism of neuronal survival by BAFF receptor (BAFF-R) signals in CNS.

Material and methods: We examined BAFF and BAFF-R expression in neurons and cultured embryonic neurons of either wild-type or A/WySnJ mice (Baffr+/+/), which carry a mutation in BAFF-R, to compare the survival of neurons of both groups in vitro. We also bred mice carrying the human Superoxide Dismutase-1 mutation G93A (mSOD1), animal models of familial amyotrophic lateral sclerosis (ALS) with Baffr+/+, and body weight and survival were assessed.

Results: Immunohistochemical analysis and RT-PCR study revealed that both BAFF and BAFF-R were expressed in mouse neurons. Primary cultured neurons of Baffr+/+ mice showed increased survival compared with those of wild-type mice (Baffr+/+/). Furthermore, mSOD1/Baffr+/+ mouse showed increased survival (114.56 days ± 2.25) vs control mice (mSOD1/Baffr+/+) (152.3 days ± 1.28); p < 0.001. mSOD1/Baffr+/+ (97.18% ± 0.61 [n = 19]); p < 0.001.

Comparable numbers of microglia/macrophages and astrocytes were observed at early- and middle-stage disease in spinal cord section of both groups.

Conclusion: Our findings suggest a novel role of BAFF as a critical member of neuroprotective factors that directs neuronal survival independent of the action for glial cells.

Severe cardiac dysautonomia in acute myelitis
R. Renna1, D. Plantone1, P. Profice1, F. Pilato2, V. Di Lazzaro3.1Dipartimento di Geriatria, Neuroscienze ed Ortopedia, Catholic University of Sacred Heart, Italy; 2Department of Neurology, National Toneyama Hospital, Osaka, Japan; 3Institute of Neurology, Campus Bio-Medico University, Rome, Italy

Background: Traumatic spinal cord injury is frequently complicated by cardiocirculatory impairment (bradycardia and hypotension). It is unknown whether the same phenomenon can manifest in acute myelitis.

Design and methods: Case report

Results: A 35-year-old woman presented with left hemisoma weakness and hypoesthesia. Neurological examination revealed left arm weakness and dysmetria, left latroparesis test at Romberg test and hypoesthesia in the left hemisoma with a C2 level lesion. Laboratory tests and CSF analysis were unremarkable. Brain MRI was negative. Cervical spine MRI showed a T2-hypertensivest C2 intramedullary lesion. An acute myelitis was diagnosed and the patient started on a course of methylprednisolone, with initial benefit. Five days after
symptom onset, she developed severe bradycardia episodes, that required atropine and dopamine treatment. Electrocardiograms revealed sinus bradycardia and prolonged QT interval. Cardiac MIBG-scintigraphy showed low early and delayed H/M ratio. Patient’s status improved during the following months and the neuroimaging follow up was negative for new lesions.

**Conclusion:** Patient’s lesion involved the dorsal funiculi, and the left lateral and ventral funiculi. The dorsal aspect of the lateral funiculi represents the localization of the descending vasomotor pathways. The most likely explanation for patient’s bradycardia is the myelitis-related disruption of descendent pathways from the brainstem cardiovascular center to sympathetic neurons into T1–T4 segment intermediolateral nuclei, resulting in sympathetic hypoactivity. Myocardial MIBG-scintigraphy confirmed this hypothesis, revealing a decreased cardiac MIBG uptake. This case extends the spectrum of the clinical presentations of cervical myelitis and emphasizes the importance of careful cardiac rhythm monitoring in the acute phase.

**Activation of GABA-A receptors in the medial prefrontal cortex produces anxiolytic-like response**

J. Solati²,², Y. Golub³, “Department of Child and Adolescent Mental Health, University of Erlangen-Nürnberg, Erlangen, Germany; “Department of Biology, Karaj branch, Islamic Azad University, Karaj, Iran

**Objectives:** There has been increasing evidence that GABAergic system is involved in neurobiology of anxiety. The present study aims to investigate the role of GABAergic systems in the modulation of anxiety in medial prefrontal cortex (MPFC) of rats, using the elevated plus maze test.

**Methods:** Rats were anaesthetized with a mixture of ketamine and xylazine, and then special cannulas were inserted stereotaxically into the MPFC. After 5–7 days of recovery, the effects of intra-MPFC administration of GABAergic agents were studied.

**Results:** Bilateral injection of the GABA-A receptor agonist muscimol (0.25, 0.5 and 1 µg/rat) produces an anxiolytic-like effect, shown by significant increases in the percentage of open arm time (%OAT) and percentage of open arm entries (%OAE). Intra-MPFC administration of the GABA-A receptor antagonist bicuculline (0.25, 0.5 and 1 µg/rat) produces significant anxiogenic-like behavior. However, intra-MPFC injection of GABA-B receptor agonist baclofen (0.05, 0.1 and 0.2 µg/rat), and GABA-B receptor antagonist CGP35348 (5, 10 and 15 µg/rat) did not alter %OAT and %OAE significantly.

**Conclusion:** The results of the present study demonstrate that the GABAergic system of the MPFC modulates anxiety-related behaviours of rats via GABA-A receptors.

**Cellular pathology and apoptosis in neoplastic myelopathy due to metastatic disease**

R. Newcombe a, R. Vink a,b, P. Reilly c, J. Finnie a,d, J. Manavis b, P.C. Blumbergs a,b. "The University of Adelaide, Australia; "The Hanson Institute, Australia; "Royal Adelaide Hospital, Australia; "Institute of Medical and Veterinary Sciences, Adelaide, SA, Australia

Solid neoplasms, whether primary or metastatic, may lead to compression of the spinal cord and development of a compressive myelopathy syndrome. Apoptotic processes of cell death are thought to contribute to cell death in chronic compressive myelopathy due to degenerative spondylolisthesis but this has not previously been described in neoplastic compression. This study aimed to characterise the spatiotemporal distribution of apoptosis and pathophysiological changes in neoplastic compressive myelopathy using human post-mortem tissue from 7 cases with extramedullary or intramedullary tumour involvement. A loss of anterior horn cells and cystic necrosis was demonstrated, as well as the presence of APP immunopositive axonal swellings in all cases. Apoptosis was shown using a panel of immunohistochemical markers including TUNEL, DNA-PKcs, PARP and AIF seen at, above and below the compression. Apoptosis was maximal at the site of tumour compression. We conclude that axonal damage and neuronal loss, as well as oligodendrogial apoptosis may be important processes in the pathophysiology of neoplastic compressive myelopathy.

**Change in brain neural activation during stress due to a continued simple cognitive task**

T. Matsuda a, O. Nitta b, A. Senoo a, T. Shiratani c, K. Aminoto b, A. Manji d, S. Watanabe e, M. Kinoshita f. “Physical Therapy, Ueusea Gakuen University, Chiba, Japan; “Tokyo Metropolitan University, Japan; “Rehabilitation, Sonoda Second Hospital, Tokyo, Japan; “Rehabilitation, Saitama-misato Sougou Rehabilitation Hospital, Saitama, Japan; “Rehabilitation, The Jikei University School of Medicine, Tokyo, Japan

**Background and objective:** Repetition of simple cognitive tasks causes stress. We report change in brain activity during such tasks.

**Subjects and methods:** Some 13 healthy subjects (mean age: 22.8 yrs) gave informed consent. Tokyo Metropolitan University Ethics Committee approved the study. Brain activity at the start and finish of cognitive tasks 3.0 T fMRI recorded activity in three 3-minute sessions of consecutive subtraction of 7, starting from 1000. Initial 36- and final 36-second stages of each session were compared. fMRI data was analyzed using SPM8 [uncorrected height threshold p < 0.001] and one-sample t-test second-order random effect model was performed to determine regions of significant change.

**Results:** Initially activity was prominent in the bilateral superior and inferior parietal lobules (SPL, IPL), left Brodmann area 44 (BA 44), left cerebellum, bilateral prefrontal cortex, and left supplementary motor cortex; finally in the left SPL and IPL, bilateral cerebellum, bilateral thalamus, cingulate gyrus, and insula (claustrum). Activity level in thalamus and cerebellum was higher in the final stage.

**Conclusion:** Initial activation in the parietal lobule and BA44, particularly significant in the region from the left parietal to frontal lobes suggests involvement of these sites in arithmetic concepts. Since temporary memory of numbers was necessary; sites related to working memory were also activated. Due to activation in the cingulate gyrus and insula (claustrum) over long-term, subjects felt stress resulting in prominent activation of sites unrelated to calculation. Repetition of simple tasks over time changes the sites of activation.

Nerve conduction abnormalities in Gullain Barre syndrome in Nairobi

E. Amayo, J. Kwasa. University of Nairobi, Nairobi, Kenya

Background: Gullain Barre syndrome is an autoimmune polyradiculopathy. The major types are AIDP AMAN and AMSAN and MFS. No neurophysiological studies of GBs have been presented from this country.

Objective: To determine the neurophysiological types of GBS in Nairobi.

Materials and methods: We reviewed the neurophysiological reports of 36 cases of GBs who presented to our lab. The nerve conduction studies were performed on Nihon Kohden neuropack S1. The mean age was 40 ± 7 years and range of 11 to 74 years. There were 20 males and 16 females. We used the distal latencies, conduction block, amplitude f and H response to determine the physiologic type. The types of neurophysiology abnormalities were AIDP 30 (83%), AMSAN 2 (5.5%) and AMAN 4 (11%).

Conclusion: AIDP is still the commonest form of GBS in our setting with a few cases of AMAN and AMSAN. This is in keeping with results found in the developing world.

embryo differentiation of neuroblasts was the same as was in FGF-treated.

Conclusions: Our model system is simpler than the embryo in vivo, but closer to normal development than the cell cultures used in other studies. The neuroblasts found were direct answer to molecular signals added. This fact is in accordance with the idea that in a multilevel process of neural differentiation, FGF is the neural inducer in mammals.

Spinal schistosomiasis: Relevance of epidemiologic and imaging features in an unusual case of myelopathy
Neurology Department, Centro Hospitalar Lisboa Central, Lisbon, Portugal; Physical Medicine and Rehabilitation Department, Centro Hospitalar Lisboa Central, Lisbon, Portugal

Background: Neuroschistosomiasis is a common cause of myelopathy in endemic regions but it is infrequent in developed countries.

Objective: Our goal is to present a case of spinal schistosomiasis where epidemiologic and imaging features played an important role.

Patients and methods: Clinical case.

Results: A 26-year-old woman from Guinea-Conakry was referred to a Portuguese Neurosurgery Department for progressive paraparesis and urinary retention. Spinal MRI showed an intramedullary lesion causing enlargement of the spinal cord from D9–10 to L1–L2. The lesion was hyperintense on T2-weighted images and showed a heterogeneous pattern of contrast enhancement. The patient improved to some extent without treatment and two weeks later she was transferred to our Neurology Department. Control MRI revealed slight decrease of the spinal enlargement and CSF analysis showed lymphocytic pleocytosis and elevated protein. Brain MRI, somatosensory evoked potentials of the lower limbs, and blood analysis including cyanocobalamine levels and autoimmunity were normal, and infectious serologies were negative except for schistosomiasis serology which came back positive.

A diagnosis of spinal schistosomiasis was established based on epidemiologic and imaging features, supported by a positive schistosomiasis serology and exclusion of other causes. Treatment consisted of an antihelminthic and corticotherapy according to guidelines, as well as physical rehabilitation. On reevaluation 7 months later there was clinical improvement and imagiological resolution.

Conclusion: Spinal schistosomiasis is rarely encountered in developed countries, making diagnosis challenging. Epidemiologic and imaging features are essential for diagnosis, leading to prompt treatment and improved prognosis.

Work stress in health care workers in Hospital El Idrissi
M. Bakrim, R. Bousalham, A. Mesfioui. Ibn Tofail University, Kenitra, Morocco

Background: Health care workers are strongly exposed to work stress, their conditions of work and multiple other factors increase their susceptibility to this adjustment disorder. Our work is an epidemiological study designed to assess the state of total health, to identify risk factors of stress, its consequences among hospital staff in of the region of Gharb Cherarda Beni Hsen (Morocco).

Methods: This study is a survey based on a questionnaire covering the Total Health Test (TST) and the Global Stress Index (GSI), distributed to doctors and nurses of the CHR and collected for statistical analysis.

Results: Our results have shown the involvement of socio-demographic factors relating to professional careers in the initiation and maintenance of stress. Our study showed the dissatisfaction of health workers, particularly females, towards working conditions. Moreover, a majority of respondents, regardless of their profile, have high TST scores reflecting an alarming exposure to stressful factors.

Conclusion: Aware of the scarcity of works dealing with stress of health care staff in morocco and negative impact that this stress has in terms of morbidity and mortality, our work aims to improve the quality of hospital work in the Gharb region and this by understanding and reducing risk factor of this disease.

Clinical features of aseptic meningitis
D. Fujii, H. Mori, K. Shindo. Department of Neurology, Kurashiki Central Hospital, Kurashiki-shi, Japan

Background: Aseptic meningitis is a self-limited common disease. But there are few reports about the clinical course, the laboratory
Patients and methods: We retrospectively analyzed the clinical features of the patients with aseptic meningitis who admitted to our hospital from January 2003 to December 2012. Evaluated points were the mean length of hospital stay and that of febrile state, meningeal irritation sign (jolt accentuation of headache, neck stiffness and Kernig’s sign), laboratory findings (white blood cells, C-reactive protein, etc.), and cerebrospinal fluid examination (cells, sugar). We compared these points to those of control patients.

Results: 251 patients (134 males, mean age 34.7 years) and 221 control patients (115 males, mean age 35.8 years) were enrolled. The mean length of hospital stay was 13.8 days, and that of febrile state was 6.8 days. Jolt accentuation of headache was present 82% vs. 60% (the patients vs. the controls). Neck stiffness was 65% vs.40%. Kernig’s sign was 31% vs. 21%. Sensitivity of jolt accentuation of headache was 0.82, specificity 0.31. Neck stiffness was 0.65/0.60 and Kernig’s sign was 0.31/0.79 retrospectively. Aseptic meningitis patients had lower white blood cell count (7209 ± 2568 vs.9479 ± 4118/mm3, Pb0.01). C-reactive protein was 4.96 mg/dL, p<0.01). We compared these findings to those of control patients.

Conclusion: Jolt accentuation of headache is not useful for diagnosis of aseptic meningitis because of its low specificity. Almost normal white blood cell and C-reactive protein are common findings in aseptic meningitis.

Methods: Twenty three children (ages 7–12 yrs, 11 ADHD patients, 12 controls) were examined as follows: all subjects were scanned while in the supine position with thighs relaxed and parallel to the magnet magnetic field direction. Images were acquired on a 1.5 T imager. Diffusion weighted gradients were applied along 15 non-collinear directions with a b-value = 800 s/mm². High-resolution images were acquired using 3DT1. Segmentation of the cerebellum CB was manually drawn on midline sagittal 3D-T1 images.

Results: Shows tract distribution in ADHD and healthy controls. We present preliminary results of white matter connectivity of tracts connected cerebellum-prefrontal area. There were no discernible ADHD-Control changes in ADC values along the connected white matter (Fig. 2) while generalized fractional anisotropy is increased (p = 0.08), as it was reported in recent literature [1]. Length of tracts vs ADC is shown in Fig. 3. In summary, as the study progresses, MD, l1, l2, and l3 will be used in order to further examine frontal-cerebellum tracts in patients with ADHD.

Resting state in Latin American child with ADHD
E. Barragán1, H. Silvia2, D. Pilar3, D.C.A. Benito1.1Neurology Department, Hospital Infantil de México Federico Gómez, Ciudad de México, Mexico; 1Imaging Department, Hospital Infantil de México Federico Gómez, Ciudad de México, Mexico; 2Faculty of Physics & Mathematics, BUAP, Puebla, Mexico City, Mexico

Objectives: ADHD is a neurological disorder in children. This illness is considered to be 80% originated by genetic factors. Here we compared infant Latin ADHD patients with healthy ones. We discuss the differences with previous studies that used different genetic pools.

Methods: 30 volunteers (8.4 ± 2 years, both sexes) were divided in two groups, healthy (H) and ADHA (AD). Volunteers laid in an MR scanner in silence while 150 brain volumes covering the whole of the brain were acquired. Resting state analysis was performed using DPARSF software. Low frequencies under 0.08 Hz were kept.

Results: Figure 1A and 1B present the results of a comparison between H and AD patients (H > AD in green and AD > H in red). H subjects presented strong left lateralization (80% vs. 20% structures). AD patients presented a stronger right lateralization (55% vs. 45%).

Conclusions: AD patients had a larger predominance of right hemisphere activations over left in contrast to healthy subjects. Previous work has reported strong involvement of the brain stem and the anterior cingulate gyrus for AD patients compared to H which we did not find. Never reported correlations with the frontal gyrus and the posterior cingulate cortex were found. Considering that similar analysis methods were followed as in previous studies, we believe that the differences shown arise by the different genetic origin of volunteers.

Clinical features of myelopathies: A cohort study in Tunisia
J. Ketata, F. Nabli, S. Ben Sassi, F. Bentari. National Institute of Neurology, Tunis, Tunisia

Introduction: Myelopathies represent a heterogeneous group of disorders with distinct etiologies, clinical and radiologic features, and prognoses, characterized by spinal cord dysfunction resulting in paresis, sensory level, and autonomic (bladder, bowel, and sexual) impairment.

Objective: The aim of this study was to determine the clinical characteristics and the management of patients with myelopathy.

Patients and methods: We conducted a retrospective study using population-based information from medical records of 100 patients with myelopathy, hospitalized in the neurology department at the National Institute of Neurology in Tunis over a period of 12 years.

Results: The mean age of patients was 38 years (9–76 years) with a sex ratio of 1.43. Most patients had a severe motor deficit. CSF studies revealed hyperproteinorachia in most patients and were normal in 31 cases. MRI showed a spinal hypersignal in almost all cases and was normal in 9 patients. Etiologies were dominated by infectious and dysimmune disorders. Intravenous methylprednisolone (1 gr/day for 3 to 5 days) was indicated for 55 patients, and an intravenous immunoglobulin cure was used in two cases. Rapid clinical improvement was observed in 33.3% of patients with full recovery in 4 patients.

Conclusion: In non-compressive myelopathies, an extensive work up is needed in order to distinguish between demyelinating, infectious, other inflammatory, vascular, neoplastic, and paraneoplastic etiologies. An algorithm for the diagnosis and management of myelopathies is necessary.

Prediction of trochlear nerve absence by superior oblique muscle volumetry in congenital superior oblique palsy
J.-M. Hwang, J.-M. Hwang, H.K. Yang, D.S. Lee, J.H. Kim, C. Kee. Seoul National University College of Medicine, Seoul National University Bundang Hospital, Seongnam, Republic of Korea; Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea

Purpose: To determine the predictability of superior oblique muscle volumetry in diagnosing trochlear nerve absence in patients with congenital superior oblique palsy (SOP).

Methods: Retrospective study of congenital SOP patients with (present group, n = 38) and without a trochlear nerve (absent group, n = 87) and controls (n = 34) using high-resolution magnetic resonance imaging (MRI) to analyze superior oblique muscle volume (SOV) and trochlear nerve absence.

Results: The paretic side SOV and normal side SOV were not significantly different in controls (p = 0.536) and in the present group (p = 0.750). However, in congenital SOP patients of the absent group, the paretic side SOV was significantly smaller compared to the normal side (p < 0.001). The cut-off value of paretic/normal side SOV ratio for diagnosing trochlear nerve absence was ≤0.75 (sensitivity 100%, specificity 100%).

Conclusion: In congenital SOP patients, the paretic/normal side SOV ratio has an excellent predictability in diagnosing trochlear nerve absence.

Relationship between the trochlear nerve diameter and superior oblique muscle volume
J.-M. Hwang, H.K. Yang, D.S. Lee, J.H. Kim, C. Kee. Seoul National University College of Medicine, Seoul National University Bundang Hospital, Seongnam, Republic of Korea; Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea

Purpose: To determine the relationship between the trochlear nerve diameter (TD) and superior oblique muscle volume (SOV) in patients with congenital superior oblique palsy (SOP).

Methods: Retrospective study of congenital SOP patients with (present group, n = 38) and without a trochlear nerve (absent group, n = 87) and controls (n = 34) using high-resolution magnetic resonance imaging (MRI) to analyze superior oblique muscle volume (SOV) and trochlear nerve absence.

Results: The non-paretic side TD (npTD) of the absent group was smaller (p = 0.04) and npTD of the present group was larger than the TD of controls (p = 0.047). SOV positively correlated with the TD of controls (p = 0.029), npTD of the present group (p = 0.02) and npTD of the absent group (p = 0.008).

Conclusion: The npTD was smaller in the absent group and larger in the present group compared with controls. The TD of controls and npTD of congenital SOP patients positively correlated with the SOV.

The relationship between optical coherence tomographic and perimetric findings in patients with papilledema
M. Morrow. Neurology, Harbor-UCLA Medical Center, Torrance, CA, USA

Background: Optical coherence tomography (OCT) provides quantitative ocular imaging in conditions causing optic neuropathy.

Objective: We compared measures of retinal and optic nerve head (ONH) anatomy to standard perimetry in patients with papilledema associated with intracranial hypertension.

Patients: We studied 69 eyes in 26 patients with papilledema (85% idiopathic intracranial hypertension) and no alternative ocular pathology. 14 patients were tested twice, at least 3 months apart.

Methods: Using spectral-domain OCT, we quantified retinal nerve fiber layer (RNFL) thickness, total macular volume and ONH volume in each eye and compared values with standard automated static perimetry.

Results: For most eyes, there was no relationship between the degree of RNFL or ONH swelling and perimeter mean deviation. In this group, even eyes with severe swelling showed normal or only mildly reduced mean deviations and RNFL thickness demonstrated a positive linear correlation with ONH volume. In a smaller group of eyes with ONH volumes at the lower end of the supranormal range, however, RNFL thickness and macular volume were paradoxically subnormal and perimeter showed moderate to severe impairment. In 4 eyes of this latter group, serial testing showed stable or improved visual fields despite declining RNFL thickness within the subnormal range.

Conclusions: Quantitative measures of tissue swelling do not correlate with visual field loss in most patients with papilledema. In a minority of eyes, RNFL and macular thickness may be reduced despite optic disk swelling, implying a combination of swollen and damaged axons. Further RNFL thinning may not portend visual field deterioration.

Biomarker development on alcohol addiction using EEG
P.L. Vuong, L. Xia. Electrical and Electronics, UTP, Tronoh, Malaysia

Alcohol addiction is harmful to society, economy and personal health. Alcohol addiction treatments intend to help addicted individuals reduce and stop compulsive alcohol use. Using biomarker, the clinicians could determine if drugs are having a desirable effect much earlier and given in correct dose for alcohol addiction treatment. This paper focuses on the usage of electroencephalography (EEG) to develop biomarker for alcohol addiction treatment including EEG methodologies and their applications.

Chronic Ritalin administration during adulthood increases serotonin pool in rat medial frontal cortex
A. Nahavandi. Iran University of Medical Sciences, Tehran, Iran

Background: Ritalin is a type II medication with a high tendency to be abused. It has been the main indication to control ADHD and/or treatment of major depression. As the college students may seek for it to improve memory, decrease the need for sleep and improvement the sense of well being (especially during exams), which all at least partially, related to serotonergic system activity, it seems worthy to evaluate the effect of Ritalin intake on a mature, brain. Although there are many studies about the effects of Ritalin on developing brain, only few studies on adults are available. The aim of present study is to find out if Ritalin can affect the SERT (serotonin transporter) density in mature medial frontal cortex or not.

Funicular myelosis with complete favorable evolution. Case report
F.D. Lima, A.A.V.O. Sousa, K.M.D.S. Franco, J.R.S. Carvalho,
aUniversidade do Estado do Pará, Brazil; bNeurology, Universidade do Estado do Pará, Belém, Brazil

Background: Vitamin B12 deficiency may present neuropsychiatric disorders. The most common is the subacute combined degeneration of the spinal cord, affecting mainly the lateral and posterior columns of the spinal cord.

Objective: Report a case of funicular myelosis by vitamin B12 deficiency in a male patient.

Material and methods: Laboratory exams were collected, such as dosage of vitamin B12, folic acid, HIV and cytomegalovirus serology, among others. Additionally image exams were done, as MRI with contrast of cervical and thoracic spine during the diagnosis and after treatment.

Results: The patient’s age was below the incidence peak of the disease, with progressive neurological deficits in six months. Surgical etiology, infectious or chronic diseases were discarded. He presented typical involvement of posterior and lateral cords of the spinal cord associated with Babinski, Romberg and Lhermitte signs. Tests showed no anemia (probably as result of previous treatments), macrocytosis, vitamin B12 deficit and seropositive for cytomegalovirus. On MRI, there were hypointense signals in posterior cervical and thoracic levels bilaterally on T2 sequence. Replacement of vitamin B12 was done, achieving complete recovery of neurologic deficits, keeping only residual cramps in the abdomen.

Conclusion: There was a complete recovery of neurologic deficits, despite the presence of Romberg and Babinsky signs, that is different from what the literature suggests. This finding may be due to patient age, under 50 years, which allows greater neuronal plasticity as described in other studies as well as for the rapid completion of treatment, even in the first six months of evolution.

Experience with rTMS in refractory cases on a third-world reference private hospital

Introduction: rTMS consists in a repetitive magnetic discharge circumscribed to a cortical brain area and subjacent subcortical structures aimed to modulate the local and distant brain activity. Constant neuronal and network activation will progressively change the basal activity. fMRI has shown changes in the connectivity strength of involved neuronal networks. rTMS effects have been described on different neuropsychiatric disorders: neuropathic pain, fibromyalgia, depression, OCD, stroke rehabilitation.

Methods: We report the experience of 1 year using rTMS on patients with refractory conditions in a third world reference private hospital.

Results: From December 2011 to December 2012 our department received 10 patients with refractory cases of neuropathic/neurogenic pain (5 patients), OCD (3 patients) and depression (2 patients). All were evaluated before and after treatment with Hamilton depression rating scale, SF-36, and Neo-FRI-R. Pain patients were also evaluated with an analog visual scale for pain, and OCD patients were evaluated with Maudsley OC Inventory. 7 of these 10 patients showed a positive result (at least a 50% improvement on the appropriate scales – pain, MOCI, HDRS – plus improvement on quality of life scales); 2 patients showed no significant improvement and 1 showed mixed results (improvement on MOCI without improvement on quality of life).

Conclusions: rTMS is a relatively underutilized tool that may be useful for the treatment of refractory cases of neuropathic pain, depression and OCD, even in an underdeveloped country.

Hemispheric Arteriovenous Malformation (AVM): A case report

C.M. Hernández, M.A. Sierra-Beltrán, J. Santos-Franco, Critical Care Medicine, INCMNSZ, Mexico; aAnesthesiology, Medica Sur Hospital, Mexico City, Mexico; bIntegral Diagnosis and Treatment Centre, Medica Sur Hospital, Mexico City, Mexico; cNeurosurgery, Medica Sur Hospital, Mexico City, Mexico

Background: Hemispheric AVM are rare and represent a serious therapeutic challenge, nowadays endovascular intervention has improved their survival and the secondary co-morbidity.

Objective: To present a 20 year old woman suffering Subarachnoid Hemorrhage (SAH) due a right Hemisphere AVM.

Materials and methods: CT, MRI scans and Cranial Arteriography were required.

Results: CT scan showed a SAH, while the MRI scan did show a parenchymal bleeding in a further study, Intracranial Arteriography demonstrated a massive AVM on the Cerebral Right Hemisphere.

Conclusions: The patient underwent three subsequent immobilization endovascular procedures and as a result there is no neurological deficit.

Injuries to patients and their bedpartners are frequent in REM sleep behavior disorder

E.K. St. Louis, Neurology and Medicine, Mayo Clinic, Rochester, MN, USA

Objective: REM sleep behavior disorder (RBD) is widely recognized to involve potentially injurious dream enactment behaviors (DEB). However, specific clinical factors associated with RBD-related injuries remain largely unknown. We aimed to identify injury predictors in RBD.

Methods: We surveyed consecutive RBD patients seen at Mayo Clinic between 2008 and 2010 regarding RBD-related injuries, and reviewed medical records to determine idiopathic (iRBD) or symptomatic RBD diagnosis. Associations between injuries prior to treatment and demographic, clinical, and medication variables were then determined with odd’s ratios and multiple logistic regression analyses. The primary outcome variables were injury and injury severity.

Results: Fifty-three (40%) responded. Mean age was 66.2 years and 35 (75%) were men. 23 (43%) had symptomatic RBD. Twenty-nine (55%) reported injury, including self (37.8%) and bedpartner (16.7%) injury. iRBD diagnosis (OR = 7.7, p = 0.002) and dream recall (OR = 10.3, p = 0.002) were associated with injury, and iRBD diagnosis was independently associated with injury and injury severity, adjusting for age, gender, and DEB frequency. Falls during DEB (p = 0.03) were also associated with more severe injury, while DEB frequency was not associated with injury, injury severity, or falls.

Conclusions: Injuries are a frequent complication of RBD. iRBD patients are more likely to suffer injury than symptomatic RBD patients. Recall of dreams was also associated with injury, and DEB-related falls were associated with more severe injuries. DEB frequency did not predict RBD-related injuries, highlighting the importance of timely initiation of treatment for RBD in patients having even rare DEB episodes.

Plasmodium falciparum histidine-rich protein-2 (pHRP-2) is a cerebrospinal fluid (CSF) biomarker for cerebral malaria (CM)

K.T. Thakur, K. Mikiita, K. Piera, C. Pardo-Villamizar, J.B. Weinberg, N.M. Anstey, J. Mukemba, S. Florence, E.D. Mwaikambo, D.L. Granger, D. Sullivan, Department of Neurology, Johns Hopkins Hospital, USA; Johns Hopkins School of Public Health, Malaria Research Institute, Baltimore, MD, USA; Menzies School of Health Research, Charles Darwin University, Kent Town, SA, Australia; Duke Medical Center, Durham, NC, USA; Veterans Affairs Medical Center, Durham, NC, USA; Hubert Kairuki Memorial University, Dar Es Salaam, Tanzania; University of Utah Health Sciences Center, Salt Lake City, UT, USA; Veterans Affairs Medical Center, Salt Lake City, UT, USA

Background: Cerebral malaria (CM) causes a rapidly developing comatose state and remains a major contributor to morbidity and mortality in malaria-endemic regions. CM may be diagnosed during life by the presence of Plasmodium falciparum parasitemia, clinical assessment and retinal changes. The plasma level of pHRP-2, a malaria histidine- and alanine-rich protein, identifies children with histologically confirmed or retinopathy-positive CM with high specificity and sensitivity. We sought to determine whether pHRP-2 levels in the CSF were detectable in CM cases.

Materials and methods: The immuno-PCR technique was adapted for malaria use by coupling a 60 base pair oligonucleotide to a monoclonal HRP2 antibody. The limit of detection was demonstrated to be 1 pg per sample with specificity over 90%. The immuno-PCR test was used on 84 CSF samples from Tanzanian CM patients and 33 non-malaria control samples.

Results: In our patient cohort, CSF pHRP-2 was present by a novel immuno-PCR in 98% (82/84) of CM samples. The geometric mean pHPR-2 concentration in CSF was 20 pg/µl with a mean and median of 10 pg/µl. A rapid diagnostic test (RDT) was positive in 81% (68/84) of the samples. In 11 matched plasma and CSF samples of CM patients, the ratio of plasma to CSF pHPR-2 was 168. The 33 non-malarial control samples did not have detectable levels of CSF pHRP-2.

Conclusions: pHRP2 is present in the CSF of patients with CM. Further studies are needed to determine the utility of CSF pHRP-2 testing in malaria-endemic regions.

HbA1c is associated with sural nerve regeneration and degeneration in diabetic neuropathy

J. Hur, K.A. Sullivan, R. Pop-Busui, B.C. Callaghan, E.L. Feldman, Neurology, University of Michigan, Ann Arbor, MI, USA; Internal Medicine, University of Michigan, Ann Arbor, MI, USA

Background: Diabetic neuropathy (DN) is the most common, debilitating, and costly complication of diabetes. Patients with DN demonstrate variable degrees of nerve regeneration and degeneration; however, risk factors affecting these processes are not understood.

Objective: To identify risk factors closely associated with nerve regeneration in patients with DN.

Materials and methods: We retrospectively examined demographic, anthropometric and biochemical data of diabetic subjects from a double-blind, placebo-controlled, 52-week trial of acetyl-l-carnitine. Based on the change of sural nerve myelinated fiber density (DMFD%), subjects were designated as Regenerator (top 16 percentiles, n = 67),
Degenerators (bottom 16 percentiles, n = 67), or Intermediate (n = 290), with dramatically increased, decreased, or steady DMFD,% respectively. Fisher's exact test, ANOVA, and multifactorial logistic regression analyses were performed to identify significant risk factors. A preliminary microarray experiment was also performed on a subset of samples to identify regeneration-related genes and pathways.

**Results:** DMFD% were 35.6 ± 17.4 (Regenerator), −4.8 ± 12.1 (Intermediate), and −39.8 ± 11.0 (Degenerator). HbA1c at baseline was the only risk factor significantly different between Regenerator (8.3 ± 1.6%) and Degenerator (9.2 ± 1.8%). Support Vector Machine classifier using HbA1c alone demonstrated 62.4% accuracy of classifying subjects into Regenerator or Degenerator. Gene expression studies revealed that up-regulated genes in Regenerators are enriched in cell cycle and myelin sheath functions, while down-regulated genes are enriched in immune/inflammatory responses.

**Conclusions:** Our data suggest that HbA1c level predicts myelinated nerve fiber regeneration and degeneration in patients with DN, and that maintaining optimal blood glucose control is essential to prevent continued nerve injury in patients with DN.

**Epigenetic miRNA dysregulation as a mechanism for sporadic amyotrophic lateral sclerosis**

C. Figueroa-Romero, J. Hur, D.E. Bender, M.D. Cataldo, A.L. Smith, R. Yung, B.C. Callaghan, E.L. Feldman, Neurology, University of Michigan, Ann Arbor, MI, USA; Internal Medicine, University of Michigan, Ann Arbor, MI, USA

**Background:** Amyotrophic lateral sclerosis (ALS) is a progressive and fatal neurodegenerative disease. The majority of cases are sporadic (sALS) with unknown causes, and the late onset of sALS suggests that long-term exposure to environmental factors may play a role in disease pathogenesis. Epigenetic mechanisms, such as miRNAs, may be driven by adverse environmental factors proposed to contribute to sALS etiology to promote an accumulation of altered gene expression, culminating in sALS.

**Objective:** Our goal is to address the role of miRNAs in sALS pathogenesis. We hypothesize that differential expression of miRNAs in human sALS spinal cord promotes dysregulation of key genes and biological pathways leading to sALS.

**Materials and methods:** We combined two high-throughput profiling assays to identify differentially expressed miRNAs (TaqMan OpenArray) and differentially expressed genes (DEGs; Affymetrix GeneChip Human Genome U133 Plus 2.0 Array) in postmortem human spinal cord tissue from sALS patients and controls. Since miRNAs negatively regulate gene expression, inverse correlations between miRNA and DEGs were identified and examined with multiple miRNA prediction target databases to determine potentially relevant miRNA/DEG pairs. Gene and miRNA expression was confirmed by qPCR.

**Results:** We identified 90 differentially expressed miRNAs and 1182 DEGs. Of these differentially expressed miRNAs and DEGs, prediction databases identified miR-125B, let-7 miRNA family members, miR-133b, and miR-140-5p as potential miRNA regulators of the gene targets FAS, CD4, EIF2C4, and CCL2.

**Conclusion:** Changes in miRNAs and their corresponding gene targets may represent, in part, a pathogenic mechanism leading to sALS.

**Spontaneous remission and relapse of primary central nervous system lymphoma: Case report and review**

J. Vilacura, F. Montoya, P. Silva, M. Rivera, Universidad de los Andes, Clinica Davila, Santiago, Chile

There are numerous reports of lesions affecting the central nervous system which disappear without treatment. They are called vanishing tumors. The most common of these is the primary central nervous system lymphoma, which accounts for 4% of all intracranial neoplasms. There are other factors that induce remission such as corticosteroid therapy, chemotherapy and radiotherapy. However, many of these vanishing tumors relapse. We present the case of a 58 year old, male patient who presented with partial third cranial nerve palsy. The brain MRI showed a periventricular mass and the biopsy was informed as diffuse large B-cell non-Hodgkin lymphoma. A control MRI was requested displaying complete disappearance of the mass. Patient was followed during 3 months with MRI, full body CT and lumbar puncture showing no evidence of the disease. One year after discharge patient presented with subtle memory alterations and progressive temporal–spatial disorientation. MRI showed a heterogeneous, hypointense, expansive process with left temporal periventricular epicenter. Spectroscopy was suggestive of lymphoma. Thoracic, abdominal, and pelvic CT scans evidenced an L1 lumbar fracture; MRI was suggestive of lymphoma metastasis. Daily methylprednisolone pulses were initiated and treatment with Methotrexate, Cytarabine and Leucovorine was begun, with clinical improvement. Many reports present relapsing vanishing tumors, suggesting that full therapy should be initiated in spite of spontaneous remission. Clinical trials should be performed in order to prove the effectiveness of this proceeding.

**Syndroma Brown-Séquard as a rare manifestation of von Hippel–Lindau disease**

I. Marjanovic, M. Jecmenica-Lukic, M. Milicev, S. Peric, I. Basta, Z. Stevic, V. Rakovic-Stojanovic, L. Lavric, D. Lavrinic, Clinical Neurology, Clinical Centre of Serbia, Serbia; Mri Center, Clinical Center of Serbia, University of Belgrade, Belgrade, Serbia

**Case report:** We report a 45-year-old female patient with Brown-Séquard Syndrome (BSS). The onset of disease was 14 years before admission to our Department, during the first pregnancy, when she felt thoracic pain. Five years later, during the next pregnancy, she felt numbness at umbilical region and drop of right foot, but all symptoms disappeared spontaneously 10 days after delivery. MRI of thoracic spine showed syrinx from Th5 to L1. Now, at the admission neurological examination revealed spasticity, increased muscle reflexes and positive Babinski’s sign on the right leg, with ipsilateral loss of tactile discrimination, vibratory, and position sensation below the level of right rib arch. Contralaterally there was reduction in pain and temperature sensation below the level of Th8. MRI of thoracic spine showed multiple intradural nodular tumors at the levels of Th3–5 and Th11 with hydroxyringomyeloma in whole spinal cord. MRI of the brain showed multiple hemangioblastomas in the cranio cervical region with spreading at the level of C1 and in both cerebellar hemispheres. Multi-slice computed tomography (MSCT) of abdomen showed multiple pancreatic cysts and suspected liver hemangioma. Ophthalmological, otological and gynecological findings were normal. Genetic analysis
revealed a deletion in von Hippel-Lindau (VHL) gene 2 exon at codon 128. It was made a diagnosis of de novo VHL disease type I (without pheochromocytoma).

Conclusion: Hemangioblastomas of the spinal cord are a rare cause of BSS, especially as a manifestation of VHL disease. Detection of these tumors and their removal could contribute to the improvement of neurological finding and prevention of further complications.

Non-invasive detection of cortical population spikes: Functional discrimination of pre- vs. postsynaptic components in SEP at 1 kHz

Introduction: Ultrafast EEG signals, featuring frequencies above 500 Hz, can be observed in scalp somatosensory evoked potentials (SEP). Usually, these recordings have a low Signal-To-Noise Ratio (SNR) because weak signals are overlaid by intrinsic noise of much higher amplitude as generated by biological sources and the amplifier. Scalp recordings of SEP show bursts above 400 Hz with submicro-volt amplitudes, which could be extracted from noise up to now only by the use of massive averaging (n > 1000) and digital signal processing.

Methods: Here, we investigate SEP up to 1 kHz elicited by median nerve stimulation with rates of either 0.99 Hz or 8.1 Hz. We exploit the increased SNR provided by a custom-made low noise amplifier technology together with an adapted implementation of Canonical Correlation Analysis algorithm, based on the assumption of high level stimulus phase locking across trials.

Results: It proved possible in 3/3 subjects to discriminate hf-SEP generators at subcortical and intracortical levels at the single trial level, relying on the different neuronal refractory properties of these components which are phase-locked to the stimulus onset.

Discussion: A custom-made low-noise EEG system enables the noninvasive detection of pre- and postsynaptic evoked activity at 1 kHz, i.e., in the frequency range housing spike-related multi-unit activity in intracortical recordings, providing the opportunity of non-invasive monitoring of multi-unit spike activity in man.

Treatment for paraneoplastic neuropathies

B. Giometta3, R. Vitaliania, W. Grisold4. "Neurology, Azienda ULSS 9 Treviso, Treviso, Italy; "Neurology, Ludwig Boltzmann Institute for Experimental and Clinical Traumatology, Vienna, Austria"

Paraneoplastic neuropathies are the most frequently reported paraneoplastic syndromes. They are, however, heterogeneous and require several therapeutic approaches. This review was undertaken to...
systematically assess any data available from randomised controlled trials (RCTs) on the treatment of paraneoplastic syndromes of the peripheral nervous system.

**Objectives:** To assess the benefits and harms of treatments for paraneoplastic neuropathies.

**Selection criteria:** We planned to include all RCTs and quasi-RCTs (in which allocation is not random but is intended to be unbiased, for example alternate allocation) of any treatment for paraneoplastic neuropathies. Since we expected that there are to be few or no included studies, we also planned to assess and summarise observational studies, prospective and retrospective comparative cohort studies, case–control studies and case series that met minimum criteria in the discussion.

**Main results:** Despite many reports on paraneoplastic neuropathy, we identified no RCT or quasi-RCTs for inclusion in this review. We found only six studies, involving 54 participants, from among the non-randomised evidence that were judged by predefined criteria to be of suitable quality for inclusion in the discussion. These studies were not readily comparable. The treatments focused on tumour treatment and immunomodulation, mainly intravenous immunoglobulin.

**Authors’ conclusions:** At present there are no RCTs or quasi-RCTs of treatment for paraneoplastic neuropathies on which to base practice. There is only evidence from case series, case reports or expert opinion (class IV evidence) for the effect of immunomodulation (intravenous immunoglobulin, plasma exchange, steroid treatment or chemotherapy) on paraneoplastic neuropathy.

**NMDA-receptor mediated excitotoxicity is involved in the pathogenesis of experimental cerebral malaria**

K.M. Wechselberger a, B. Taferner b, R. Beer b, G. Broessner b, R. Helbok a, M. Fischer a, N. Singewald b, E. Schmutzhard a, P. Lackner a*, a Translational Neurocritical Care, Department of Neurology, Medical University Innsbruck, Austria; b Universität Innsbruck, Innsbruck, Austria

A major cause of morbidity and mortality of *Plasmodium falciparum* malaria is cerebral malaria (CM). Mortality is high and neurological sequelae are observed frequently. A deeper understanding of the pathophysiology is missing yet. In addition to ischemia and inflammation, excitotoxicity might be an important factor. The current study investigates the role of NMDA-receptor mediated excitotoxic cell death during CM and its potential for the development of adjunctive treatment strategies.

C57BL/6j mice were infected with *Plasmodium berghei* ANKA. Cerebral Microdialysis was performed and glutamate levels were measured. Animals with CM were randomized for treatment with artesunate, MK801 (a non-competitive NMDA-receptor antagonist), artesunate and MK801 or vehicle over 5 days. Glutamate levels were significantly elevated in mice with CM compared to control animals. Subsequently NMDA antagonisation was investigated. Twenty-eight animals were randomized. No animals survived in the MK801 or vehicle treated group. In contrast, 33.3% of the animals in the artesunate group and 74.1% in the MK801/artesunate combination treatment group survived. Kaplan Meier survival curves yielded a significantly longer survival of the animals in the combination treatment group compared to the vehicle or MK801 treatment group. Histological analyses yielded a lower number of micro-hemorrhages and Fluoro-Jade B positive cells in the artesunate/ MK801 treated animals compared to artesunate treated mice. In conclusion, glutamate levels in the brain are increased early in the course of CM.

Treatment with MK801 rescues mice from CM. NMDA-receptor mediated excitotoxicity plays a role in the pathogenesis of CM and could represent a target for adjunctive treatment strategies.

**The effect of stress on long-term memory consolidation: An update**

R. Patel, Basildon Hospital, Basildon, UK

**Background:** It has long been recognised that stress has a profound effect on long-term memory consolidation. The past decade has seen substantial growth in efforts to characterise this relationship. Numerous potential mechanisms have been highlighted, involving biochemical regulators of emotional arousal and specific neural pathways. More recently, research has led to increased understanding of interactions between regions of the brain previously not acknowledged to contribute to memory consolidation.

**Objectives:** We present a systematic review to expound the prevailing theories behind this relationship, in addition to the supporting experimental evidence and potential clinical implications.

**Materials and methods:** The review was performed using Medline/PubMed and Embase, using search terms [(stress) AND (memory)], under constraints of “English language” and “humans”.

**Results:** Behavioural and physiological evidence has begun to establish a convincing role for stress; consistently demonstrating enhanced memory under stressful conditions. Wide support is found for effects of epinephrine and glucocorticoids on consolidation, in addition to electrophysiological evidence for specific neural influences. Functional imaging advocates an interaction between the basolateral amygdala, nucleus accumbens and locus coeruleus with the hippocampus, although uncertainty prevails regarding the pathways involved. Clinical implications of the stress–memory relationship are undoubtedly far-reaching, and are discussed herein.

**Conclusions:** Although precise mechanisms by which stress affects memory remain unclear, the advent of functional neuroimaging and growing interest in memory consolidation has produced rapid advances in understanding. Research clarifying the relationship between stress and memory consolidation undoubtedly merits further attention given the additional insights provided by these advances and their significant therapeutic potential.

**Comorbidities and mortality associated with intracranial bleeds and ischaemic stroke**

J. Sangha a, A. Natalwala b, H. Uppal b, R. Potluri b, a University of Birmingham, Birmingham, UK; b Queen’s Medical Centre, Nottingham, UK; Coventry and Warwickshire Partnership NHS Trust, Coventry, UK; d University of Manchester, Manchester, UK

**Background:** Stroke is a leading cause of mortality and acquired disability, however to date, there exists no comprehensive comparison of risk factors between stroke sub-types.

**Objective:** The aim of the present study was to compare risk factors and mortality across different intracranial pathologies; subdural haematoma, subarachnoid haemorrhage, ischaemic stroke and haemorrhagic stroke.
Patients and methods: We compiled a database of all patients (n = 4804) admitted with these conditions to a large teaching hospital in Birmingham, UK during the period 2000–2007. The ICD 10th revision coding was used to identify these cases. Multinomial logistic regression was performed to analyse differences in the frequencies of comorbidities, associations were regarded as significant when p < 0.001 only.

Results: Subdural haematoma patients had lower prevalences of hypertension and pneumonia, whereas alcohol abuse was more common. In subarachnoid haemorrhage, epilepsy was less frequent (OR: 0.37; CI: 0.22–0.64). As would be expected, a range of cardiovascular risk factors were more common in ischaemic stroke including for example type II diabetes mellitus and ischaemic heart disease. Brain tumours were more common in haemorrhagic stroke. There was no difference in the duration of hospital stay between the four groups. Mortality was significantly higher in ischaemic and haemorrhagic strokes, and the duration to death was greater in ischaemic stroke.

Conclusion: Our findings provide novel associations to inform the preventative measures undertaken by healthcare professionals and this may lead to more rigorous control of risk factors. Further studies are required to elucidate the mechanisms by which subarachnoid haemorrhage protects against epilepsy.

Predictors of mortality in ischaemic stroke patients — A hospital admissions study: 2000–2012
R. Potluri1, J. Sangha2, H. Uppal3, 4University of Manchester, Manchester, UK; 5University of Birmingham, Birmingham, UK; 6Coventry and Warwickshire Partnership NHS Trust, Coventry, UK

Background: Ischaemic Stroke is a leading cause of mortality and morbidity in the UK, accounting for 9% of all deaths.

Objective: We aimed to identify predictors of mortality in Ischaemic Stroke patients, in a large hospital population in the UK.

Patient and methods: Anonymous information on patients with Ischaemic Stroke, attending a large multi–ethnic general hospital in Manchester, UK during the period 2000–2012 was obtained from the hospital activity analysis register using ICD-10 and OPCS coding systems. Statistical analysis was performed using SPSS version 20.

Results: Out of 458,410 patients admitted, there were 3541 (0.8%) patients with Ischaemic Stroke; mean age 69.7 yrs ± 14.6 (SD). The main comorbidities were Hypertension (48.5%), Type 2 Diabetes Mellitus (21.5%), Atrial Fibrillation (18.7%), Hyperlipidaemia (15.3%), Myocardial Infarction (11.2%), and Heart Failure (9.2%). A multinominal logistic regression model accounting for variations in age, sex and ethnic group showed that Hypertension (OR: 0.8; CI: 0.7–0.9), Type 2 Diabetes Mellitus (OR: 1.2; CI: 1.0–1.5), Atrial Fibrillation (OR: 1.4; CI: 1.2–1.8), Hyperlipidaemia (OR: 0.4; CI: 0.3–0.6), Heart Failure (OR: 3.0; CI:2.2–4.1) and Duration of stroke (OR: 1.0; CI: 1.0–1.0) as significant predictors of mortality (p < 0.05).

Conclusion: We have shown that Hypertension, Type 2 Diabetes Mellitus, Atrial Fibrillation, Hyperlipidaemia, Heart Failure and Duration of stroke are significant predictors of mortality in patients with Ischaemic Stroke from a large hospital based sample in the UK. Our improved understanding of these predictors will guide clinicians to focus on these high risk groups to improve clinical practice and outcomes in patients with Ischaemic Stroke.

Waterhouse–Friderichsen syndrome induced by meningococcal meningitis in young adult with SLE
D. Athanasopoulos, A. Liverezas, D. Kitsos, C. Karageorgiou, S. Tsiraie. GNA G. Gennimatas, Athens, Greece

Background: Although patients with systemic lupus erythematosus are more susceptible to infections, meningococcal meningitis is relatively rare among these patients.

Case report: We report a case of neisserial meningitis in an 18 years old male that was under treatment for SLE (monotherapy with hydroxychloroquine). The patient presented with one day fever, headache, arthralgias, purpuric rash on two sites (right gluteal region, left arm) and neck rigidity. CSF had a cell count of 5200 RBC/μL, 25 WBC/μL with 13 NEU/μL (corrected for 20 WBC/μL) and the stain and combo tests were negative for bacteria. Both CSF and blood cultures revealed Neisseria meningitidis group B. Total blood count displayed low platelet count. Biochemistry revealed elevated creatinine and CRP. Despite the prompt diagnosis and treatment, the disease progressed rapidly with major complications, such as sepsis, DIC, purpura fulminans, myocardiopathy, respiratory distress and finally evolved to Waterhouse–Friderichsen syndrome.

Discussion and conclusion: This is a rare case of meningococcal serogroup B meningitis in a patient with SLE. In SLE meningitis, the most common pathogens are Mycobacterium tuberculosis, Cryptococcus neoformans and Listeria monocytogenes. It is interesting that the laboratory tests at presentation did not absolutely reflect the severity and rapid progression of the infection. In addition, although there are references of corticosteroid use as a predisposing factor to meningitis, there are no reports for hydroxychloroquine alone.

Brain imaging in chorea in Tunisian children
A. Nasri1, H. Benhouma2, I. Rebai3, I. Kraoua3, C. Driss3, H. Kla3, N. Ben Achour4, A. Rousii4, N. Ghouider-Khouja5, M. Ben Hammouda5, I. Turk4. 1Child and Adolescent Neurology Department, National Institute of Neurology of Tunis, Tunis, Tunisia; 2Neuroradiology Department, National Institute of Neurology of Tunis, Tunis, Tunisia

Background: Studies on brain imaging aspects of chorea are scarce, and there is no such study in Tunisia in children.

Objective: To determine imaging characteristics of chorea in Tunisian children.

Patients and methods: We conducted a descriptive study over an 8-year period (2004–2012) including all children diagnosed with chorea and followed at our department. All the patients had a brain MRI and 23 of them a brain CT-scan. The imaging aspects have been analysed.

Results: 54 children presented with chorea (sex ratio = 1:1, mean age = 7.6 years, mean age of onset = 3.1 years). Brain CT scan (23 patients) was abnormal in 18%, mainly in metabolic diseases. Brain MRI was abnormal in 74%, especially in metabolic causes (31%) and cerebral palsy (14%). Imaging abnormalities are dominated by abnormalities of the brain white matter (24%) and cortico-sub-cortical atrophy (14%). Basal ganglia (mainly putamen) and thalamus show abnormalities in only 5%, in association with other movement disorders.

Conclusion: Our study is the first to discuss imaging aspects of chorea in childhood in Tunisia. The high frequency of imaging abnormalities in metabolic diseases and cerebral palsy may be explained by the
vulnerability of basal ganglia to hypoxic-ischemia in cerebral palsy, and variations of metabolism and associated leukodystrophy in neuro-metabolic disorders. Atrophy could be a sequelae, or of degenerative origin. Therefore, brain imaging, especially brain MRI, should be done in every child with chorea.

Cortical afferent inhibition is reduced in patients with idiopathic REM sleep behavior disorder and cognitive impairment: A TMS study
A.B. Kunz, S.M. Golaszewski, J. Bergmann, F. Brigo, M. Seidl, M. Christova, F. Tezzoni, E. Trinka, R. Nardone. aDepartment of Neurology, Paracelsus Medical University, Christian-Doppler-Klinik, Salzburg, Austria; bKarl Landsteiner Institute of Neurorehabilitation and Space Neurology, Vienna, Austria; cNeuroscience Institute, Salzburg, Austria; dDepartment of Neurology, Franz Tappeiner Hospital, Merano, Italy; eInstitute of Physiology, Medical University Graz, Graz, Austria

Background: Impaired cognitive profile and electroencephalography (EEG) slowing have been reported in patients with REM sleep behavior disorder (RBD), but the neurobiological significance of these findings remains unknown. The cholinergic system is known to play a key role in all attentional processes and cognitive functions.

Objective: A transcranial magnetic stimulation (TMS) protocol may give direct information about the function of some cholinergic circuits in the human brain; this technique relies on short latency afferent inhibition (SAI) of the motor cortex. The objective of this study was to test the hypothesis that cognitive performance and cortical activation in RBD patients are associated with a dysfunction of the cholinergic system.

Materials and methods: We applied the SAI technique in a group of 10 patients with idiopathic RBD (iRBD) and compared the data with those from a group of 15 age-matched healthy subjects. All the iRBD patients and the control subjects also underwent an extensive neuropsychological evaluation.

Results: Mean SAI was significantly reduced in patients with iRBD when compared with controls. Neuropsychological examination showed mild cognitive impairment in six out of the 10 iRBD patients. SAI values correlated strongly with tests measuring episodic verbal memory and executive functions.

Conclusions: These results support the hypothesis of cholinergic dysfunction in some patients with iRBD who develop cognitive impairment. Our findings raise the possibility that the presence of SAI abnormalities may indicate increased risk of cognitive impairment in patients diagnosed with iRBD.

Identifying interactions between EphB3 and EphA4 dependence receptors using bimolecular fluorescence complementation
S. Jimsheleishvili, J. Ricard, C. Nelers, D. Liebl. University of Miami, Miami, FL, USA

Objectives: The goal of our study is to identify protein–protein interactions of membrane-bound receptor tyrosine kinases that regulate cellular functions after CNS trauma. We discovered that Eph receptors influence cell survival following CNS injury through pro-apoptotic ‘dependence receptors’, which induce cell apoptosis after cellular stress. To examine their interaction we used bimolecular fluorescence complementation (BiFC).

Methods: To visualize protein interactions, cDNA of EphB3 and EphA4 was amplified by PCR and cloned with sequences encoding Cyan Fluorescent Protein (CFP). Eph vectors were transfected into human embryonic kidney (HEK) cultured cells, with GFP and empty vectors as controls. The BiFC of Jun and Fos fragments fused to N- and C-termini of mutated yellow fluorescent protein (YFP) Venus was also performed as positive control.

Results: Green fluorescence was observed after 24 hours of transfection of GFP into HEK cells. Using the GFP filter, we also observed fluorescence with Venus-based fragments Jun and Fos. Introducing EphB3 fused with C terminus of CFP with EphB3 with N terminus did not show expected blue fluorescence, which might reflect inadequate linker lengths between the receptor and CFP fragments.

Conclusion: BiFC assay was used to study the interaction between EphB3 and EphA4 in live HEK cells. The N- or C-terminal halves of a CFP are linked to EphB3 and EphA4, respectively. Since blue fluorescence was not observed between two EphB3 receptors that are known to interact, the next step is to modify linkers. Future studies examine variable linker lengths required for membrane receptor interactions to occur in living cells.

Paraneoplastic encephalitis due to Merkel cell neuroendocrine skin carcinoma  
E. Giannouli a, D. Athanasopoulos a, G. Panagopoulos a, S. Tsiara a,  
C.E. Karageorgiou b, c  
*aNeurology, General Hospital of Athens “G. Gennimatas”,  
Holargos, Greece; bNeurology, Iatrikon Center of Athens, Marousi, Greece  
Background: We report a case of a 57-year-old man with subacute cerebellar ataxia related to Merkel cell carcinoma.  
Case description: A 57-year-old man presented with a subacute, progressive cerebellar ataxia with gait instability, marked trunk ataxia and explosive speech. Brain MRI, whole-body CT and complete blood work-up were negative. CNS showed elevated protein but a complete CNS serological (all known viruses), immunological and paraneoplastic antibody testing was negative. PET-scan showed an inflamed inguinal lymph node (attributed to skin infection). Genetic testing for inherited ataxias was negative. The patient received high-dose corticosteroids with remarkable improvement. One month later his symptoms reemerged. A second course of corticosteroids succeeded in controlling his symptoms but significant side effects led to their discontinuation. A third relapse occurred. Although the lymph node had diminished, a biopsy was decided which showed Merkel cell carcinoma. Complete skin examination revealed no abnormal skin nodule and a second PET scan was now negative. The patient showed remarkable improvement of his neurological symptoms after the lymph node removal and is receiving chemotherapy.  
Conclusion: Merkel cell skin carcinoma (MCC) is a rare, aggressive cutaneous malignancy linked to UV radiation exposure, infection with the Merkel cell polyomavirus, and immunosuppression. To our knowledge no case of related paraneoplastic encephalitis has ever been reported and although no direct link is determined between the tumour and the cerebellar insult the fact that the removal of the lymph node (primary tumour), led to an almost complete neurological recovery is a strong indication that the two are connected.

Effect of Satureja khouzestanica essential oil on acquisition, extinction and reinstatement of morphine induced conditioned place preference in male rat  
R. Assaeia,b, K. Rastegar a, N. Pajouhi a, A. Rafati a  
*aNeuroscience Research Center, Shiraz University of Medical Sciences, Iran; bEndocrine and Metabolism Research Center, Namazi Hospital, Iran; cDepartment of Physiology, Medical School, Shiraz University of Medical Sciences, Shiraz, Iran  
Background: Drug addiction is an impulsive, unconscious drug seeking behavior associated with neurobiological changes. This neurobiological disorder accompanies high recurrence even after long period of treatment. The present study, investigated the effects of Satureja khouzestanica essential oil (SKEO) a well-known Iranian traditional medicine, on acquisition and reinstatement of morphine-induced conditioned place preference (CPP) in rats.  
Methods: CPP was induced by intraperitoneal injection of morphine (10 mg/kg) as an 8-day conditioning schedule. The effects of SKEO on the rewarding properties of morphine were tested in rats receiving SKEO (10, 15, and 20 mg/kg i.p.) 30 min prior to each morphine injection (acquisition) or prior to the CPP test on day 6 (expression). Once established, CPP was extinguished by repeated testing, during which conditioned rats were injected daily with different doses of SKEO. Finally, the efficacy of SKEO in blocking reinstatement of CPP provoked by priming injections was also evaluated.  
Results: SKEO administration showed dose dependency for prevention of establishment of CPP. However it had no effect in facilitating extinction of morphine-induced CPP. SKEO suppressed priming induced reinstatement of CPP.  
Conclusions: In conclusion, as SKEO was effective for reducing craving and vulnerability to relapse, it might be a very effective natural remedy for the treatment of opioid addiction.

Apathy is associated with a single-nucleotide polymorphism in a dopamine-related gene  
S. Mitaki, M. Isomura, M. Yamasaki, A. Nagai, T. Nabika, S. Yamaguchi  
Shimane University, Izumo, Japan  
Background: Dopaminergic neurotransmission is an important factor in the pathogenesis of apathy. In addition, the contribution of genetic factors to the regulation of brain dopaminergic activity is widely acknowledged. Therefore, we hypothesized that genes associated with brain dopaminergic activity may have some effects on apathy.  
Objective: In the current study, we evaluated the association between four functional single-nucleotide polymorphisms (SNPs) in specific genes related to dopaminergic neurotransmission and apathy in a general population.  
Methods: Participants in the health examination at the Shimane Institute of Health Science were recruited for this study (n = 963). Apathy was assessed using the Japanese version of the apathy scale. SNPs were genotyped using the TaqMan method.  
Results: In our population, 22.1% had apathy. We confirmed that apathy was associated with decreased cognitive function and depressive state. A significant association was found between an SNP in the catechol-O-methyltransferase (COMT) gene (rs4680) encoding the low-activity Met allele and apathy (GA: OR = 0.67, p = 0.01, CI = 0.48–0.92 and AA: OR = 0.47, p = 0.02, CI = 0.23–0.89). This relationship was still significant after adjustment for confounding factors (GA: OR = 0.59, p = 0.003, CI = 0.42–0.84 and AA: OR = 0.34, p = 0.002, CI = 0.15–0.67).  
Conclusions: Our study indicates an association between rs4680, an SNP in the COMT gene, and lower risk of apathy. Considering the function of rs4680, the current study suggests the importance of dopaminergic neurotransmission in the pathogenesis of apathy in a general population.

Sensory-motor integration after selective stimulation of intraepidermal Aδ nociceptors  
Z. Matur a, Z. Acar b, A.E. Öge c  
*aDepartment of Neurology, Istanbul Bilim University School of Medicine, Turkey; bDepartment of Neurology, 29 Mayis Hospital, Turkey; cDepartment of Neurology, Istanbul University, Faculty of Medicine, Istanbul, Turkey  
Background and objective: Previous studies on sensory-motor integration (SMI) between somatosensory afferents and the motor
responses to transcranial magnetic stimulation (TMS) have been performed with electrical stimulation of the nerves, revealing early (20–30 ms) and late (after 100 ms) afferent inhibitions with an intervening facilitation. This study was planned to investigate the effects of selective electrical stimulation of intraepidermal Aβ fibers (IES) on SMI.

**Material and methods:** Fourteen healthy volunteers aged between 22 and 40 were included. Paired stimuli at 2 times the sensory threshold were applied with custom made IES electrodes placed on the 1st dorsal web space of the dominant hand. A butterfly shaped coil was placed over the cortical hot spot for the first dorsal interosseous muscle adjacent to the IES and the TMS intensity was adjusted for responses >1 mV in amplitude at >5/10 stimulations. Inter-stimulus intervals (ISI) between the IES and TMS consisted of 18 steps between 20 and 450 ms. Eight stimulations for each ISI were performed randomly. Mean amplitudes and areas of the motor responses elicited at each ISI were divided by those evoked by TMS alone and graphs for SMI were created.

**Results:** SMI curves showed an afferent inhibition that began after ISI 80 ms and lasted until 300 ms.

**Conclusion:** Later beginning of afferent inhibition after IES can be 80 ms and lasted until 300 ms.

**Functional outcomes after rehabilitation of tuberculous myelitis 14 case reports**

**Introduction:** Tuberculosis including its medullar location is a public health problem in Morocco.

**Objective:** We report the epidemiological characteristics, clinical and functional aspects in a group of patients suffering from tuberculous myelitis after rehabilitation.

**Material:** Over a period of 4 years, 14 cases of tuberculous myelitis (F/H = 6:8) were admitted for rehabilitation. We noted epidemiological, clinical and complication characteristics. The ASIA neurological status, the mobility and the sphincter control were assessed by the MIF.

**Results:** Most patients were male (F/M = 6:8), the average age was 29 years (19–39), the average length of stay in the rehabilitation was 79.1 days (21–103), paraplegia was complete in nine patients according to ASIA classification. Six patients had multifocal tuberculosis. All patients had sphincter dysfunctions, and had to learn self catheterization, three patients had complications. All patients returned to their homes after discharge, one patient died after 6 months, one patient, seen after 2 years, has recovered autonomous walking capacity. The results of the MIF averaged 54.1 out of 126 (42–59) at admission and 75 (69–89) at discharge.

**Conclusion:** Tuberculosis including its medullar location is a public health problem in Morocco. The main goal of rehabilitation is to increase patient independence and reduce disability. A large proportion of patients with non-traumatic spinal cord can reach a good level of mobility and sphincter independence. Disability was significantly reduced during rehabilitation.

**Pathologic reflexes of proximal segments in ALS patients**

G.A. Albanese, P. Landrissina, J. Riveros, L. Fiorotto, F. Rodriguez, G.A. Moviglia. *Neurology, Hospital Argerich, Capital Federal, Argentina*

**Introduction:** Amyotrophic Lateral Sclerosis is a neurodegenerative disease that affects both motor cortex and anterior horn motoneurons producing a progressive amyotrophy of all voluntary muscles including the ones innervated by the cerebral bulb. The atrophy progresses from the distal muscles of the limbs to the central ones, this is clearly detected by an electromyography study. The hyper reflexia of ankles, knees, wrists and elbow are pathognomic signs of cortical liberation of the spinal cord reflex arches. Absences of this sign talk against the first neuron compromise inducing a more benign diagnosis. In the hospital setting several patients came with advanced stages of ALS, but their diagnosis became difficult because the amyotrophy of the distal members is hidden the above mentioned hyper reflexia. To find out a low cost way to overcome these problems there was a study of the presence of shoulder and hip muscular tendon reflexes.

**Methods:** 10 patients that met all El Escorial ALS Criteria were studied and followed for at least one year. The three joint reflexes of each limb were assessed every three months for, at least, a year.
Results: 10/10 patients showed the three reflexes present in the four limbs. After a year 8/10 had lost the two distal reflexes keeping the hyper reflexia of shoulder and limbs.

Discussion: There is a lack of previous reports on these findings but, even when the study of a larger number of patients should be studied to validate this clinical sign, it seems to help the first time diagnostic.

A novel heteroplasmic mutation in the mitochondrial ATP6 gene associated with Parkinson’s syndrome and epilepsy
A. Baumgartnera, S. Niaa, M. Erdlera, K. Lackmayera, C. Baumgartnera, W.M. Schmidt, R.E. Bittner, "Karl Landsteiner Institute for Clinical Epilepsy Research and Cognitive Neurology, Austria; "Neuromuscular Research Department, Center of Anatomy and Cell Biology, Medical University of Vienna, Vienna, Austria

Background: Mutations in the mitochondrial DNA are maternally inherited and may lead to multisystem disorders. A tissue-specific threshold-level of the respective mtDNA-mutation load must be exceeded to give rise to a phenotypic manifestation.

Objective and methods: We report on a 44-year-old male patient with a history of dysartria and tremor since childhood and epilepsy starting at age 16. In addition, he is of short stature and has mild mental retardation. Previously, diagnosis of Parkinson’s disease and multiple sclerosis had been established. At age 42, sensorineural hearing loss was diagnosed. When he was admitted to our hospital, we found that lactate was elevated in blood and CSF. Due to elevated lactate levels, short stature, extrapyramidal symptoms and epilepsy a muscle biopsy was performed.

Results: A hitherto unreported point mutation in the mitochondrial ATP6 gene (mt.8969G→A) was detected (homoplasmic in the muscle, heteroplasmic in blood: ~80%, urine sediment: ~90%). The detected missense mutation is predictably pathogenic due to the replacement of a highly conserved serine residue by asparagine at position 148 within the fourth transmembrane domain of the ATP synthase F0 subunit 6. This mutation was also detected in the patient’s asymptomatic 39-year-old brother, however, with lower heteroplasmy levels (~50% in blood and ~70% in urine sediment, respectively).

Conclusion: We present strong evidence, that a hitherto unreported mtDNA mutation (mt.8969G→A) affecting the ATP synthase F0 subunit 6 of the mitochondrial respiratory chain complex V, leads to the complex clinical presentation of a mitochondrial epilepsy syndrome accompanied by dysartria, sensorineurial hearing loss, and mental retardation.

MicroRNA-214 expression in dorsal root ganglion neurons and response to peripheral nerve injury
X.-N. Yi, A.-J. Lu, Z.-F. Huang, C.-Y. Zhang, S. Wu, "Department of Anatomy, Hainan Medical College, Haikou, China; Department of Orthopaedics, The Third-Xiangya Hospital, Central South University, China; Research Center of National Health Ministry on Transplantation Medicine, Central South University, Changsha, China

Background: The complicated regenerative process of peripheral nervous system (PNS) can be impacted by many factors. MicroRNAs (miRNA(s), miR(s)) are non-coding RNA molecules that regulate gene expression in a wide variety of biological processes mainly at the post-transcriptional levels.

Objective: This study investigated the possible involvement of miRNAs in gene regulation relevant to peripheral nerve regeneration.

Material and methods: A miRNA microarray analysis detected change in 3 miRNAs after sciatic nerve transection (ScNT) among which miR-214 was dramatically reduced. MiR-214 was predicted to target 3′-UTR of Slat-200 GTPase-activating protein 3 (srGAP3), a member of axon guidance pathway. The down-regulation of miR-214 was further validated using quantitative reverse transcriptase PCR (qRT-PCR). srGAP3 was confirmed to be the target of miR-214 by in situ luciferase reporter experiment.

Results: In situ hybridization (ISH) experiments using locked nucleic acid (LNA) microRNA detection probe verified that miR-214 was located in primary neurons of DRG and down-regulated following ScNT. Combination of ISH and immunofluorescence revealed that miR-214 and srGAP3 were colocalized in primary DRG neurons. Analysis of western blot suggested that srGAP3 was negatively regulated by miR-214 in DRG neurons after ScNT.

Conclusion: These data demonstrate that miR-214 is located and differentially expressed in primary DRG neurons and may participate in the course of neural regeneration by regulating gene expression of srGAP3 after sciatic nerve transection.

Use of Rituxan in neurological disease and outcomes in key disease groups
K. Garneau, A. Genge. "Montreal Neurological Institute and Hospital, McGill University, Montreal, QC, Canada

Background: This presentation outlines patients with myasthenia gravis, dermatomyositis, neumomelitis optica, NMDA, encephalitis, vasculitis, and CIDPN who were treated with Rituxan. These diseases are considered treatable and even have the potential to go into remission. However, many patients only improve with multiple therapies – such as steroids, azathioprine, IVlg and plasmapheresis –
on a chronic basis. Rituxan is being increasingly used in order to improve the clinical status in patients who either do not respond or respond but remain dependent on these therapies long term.

**Objective:** This study is a description of the cases that received Rituxan and the response and lack of response as measured by clinical symptoms and dependence upon other therapies. The outcome measures include improvement to a minimally affected state and withdrawal of other therapies as an indicator of response to therapy and potential remission.

**Patients and methods:** Forty patients received Rituxan after being either intolerant or poorly responsive to traditional therapies.

**Results:** Patients with inflammatory myopathies responded significantly to Rituxan, allowing a decrease in other therapies. Patients with myasthenia gravis demonstrated dramatic improvement in clinical symptoms and were able to reach minimal clinical symptomatology and complete remission combined with withdrawal of other therapies, particularly IVIg and plasmapheresis. Little to no response was seen in patients with CIDPN; all patients with this disorder continued previous therapy.

**Conclusion:** Rituxan can be safely recommended for treatment of inflammatories and myasthenia gravis, however, it is not recommended for the treatment of CIDPN based on our local experience.

**Do young European neurologists know enough to comfortably treat patients with neurotrauma?**

M. Rakusa1, S. Gakb1, E. Ehlerc1, Y. Alekseenko1, J. Opara1, D. Muresanu,1, P. Vos1.  
1Department of Neurology, University Medical Centre Maribor, Maribor, Slovenia; 2Department of Neurology, Sechenov Moscow State Medical University, Moscow, Russia; 3Department of Neurology, Parubsk Regional Hospital, Parubsk, Czech Republic; 4Department of Neurology and Neurosurgery, Vitebsk Medical University, Vitebsk, Belarus; 5Repty Rehab Centre, Tarnowskie Gory, Poland; 6Department of Neurosciences, University of Medicine and Pharmacy Iuliu Hatieganu, Cluj-Napoca, Romania; 7Department of Neurology, Singeland Hospital, Doetinchem, The Netherlands

**Background:** Traumatic brain injury (TBI) and spinal cord injury (SCI) are taking together total (in)direct medical costs among the diseases with the highest annual costs (US-40 billion dollars). Despite the clinical and societal impact of TBI, young neurologists lack the opportunities for formal training in this topic.

**Objective:** We wanted to evaluate motivation, knowledge and obstacles in treating patients with neurotrauma and how to improve the training.

**Patients and methods:** Sixty neurologists were included (33 women) from 10 central and eastern European countries. Survey consisted of fifteen questions testing both knowledge (nine multiple choice questions) and exploring opinions.

**Results:** The mean age of the participants was 30.8 ± 5.6 years. The majority (60%) were resident or consultant (up to 5 years of post-academic experience). They had at least one patient with traumatic brain, spine or peripheral nerve injury per week in their daily practice (45%). The majority (63%) didn’t have any formal training and 82% was certain that the diagnosis and treatment of traumatic brain injured patients would significantly improve, if neurologists become more involved.

**Conclusions:** Our results clearly indicate that young European neurologists need and wish to improve their knowledge in neurotraumatology. Since there is little formal training, teaching/special sessions/courses at European congresses may be first step to improve education in this field.

**Sleep disturbances in systemic lupus erythematosus**

C. Falup-Pecurariu ab,1, L. Duca2, M. Moarcas2, aDepartment of Neurology, County Emergency University Hospital, Romania; 2Faculty of Medicine, Transylvania University, Romania; 3Department of Immunology, County Emergency University Hospital, Brasov, Romania

Knowledge about sleep complaints in systemic lupus erythematosus (SLE) is limited.

**Method:** Prospective study on 42 consecutive patients with SLE (95, 23% women, the mean age 53, 43 + 22, 69 years). There was a direct interview with a standardized questionnaire which contained demographic characteristics and validated scales.

Main outcome measures included: Pittsburgh Sleep Quality Index (PSQI), Epworth Sleepiness Scale (ESS), EQ-5D, Fatigue Severity Scale (FSS), Lupus QoL questionnaire, Hospital Anxiety and Depression Scale. The Pittsburgh Sleep Quality Index (PSQI) was used to quantify sleep quality. Poorer sleep quality was correlated with higher PSQI scores.

**Results:** Mean PSQI scores were significantly higher in patients with higher Lupus QoL scores, depression, and fatigue. PSQI had significant correlations with worse QoL (p < 0.01). Patients reported difficulties falling asleep (73.8%), reduced subjective sleep quality (88.09%), and disturbed sleep (90.47%).

**Conclusions:** Sleep disturbances are frequently encountered in SLE patients and are significantly linked to quality of life and depression. A better management of sleep alterations could improve these symptoms.

**Quality of sleep in medical students**

A. Ergin1, A. Erdogan2, A.I. Bozkurt3, N. Ergin4,  
1Pamukkale University, Turkey; 2Denizli Government Hospital, Denizli, Turkey

**Objective:** To determine the sleep quality and related factors of the 1st, 4th and 6th year medical students in Pamukkale University, Denizli, Turkey.

**Methods:** This study is a cross-sectional survey. It was carried out after obtaining an IRB permission. The study group included in the 1st, 4th and 6th year medical students. There were 113 (88.9%) participants from the 1st, 62 (73.8%) from the 4th, and 46 (93.8%) from the 6th year in the study. The questionnaire consists of two parts. The first part had questions on the demographic characteristics of the participants. The Family Welfare Scale was used to determine the socio-economic levels. The second part was consisted of the Pittsburgh Sleep Quality Index (PSQI).

Is it post-malaria neurological syndrome or viral encephalitis?
A. Caetano1, M. Mendonça2, M. Pinto2, N. Ferreira3, L. Alves4.
1Neurology, Hospital Egas Moniz (Centro Hospitalar de Lisboa Ocidental), Portugal; 2Internal Medicine, Hospital São Francisco Xavier (Centro Hospitalar de Lisboa Ocidental), Lisbon, Portugal

Introduction: Post-malaria neurological syndrome (PMNS) is a rare self-limited clinical syndrome in which patients develop neurological and/or psychiatric symptoms within 2 months of a severe falciparum malaria infection, after the parasites have cleared from the peripheral blood.

Case report: A 60-year-old Caucasian man presented with a confusional state associated with ataxia that had started 3 days earlier. On admission, he had a generalized seizure. He had recently returned from Angola, where he had been treated with quinine in an intensive care unit for a severe malaria infection, and later discharged, following full recovery and clearance of parasitemia. He had had no fever during the previous 15 days. CSF analysis revealed lymphocytic pleocytosis (123 cell/μL) and hyperproteinorrhachia (188 mg/dL). Brain MRI showed no abnormalities. The EEG detected slightly slowed fronto-temporal activity. No evidence of central nervous system (CNS) infection was found, with negative CSF polymerase chain reaction (PCR) testing for common neurotropic viruses and negative CSF and blood cultures. The patient was empirically treated with ceftriaxone and acyclovir, with full symptomatic recovery following the first day of treatment.

Conclusion: We report the case of a patient who had fully recovered from a severe malaria infection and later developed a diffuse encephalopathy. PMNS, usually a self limited entity, should be considered in the differential diagnosis, taking into account the patient’s recent history. Nevertheless, the lack of relevant changes on brain MRI and EEG, along with a clinical picture suggestive of viral encephalitis means we shouldn’t exclude a false negative CSF PCR viral encephalitis.

Mitochondrial DNA variations and evidence of haplogroups in Indian Friedreich's ataxia (FRDA) patients
L. Mudila1, F. Mohammed2, A. Srivastava3, 4Neurology, All India Institute of Medical Sciences, India; 4Functional Genomics Unit, Institute of Genomics and Integrative Biology, New Delhi, India

Objective: This study is aimed to evaluate FRDA patients for mtDNA sequence variations and identify related haplogroup in FRDA patients from Indian population.

Background: FRDA is an early onset autosomal recessive disorder, caused by loss of function of the frataxin protein. Frataxin is required for the biogenesis of the iron–sulphur-cluster (ISC) which is vital for the synthesis of the respiratory chain complexes I–III enzymes and aconitase in mitochondria.

Methods: Considering D loop, NADH dehydrogenase and ATP region as hotspots for the mitochondrial pathogenic mutations in neurodegenerative diseases, these regions were sequenced by direct sequencing method for 30 FRDA patients and 63 ethnically and age matched controls. The FRDA patients were genetically confirmed with southern blot and TP PCR protocols.

Results: 185 variations were observed in all 30 patients. 101 variations were in coding region (ND genes and ATP) while non-coding (D Loop) had 84 variations. Variations at positions 16519, 4883 and 5178 were found significantly associated with patients (P < 0.05). Haplogroup analysis using D loop results had revealed that 57% of patients belong to haplogroup M, while control constitutes only 18.6%. Variations at positions 489 and 195 were found in 100% of patients belonging to the M group, while control at these locus were under represented.

Conclusions: Variations at positions 16519, 4883 and 5178 suggest that these variations may act as modifier for the disease. Significant association of haplogroup M with patients suggests possible impact of
Inborn error of metabolism (IEM) involving CNS encompasses a wide spectrum of inherited disorders. We present and discuss imaging features of the more common and important IEMs involving CNS that diagnosed molecularly in Iran. Our pattern approach for neuroimaging classification of Common Metabolic Disorders was according to anatomic evaluation:

White matter (WM)
- Primarily affecting periventricular
- Primarily affecting subcortical

Gray matter (GM)
- Primarily affecting cortical
- Primarily affecting deep

Disorders involving WM and GM
During 3 past years, we studied systematically neuroimages of our patients and finally we classified our cases pre- and post-molecular diagnosis as below:

Initially affecting periventricular WM
- Metachromatic leukodystrophy (12 cases)
- Krabbe disease (4 cases)
- X-linked adrenoleukodystrophy (6 cases)
- Phenylketonuria (21 cases)
- Maple syrup urine disease (18 cases)
- Homocystinuria (7 cases)
- Merosin-deficient congenital muscular dystrophy (10 cases)

Initially affecting subcortical WM
- Canavan disease (8 cases)
- Alexander disease (5 cases)
- Lack of myelination
- Pelizaeus–Merzbacher disease (5 cases)
- Cortical gray matter
- Neuronal ceroid lipofuscinoses (9 cases)
- Mucolipidosis type I (5 case)

Deep gray matter
- Deep gray matter involvement
  - Primarily affecting globus pallidus:
    - Canavan disease (2 cases)
    - Kearns–Sayre disease-subcortical U fiber (4 cases)
    - Methylmalonic acidemia-deep WM (8 cases)
    - Maple syrup urine disease-dorsal WM (8 cases)
  - Primarily affecting striatum:
    - Leigh disease (13 cases)
    - MELAS (10 cases)
    - Glutaric aciduria type I (6 cases)
  - Wilson disease (6 cases)

Gray matter
- Initially affecting cortical
- Initially affecting deep

Organic acidopathies (31 cases)

Levodopa-responsive parkinsonism and autonomic (small fiber) dysfunction in patients with Wilson’s disease (WD)
Internal Medicine-Neurology Division, Brazil; Universidade Federal do Ceará, Fortaleza, Brazil

Background: Autonomic dysfunction has been rarely described in WD patients.
Objective: To describe a series of patients with WD, levodopa-responsive parkinsonism and autonomic dysfunction.
Methods: After IRB approval, we evaluated 4 patients with WD and parkinsonism for the presence of neuromuscular dysfunction and performed water-induced skin wrinkling test — SWT (Teoh, JNNP 2008;79:835).

Results:
Patient 1: A 37 year old female presented with cirrhosis at age 33 was diagnosed with WD and treated with ZnSO4, penicillamine and piridoxine/complex B vitamins. Since age 35 she developed pramipexole and levodopa-responsive parkinsonism, with burning and numbness in arms and genital area and urinary incontinence. NCS/EMG was normal. Water-induced SWT revealed small fiber dysfunction (mean 4-digit wrinkling of 1).

Patient 2: A 23 year old male was diagnosed with WD at age 14 and was treated with penicillamine + piridoxine. Since age 21, he developed levodopa-responsive parkinsonism, with resting tremor, weight loss, dysphagia and dysphonia. NCS/EMG was normal but water-induced SWT was abnormal (mean wrinkling of 0.25).

Patient 3: A 34 year old male presented with psychosis, behavioral dysfunction, levodopa-responsive parkinsonism and episodes of loss of consciousness. He was treated with penicillamine and complex B vitamins. NCS/EMG and water-induced SWT were normal (mean wrinkling of 4).

Patient 4: A 38 year old female presented with liver dysfunction, behavior changes and parkinsonism at age 24. She was diagnosed with WD and treated with penicillamine and hiperiden. Parkinsonism almost completely subsided with penicillamine. SWT was normal (mean wrinkling of 3.6).

Conclusions: A subset of WD patients with levodopa-responsive parkinsonism also exhibits abnormalities on SWT (autonomic dysfunction).

Sleep disorders in HIV–AIDS patients in Cameroon, sub-Saharan Africa
Neurology, Cameroon; General Medicine, University of Yaounde 1, Cameroon; Public Health, Ministry of Public Health, Cameroon; Neurology, Central Hospital of Yaounde, Cameroon; Cardiology, General Hospital of Yaounde, Yaounde, Cameroon

Background: Sleep disorders have been reported to be more common among people living with HIV–AIDS (PLWHA) than matched controls in Western countries, but few data exist on the subject in Africa. In Cameroon, no study has been done on the prevalence and characteristics of sleep disorders in PLWHA, the object of this study.

Methods: A case–control study including 39 PLWHA age- and sex-matched with 43 HIV negative controls. We used the Pittsburg Sleep Quality Index (PSQI) to assess sleep quality, the Epworth Sleepiness Scale (ESS) for daytime sleepiness and the Berlin Questionnaire (BQ) for obstructive sleep apnea (OSA).

Results: HIV + participants had poorer sleep quality than the controls: 66.7% versus 11.6%, (AOR 20.60; 95% CI, 2.98–142.19) and took significantly longer to fall asleep (33.08 ± 27.35 min versus 20.81 ± 16.61 min, p = 0.015). Poor sleep quality was significantly more common in HIV, cases compared to HIV2, (100.0 versus 0.0% respectively, p = 0.001). No significant differences were observed with respect to age at HIV diagnosis, disease duration, CD4 count, disease (WHO) stage, being on HAART or not, 1st or 2nd line treatment or being on Efavirenz. Daytime sleepiness and OSA were significantly more common in the cases compared to the controls: 23.1% versus 2.3% (p < 0.001) and 43.6% versus 14.0%, (p = 0.003) respectively.

Conclusion: Sleep disorders are common in Cameroonian HIV-positive patients. The use of sleep scales in the clinical assessment of patients could contribute to better management and improves quality of life.

Pathways of care of Italian patients in vegetative state and minimally conscious state: Results from a national study
Department of Clinical Neurosciences — DINEC, Neurological Institute Carlo Besta IRCCS Foundation, Milan, Italy

Evidence has described heterogeneous pathways of taking care of patients with disorders of consciousness (DOC) both at the national and local level, with inter- and intra-regional differences. The aim is to collect data on the clinical condition and pathways of taking care of a sample of patients in Vegetative State (VS) and Minimally Conscious State (MCS) in Italy. Based on the national projects “Functioning and disability in VS and MCS” (T0), the follow-up PRECIOUS “Taking care of people with acquired severe brain injury” (T1) collected information on a sample of patients with DOC in 107 post-acute rehabilitation and long term institutions, located in the North, Central and South of Italy.

Out of 600 patients collected in T0, 587 patients were followed up. After two years, 380 (64.7%) were still alive and 109 of them (28.7%) changed place of care. About them, 22% changed region. Movements to rehabilitation centres range from 3% (South) to 7% (North). 51.3% of patients housed in northern structures moved to a long term care and 41.0% to domicile. In the Centre, 69.6% went to domicile and 26.1% to long term care. In the South, instead, 82.8% moved to domicile and 13.8% to a long term care. As Italian Ministry of Health recommends, equal opportunities of care should be provided to all patients, wherever they live in the country. The high levels of people at home in centre and south Italy, where also home care is inadequately represented, represent a lack in the health and social systems.

Italian study on functioning and disability of people with disorder of consciousness
Department of Clinical Neurosciences, Neurological Institute Carlo Besta IRCCS Foundation, Milan, Italy

Background: The vegetative state (VS) and minimally conscious state (MCS) are neurological conditions in which patients appear to be awake but show no or partial signs of awareness of themselves or of their environment. Patients require adequate health pathways but the lack of epidemiological information creates difficulty in the organisation of medical care and treatments.
Objective: The aim is to describe the results of a National Italian Research that collected epidemiological and clinical data of adults and children in VS and MCS and to highlight issues related to management, treatment and care.

Material and methods: This was an observational cross-sectional study, conducted in 69 Italian centres specialized in post-acute rehabilitation treatment or in long-term care of patient with disorder of consciousness (DOC). Data collection was performed between June 2009 and March 2010. An ad hoc protocol was used collecting sociodemographic, clinical and functional data.

Results: 600 patients were enrolled (69.7% in VS). 64.3% of cases had non-traumatic aetiology. Patients in VS and MCS were similar for age at acute event and at enrolment (~50 years old). Disease duration was similar for both conditions and 2.6% of VS and 4.8% of MCS patients survived for more than 10 years. Mean number of drugs per adult patient was four and decrease with increased disease duration.

Conclusion: This study reports data based on a large sample of patients with DOC. Results may be useful to analyse health and social issues on people in VS and MCS that need a large amount of environmental facilitators.

Horizontal epidemiology approach: Functioning and disability in patients with neurological disorders
A.M. Giovannetti, R. Quintas, M. Cerniauskaite, V. Covelli, A. Raggi, S. Schiavolin, P. Meucci, M. Paganì, D. Sattin, C. Sabatiergo, A. Ciez, M. Coen, M. Leonardi, a Department of Clinical Neurosciences — DINEC, Neurological Institute Carlo Besta IRCCS Foundation, Milano, Italy; bDepartment of Medical Informatics, Biometry and Epidemiology (IBE), Ludwig-Maximilians-University, Munich, Germany; cAcademic Unit Psychology, Faculty of Social and Human Sciences, University of Southampton, Southampton, UK

Neurological disorders (ND) lack comprehensive understanding of psychosocial difficulties (PSDs) and determinants. PSDs are defined as impairments, activity limitations, participation restrictions and environmental factors.

This study aimed to identify PSDs that a person with ND experience in everyday life and their determinants according to the framework of horizontal epidemiology.

400 adult patients with stroke, epilepsy, Parkinson’s disease, migraine and multiple sclerosis were interviewed using the PARA-DISE protocol to collect self-reported PSDs associated to brain disorders (www.paradiseproject.eu). PSDs reported by at least 45% of the patients in all the conditions are described below.

Mean age: 49.6 years (SD 11.5); 57.2% females; 68.1% married; 67.6% with at least high school education; and 53% working. Neurological patients mostly report PSDs related to restlessness (71.2–95.0%), sleeping problems (46.2–71.2%), being emotionally affected by health condition (66.2–88.7%), anxiety (61.2–87.5%), depressive symptoms (61.2–81.2%), coping functions (55.0–81.2%), pain (48.7–93.7%), and daily activities (45.0–68.7%). 52.1% of patients rated their health at least as good. Main determinants acting as moderate or strong environmental facilitators were family (92.1%), health professionals (90.6%), and medicines (94.8%), despite 54.0% of the sample reporting side-effects of medicines as environmental barriers. More than half of the sample (57.5–78.7%) reported that they felt to be a different person after the beginning of the disease/acute event.

Perceived PSDs and determinants that contribute to the course of PSDs were identified, suggesting that it is important to consider not only impairments and symptoms but also environment’s impact on health and disability to plan tailored intervention for person with ND.

Disability, quality of life and well-being in patients undergoing brain surgery
S. Schiavolin, R. Quintas, M. Paganì, A. Raggi, V. Covelli, A.M. Giovannetti, M. Cerniauskaite, P. Meucci, D. Sattin, S. Brock, P. Ferroli, M. Leonardi, a Neurology, Public Health, and Disability Unit, Clinical Neurosciences Department — DINEC, Neurosurgery II Unit, Italy; bNeurology, Public Health, and Disability Unit, Clinical Neurosciences Department — DINEC, Italy; cNeurosurgery II Unit, Neurological Institute Carlo Besta IRCCS Foundation, Milan, Italy

Background: The assessment of quality of life (QoL) has become an important endpoint in clinical trials in brain tumours and cerebrovascular diseases, helping clinicians in providing the best and most complete treatment and care.

Objective: This study aimed to evaluate disability, Qol and well-being in patients undergoing brain surgery at National Neurological Institute Besta.

Patients and methods: Adult patients with brain tumour and cerebrovascular diseases undergoing neurosurgery from May 2012 to February 2013 were enrolled and interviewed using a research protocol composed of evaluation of disability levels (WHODAS-12), self-perception of well-being (PGWB-S) and quality of life (EUROHIS-Qol).

Results: Eighty seven adult patients were included: mean age was 51 years, 55% were females, 49% has high school education or higher, 63% has a tumour and 37% cerebrovascular disease. On WHODAS-12, where epilepsy patients rank 13.6 and stroke patients 25.9, the levels of mean score of our sample were 22.9, suggesting high levels of disability compared to Italian population. Patients reported lower levels of well-being (63) when comparing with the general population (69.7). Qol was rated as slightly lower (3.43) than the general population (3.68).

Conclusions: This study shows that patients undergoing brain surgery present high disability levels, low levels of well-being and Qol. In this sense, data on functioning and disability and the impact of environment in which person lives should be considered for a prognostic evaluation of patients and are necessary to define tailored and personalised treatments.

Neurological diseases of ageing people with Down syndrome: A review from 1960 to 2011
P. Meucci, V. Covelli, M. Cerniauskaite, R. Quintas, M. Paganì, A. Giovannetti, D. Sattin, S. Schiavolin, A. Raggi, M. Leonardi, a Neurological Institute C. Besta IRCCS Foundation, Milan, Italy

Background: The scientific literature reports that people with Down syndrome (DS) start aging prematurely so that they can be considered old people at the age of 45.

Objective: To highlight the evidences of the scientific literature on neurological diseases of ageing people with DS.

Methods: Our review was conducted through two electronic databases: PUBMED and ScienceDirect covering the period from 1960 to 2011.

Results: In all studies the prevalence of Alzheimer’s increases with age: from 30 to 39 years is 10%, from 40 to 49 years is 25%, from 50 to
55 years is 28% and after 60 years is 75%. The average age of onset is 57 years. The Dementia Alzheimer's type in people with DS is characterized by: changes in behaviour and personality, decline in cognitive functions, psychological changes, ataxia, seizures, urinary and fecal incontinence. Alzheimer’s and Parkinson’s disease with severe dementia occurring in about 15% of patients with DS aged over 40. 26% of adults with DS suffer from epilepsy and the average onset is 37 years.

Conclusion: Due to early ageing, Alzheimer's and epilepsy in people with DS appear before and more frequently than in general population. So it is appropriate that we share more awareness about adult DS health needs while they age. It is also necessary to combine the medical evaluation of disorders presenting in people with DS due to ageing with the relevant information about social and personal life, according to a broader biopsychosocial perspective.

Neuro expressionism: Contributions at the beginning of the 20th century
A.I. Fumagalli, Department of Neurology, Sanatorio Parque, Rosario, Argentina

The term expressionism is used to describe any art that raises subjective feelings above objective observations. Affected by the anxieties of accelerated social change, expressionist artists employed violent exaggerations and distortions of form and colour. Austrian expressionist artist Egon Schiele (1890–1918) made exhibitionism and persecution-mania in a dystonic way with stronger linear effects and harsher outlines, one of his major themes. Arthur Schüller (1874–1957), the father of neuroradiology, was born in Vienna. In 1905 his first book, The skull base on the radiogram, was published and expressionism developed almost simultaneously in different countries. It was a comprehensive description of normal and pathologic anatomy as well as of many special radioproductions, like Schiele’s linear effects, of the skull base. Heinrich Quincke (1842–1922) who should be credited with the discovery of lumbar puncture, performed research in many fields of medicine, including internal medicine, surgery, paediatrics, neurology and dermatology. Christfried Jakob (1866–1956) a great neuropathologist, neurobiologist, philosopher, professor and artist was born in Germany and lived and worked for 57 years in Argentina. Otto Klemperer (1885–1973). First as revolutionary ground-breaker, later as champion of the classics from Bach to Mahler, amassed a recording legacy of the 20th century — Dio: 10.1016/j.jns.2013.07.2456

A case of Pancoast tumor: Unusual presentation and successful therapy
B. Calabek, S. Meng, S. Pollanz, W. Klepetko, K. Hoetzenecker, F. Oberndorfer, W. Grisold. "Neurology, Kaiser Franz Josef Hospital, Austria; "Radiology, Kaiser Franz Josef Hospital, Austria; "Thoracic Surgery, University Hospital of Vienna, Vienna, Austria; "Clinical Institute of Pathology, University Hospital of Vienna, Vienna, Austria

Background: The Pancoast syndrome (PS) presents with a variety of clinical manifestations. Neurological symptoms are pain, radicular sensory and motor syndromes, and Horner's syndrome. PS often bears a grim prognosis.

Patients and methods: A 45 year old lady came for neurologic evaluation, due to pain radiating into her right elbow for nine months and numbness in her 5th finger. Sensory loss in her fourth and fifth fingers resulted in clumsiness in her right hand. She presented right sided Horner's syndrome and a decreased triceps jerk; the right hand had a mild atrophy of the small hand muscles. NCV and EMG studies were not conclusive. CT-scan and MRI of the lung and brachial plexus revealed a large mass of the lung, infiltrating into the brachial plexus.

Results: After preoperative chemo- and radiotherapy the tumor could be surgically removed. Histologically, the nerve fascicles were embedded in tumor tissue, which also spread along the affected fascicles. Postoperatively she suffered from severe neuropathic pain, which could be successfully managed. The right hand has only crude sensory perception left and loss of function of lower arm and hand muscles.

Conclusion: This case report describes an atypical onset of lung tumor causing a PS. NCS were not conclusive. The diagnosis was confirmed by MRI, CT-scan and biopsy. Despite considerable loss of distally sensorimotor function of the right hand, the patient is able to use the extremity in her professional life. This observation demonstrates the successful management of lesions of the peripheral nervous system caused by cancer.

Pathogenesis of the hemifacial hyperhidrosis
Y. Inukai, S. Iwase, Y. Shimizu, M. Sato, N. Nishimura, C. Onizuka, Y. Kuwahara, J. Sugenooya, M. Sato. Department of Physiology, Aichi Medical University School of Medicine, Nagakute, Japan

Background: Facial hyperhidrosis may be often compensatory hyperhidrosis due to the contralateral hemifacial anhidrosis, but little is known on the pathogenesis.

Objective, patients and methods: We analyzed it for 14 patients with this symptom by defining the total body sweating pattern using Minor's starch–iodine test, total skin temperature distribution using infrared thermography, local skin blood flow using laser Doppler flow meter, and MRI to confirm the lesions.

Results: The sweating patterns were classified as follows: I. Systemic unilateral hyperhidrosis (4 patients from 41 to 68 years old); might be compensation due to the contralateral systemic unilateral anhidrosis. This might be caused by cervical disk herniation, protruding to a spinal median, which might induce minor circulatory disturbance of the central artery of the spinal cord on the compressed side; and II. Segmental unilateral hyperhidrosis (10 patients).

a) Hyperhidrosis and flushing (harlequin syndrome) from hemifacial to the ipsilateral cervical innervation area during body heating (1 y 9 m, 2 y 1 m, 5 y 6 m, and 9 y male): might be compensation due to the contralateral anhidrosis caused by injury of cervical sympathetic trunk preganglionic fibers. Since cervical traction side at delivery corresponded with the disorder side, obstetric traumatisms might contribute to the etiology;

b) Segmental well demarcated hyperhidrosis along the cervical innervated areas (63, 74, and 37-year-old patient): might be compensation due to the anhidrosis of the adjacent lower area. They had cervical disk herniation protruding at 3 mm lateral from the median;

c) Other symptomatic segmental hyperhidrosis.
Conclusion: Defining sweat distribution is prerequisite for elucidating the pathogenesis and treatment of hemifacial hyperhidrosis.

7-Tesla MRI reveals no structural lesions of the vestibulocochlear nerve in patients with vestibular paroxysmia (VP)

1Neurology, Medical University of Vienna, Vienna, Austria; 2Radiology, Medical University of Vienna, Vienna, Austria

Introduction: Vestibular paroxysmia is a rare entity causing recurrent attacks of vertigo. A neurovascular cross-compression (NVCC) is assumed to be responsible for the symptoms. In conventional MRI the contact between the nerve and the artery can be best shown on CISS-sequences. After years of symptoms a structural lesion in the nerve may be assumed, which has to date not yet been confirmed. The aim of the current study is to investigate whether a pathologic enhancement in the vestibulocochlear nerve following NVCC can be shown by means of 7-Tesla-MRI.

Patients and methods: Six patients with chronic VP were included in this study. In all patients the diagnosis was established according to the clinical symptoms, the finding of a NVCC in MRI (1.5 or 3 T) and the cessation of symptoms after the administration of gabapentin or carbamazepine.

Results: All patients exhibited a NVCC on 7-Tesla-MRI, confirming the findings of conventional MRI. None of the patients showed an enhancement in the vestibulocochlear nerve at the site of the NVCC in 1.5 or 3 T MRI.

Discussion: In all our patients the results of the CISS sequence in 1.5 T or 3 T MRI could be confirmed by FLAIR sequences in 7 T MRI. None of the probands showed pathological enhancement or a structural lesion in the vestibulocochlear nerve. The findings imply that the symptoms of VP cannot be understood as vestibular hypofunction due to structural pathologies but rather as the result of sensory stimulation of the 8th nerve.

Carpal tunnel syndrome is the most common entrapment neuropathy of the upper extremity. Usually physical examination and nerve conduction velocity studies are used to confirm the diagnosis. In the last years ultrasound has gained wide acceptance for imaging of peripheral nerve diseases. Our objective was to evaluate the wrist-to-forearm ratio as an imaging method for the diagnosis of carpal tunnel syndrome. Patients with electrodiagnostically proven carpal tunnel syndrome underwent an ultrasonographic examination of the median nerve at the wrist and forearm. The cross-sectional area of the median nerve was measured at these points and used for calculating the wrist-to-forearm ratio. The results were compared with the values from healthy volunteers. The average cross-sectional area of the median nerve at the wrist alone.

Serum glucose adjusted cut-off values for cerebrospinal fluid/serum glucose ratio

H. Hegen, M. Auer, F. Deisenhammer. Department of Neurology, Innsbruck Medical University, Innsbruck, Austria

Background: Calculation of the cerebrospinal fluid/serum glucose (CSF/S$_{serum}$) ratio is part of the routine CSF work-up, however, different cut-off values ranging from 0.3 to 0.5 have been suggested so far to distinguish physiological from pathological conditions.

Objective: To determine normal cut-off values of the CSF/S$_{serum}$ ratio.

Patients and methods: As an Austrian reference laboratory we screened our database for paired CSF and serum samples, which have been collected by lumbar puncture, were processed within 1 h after withdrawal, showed clear supernatant, cell count $< 5/\mu l$, erythrocyte count $< 500/\mu l$, total protein $< 55$ mg/dl, and albumin quotient $< 8$ and were considered as normal by the evaluating neurologist resulting in 318 sample pairs. Glucose concentrations in CSF and serum were measured by enzymatic spectrophotometry.

Results: Glucose concentrations in CSF were approximately 60% of those in serum. CSF/S$_{serum}$ ratios significantly correlated with glucose levels in CSF (R = 0.225, p < 0.001) and serum (R = $-0.572$, p < 0.001). For serum samples with a glucose concentration of $< 100$ mg/dl (median 85), 100–149 mg/dl (median 115) and $≥ 150$ mg/dl (median 188) the 5 percentile of CSF/S$_{serum}$ ratio was 0.52, 0.43 and 0.28.

Conclusion: CSF/S$_{serum}$ ratio inversely correlates with serum glucose concentrations in a non-linear manner. These findings suggest that cut-off values for CSF/S$_{serum}$ ratio distinguishing normal from pathological conditions must be adjusted to serum glucose levels, and, furthermore, that an active mechanism is responsible for glucose transport from blood into CSF.

Psychosocial factors relevant to brain disorders in Europe (PARADISE)

A. Ciezak$^{ab}$, C. Sabariego$^c$, M. Coenen$^a$, J.-L. Ayuso-Mateos$^d$, M. Leonardi$^e$, S. Chatterji$^f$, J. Bickenbach$^g$, M. Baker$^h$, S. Hartley$^i$, M. Anczewska$^j$, T. Pitkänen$^{PARADISE}$ Consortium, $^a$Faculty of Social and Human Sciences, University of Southampton, Southampton, UK; $^b$Chair for Public Health and Health Services Research, Ludwig Maximilian University of Munich, Munich, Germany; $^c$Swiss Paraplegic Research, Nottwil, Switzerland; $^d$Universidad Autónoma de Madrid, Madrid, Spain; $^e$Istituto Neurologico ‘Carlo Besta’, Milan, Italy; $^f$World Health Organization (WHO), Geneva, Switzerland; $^g$European Brain Council, Brussel, Belgium; $^h$University of East Anglia, Norwich, UK; $^i$Instytut Psychiatrii i Neurologii, Warszawa, Poland; $^j$A-Klinikkasäätiö, Haarajoki, Finland

Introduction: The EC funded project PARADISE was conducted in terms of the theoretical conceptualization of “horizontal epidemiology”, that is that the psychosocial difficulties (PSDs) people live with when they have a brain disorder – either psychiatric or neurological – and the determinants of those SDSs are common across disorders.

Objective: To develop and test as a proof of concept an innovative approach to collect clinical and epidemiological data on PSDs based on horizontal epidemiology. The specific aims are:

1) to determine the PSDs and determinants that are common across brain disorders;
2) to develop a metric to assess PSDs and their determinants across brain disorders.

Methods: For aim

1) literature reviews and focus groups in 9 brain disorders (dementia, depression, epilepsy, migraine, multiple sclerosis, Parkinson’s disease, schizophrenia, stroke and substance use disorders) as well as data analyses of surveys and expert consultations were carried out. For aim
2) a cross-sectional study with 720 patients across Europe was conducted. Data was analysed by means of Rasch analyses and Random Forest regression.

Results: 24 PSDs common across brain disorders and covering the complete severity continuum of PSDs made up the PSD metric. 11 determinants of the extent of difficulty were identified.

Conclusions: PARADISE is a proof of concept of the hypothesis of horizontal epidemiology. The developed metric to assess PSDs across brain disorders points to a novel approach to data collection that can profoundly change how we collect epidemiological data on the burden of brain disorders and assess the effectiveness of interventions.

Reduced expression of hippocampal BDNF, NGF and their cognate receptors in postmortem brain of suicide victims
A.C. Mondal, Physiology, Raja Peary Mohan College, Uttarpara, India

Background: The role of neurotrophins in directing brain growth and neuronal functioning is being increasingly recognized. Neurotrophins not only play an important role in cellular proliferation, migration, and phenotypic differentiation and/or maintenance in the developing CNS but also their presence is required in the adult CNS for maintenance of neuronal functions, structural integrity of neurons, and neurogenesis, which suggests that neurotrophins are biologically significant over the entire lifespan.

Objectives: Investigation of expressions of BDNF, NGF with their respective receptors and few downstream signaling molecules in the hippocampus of the suicide victims.

Materials and methods: These studies were performed in the hippocampus obtained from 20 suicide and 20 non-psychiatric control subjects. The neurotrophin levels were quantitatively measured through Sandwich ELISA, the expression of neurotrophin receptors and the downstream signaling molecules were determined by Western Blot. Finally mRNA levels of BDNF, TrkB and NGF, TrkA were determined by RT PCR.

Results: A unique parallel decrease of the protein levels of BDNF, NGF and their cognate receptors in post-mortem suicide victims clearly correlated with the significant reduction of their mRNA levels at the hippocampal regions compared to the normal individuals. A marked decrease in the expression profiles of downstream signaling molecules like PLCγ, PKCδ, ERK 1, 2, Akt and CREB of suicide victims compared to non-psychiatric controls.

Conclusion: Significant reduction of BDNF, NGF and their cognate receptors along with the dysregulation in BDNF/TrkB and NGF/TrkA signaling cascades in post-mortem brains might be of relevance to its pathophysiology of depression.

hearing screen at 8–10 weeks utilizing otoacoustic emissions (OAE). Excluded were children who had concomitant bacterial infections. Children who failed the hearing screen or had caregiver concerns about hearing or language development underwent formal audiology evaluation. Data was collected on gestational maturity, Gentamicin administration and hyperbilirubinemia.

Results: We enrolled 103 children, 54 males and 49 females, aged 3 days to 16 years. Eighty-three (80.5%) were chronologically younger than 90 days. Eighty-four (81.5%) received Gentamicin at 5–7.5 mg/kg/day for a median duration of two days. Eleven (10.6%) were premature; none had significant hyperbilirubinemia. Eighteen children (17.5%), 16 younger than one year, failed the initial hearing screen. Formal audiology testing of these 18 children revealed no hearing loss.

Conclusions: Outcome for hearing in children after non-polio enteroviral meningitis is good. Routine objective hearing screening may not be indicated following enteroviral meningitis.

Actigraphy in the assessment of sleep patterns in sickle cell disease patients in Cameroon (Sub-Saharan Africa)
1Neurology, Yaounde Central Hospital, Cameroon; 2General Medicine, University of Yaounde 1, Yaounde, Cameroon; 3Basic Health Sciences, Qassim University, Buraydah, Saudi Arabia; 4Public Health, Ministry of Public Health, Cameroon; 5Neurology, Yaounde Central Hospital, Cameroon; 6Cardiology, General Hospital of Yaounde, Yaounde, Cameroon

Background: Sleep disorders are more common among people living with HIV-AIDS (PLWHA) in Western countries, but few data exist on the subject in Africa. This study sought to characterize sleep patterns in PLWHA using actigraphy, a validated user-friendly sleep study tool.

Patients and methods: 16 PLWHA and 16 age and sex-matched HIV-negative controls wore wrist actigraphs for a minimum of 72 h and kept a sleep diary. Actigraphy data was analyzed with Action4® and MATLAB® software. Data on total sleep time, sleep onset latency (SOL), sleep cycle mesor, acrophase, amplitude, inter-daily stability (IDS), intra-daily variability (IDV) and F-ratio were collected, analyzed and reported.

Results: Though PLWHA took significantly shorter time to fall asleep than controls (mean SOL: 83.50 ± 48.89 versus 174.94 ± 103.57 min, p = 0.003), they slept significantly longer than the controls (582 ± 12.00 versus 433.50 ± 170.57, p = 0.008) and had more frequent night awakenings (20.06 ± 11.072 versus 12.13 ± 6.41, p = 0.019). But for the acrophase time (13:14 ± 1:23 and 14:26 ± 1:09, respectively for PLWHA and controls, p = 0.007), cosinor rhythmometry was not significantly different for both groups for the mesor, amplitude, the F-ratio and goodness of fit. Intra-daily variability was higher in PLWHA than in controls (0.235 ± 0.023 versus 0.186 ± 0.009, p = 0.03). The reverse was true for inter-daily stability (0.97 ± 0.001 versus 0.96 ± 0.003, p = 0.015).

Conclusion: This is the first report in Africa showing that sleep and circadian rhythm disorders that are common in PLWHA, can be easily characterized using actigraphy. We propose the use of actigraphy in routine sleep evaluation in PLWHA after validation of the technique.

Clinical predictors of sleep disorders in sickle-cell disease (SCD) patients in Cameroon
1Neurology, Yaounde Central Hospital, Cameroon; 2Basic Health Sciences, Qassim University, Buraydah, Saudi Arabia; 3Public Health, Ministry of Public Health, Cameroon; 4General Medicine, University of Yaounde 1, Yaounde, Cameroon; 5Neurology, Yaounde Central Hospital, Cameroon; 6Cardiology, General Hospital of Yaounde, Yaounde, Cameroon

Background: Good sleep quality is important for optimal brain function and quality of life while poor sleep may precipitate acute pain crises in sickle cell disease (SCD). Data on sleep disorders in SCD as well as their clinical predictors is limited in Africa and does not exist in Cameroon to the best of our knowledge.

Patients and methods: As part of a case–control study, binary logistic modeling was used to identify clinical predictors of obstructive sleep apnea (OSA) and restless legs syndrome (RLS) in 45 SCD patients (hemoglobin SS) aged 2 to 17 years screened for sleep disorders with the pediatric Sleep Quality (PSQ) scale.

Results: The prevalence of OSA and RLS was respectively 26.7% and 22.2%. An enlarged tonsil and vaso-occlusive crises were predisposing

Obstructive sleep apnea in sickle-cell disease patients in Cameroon

J.V. Fonsah, E.T. Chokote, E.N. Mbong, L.N. Nfor, L. Ngarka, A.A. Njoh, N. Koki, A.K. Njamnshi, W.F.T. Muna. Neurology, Yaounde Central Hospital, Cameroon; General Medicine, University of Yaounde 1, Cameroon; Public Health, Ministry of Health, Cameroon; Pediatrics, Chantal Biya Foundation, Cameroon; Cardiology, Yaounde General Hospital, Yaounde, Cameroon.

Background: Obstructive sleep apnea is a major cause of poor sleep in sickle-cell disease (SCD). Poor sleep affects functional status, quality of life and may precipitate acute pain crises. Data on OSA in SCD is limited in Africa and does not exist in Cameroon to our knowledge.

Patients and methods: A case–control study of 45 SCD patients (hemoglobin SS) age- and sex-matched with 45 non-sickle cell anemia controls aged 2 to 17 years employed the Pediatric Sleep Quality (PSQ) scale to screen for obstructive sleep apnea (OSA) and the Epworth Sleepiness Scale (ESS) for daytime sleepiness.

Results: Obstructive sleep apnea was significantly more common in sickle-cell patients compared to the controls (26.7% versus 2.2%, p = 0.001, OR 15.9 95% CI 1.98–121). Snoring as well as inattention hyperactivity PSQ scores were significantly higher in the cases compared to the controls (0.91 ± 1.18 versus 0.09 ± 0.29, p < 0.001 and 2.11 ± 1.90 versus 0.96 ± 1.92 p = 0.002). More sickle-cell patients with OSA had enlarged tonsils than not (47.4% versus 12.5% p = 0.017 OR 6.30 95% CI: 1.39–28.46). Excessive daytime sleepiness was more common in sickle-cell patients with OSA compared to those without (100.0% versus 46.2%, p = 0.044). This was observed for RLS and daytime sleepiness, though not significantly (100.0% versus 56.2%, p = 0.263 and 100.0% versus 50.0%, p = 0.106).

Conclusion: Bedwetting and enuresis are common in sickle-cell disease in Cameroon and appropriate management strategies are needed.

Vitamin B12 status does not influences central motor conduction time in asymptomatic elderly people: A transcranial magnetic stimulation study

J.M. Matamala, R. Verdugo, C. Nuñez, L. Lera, H. Sanchez, C. Albala, J.L. Castillo. Department of Neurological Science, Faculty of Medicine, University of Chile, Chile; Public Health and Nutrition Unit, Nutrition and Food Technology Institute, University of Chile, Santiago, Chile

Background: Vitamin B12 deficiency causes neurologic and psychiatric disease, especially in older adults. Subacute combined degeneration is characterized by damage to the posterior and lateral spinal cord affecting the corticospinal tract.

Objective: To test corticospinal tract projections using motor evoked potentials (MEPs) by transcranial magnetic stimulation (TMS) in asymptomatic older adults with low vitamin B12 (B12) levels.

Patients and methods: Cross-sectional study of 53 healthy older adults (>70 years). MEPs were recorded in the abductor pollicis brevis and tibialis anterior muscles, at rest and during slight tonic contraction. Central motor conduction time (CMCT) was derived from MEP latency and peripheral motor conduction time (PMCT). Neurophysiological variables were analyzed statistically according B12 status.

Results: Median age was 74.3 ± 6.2 years (53.5% women). Twenty-six out of the 53 subjects had low vitamin B12 levels (B12 < 221 pmol/L). MEPs were recorded for all subjects in the upper and lower extremities. There were no significant differences in either latency or amplitude of MEPs and CMCT between low and normal B12 groups. There was a significant PMCT delay in the lower extremities in the low B12 group (p = 0.014).

Conclusion: No subclinical abnormality of the corticospinal tract is detected in asymptomatic B12 deficient older adults. The peripheral
nervous system appears to be more vulnerable to damage attributable to this vitamin deficit.

Paraneoplastic cerebellar degeneration (PCD) — Improvement after oophorectomy and PLEX. Case report
R. Boneke, P. Bochniak, M. Grabiec. Neurology, Regionalny Szpital Specjalistyczny, Grudziadz, Poland; Gynecology, Szpital Uniwersytecki Nr 2, Bydgoszcz, Poland

Objectives: Paraneoplastic cerebellar degeneration (PCD) is a rare syndrome associated with systemic malignancies, most in ovarian cancer, breast cancer and lung cancer. Clinical symptoms develop within a few weeks or months. In the course of PCD most often found in incidence of anti-Yo, that accompany ovarian cancer.

Methods: The authors describe a case PCD without the presence of ovarian cancer, with a high titer of anti-Yo where clinical improvement occurred after ovariectomy and PLEX.

Results: A 52 year old postmenopausal female subacutely developing ataxia, tremor, nystagmus, dysarthria and dysphagia with progression of symptoms during several weeks, resulting in the inability of sitting and standing. The study demonstrated the presence of serum anti-Yo titer 1:10000 in IIFT (confirmed test Euroline), and elevated levels of tumor marker CA-125 83.530 U/ml. The patient was previously treated with pulses of methylprednisolone and PLEX no clinical effect. A study of PET and CT of the chest, abdomen and pelvis. There was no cancer present. Observed accumulation of physical disability, the patient confined to bed. For this reason, an oophorectomy was performed, upon histopathology there was no presence of the tumor. A month after the operation was repeated treatments of PLEX provide clinical improvement — patient sitting alone.

Conclusion: This report shows efficacy oophorectomy and PLEX in PCD with the presence of anti-Yo and elevated Ca-125 without the presence of an ovarian tumor.

A longitudinal study in a case of Köhleimer–Degos-disease with CNS-involvement: Clinical and neuroradiological evolution
A. Skrobal, E. Wolf, E.V. Hartl, M. Skrobal, A. Udvardi, K. Zouboulis, D. Garnhaft, M. Räuchle, C. Bacher, M. Breitenseher. Neurology, LK Horn, Horn, Austria; Dermatology, Donaupital, Vienna, Austria; Dermatology, Klinikum Dessau, Dessau, Germany; Radiology, LK Horn, Horn, Austria

Köhleimer–Degos disease is a small vessel angiopathy with primarily cutaneous manifestation (papulosus atrophicans), targeting only the skin in the benign variant of the disease (majority of diagnosed cases); in 30% there may be also an additional involvement of other organ systems: gastrointestinal tract, urogenital tract, CNS, ophthalmic and cardiac manifestations.

As etiological factors, recently a C5b/IFN-alpha-mediated mechanism targeting the endothelium, altered fibrinolysis and platelet functions was identified as a cause for this systemic vaso-occlusive disorder.

Köhleimer–Degos disease is a rare systemic disease, with a high risk of morbidity and mortality.

Conclusion: Neurobrucellosis should always be considered in the diagnosis of chronic inflammatory CSF changes in endemic areas, and should be kept in mind when evaluating a patient with acquired spastic paraparesis, particularly when associated with hearing loss.

Neurological manifestations of visceral leishmaniasis

Background: Visceral leishmaniasis is common in our country. The neurological manifestations were found in some patients as it carries a high risk of morbidity and mortality.

Objectives: The study aimed to investigate the presence of neurological manifestations in a group of Sudanese adult patients with visceral leishmaniasis.
Patient and methods: This is a descriptive prospective cross sectional hospital based study. It was conducted at Omdurman tropical teaching hospital in Khartoum state; it implies 100 beds and 3 units of general medicine and specialists in tropical medicine. Hundred patients with visceral leishmaniasis were examined for neurological manifestations using standardized questionnaire including medical history, clinical examination and investigation including, EMG and brain MRI.

Results: Male to female ratio was found to be 3:1 and common age group affected was <30 years. Peripheral neuropathy was found to be the commonest neurological manifestations followed by epilepsy, cranial nerves involvement and encephalopathy.

Conclusion: Patients with visceral leishmaniasis can present with neurological manifestations.

Neurological manifestations of sickle cell anaemia

A. Hussien1, H. Ibrahim2, O. El-Adib2, ’University of Khartoum, Sudan; 4University of Khartoum, Khartoum, Sudan

Introduction: Central nervous system involvement is one of the most devastating aspects of SCD.

Objectives: The aims of this review are to document the neurological complications of sickle cell disease.

Methods: This is a prospective hospital based, cross-sectional study. One hundred Sudanese patients with Sickle cell anaemia were included in the study from the period from March to July 2012.

Results: The most common age group affected was below 20 years, Male to female ratio was almost equal; irritability & headache were the most common symptoms, 41% and 40% respectively. Numness was observed in 25%, hemiplegia in 24%, seizure in 19%, recurrence of hemiplegia occurred in 8%, gait was found to be spastic in 14%, limping gait (due to non neurological causes) in 7%, while inability to walk in 6% and cerebellar manifestation in 2%.

Conclusion: The study revealed high incidence of irritability and headache followed by numbness then hemiplegia. Hemiplegia is usually ischemic in children and haemorrhagic in adults. Silent brain infarcts occur in 17% of our patients. Convulsions occur as an isolated event but frequently associated with stroke.

Vernet syndrome as a presentation of varicella-zoster virus infection

J. Ferreira1, A. Franco2, S. Agostinho3, C. Santos4, T. Teodoro5, M. Coelho2, L. Albuquerque2, 1Neurology, Hospital Santa Maria, University of Lisbon, Lisbon, Portugal; 2Otorhinolaringology, Hospital Santa Maria, University of Lisbon, Lisbon, Portugal; 3Neuroradiology, Hospital Santa Maria, University of Lisbon, Lisbon, Portugal

Background: Vernet syndrome is defined by a unilateral palsy of glossofaryngeal, vagus and accessory nerves and may occur due to different causes. We present a rare case associated with an infection by the varicella-zoster virus (VZV).

Case report: A 76-year-old man, with previous history of polymyelitis, presented with one week-long symptoms of dysphonia and dysphagia, mild right temporo-parietal headache extending to the ipsilateral ear and worsening of previous right arm weakness. Neurological examination showed dysphonia, asymmetrical elevation of soft palate with left deviation, paresis of the right trapezius and several vesicular lesions in the right ear's concha. Laryngoscopic examination demonstrated right vocal cord palsy. Cerebrospinal fluid (CSF) examination revealed 6 cells/mm³ and normal levels of glucose and proteins. Head MRI disclosed thickening and gadolinium enhancement of right IX, X and XI cranial nerves in T1 sequences. Antibody titer for VZV was initially elevated in serum-IgM and IgG-progressing to isolated IgG elevation several weeks later. VZV-DNA was not detected by PCR in CSF. The patient had a remarkable clinical improvement after initiation of acyclovir and prednisolone therapy.

Conclusions: VZV infection with lower cranial nerves palsy is extremely rare. The absence of VZV-DNA in CSF does not exclude the diagnosis, since the test for this particular virus has a low sensitivity (42-53%). In this case, the diagnosis of Vernet Syndrome, as a result of VZV infection, is demonstrated by clinical, laboratory and imaging data. Awareness to this rare presentation of VZV infection is important since it benefits from specific therapy.

Ischemic stroke in cerebrotendinous xanthomatosis

S. Dias, J. Sequeira, C. Capela, J. Morgado, M. Almeida. Neurology Department, Centro Hospitalar Lisboa Central, Lisbon, Portugal

Background: Cerebrotendinous xanthomatosis (CTX) is an extremely rare treatable lipid storage disease, characterized by early-onset cataracts, tendinous xanthomas and progressive neurological dysfunction due to cholestanol accumulation. Despite an antiatherogenic lipid profile, premature atherosclerosis and heart disease are common, but cerebrovascular disease has seldom been reported.

Objective: Our aim is to describe an unusual manifestation of CTX, and discuss the relevance of cerebrovascular disease in this condition.

Materials and methods: Case report.

Clinical report: A 35-year-old man presented with acute right-sided weakness. He had a long-standing history of cognitive impairment, lower limb deformities, and a recent diagnosis of cataracts and hypertension. He had a sister with cataracts and cognitive impairment and no other known family history. Neurological examination revealed right-sided hemiparesis, dysarthria and ipsilateral facial and hypoglossal palsy, as well as pyramidal and extrapyramidal dysfunction. He had prominent xanthomas in the Achilles tendons, patellar tendons, and hand and elbow extensors. Brain MRI revealed diffuse cerebral and cerebellar atrophy, basilar dolichoectasia and an ischemic lesion involving the left thalamus and cerebral peduncle. Carotid ultrasound showed small bulbar plaques bilaterally and bloodwork revealed normal total and LDL cholesterol, low HDL and mild hypertriglyceridemia. Serum cholestanol was elevated, confirming the diagnosis of CTX, and the patient was started on antiplatelet, statin and chenodeoxycholic acid treatment.

Conclusion: Although cerebrovascular disease is not traditionally associated with CTX, it may be an underreported complication of accelerated atherosclerosis in these patients. Further data are required to define a causal association.

Astrocytes in infantile neuronal ceroid lipofuscinosis (INCL)  
S. Saravanabavan. King's College London, London, UK  
Background: INCL is the commonest pediatric neurodegenerative disorder caused by autosomal recessive mutation. Children affected
by INCL develop visual defects, seizures and cognitive deficits, leading to premature death. INCL is directly caused by mutation in CLN1 gene that encodes for lysosomal enzyme Ppt1. Despite our knowledge of the mutation and the role of the protein, we have no understanding of how faulty PPT1enzyme leads to these phenotypes. Although INCL is classified as neurodegenerative disease, astrocytes are activated prior to neuronal death. Hence my aim was to observe the astrocytes of PPT1−/− and WT mice in vivo and in vitro.

**Aims:**
- To determine if PPT1 deficient astrocytes behave differently to wild type astrocytes.
- To identify any difference in lysosomes of WT and PPT1 mice brain.

**Results:** PPT1−/− astrocytes were abnormal in 4 domains: they were stimulated very early in development leading to increased proliferation, variable morphology, altered protein expression and secretion.

Initially these observations were localized to the thalamus and the cortex, however in older mice these abnormalities were generalized in the brain indicating progression of the disease.

**Conclusion:** PPT1−/− astrocytes behave rather different to the WT astrocytes in all fundamental cellular behaviors. They are stimulated early in the brain: with proliferation, altered protein expression and cytokine secretion. These alterations may result in secretion of substances which are harmful and halt secreting cytokines which are necessary leading to the development of a toxic environment for the neurons. Hence neuronal death is localized to these changes and observed soon after.

**A case of primary central nervous system lymphoma**

O.Y. Cakmak, S. Kibaroglu, I. iyigündogdu, U.S. Benli. Neurology, Baskent University, Faculty of Medicine, Ankara, Turkey

**Background:** Primary central nervous system lymphomas (PCNSL) are rare non-Hodgkin lymphomas, constitute 3–4% of primary brain tumors, and most cases are diffuse large B-cell lymphomas. Brain biopsy is essential to a precise histological diagnosis.

**Objective:** We present a case of a patient whose definitive diagnosis was delayed due to non-specific MRI and pathology findings.

**Case:** Previously healthy 53 year-old female patient, presented with a 2-month history of vertigo, ataxia and diplopia. Neurologic examination revealed left fourth nerve palsy and gait difficulty. MRI showed irregular nodular contrast enhancement, an increase in diffuse intensity on the left periventricular white matter. MRI findings were considered to be likely demyelinating disease or lymphoma. PET/CT evaluation revealed multifocal CNS lymphoma. A CT guided stereotactic brain biopsy was accomplished but histological examination revealed no tumoral cell. For differential diagnosis of vasculitis, demyelinating and metastatic diseases, extensive tests and imaging techniques were performed. CSF examination showed just a slight increase in protein content. Patient’s symptoms gradually worsened, so intravenous steroid treatment was started (1 gr/day for 5 days) empirically. Her symptoms improved rapidly but exacerbated 4 weeks later when therapy was withdrawn. Granial MRI was repeated and revealed lymphoma, consequently a second stereotactic brain biopsy was performed and pathology results were reported as PCNSLs (diffuse large B cell). Patient was treated with methotrexate and cytarabine therapy.

**Conclusions:** PCNSL forms solitary or multiple mass lesions with homogeneous contrast enhancement on brain MRI. For the differential diagnosis steroid responsiveness is important and brain biopsy is essential.

**Brain metastases: A new Graded Prognostic Assessment (GPA) index**

M. Ahluwalia, S. Daihya, P. Elson. Cleveland Clinic, Cleveland, OH, USA

**Background:** The Graded Prognostic Assessment (GPA) is a commonly used index based on prior randomized trials. The purpose of this study was to validate GPA index in a recent cohort of cancer patients with brain metastases (BM) at a large tertiary care center.

**Methods:** Cleveland Clinic Neuro-Oncology Center’s database was used to identify BM treated in the recent era (2000–12). A proportional hazard model was used to assess overall survival (OS), measured from the date of diagnosis of brain metastases to death or last follow-up.

**Results:** 877 BM patients (46% males) median age 57 years (range 23–84) were included. 490 patients with lung cancer, 161 patients with breast cancer, 90 with melanoma and 136 with renal cell carcinoma were analyzed. The median number of brain metastases was 1 (range, 1–47). OS was 14.3 months (95% CI: 12.9–15.5), and is highly dependent on the underlying primary tumor. The original GPA was prognostic for survival (p < 0.0001). However we found that these factors can be employed to propose a new GPA that improves on the conventional GPA based on the following characteristics: the primary is controlled, the number of extracranial metastases present, and the interval from initial diagnosis of the primary to the diagnosis of BM (p < 0.0001).

**Conclusion:** A new index developed based on a revised set of independent prognostic factors (primary controlled, diagnosis to brain metastases, and number of extracranial metastases) is proposed.

**Limbic encephalitis, clinical features and autopsy findings**

B. Surböhö, O. Berger, S. Pollanz, S. Urbanits, B. Horvath-Mechtl, W. Hulla, W. Grisold, Kaiser Franz Josef Hospital of Vienna, Vienna, Austria; Radiology, Kaiser Franz Josef Hospital of Vienna, Vienna, Austria; Pathology, Kaiser Franz Josef Hospital of Vienna, Vienna, Austria

**Background:** Paraneoplastic limbic encephalitis (PLE) is a rare disorder characterized by behavioral change, depression and memory loss, sometimes associated with dementia, psychosis and seizures. Antineuronal antibodies may be detected. Imaging results present variable results.

**Case report:** A 42 year old white winegrower developed an anti-Hu antibodies positive of PLE. The patient presented initially with ataxic gait, peripheral facial palsy and loss in short term memory. Double vision and insecure gait developed within half a year. First MRI was unsuspicious. Follow-up MRI four months later demonstrated hyperintense temporomedial enhancement. Two lumbar punctures had unsuspicious results (cell count, cell morphology). Anti-Hu-antibodies and oligoclonal bands were positive. EEG findings revealed slowing, but no ictal pattern. The tumour screening (CT thorax and abdomen) was negative. PET scan described a tracer enhancement mesiotemporally in the brain. After intravenous steroids over 5 days the ataxia improved. Cognitive deficits
persisted unchanged. Episodes with visual hallucinations and psychomotor agitation occurred. After the positive MRI-scan, we administered two series of intravenous immunoglobulins (IVIG). The cognitive impairment improved slightly. His general condition and dysphagia deteriorated. The patient died of aspiration and cardiorespiratory arrest. The general autopsy did not reveal a tumour. Brain autopsy showed no macroscopic changes; in histology patchy lymphoid infiltrates mainly perivascular were discovered in the brain parenchyma. Most of the lymphoid cell stained positive with T cell markers.

**Conclusion:** The case describes the clinical course of a Hu positive PLE, which could be followed up anatomically and confirmed the inflammatory changes in the brain parenchyma.

**Background:** Despite the fact, that borreliosis has a well documented involvement of the CSF and the nerve roots, reports on CNS manifestations of borreliosis are scarce. **Objective:** Case report of a patient with neuroborreliosis and atypical MRI manifestations.

**Case report:** We report a 70 year old female with diplopia and unsteady gait for 3 weeks before admission. Medical history revealed no relevant diseases, except for unspecific symptoms like depression and weight loss of 15 k in the last 6 months. Neurological examination showed horizontal diplopia in all viewing directions and an unsteady gait with retropulsion. MRI exhibited T2-weighted, hyperintense lesions in the brainstem and rostrally up to the basal ganglia in both hemispheres resembling a perivascular spread of either periventricularly and in the brainstem. MRI manifestations.

**Objective:** To describe where Shelden trained, explain why he was chosen to start the neurology section at Mayo, and identify his local and national neurologic influence.

**Material and methods:** Review of material concerning Shelden in the Mayo and University of Vienna Archives.

**Results:** Shelden graduated from Rush Medical College in 1895, spent two years as an intern at Cook County Hospital, and worked as a general practitioner in Reedsburg, Wisconsin for four years. He then received internal medicine training at the University of Vienna for 1.5 years, working with Neusser, Kovacs, Frankl-Hochwart (neurology), Finger, and Monti. He subsequently had a private internal medicine practice and taught at the University of Minnesota for 10 years. He was known as an excellent bedside teacher and diagnostician, and a proficient neurologist. In 1913 he was asked by W.J. Mayo to start the Mayo neurology section. Shelden was head of the neurology section until 1930.

**Conclusion:** Shelden exemplified the benefit of post-graduate training in Vienna for the well-prepared American physician. His recruitment to Mayo Clinic gives insight into how W.J. Mayo chose diagnosticians and developed specialty sections. Shelden was an internist who focused primarily on neurology over time. The section of neurology at Mayo Clinic was more like internal medicine than neuropsychiatry because of Shelden’s background. He did not publish much and therefore did not have a significant, direct, national influence, but he had an indirect influence via his trainees (H. Woltman, L. Eaton).

**Background:** Wernicke’s encephalopathy (WE) is a potentially dangerous neurological disorder, caused by thiamine deficiency. WE is most commonly seen in chronic alcoholics, yet it can manifest in any other patient with reduced thiamine intake. **Objective:** To describe serial MRI findings, including diffusion-weighted imaging (DWI), during the course of WE in a patient with pyloric stenosis.

**Results:** A 52-year-old woman was admitted to our department with a 5-day history of diplopia. Cognitive functions were normal; there was no history of alcohol abuse. Neurological examination showed bilateral lateral rectus palsy with absent tendon reflexes. During hospitalization the patient’s neurological condition deteriorated, with development of vomiting, complete ophthalmoplegia and anterograde amnesia. gastroscopy showed severe pyloric stenosis. Brain MRI showed symmetrical lesions involving medial thalami, fornix and periaqueductal gray matter, with restricted diffusion on DWI, indicative of cytotoxic edema. During the ensuing week, the patient’s condition worsened further, with ataxia, somnolence and finally coma. A new MRI scan showed spreading lesions to the cerebellar vermis, as well as to the medullary tegmentum. Serum thiamine was well below normal limits. Following intravenous thiamine administration, consciousness was fully restored; moreover there was a complete resolution of ataxia and ophthalmoplegia. The patient was left with a residual Korsakoff syndrome; a follow-up MRI demonstrated complete remission of signal abnormalities.

**Conclusion:** DWI has the potential to become an invaluable tool for early diagnostic suspicion of WE; it may also monitor the clinical course of the disorder as well as its response to treatment.

**Background:** Shelden started the neurology section at Mayo in 1913.

**Objective:** To describe where Shelden trained, explain why he was chosen to start the neurology section at Mayo, and identify his local and national neurologic influence.

**Material and methods:** Review of material concerning Shelden in the Mayo and University of Vienna Archives.

**Results:** Shelden graduated from Rush Medical College in 1895, spent two years as an intern at Cook County Hospital, and worked as a general practitioner in Reedsburg, Wisconsin for four years. He then received internal medicine training at the University of Vienna for 1.5 years, working with Neusser, Kovacs, Frankl-Hochwart (neurology), Finger, and Monti. He subsequently had a private internal medicine practice and taught at the University of Minnesota for 10 years. He was known as an excellent bedside teacher and diagnostician, and a proficient neurologist. In 1913 he was asked by W.J. Mayo to start the Mayo neurology section. Shelden was head of the neurology section until 1930.

**Conclusion:** Shelden exemplified the benefit of post-graduate training in Vienna for the well-prepared American physician. His recruitment to Mayo Clinic gives insight into how W.J. Mayo chose diagnosticians and developed specialty sections. Shelden was an internist who focused primarily on neurology over time. The section of neurology at Mayo Clinic was more like internal medicine than neuropsychiatry because of Shelden’s background. He did not publish much and therefore did not have a significant, direct, national influence, but he had an indirect influence via his trainees (H. Woltman, L. Eaton).

**Background:** Despite the fact, that borreliosis has a well documented involvement of the CSF and the nerve roots, reports on CNS manifestations of borreliosis are scarce. **Objective:** Case report of a patient with neuroborreliosis and atypical MRI manifestations.

**Case report:** We report a 70 year old female with diplopia and unsteady gait for 3 weeks before admission. Medical history revealed no relevant diseases, except for unspecific symptoms like depression and weight loss of 15 k in the last 6 months. Neurological examination showed horizontal diplopia in all viewing directions and an unsteady gait with retropulsion. MRI exhibited T2-weighted, hyperintense lesions periventricularly and in the brainstem and rostrally up to the basal ganglia in both hemispheres resembling a perivascular spread of either infection or granulomatous process. CSF revealed increased cell count of 180/mm³ and a mixed cell type pattern consisting of lymphocytes, monocytes and plasma cells. The serology for borreliosis was positive, while diagnostic workup for autoimmunological, neoplastic and infectious etiology remained negative. The patient improved well under intravenous antibiotics for 3 weeks and could be discharged in a normal condition without neurological symptoms.

**Conclusion:** Neuroborreliosis usually presents with a polyradiculitis of spinal and cranial nerves or varying symptoms arising from a meningoencephalitis, although rare manifestations like myelitis or borrelia induced cerebral vasculitis can be observed. The distribution of MRI lesions at first indicated a suppurative disease, and also demyelinating diseases were considered. This case with atypical MRI manifestation underlines the importance of considering neuroborreliosis in clinical diagnosis of inflammatory CNS diseases.

Vertebrobasilar Doppler sonography in patients with vertigo

Background: Vertigo as symptom of vertebrobasilar insufficiency (VBI) is a common neurovascular problem. It is caused by a reduction of vertebral artery flow, from atherosclerotic and degenerative changes of vertebral spinal structures. Color Doppler flow imaging has improved investigations of the vertebral arteries (VA). The aim of this study was to evaluate the blood flow characteristics of extra cranial segments of vertebral artery in patients with vertebrobasilar insufficiency.

Methods: Bilateral VA were examined sonographically in the prevertebral (V1 segment), intertransverse (V2 segment) and sub-occipital (V3 segment) in 80 patients with VBI. Angle-corrected peak systolic (Vps), end-diastolic (VED), and time-averaged maximum blood flow velocity (TAV) were measured in pulsed Doppler mode, and the resistance index (RI) was calculated. The cross-sectional area (A) was measured on gray-scale images and flow volume was calculated.

Results: Left VA were dominant in 65% of patients. RI values increased and flow decreased with age. Blood flow velocity and volume were higher, and RI was lower in the left than in the right VA. In VBI patients peak systolic velocity and RI were significant higher in V1 segment, and lower in the V2 and V3 segments: VpsV1 = 62.7 ± 16.4 cm/s; VpsV2 = 46.5 ± 15.1 cm/s; VpsV3 = 45.6 ± 17.7 cm/s; RI1 = 72.2 ± 10.1; RI2 = 68.7 ± 12.9; RI3 = 64.6 ± 14.4.

Conclusion: The Doppler sonographic assessment of extra cranial VA may be useful for the study of hemodynamic changes in patients with vertebrobasilar insufficiency.

Pathology of the main arteries of the patients with controlled and uncontrolled arterial hypertension

A. Liseenko. Yaroslavli State Medical Academy, Yaroslavl, Russia

Research objectives: To compare the structural changes of the carotid arteries of the patients with controlled and uncontrolled arterial hypertension.

Materials and techniques: 56 people have been examined (average age was 58.6). The first group (n = 24) included patients with uncontrolled arterial hypertension with episodic high blood pressure (>180 mm Hg) for the last 3 months while treating. The second group (n = 14) included patients with controlled hypertension, there was episodic high blood pressure in their medical history, but while treating for the last 3 months blood pressure was of ≤180 mm Hg. The third group (n = 17) included patients with no arterial hypertension. Patients of all 3 groups matched on age and sex.

Results: 33% of the patients of the 1st group (n = 8) and 7.1% of the patients of the 2nd group (n = 1) had episodic cerebrovascular accidents (NIHSS average score 4.5). Patients of the 1st group had more subjective symptoms than the others, especially concerning giddiness. 87.5% of the patients of the 1st group (n = 21), 87.5% of the patients 2nd group (n = 12) and 76.4% patients of the 3rd group (n = 13) had arterial sclerotic disease of the carotid arteries and vertebral arteries.

Conclusion: While researching we discovered that patients with arterial hypertension had arterial sclerotic disease of the extracranial artery and main artery deformities of the brain. At that, patients with uncontrolled arterial hypertension suffered from sclerotic disease of the arteries more often. Detection frequency of the main arteries deformity of the patients with controlled and uncontrolled arterial hypertension was approximately the same.

Sleep disorders in sickle cell disease patients in Cameroon

A.K. Njamnshi1,2, S.E.T. Chokote2, E.N. Mbong3, L. Ngarka4, L.N. Nfor5, A.A. Njoh1, J.Y. Fosah, N. Koki6, W.F.T. Muna7, 1Neurology, Central Hospital of Yaounde, Cameroon; 2Internal Medicine, Faculty Medicine and Biomedical Sciences, Cameroon; 3General Medicine, University of Yaounde 1, Cameroon; 4Public Health, Ministry of Public Health, Cameroon; 5Pediatrics, Chantal Biya Foundation, Cameroon; 6Cardiology, General Hospital of Yaounde, Yaounde, Cameroon

Background: Chronic symptoms such as sleep complaints in sickle-cell disease (SCD) patients are often ignored in favour of more acute phenomena such as pain and anaemia. Poor sleep affects functional status and may precipitate acute pain crises. Data on sleep in SCD is limited in Africa and does not exist in Cameroon.

Patients and methods: A case–control study of 45 SCD patients (hemoglobin SS) age- and sex-matched with 45 non-sickle cell anemia controls aged 2 to 17 years. We used the Pediatric Sleep
Quality (PSQ) scale to screen for obstructive sleep apnea (OSA) and restless legs syndrome (RLS), and the Epworth Sleepiness Scale (ESS) for daytime sleepiness.

Results: The prevalence of OSA, RLS and daytime sleepiness was significantly higher in the cases than in the controls (26.7% versus 2.2%, p < 0.001, 22.2% versus 2.2%, p = 0.007 and 6.8% versus 2.2%, p = 0.051 respectively). In adjusting for socio-economic status (SES) the odds of OSA in the cases compared to the controls was 12.53 (95% CI: 1.41–114.43) and on adjusting further for depression 5.90 (0.48–72.54).

Conclusion: Sleep disorders are common in sickle-cell patients in Cameroon. Depression and socio-economic status may mediate the occurrence of OSA and RLS. Clinical sleep quality assessment (with the aid of sleep scales) in SCD may contribute to better management and improve life quality.

Laparoscopic assisted ventriculoperitoneal shunting in patients with normal pressure hydrocephalus

F. Nigim, E.M. Kasper. Neurosurgery/Neuro-Oncology, Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA, USA

Background: Normal pressure hydrocephalus is a potential reversible neurological decline characterized by the clinical triad: gait disturbance, urinary incontinence, and dementia, with dilated cerebral ventricles and normal cerebrospinal fluid (CSF) pressure. Indications, techniques and outcome measures for shunting remain under debate.

Objective: We evaluated outcome of NPH patients 3 months and one year after ventriculoperitoneal shunt placement with either laparoscopic or conventional surgical technique.

Material and methods: A total of 67 patients (mean age, 71.2 ± 16.6 years) had VPS-surgery at BIDMC between 2004 and 2012. Clinical assessment included CT, neuropsychological evaluation and lumbar CSF tap.

Results: There was no significant difference in outcome or in surgical morbidity between the two groups of patients. At 3-month and 1-year follow-up, 95% of patients improved in gait, 90% in urinary incontinence, and 75% in memory. Only 3 of 67 patients did not benefit from shunting. Evans ratio in our cohort was 0.37 (range, 0.24–0.5) in the pre-operative CT and 0.28 (range 0.2–0.5) in the post-operative CT done after 3 months.

Conclusion: In patients with NPH, laparoscopic shunt surgery is equally safe and useful and shows a low morbidity and failure rate with overall improvement in >90% of patients at one year follow-up. Laparoscopic surgery carries a number of distinct advantages such as shorter OR times, shorter hospital stays, less pain medications and earlier mobilization as well as a lower incidence of ileus. This technique should especially be considered in obese and medically frail patients.

Lateral antebrachial cutaneous neuropathy

E. Eken. Neurology, Silifke State Hospital, Mersin, Turkey

Compression neuropathy of the lateral antebrachial cutaneous nerve presents as purely sensory lesions, manifesting as elbow pain or dysesthetic pain over the lateral forearm. It is an infrequent clinical entrapment syndrome. In this report, we present a case of lateral antebrachial cutaneous nerve injury which occurs after splint use. A 48 year old female patient had fallen 2 months ago and then a forearm splint was applied. Numbness and a painful dysesthesia over the right radius had started 15 days following splint use. On physical examination, there was tenderness and swelling at the lateral forearm. There was no motor deficit. Plain radiographs of the arm and the forearm showed no abnormality. Electromyography showed no differences between the SNAP amplitudes of right and left superficial radial nerves and median sensory nerve of the first digits. However SNAP amplitude of the right lateral antebrachial cutaneous nerve was significantly (70%) lower than the contralateral side. The patient was treated conservatively with physical therapy and pregabalin. The result of this intervention was that the patient’s dysesthesia was reduced.

Compression neuropathy of the lateral antebrachial cutaneous nerve is uncommon, and is easily overlooked. It is important to rule out other conditions that may produce similar symptoms including lateral epicondylitis, biceps strain, cervical radiculopathy, musculocutaneous nerve injury, and brachial plexopathy.

Application of MSCTA combined with VRT in the operation of intra-extra cervical spinal canal dumbbell-shaped tumors

Y. Guo1, W. Wang2, X. Zhao2, Y. Wu2, Q. Liang2, Y. Zhao2. 1Department of Neurosurgery, China–Japan Union Hospital, Jilin University, Changchun, China; 2Department of Breast Surgery and Breast Disease Institution of Jilin Province, China–Japan Union Hospital, Jilin University, Changchun, China

Background: The operative management of the dumbbell-shaped tumors of the intra-extra cervical spinal canal is challenging. The complicated spatial relationship between tumor and the surrounding tissues is hardly understood by MRI and CT scans. However, the reconstruction of the three-dimensional space around the dumbbell-shaped tumors through multi-slice spiral CT angiography (MSCTA) combined with volume rendering technique (VRT) can predict favorable preoperative imaging data for surgery.

Objective: To probe the significance of MSCTA combined with VRT in the surgery of dumbbell-shaped tumors of the intra-extra cervical spinal canal.

Patients and methods: We examined 11 patients from 2010 to 2013 who exhibited dumbbell-shaped configuration tumors of the intra-extra cervical spinal canal by using MRI. MSCTA was performed before surgery. The tumor three-dimensional images were reconstructed by MSCTA along with the use of VRT, and the relationships among spinal cord, vertebral artery and vertebral bodies were clearly enough to imitate the approach of operation. The reconstruction images were compared with the surgical findings as control.

Results: All of the reconstruction images clearly showed the shape of the tumors and their three-dimensional relationships with adjacent vessels and vertebra, which were in accordance with the intraoperative findings. By imitating the operation, all patients were designed the best surgical approach for tumor resection, effectively avoided unnecessary nerve and vascular injury, and reduced the blood loss in surgery while maintaining maximum cervical spine stability.

Conclusion: By coupling MSCTA with VRT, we can imitate the surgical operations in multi-angle and choose proper surgical techniques to achieve the best surgical outcomes.

Dynamic change of CSF flow at lumbosacral level
K. Kim, J. Leigh, K.-D. Kim, Y. Cho, C.-H. Sohn, "Rehabilitation Medicine, Seoul National University Hospital, Republic of Korea; Department of Public Rehabilitation Service, National Rehabilitation Center, Republic of Korea; Radiology, Seoul National University Hospital, Seoul, Republic of Korea"

The hydrodynamics of the cerebrospinal fluid (CSF) in the brain can be directly inferred from structural change of the ventricles, whereas that in the spinal canal cannot be. As such, CSF flow at the lumbosacral level has not been a subject of clinical interest and little has been revealed thus far. In this study, we investigated how the CSF flow changes according to the posture using phase contrast magnetic resonance image (3.0 T Siemens, German). Velocity encoding parameter was optimized after trials and periodicity of CSF flow was normalized per cardiac cycle. Phase contrast image in the axial plane was obtained at the L2 and S1 levels and phase contrast image in the sagittal plane was also recorded. During the study, lumbar flexion was maintained with the hip flexed in supine position and was supported by cushions. Ten subjects (25–77 years old, 5 male) participated in this study. In every case, the flow rate at the sacral level was significantly slower than at the lumbar level. During one cycle, steady cephalad flow was dominant in the early cycle and phasic caudal flow was dominant in the late cycle, either in neutral or in flexion posture. With lumbar flexion, the cephalad flow

Evaluation of quality of life with SF36 test in patient with obstructive sleep apnea syndrome
A.C. Köylioglu, A. Sönmezler, O. Kocatürk, T.K. Yoldas, S. Sanikaya, Neurology, Harran University, Sanliurfa, Turkey

Objective: To evaluate the quality of life in patients with obstructive sleep apnea and the relationship between the severity of obstructive sleep apnea and impairment of quality of life.

Methods: 69 patients who had undergone polysomnography (PSG) examination at Harran University sleep laboratory were enrolled in the study. 49 of them were male and 20 were female. 32 patients whose Apnea–Hipoapnea index (AHI) was below 5, were taken as controls. The severity of obstructive sleep apnea syndrome (OSAS) according to AHI were as follows: 9 patients whose AHI was between 5 and 14.9 were considered to have mild sleep apne, 7 patients whose AHI was between 15 and 29.9 were considered to have moderate sleep apnea, 21 patients whose AHI was above 30 were considered to have severe sleep apnea. Short Form 36 (SF-36) quality of life questionnaire was performed to all patients.

Results: In the control group 17 were male and 15 were female, and the average age of the 32 patients was 40.34 ± (8.14). The study group consisted of 37 patients, including 5 women and 32 men. The mean age of the group was 44.27 ± (8.87). The SF-36’s scores for OSAS patients were lower than those of the control group in all parameters. All parameters (general health, bodily pain, physical functioning, social functionality, physical role, and emotional aspects) except mental health and vitality were statistically significant (p < 0.05).

Conclusion: This study of sleep apnea syndrome, compared to the healthy control group, suggests a major health problem affecting quality of life.

The severity of obstructive sleep apnea syndrome (OSAS) according to AHI were as follows: 9 patients whose AHI was between 5 and 14.9 were considered to have mild sleep apne, 7 patients whose AHI was between 15 and 29.9 were considered to have moderate sleep apnea, 21 patients whose AHI was above 30 were considered to have severe sleep apnea. Short Form 36 (SF-36) quality of life questionnaire was performed to all patients.

Results: In the control group 17 were male and 15 were female, and the average age of the 32 patients was 40.34 ± (8.14). The study group consisted of 37 patients, including 5 women and 32 men. The mean age of the group was 44.27 ± (8.87). The SF-36’s scores for OSAS patients were lower than those of the control group in all parameters. All parameters (general health, bodily pain, physical functioning, social functionality, physical role, and emotional aspects) except mental health and vitality were statistically significant (p < 0.05).

Conclusion: This study of sleep apnea syndrome, compared to the healthy control group, suggests a major health problem affecting quality of life.

rate of the CSF at the L2 level increased marginally compared to with
neutral (0.53 ± 0.41 m/s at neutral, 0.94 ± 0.79 m/s at flexion). The AP
diameter of the spinal canal increased insignificantly with lumbar
flexion. In conclusion, the hydrodynamics of the CSF at lumbosacral
level changed according to postures.

Global functional connectivity is related to age and memory
performance in healthy adults: A resting-state fMRI study

Institute of Psychiatry, Laboratory of Psychiatric Neuroimaging (LIM-21),
Faculty of Medicine, University of São Paulo, São Paulo, Brazil

Background: Global functional connectivity (GFC) is considered an
estimate of a region’s overall synchronization with the brain. Recently
GFC has been used to identify associations with cognitive performance
and changes in neuropsychiatric conditions. We are not aware of any
study that investigated the relationship between age, episodic memory
and GFC obtained from resting-state functional MRI (rs-fMRI) in
healthy adults.

Objective: To investigate whether GFC during resting-state is
associated with age and performance in episodic memory in adults
with no neurological or psychiatric disorders.

Methods: Episodic memory performance and rs-fMRI were obtained
from 37 cognitively healthy adults (age range: 19–75 years). The rs-fMRI
was preprocessed and then, for each grey matter voxel, the mean of the
z-transformed correlation coefficient between this voxel and every other
grey matter voxel was calculated, resulting in a GFC map for each subject.
To test the relationship between GFC, age and episodic memory
performance we used the partial least squares method for neuroimaging.

Results: There were significant negative correlations between age and
performance on the Wechsler Logical Memory test, both immediate
and delayed recall (r = −0.36; p = 0.03) and delayed recall (r = −0.35; p = 0.03).
Increased GFC in the bilateral motor cortex, left dorsolateral prefrontal
cortex, bilateral superior temporal gyr, right visual cortex and left
thalamus was significantly associated with aging and with worse
performance in memory tests (permuted p = 0.022; absolute bootstrap
ratio > 3).

Conclusion: Age-related increases in GFC were associated with poorer
episodic memory performance. Interestingly, the most reliable findings
were in brain regions not related to the default mode network.

Case report — Viral encephalitis complicated by cerebral venous sinus
thrombosis
A.E. Ahmed a,b, A.M. Musa c, aPhysiology/Neurology, Faculty of Medicine,
University of Khartoum, Sudan; bSociety of Neurosciences, Dean Faculty of
Medicine, University of Khartoum, Khartoum, Sudan; cPhysiology, Faculty of
Medicine, University of Khartoum, Khartoum, Sudan

Background: Encephalitis is the inflammation of the brain often of
unknown cause. The most common cause is viral infection. Cerebral
venous sinus thrombosis (CVST) as a complication of encephalitis is a
very rare phenomenon.

Objectives: To report cerebral venous sinus thrombosis as a
complication of viral encephalitis.

Case presentation: This is a case report of a 23 year old male Sudanese
university student who presented on the 26th of December 2012 with
fever, headache, confusion and convulsions. There was no history
suggestive of hypercoagulable states, vasculopathies or head & neck
infections. On examination, he was confused, disorientated to time,
anxious, agitated with mild neck stiffness. Fundoscopy was normal. He
refused lumbar puncture. Full blood count showed lymhocytosis.

Conclusion: Age-related increases in GFC were associated with poorer
episodic memory performance. Interestingly, the most reliable findings
were in brain regions not related to the default mode network.

Effect of mobile phones on hearing
I.H. Siddique a, N. Elawad b, A.E. Ahmed c, d, aPhysiology, Faculty of
Medicine, University of Khartoum, Sudan; bENT Surgery, Faculty of Medicine,
University of Khartoum, Sudan; cPhysiology/Neurology, Faculty of Medicine,
University of Khartoum, Sudan; dSociety of Neurosciences, Dean Faculty of
Medicine, University of Khartoum, Khartoum, Sudan

Background: In the last two decades the use of mobile phone has
increased globally. This has focused interest on its possible biological
effects. The surprising huge increase in the usage of mobile phone in
Sudan has been a strong justification for conducting such a study, on
the possible harmful effects of mobile phone on hearing sense.

Objectives: To explore possible effects of mobile phone use on hearing
level in humans and to compare between level of exposure and
threshold for hearing.

Methods: This is an observational cross-sectional population-based
study, conducted in Khartoum state — Sudan. Two hundred volunteers
filled questionnaires and had their hearing tested by diagnostic
audiometer. Those who use the mobile phone for a minimum of 2 h
day are classified as heavy users, and those who use the mobile
phone for less than 2 h are classified as moderate users, while those
who do not use the phone are classified as non-users.

Results: Heavy users of mobile phones show statistically significant
prevalence of mild sensorineural hearing impairment, with no other
possible underlining causes or risk factors. This is in comparison with
the moderate users and the non-users, who all show normal hearing.
Heavy users also show elevated auditory threshold at the minimum
speech tone, compared to the other two classes, which means that they
might be, at more risk for developing sensorineural hearing
impairment. This study does not show association between long-term use of
the mobile phone in years and hearing impairment.

Conclusion: The use of mobile phones has adverse effects on auditory
function in humans. These effects need to be more thoroughly
investigated.

the presence of sigmoid sinus thrombosis. Acetazolamide, heparin & warfarin were added to the treatment protocol. The patient showed remarkable response and is being regularly followed up.

**Conclusion:** Cerebral venous sinus thrombosis is a very rare complication of viral encephalitis. To our knowledge, this is one of the very few documented case reports in Sudan & worldwide.

**Structural features of denticulate ligaments spinal cord. Implications for transport cerebrospinal fluid**

S. Huseyynova, A.A. Aliyarbayova, R. Chaffarzadagan, E. Gasimov.

Department of Histology, Embryology and Cytology, Azerbaijan Medical University, Baku, Azerbaijan; City of Zurich Medical Services, Zurich, Switzerland

Recent research demonstrated that at least one-fifth of the cerebrospinal fluid (CSF) is reabsorbed from the spinal part of subarachnoid space. However, until now the structure involved in this process has not been clarified. The aim of this research was to investigate the structural elements of denticulate ligaments using light optical and electron microscopic techniques. The material of this study is the denticulate ligaments of domestic ducks. Our findings determine that a denticulate ligament together with cellular elements consist of mainly collagen fibrils (with a diameter 23–199 nm) and elastic fibers (with a diameter 114–706 nm). The absence of latter in the subpial space proved that the source formation of denticulate ligaments is the dura mater of the spinal cord. The study of serial semi-and ultrathin sections shows that the barrier and reticular cell layers of arachnoid covered only the initial part of the denticulate ligaments. The other parts of denticulate ligaments in subarachnoid space are not fully covered by a reticular cell layer of arachnoid. It should be noted that between the structural elements of denticulate ligaments and dura mater there are no structures that perform a barrier function, because the fibrillary elements of denticulate ligament without any boundaries merge into the dura mater. Given the known role of collagen fibrils in the transport of interstitial fluid and high hydrostatic pressure of the CSF it may be noted that one of the main ways of outflow CSF from the subarachnoid space can serve as a denticulate ligament.

**Inhibitory effects of fulvestrant on the growth of estrogen-induced prolactinoma in Fischer 344 rats and its possible mechanism**

Department of Neurosurgery, China–Japan Union Hospital, Jilin University, Changchun, China; Department of Breast Surgery and Breast Disease Institution of Jilin Province, China–Japan Union Hospital, Jilin University, Changchun, China; Department of Neurosurgery, Medical University of Vienna, Vienna, Austria

**Background:** Prolactinoma is an estrogen-related tumor, and some anti-estrogen agents have suppressive effects on prolactinoma. Previous studies have suggested that fulvestrant, a selective estrogen receptor antagonist, has inhibitory effects on the proliferation and prolactin secretion of MMQ and GH3 cells in vitro. However, there is still limited evidence of the inhibitory effects of fulvestrant on prolactinoma in vivo.

**Objective:** To investigate whether fulvestrant can inhibit the growth or the prolactin release of prolactinoma in vivo, and identify the signaling pathways that mediate the effects.

**Material and methods:** Pituitary prolactinomas were induced in male Fisher 344 rats by s.c. implantation of silastic tubes containing diethylstilbestrol. The effects of treatment with fulvestrant on pituitary weight, prolactin release, cell proliferation and apoptosis were evaluated. The expression of signaling molecules in the apoptosis pathways and the expression of Wnt signaling pathway-related proteins β-catenin, c-Myc and cyclin D1 were analyzed by Western blotting to investigate the possible mechanisms.

**Results:** Fulvestrant treatment caused significant reduction in pituitary weight and prolactin release. High β-catenin level in cytoplasm and low β-catenin level in nucleus were detected, and the expression levels of cyclin D1/c-Myc were significantly decreased; the expression levels of p53 and Bax were increased, and Bcl-2 was decreased; Caspase-8 and Caspase-9 cleave bands were detected; Caspase-3 and its substrate PARP were activated in the fulvestrant-treated pituitary tissues.

**Conclusion:** We demonstrate that fulvestrant could inhibit prolactinoma growth, decrease prolactin release, induce cell apoptosis by the mitochondrial and receptor apoptotic pathways, and inhibit cell proliferation through Wnt pathway.

**Revisiting the observation of anxiety-like behavior and assessing phenotypic progression in PGC-1α-deficient mice**

Department of Neurology, University of Szeged, Faculty of Medicine, Szeged, Hungary

**Introduction:** Mice deficient in full-length peroxisome proliferator-activated receptor gamma coactivator-1alpha (FL-PGC-1α) have been implicated as model animals for mitochondrial spongiform leukoencephalopathies. In previous behavioral studies that these mice were reported to exert hypomotility and weakness, and were proposed to show anxiety-like behavior. However, studies confirming this anxiety-like behavior in validated experimental models of anxiety have been lacking, and no studies have yet addressed the issue of progressivity of motor symptoms in larger scale studies.

**Materials and methods:** To revisit the issue of anxiety we applied elevated plus maze and light-dark box tests, whereas locomotor performance and muscle strength were assessed by automated open-field motility and wire-hang test. FL-PGC-1α-deficient (n = 27) and wild-type (n = 33) mice were distributed and analyzed along two age categories (mature 26.2 ± 2.21 w and aged 57.5 ± 1.4 w).

**Results:** Locomotor exploratory behavior and muscle strength were significantly decreased in FL-PGC-1α-deficient mice compared to wild-type controls. Unexpectedly, however, FL-PGC-1α-deficient mice demonstrated a behavior consistent with the complete lack of anxiety behavior. Both routine models applied failed to generate normal anxiety in FL-PGC-1α-deficient mice. The results were consistent in both age categories, and comparing to the age-related decline in motor performance observed also in the control group we could not detect additional phenotypic progression in the FL-PGC-1α-deficient group in the observed alterations.

**Conclusion:** Deficiency in FL-PGC-1α in mice evokes a behavior consistent with weakness and hypomotility, and associates with a decreased susceptibility to produce anxiety behavior in conventional models.
